Secret Server Documentation

Introduction

Delinea Secret Server is an enterprise-grade password management solution designed to help organizations securely store, manage, and control access to privileged credentials. It aims to improve the security of sensitive data, reduce the risk of data breaches, and streamline the password management process.

Here are the key features of Delinea Secret Server:

- Secure Password Storage: Secret Server stores privileged credentials in an encrypted format, protecting sensitive information from unauthorized access.
- Access Control: Secret Server implements role-based access control, allowing administrators to set Delinea permissions and control who has access to sensitive information.
- Privilege Escalation Management: Secret Server integrates with Windows systems to provide privilege escalation management, helping to reduce the risk of data breaches.
- Auditing and Reporting: Secret Server provides detailed audit logs and reports, making it easier for organizations to track access to sensitive information and detect any unauthorized activity.
- Automated Password Management: Secret Server supports automated password management, helping to streamline the password management process and reduce the risk of manual errors.
- Multi-Factor Authentication: Secret Server supports multi-factor authentication, helping to improve the security of sensitive information.
- Integration with Other Tools: Secret Server integrates with a variety of other tools, including Active Directory, Microsoft Azure, and cloud-based applications, making it easier for organizations to manage their passwords and access controls.

This section of the Delinea documentation portal supports Secret Server.

Navigate using the dynamic table of contents on the left, the page contents on the right, or by entering a search term above. Many pages in this documentation have sub-pages. The container (parent) pages can have introductory text or simply a heading with no text. Please click the table of contents on the left to see any sub-pages it might have.

Documentation

You are at the home page of the current Delinea Document Portal for Secret Server. It contains:

- New material.
- Links to legacy knowledge bases article that have yet to be converted or archived. There are very few of these left.
- Links to legacy PDF documentation. These are also rare, and if you do find one, its target is very likely out of date.

Getting Started

- "Secret Server Business User Guide" on page 75 (for non-technical users)
- Getting Started Tutorial (for technical users)
- "Installation" on page 72
- "System Requirements for Secret Server" on page 94

Best Practices

- "Configuration Best Practices" on page 14
- "Discovery Best Practices" on page 562
- "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343 (PDF)
- "Security Hardening Guide" on page 1419

Delinea Blog

The Delinea blog offers cybersecurity insights and expertise from industry leaders. With a focus on zero trust, identity management, and privileged access, the blog provides practical advice and thought leadership to help organizations strengthen their security posture. As a trusted voice in cybersecurity, Delinea leverages the blog to empower customers embracing zero trust and demonstrate their commitment to innovation.

Video Tutorials

We offer a range of training videos on the Delinea training site. This is a subscription service. Please contact your account manager for details.

Developer Resources

"Developer Resources" on page 1494

Help

The Help section is a central resource designed to assist users in navigating and utilizing the product effectively. It includes essential documents such as Document Conventions, which clarify the format and terminology used throughout the documentation, and the Secret Server Glossary, providing definitions of key terms. Additionally, the Self-Help Resources provides other support, while the Technical Support section offers information on how to

contact support teams for further assistance. This section empowers users with the knowledge and tools needed for efficient problem-solving and system navigation.

Document Conventions

Capitalization

Technical writing is typically so awash in capitalization that it often denotes nothing and harms legibility. To counter that, in general, this document follows the IBM Style Guide rule:

"Do not capitalize the names of features and components unless they are sold separately or are trademarked."

More specifically, the only things capitalized in this document are:

- Company, person, country, geographic place, or organization names
- Official or trademarked products or services, unless they officially have atypical capitalization, for instance *iPod*.
- Acronyms and initializations
- When referring to any UI labels that are capitalized, including page names
- When the word begins a sentence or phrase

Code and Command Line Text

Variable text in literal typed-in text and command-line parameters follow these industry-wide standards:

- All code and command-line interface text appears in `monospaced` text.
- Required parameters appear in angle brackets: `ping <hostname>`
- Optional parameters appear in square brackets: `mkdir [-p] <dirname>`
- Repeated parameters are followed by ellipses: `cp <source1> [source2...] <dest>`
- Multiple choice items are separated by vertical bars and grouped by curly brackets: `netstat {-t|-u}`

Keyboard Shortcuts

- Keyboard keys are bolded and surrounded with square brackets: **[Enter]**
- Concurrent key presses are denoted with plus signs: **[Ctrl]+[Alt]+[Del]**
- Sequential key presses are denoted by commas: **[Page Down]**, **[Enter]**

Notes

There are two types of notes: *notes* and *important notes*.

A note contains tangential (an aside) or supplemental information (a tip or clarification).

An important note contains substantive information that should be heeded, or negative consequences can occur, involving frustration, wasted time, or even data loss.

Other Special Text

- Email addresses and URLs are usually denoted by a colored underline: support@delinea.com.
- When URLs are part of the instruction, as opposed to clickable link, they appear in monospaced text: Type `https://www.somewhere.com` or click https://www.somewhere.com.
- Cross-references to headings are hyperlinks: See Booting a Server.
- Document or article names (not sections) appear in italics: See the *Server Administration Guide*. They may or may not be hyperlinks.
- All file and folder paths appear in monospaced text: `app\bin\web_config.xml`
- File names by themselves do *not* appear in monospaced text: web_config.xml. If the file name contains spaces, the name is surrounded by quotation marks: "web config.xml".

Ending punctuation may be omitted for clarity when following typed-in text, including URLs.

Screen Components and Attentional Targets

- Mouse-click, keyboard, and other attentional targets (anything a looks for) are denoted by bold type: **OK** button or **Login** link.
- Attentional Targets and screen component names in system *responses* are not bolded: "The OK button appears" verses "Click the **OK** button."
- Names of screen components, such as tabs, buttons, and text boxes, are corrected for spelling and capitalization. The component type appears in lowercase.

Secret Server Glossary

Table: Terms and Definitions

Term	Definition	Description
2FA	Two-Factor Authentication	A security process in which a user provides two different authentication factors to verify their identity. Typically, this includes something they know (like a password) and something they have (such as a mobile device with a verification code).
AAD	Azure Active Directory	A cloud-based identity and access management service by Microsoft that allows users to sign in and access multiple resources such as Microsoft Office 365, the Azure portal, and thousands of other SaaS applications.

Term	Definition	Description
AC	Access Control	The process of granting or denying specific authorization to access data, functions, and other computer resources. It ensures that users access only what they are allowed to and prevents unauthorized users from accessing sensitive information.
Access Offline Secrets on Mobile		Role permission: Allows a user to cache their Secrets in the Secret Server mobile application for offline use. This permission does not automatically come with the Administrator role.
Access Request		The access request feature allows a secret to require approval prior to accessing the secret.
Access Request Workflows		See Workflows.
Account Lifecycle Manager (ALM)		Account Lifecycle Manager (ALM) controls the creation, management, and decommissioning of Active Directory Service Accounts running on your organization's network.
ACE	Access Control Entry	A part of an access control list that specifies Delinea user or group permissions for a specific object, such as a file or directory.
ACL	Access Control List	A list of Delinea permissions attached to an object that specifies which users or system processes can access that object and what operations they can perform.
ACS	Access Control Server	A server used to authenticate and authorize users. It typically integrates with network access devices and identity databases to provide access control services.
Active Directory Account		Built-in secret template.
AD	Active Directory	A Microsoft technology used to manage computers and other devices on a network. It includes a range of services, such as LDAP directory services and Kerberos-based authentication.
Add Secret		Role permission: Allows a user to create new Secrets. The Add permission no longer include the role permission View Secret.

Term	Definition	Description
Add Secret (Folder Permission)		Allows the user to add a secret in that folder. Does not grant access to the added secret.
Add Secret Custom Audit		Role permission: Allows a user to make a custom audit entry when accessing a Secret using the web services API.
ADFS	Active Directory Federation Services	A software component developed by Microsoft that provides single sign-on (SSO) to authenticate a user in multiple web applications in a single session.
ADGUID	Active Directory Globally Unique Identifier	A unique identifier used within Microsoft's Active Directory for objects.
ADM	Administrator	
Administer Active Directory		Role permission: Allows a user to view domains, edit existing domains, delete domains, and add new domains. Also allows a user to force synchronization or set the synchronization interval.
Administer Automatic Export		Role permission: The user can do everything the other automatic export Delinea permissions allow and edit the automatic export configuration.
Administer Backup		Role permission: Allows a user to view and configure automated backups for Secret Server. Users with this role permission can change the backup path, disable backups, and set the backup schedule.
Administer Configuration		Role permission: Allows a user to view and edit general configuration options. For example, a user with this role permission can turn on "Force HTTPS/SSL" and disable "Allow Remember Me".
Administer Configuration Proxying		Role permission: Allows a user to view and edit SSH Proxy settings.
Administer Configuration SAML		Role permission: Allows a user to view and edit SAML integration settings on the Login tab of Configuration settings.

Term	Definition	Description
Administer Configuration Security		Role permission: Formerly "Administer Security Configuration," allows a user to view and edit security configuration options in Secret Server. Currently, these include enabling FIPS compliance mode and protecting the encryption key.
Administer Configuration Session Recording		Role permission: Allows a user to view and edit session recording settings on the Session Recording tab of Configuration settings.
Administer Configuration Two Factor		Role permission: Allows a user to change the configuration settings of the two factor authentication that are available for users logging into Secret Server.
Administer ConnectWise Integration		Role permission: Allows a user to view and edit configuration options for synchronizing with ConnectWise. This can be accessed through the "Folder Synchronization" link on the Administration page. Note that you need at least view access on the sync folder in order to set up or edit the ConnectWise integration.
Administer Create Application Accounts		Role permission: Formerly "Create Application Account", allows a user to create application user accounts to be used exclusively for accessing Secret Server via the API.
Administer Create Users		Role permission: Allows a user to create new local users in Secret Server, but not edit them once created.
Administer Custom Password Requirements		Role permission: Allows a user to view and edit custom password requirements that can be configured under the Security tab for individual Secrets.
Administer Data Retention		Role permission: Can manage audit data retention, such as editing and running now. This permission does not automatically come with the Administrator role.
Administer DevOps Secrets Vault Tenants		Role permission: Add, remove, and edit DSV tenants that automatically synchronize with Secret Server on a schedule.

Term	Definition	Description
Administer Disaster Recovery		Role permission: Allows a user to configure instances as data sources or replicas for Disaster Recovery. Also allows user to initiate or test Data Replication and view related logs and audits.
Administer Discovery		Role permission: Allows a user to view and import computers and accounts that are found by Discovery.
Administer Distributed Engine Configuration		Role permission: Allows a user to update the Distributed Engine configuration.
Administer DoubleLock Keys		Role permission: Allows a user to view, edit, create, and disable DoubleLock keys. A DoubleLock key acts as a separate encryption key to protect your most sensitive secrets. This option allows users to access and use the "DoubleLocks" link on the Administration page.
Administer Dual Control		Role permission: Allows a user to view, edit, create, and disable Dual Control settings for reports and recorded sessions.
Administer Event Subscriptions		Role permission: Allows a user to view, edit and create event subscriptions.
Administer Export		Role permission: Allows a user to view the export log. Also allows users to export Secrets to which they have access to a clear text, CSV file.
Administer Folders		Role permission: Allows a user to view, edit, create, move, and delete folders. Users still need the relevant view, edit, and owner permissions on the folders to perform these tasks.
Administer Groups		Role permission: Allows a user to view, edit, create, and disable groups. Also allows users to assign users to groups and remove users from groups.
Administer HSM		Role permission: Allows a user to change configuration or disable the use of a Hardware Security Module (HSM).
Administer Inbox		Role permission: Administer notification settings for the inbox.

Term	Definition	Description
Administer IP Addresses		Role permission: Allows a user to create, edit, and delete IP Address Ranges. These ranges are used to restrict certain users to specific IP Addresses.
Administer Jumpbox Route		Role permission: Allows a user to create, edit, or deactivate jump server routes.
Administer Key Management		Role permission: Allows a user to enable, change, or disable the Key Management (Secret Server Cloud only).
Administer Languages		Role permission: Allows a user to change the default language of Secret Server.
Administer Licenses		Role permission: Allows a user to view, edit, install, and delete licenses.
Administer Lists		Role permission: Add, remove, and modify lists and list contents in Admin > Lists.
Administer Metadata		Role permission: Manage metadata fields and sections added to secrets and users in Secret Server.
Administer Nodes		Role permission: Allows a user to view and edit server nodes and clustering settings.
Administer OpenID Connect		Role permission: Allows a user to manage OpenID connections.
Administer Password Requirements		Role permission: Allows a user to view and edit character sets and password requirements.
Administer Pipelines		Role permission: Allows a user to create, edit, and remove event pipelines and event pipeline policies.
Administer Platform Integration		Role permission: Allows a user to manage the Secret Server connection to the Delinea platform.
Administer Remote Password Changing		Role permission: Allows a user to turn Heartbeat and Remote Password Changing on and off globally. Also allows users to create new password changers and install password changing agents on remote machines.

Term	Definition	Description
Administer Reports		Role permission: Allows a user to view, edit, delete, and create reports. Also allows users to customize report categories.
Administer Role Assignment		Role permission: Allows a user to view which users and groups are assigned to which roles. Also allows users to assign users and groups to different roles.
Administer Role Permissions		Role permission: Allows a user to view, edit, create and delete roles. Also allows users to assign different Delinea permissions to each role.
Administer Scripts		Role permission: Allows a user to view, edit, and add PowerShell, SQL, and SSH scripts on the Scripts Administration page.
Administer Search Indexer		Role permission: Allows a user to view and edit search indexer options. These options control how searching in Secret Server works. For example, a user with this role permission could enable search indexing, which allows users to search on fields within a secret.
Administer Secret Policy		Role permission: Allows a user to create and edit Secret Policies.'
Administer Secret Templates		Role permission: Allows a user to view, edit, disable, and create Secret Templates.
Administer Security Analytics		Role permission: Allows a user to view and edit the settings for Privilege Behavior Analytics.
Administer Session Monitoring		Role permission: Allows a user to view and terminate active launcher sessions.
Administer SSH Menus		Role permission: Allows a user to edit and create SSH Menus, used in allowlisting commands that can be used on a SSH session.
Administer System Log		Role permission: Allows users to view and clear the System Log, which shows general diagnostics information for Secret Server.
Administer Teams		Role permission: Users can create, delete, and view all teams.

Term	Definition	Description
Administer Template Custom Columns		Role permission: Allows a user to enable the "Expose for Display" setting of a Secret template field to make it available for use in Dashboard custom columns.
Administer Users		Role permission: Allows a user to create, disable, and edit users in the system. This permission also allows a user to create and edit SDK/CLI rules.
Administer Unlimited Vault Access Configuration		Role permission: Formerly "Administer Configuration Unlimited Admin," allows a user to turn on unlimited vault access mode. When this mode is enabled, users with the "unlimited vault access" role permission can view and edit all Secrets in the system, regardless of Delinea permissions. Note that you can assign "administer unlimited vault access configuration" to one user and "unlimited vault access" to another user. This would require one user to turn on the mode and another user to view and edit secrets.
Administer Workflows		Role permission: Allows users to manage workflows (advanced access management).
Administration Side Panel		The administration side panel and page is a control panel for administering Secret Server.
Administrator		Administrator is a default role that comes preconfigured with. Roles control access to features within. This role can be customized to have different Delinea permissions. In this guide, administrator (lowercase) is used when referring to users who manage the system and have control over global security and configuration settings. Note that administrators in do not automatically have access to all data stored in the system—access to data is still controlled by explicit Delinea permissions on that data.
ADMX	Administration XML	An ADMX file is a Group Policy Administrative Template file used with the Group Policy Management Console (GPMC) in Microsoft Windows operating systems. “.admx” is the file extension. The file format is XML-based and replaces the older ADM format, which was used in earlier versions of Windows.

Term	Definition	Description
ADS	Advanced Directory Services Integration.	Allows Secret Server to integrate with Active Directory for user authentication and management.
ADSI	Active Directory Service Interfaces	A set of COM interfaces used by Windows to interact with and manage Active Directory.
Advanced Import		Role permission: Allows a user to import Secrets from an XML file. Users with the this permission can import groups, folders, site connectors, sites, and secret templates, without having to create a secret. Users must have the Secret Server permissions needed for the objects listed in the XML.
Advanced Session Recording		Advanced Session Recording (ASR) is a licensed feature of Secret Server that adds capabilities to those offered by basic session recording. You install the Advanced Session Recording Agent (ASRA), which uses the Remote Desktop Protocol, on any client machine where you want more information from the sessions recorded.
Advanced Session Recording Agent		The session recording software on a user's computer that performs ASR.
AES	Advanced Encryption Standard	A symmetric encryption algorithm widely used across the globe.
AES128	128-bit AES	
AES192	192-bit AES	
AES256	256-bit AES	
AIX	IBM's Unix operating system	
AJAX	Asynchronous JavaScript and XML	A set of web development techniques using various technologies to create asynchronous web applications.

Term	Definition	Description
All Secrets		All Secrets is a master table of the secrets stored on . It is a one-stop, searchable location for examining the status and properties of secrets. It is a supplement to, not a replacement for, the secret folder tree. It lists and you can sort by secret template, heartbeat status, sync status, machine, access date, username, and much more. You can customize which characteristics are displayed.
Allow Access Challenge		Role permission: Allows a user be challenged by Privileged Behavior Analytics if their behavior deviates from their normal behavior and meets certain requirements set by Privileged Behavior Analytics. Administrators do not have this permission by default.
Allow List Secret Access for Assigning Policy		Role permission: Allows users with list access to a secret to assign policies. Users need the view permission if they do not have this one.
ALM	Account Lifecycle Manager	See Account Lifecyle Manager.
Amazon IAM Console Password		Built-in secret template.
Amazon IAM Key		Built-in secret template.
AMQP	Advanced Message Queuing Protocol	A protocol that enables client applications to communicate with middleware brokers.
ANSI	American National Standards Institute	A private non-profit organization that oversees the development of voluntary consensus standards for products, services, processes, systems, and personnel in the U.S.
APAC	Asia Pacific region	A geographic region comprising East Asia, South Asia, Southeast Asia, and Oceania.
API	Application Programming Interface	A set of protocols and tools for building software and applications.
APM	Application Performance Monitoring	The practice of monitoring software application performance to ensure quality and detect issues.

Term	Definition	Description
Application Dashboard		The main page for searching and viewing secrets. You access it by clicking the Dashboard menu item.
Approve via Duo Push		Role permission: Allow a user to approve access requests via Duo push notifications. Administrators do not have this permission by default.
ARCFOUR	Alleged RC4 cipher	A stream cipher that was used in TLS prior to TLS 1.2.
ARGV	Argument Vector	Represents command-line arguments that are passed to a program.
ARN	Amazon Resource Name	A unique identifier for AWS resources, allowing for easy identification and interaction within AWS.
AS400	IBM mid-range server brand	Refers to IBM's range of mid-sized servers, now known as IBM i.
ASA	Adaptive Security Appliance	A security device from Cisco that combines firewall, antivirus, intrusion prevention, and virtual private network (VPN) capabilities.
ASCII	American Standard Code for Information Interchange	A character encoding standard for electronic communication.
ASHX		A web file extension used with Microsoft's ASP.NET | Open-source web framework for .NET for handling HTTP requests.
ASP	Advanced Server Pages	Microsoft's server-side script engine for dynamically generated web pages.
ASPNET	ASP.NET | Open-source web framework for .NET	A framework for building dynamic web sites, applications, and services.
ASR	Advanced Session Recording	A feature that records user sessions for monitoring or compliance purposes.
ASRA	Advanced Session Recording Agent	A component responsible for capturing the data needed for session recording.
Assign Pipelines		Role permission: Allows the user to assign an event pipeline policy to secret policies, or folders.

Term	Definition	Description
Assign Secret Policy		Role permission: Allows a user to assign Secret Policies to folders and secrets.
Automatic Secret Export		This feature allows you to automatically export secrets on a schedule to an external location in an encrypted, password-protected archive.
Automatic Sudo or Su Privilege Elevation		A convenience feature that eliminates the need to manually enter a su or sudo command's password when using a proxied SSH session to a Unix or Linux server. When a user manually types a su or sudo command with a valid secret ID, the SSH proxy automatically provides the username and password to use. The user does not need to know either.
AWS	Amazon Web Services	A subsidiary of Amazon providing on-demand cloud computing platforms and APIs to individuals, companies, and governments, on a metered pay-as-you-go basis.
Azure AD Account		Built-in secret template.
Bank Account		Built-in secret template.
Basic Session Recording		Basic session recording is a licensed feature in Secret Server. It relies on the protocol handler configured on client machines through Secret Server's launcher. Using the launcher, Secret Server captures second-by-second screenshots on the client machine during a user's recorded session. These images of the user's screen are compiled into a video that can be downloaded and played back for auditing and security purposes. Activity recorded in the session is based on screen changes only.
BLOWFISH		An encryption method where the same key is used for both encrypting and decrypting the data.
BMC	Business Machine Code	Machine code or instructions used to operate business machinery such as mainframe computers.

Term	Definition	Description
Browse Reports		Role permission: The "Browse Reports" role allows access to reports restricted by Delinea permissions. Deliea permissions are configurable at the category and report levels and share a similar inheritance model to secrets and folders. You can define users or groups with "view" or "edit" permissions for each category or report.
BSD	Berkeley Software Distribution	A Unix operating system derivative developed and distributed by the Computer Systems Research Group at the University of California, Berkeley.
Bypass Direct API Authentication Restriction		Role permission: Allows users to ignore the PreventDirectApiAuthentication advanced setting and log in via the API with a non-application account.
Bypass SAML Login		Role permission: Allows a user to login with local account without using SAML.
CA	Certificate Authority	An entity that issues digital certificates used to verify the identity of the certificate holder and provide the public key necessary to enable secure communications.
CAC	Common Access Card	A smart card used primarily by the United States Department of Defense for identification and secure access.
CAL	Certificate Authority List	A list of trusted certificate authorities that a browser or operating system will trust for secure communications.
CALs	Client Access Licenses	A license that grants a user or device the right to access services, such as RDS, from a server running the Windows Server operating system.
CAPTCHA	Completely Automated Public Turing test to tell Computers and Humans Apart	A challenge-response test used in computing to determine whether the user is human.
CAST	CAST-128 encryption algorithm	A symmetric encryption algorithm used to encrypt and decrypt data, utilizing a 128-bit key.

Term	Definition	Description
CAST128	128-bit key CAST encryption algorithm	A variant of the CAST-128 algorithm that specifically utilizes a 128-bit encryption key.
CBC	Cipher Block Chaining	A block cipher mode that provides confidentiality by combining each plaintext block with the previous ciphertext block before encryption.
CC	Common Criteria	An international standard for evaluating the security of information technology products.
CD	Compact Disc	A digital optical disc used to store data, including music and data files.
CDATA	Character Data	Special notations used in XML to represent characters that may be confused with markup elements.
CDN	Content Delivery Network	A system of distributed servers that deliver pages and other web content to users based on their geographical location.
CEF	Common Event Format	A standardized text file format for log management and interoperability among security tools.
CER	Certificate	A file format and extension that holds digital certificates
CERT	Computer Emergency Response Team	An expert group that handles computer security incidents.
CFG	Configuration file	A file used to configure the operations of a computer program.
CGI	Common Gateway Interface	A standard for interfacing external applications with servers to produce dynamic web pages.
CHACHA20	ChaCha20 stream cipher	A modern symmetric encryption algorithm designed for speed and security.
Checkout Hook		In addition to changing the password on check in, secret owners can also specify administrator-created PowerShell scripts, called hooks, to run before or after checkout and check in. These are accessed from the Hooks tab of the secret, which only shows if checkout is enabled and PowerShell scripts have been created by an admin.

Term	Definition	Description
CHGUSRPRF	Change User Profile	A command used to change the values specified in a user profile on an IBMi, iSeries, or AS400 system
CI	Continuous Integration	A software development practice where developers regularly merge their code changes into a central repository, followed by automated building and testing.
CID	Column Identifier	A unique identifier for a column in a database or other data structure.
CIDR	Classless Inter-Domain Routing	A method for allocating IP addresses and routing Internet Protocol packets.
CIFS	Common Internet File System	A protocol that allows programs to make requests for files and services on remote computers on the Internet.
CIS	Center for Internet Security	A nonprofit organization that provides cybersecurity tools, benchmarks, and guidelines.
Cisco Account (SSH)		Built-in secret template.
Cisco Account (Telnet)		Built-in secret template.
Cisco Enable Secret (SSH)		Built-in secret template.
Cisco Enable Secret (Telnet)		Built-in secret template.
Cisco VPN Connection		Built-in secret template.
CISO	Chief Information Security Officer	A senior-level executive responsible for an organization's information and data security.
CKM	Cryptographic Key Management	The process of managing cryptographic keys for a cryptosystem, including generation, use, storage, exchange, and replacement.
CLI	Command Line Interface	Allows managing systems such as Secret Server via command-line scripts and tools.

Term	Definition	Description
Cloud Suite		Cloud Suite is a part of a broader portfolio of identity and access management solutions, designed to extend privileged access management (PAM) and identity services to cloud environments. This enables organizations to secure access to cloud resources and applications through the same identity platform that they use for on-premises resources.
CLR	Common Language Runtime	A managed execution environment that is part of Microsoft's .NET framework.
CLSID	Class Identifier	A GUID that represents a specific class within the .NET framework.
CM	Configuration Management	The process of maintaining the consistency and integrity of a system or product throughout its lifecycle.
CM	Connection Manager	See Connection Manager.
CMAK	Connection Manager Administration Kit	A tool used to manage network connections in Windows.
CMDLINE	Command Line	An interface that allows users to interact with software by typing commands.
CMK	Customer Master Key	A key used in Amazon Web Services Key Management Service to encrypt and decrypt data.
CMVP	Cryptographic Module Validation Program	A program by the National Institute of Standards and Technology to validate cryptographic modules to Federal Information Processing Standards.
CN	Common Name	An attribute used in the subject field of a certificate to identify the entity that the certificate represents.
CNG	Cryptography API: Next Generation	An application programming interface for cryptography, provided by Microsoft.
COM	Component Object Model	A binary-interface standard for software components to communicate.
COM+ Dependency Scanner		The COM+ Dependency Scanner allows for an Active Directory domain discovery source to locate COM+ Applications running on machines on the domain that are being run by Domain Accounts.

Term	Definition	Description
Combination Lock		Built-in secret template.
Common Criteria		The Common Criteria for Information Technology Security Evaluation (ISO/IEC 15408), known as "Common Criteria," is an international standard for certifying security of computer systems, networks, and application software. Certification ensures that claims about the security attributes of the evaluated product have been independently verified in the specified, evaluated configuration and environment. The certification does not validate any security claims when the product is used outside of that evaluated configuration or environment.
Company Policy Login Banner		A login banner for usage agreements and conditions to be visible when users log into Secret Server
Configuration Overview Page		The Configuration Overview page (also called the "configuration preview") is a dynamic, one-stop locator for Secret Server configurations.
Connection Manager (CM)		Connection Manager provides secure connections to remote servers using RDP and SSH, allowing IT teams to launch ad-hoc connections to manage sessions with remote resources. Management of multiple active sessions is easy. You can store and organize connections by adding them to your favorites and import any folder structure or connections used in other tools for a single management hub. It includes remote connectivity tools closely integrated with Secret Server. It permits technical staff to quickly access resources using the convenience of a familiar, rich desktop interface while maintaining all the safeguards and workflows included with Secret Server.
Contact		Built-in secret template.
Copy Secret		Role permission: Allows a user to copy secrets when that user also has Own Secret role permission.
CORS	Cross-Origin Resource Sharing	A security feature implemented in web browsers to control the interactions between web pages from different domains.

Term	Definition	Description
CPAN	Comprehensive Perl Archive Network	A repository of over 250,000 software modules and accompanying documentation for the Perl programming language.
CPIC	Common Policy Implementation Criteria	Criteria used to assess the alignment of policies and procedures with common or accepted standards.
CPU	Central Processing Unit	The primary unit of a computer that performs most of the processing.
CQRS	Command and Query Responsibility Segregation	A pattern in software architecture where the data modification command responsibilities are separated from the data reading query responsibilities.
Create Root Folders		Role permission: Allows a user to create new folders at the root level of the folder structure.
Credit Card		Built-in secret template.
CRL	Certificate Revocation List	A list of digital certificates that have been revoked by the issuing certificate authority.
CRM	Customer Relationship Management	An approach to manage a company's interactions with current and potential customers using data analysis.
CRQ	Change Request	A formal proposal for an alteration to some product or system.
CRT	Certificate	File extension
CSA	Cloud Security Alliance. An industry group focused on cloud security best practices that Secret Server aligns with.	An industry group focused on cloud security best practices, including alignment with tools like Secret Server.
CSR	Certificate Signing Request	Used by systems like Secret Server to obtain SSL certificates from a certificate authority.
CSS	Cascading Style Sheets	A style sheet language used for describing the look and formatting of a document written in HTML.
CSV	Comma Separated Values	A file format that stores tabular data in plain text, with columns separated by commas.

Term	Definition	Description
CTL	Certificate Trust List	A list of trusted certificates used by Windows to determine if a certificate issued by a particular certificate authority is to be trusted.
Custom Password-Exclusion Dictionary		A list of words that you do not want users to choose as part of a password, for example, your company name. The dictionary becomes an option when creating or editing a password requirement object. Those, in turn, appear as options when creating a secret template. Finally, when a secret is created based on that template, the words in the dictionary are not allowed when creating a password (the "weak" warning appears).
CVE	Common Vulnerabilities and Exposures	A dictionary of publicly known information security vulnerabilities and exposures.
CVSS	Common Vulnerability Scoring System	A standard used to classify and rate the severity of security vulnerabilities in software.
Ciphertext		The result of encryption performed on plaintext using a cipher algorithm.
DAT	Data	File extension.
DB	Database	A structured collection of data stored in a computer, often in a tabular form, and managed using software to facilitate rapid search and retrieval.
DBA	Database Administrator	A person responsible for maintaining and optimizing a database, and ensuring its availability, performance, and security.
DBMS	Database Management System	Software that is used to create, manage, and manipulate databases.
DBO	Database Owner	A role in database systems that has complete control over the database, including Delinea permissions, schema modification, and data manipulation.
DC	Domain Controller	In a network, it is a server that responds to security authentication requests and maintains the security policy and user account information.

Term	Definition	Description
DCOM	Distributed Component Object Model	An extension of the Component Object Model (COM) that allows COM objects to communicate across network boundaries.
DCS	Dynamic Credentials	A feature that automatically updates or rotates credentials based on configurable rules to enhance security.
DE	Distributed Engine	An engine that spreads tasks across multiple servers or nodes to distribute the workload and improve performance.
Deactivate Secret		Role permission: Allows a user to mark secrets as deactivated.
Delete Secrets from Reports		Role permission: Allows a user to run the delete Secrets action from a report.
Delinea Mobile App		The Delinea Mobile app provides MFA verification for the Delinea Platform as well as portable access to secrets managed in Secret Server.
Delinea Platform (DP)		The Delinea Platform seamlessly extends privileged access management across your company's hybrid multi-cloud infrastructure, with adaptive controls that help IT and cybersecurity teams to rapidly meet compliance and reduce risk.
Dependency (Secret)		Secret dependencies are items that rely on the username, password, or SSH private key stored in the secret. By adding them to the Dependencies tab, they are automatically updated when the secret's password is changed, ensuring they are up to date with the account on which they depend.

Term	Definition	Description
Dependency Group (Secret)		By default, all dependencies are updated in the order listed. There are cases where you may want to split out different sets of dependencies into separate groups. Typically, this is because a single service account may run services across different segregated networks that can communicate with the domain but not each other and have different distributed engine sites assigned. In this case you can create two dependency groups and assign them to different distributed engine sites to solve connectivity issues.
DES	Data Encryption Standard	A symmetric encryption algorithm that was widely used but is now largely obsolete due to its vulnerability to brute-force attacks.
DevOps	Development and Operations	A set of practices that involve the collaboration and communication of both software developers and IT professionals to automate the process of software delivery and infrastructure changes.
DevOps Secrets Vault (DSV)		Delinea's DevOps Secrets Vault is a high velocity vault that centralizes secrets management, enforces access, and provides automated logging trails. This cloud-based solution is platform agnostic and designed to replace hard-coded credentials in applications, micro-services, DevOps tools, and robotic process automation. This vault ensures IT, DevOps and Security teams the speed and agility needed to stay competitive without sacrificing security. DevOps Secrets Vault is deployed as an API-as-a Service.
DevOps Secrets Vault Client Credentials		Built-in secret template.
DH	Diffie-Hellman key exchange algorithm	A method of securely exchanging cryptographic keys over a public channel, often used in secure communications protocols.
DHE	Ephemeral Diffie-Hellman key exchange	A variation of the Diffie-Hellman key exchange that uses temporary or "ephemeral" keys for each session, increasing security.

Term	Definition	Description
DIM	Dimension	In computing and data science, this term often refers to a particular aspect or feature of data, used to provide some context or analysis. In databases, it could refer to an attribute or set of attributes in a data set used to provide some form of classification.
Directory Services		Directory services are components of network operating systems that map the names of network resources to their network addresses. Their shared information infrastructure locates, manages, and organizes network resources, which can include volumes, folders, files, users, groups, devices, and much more. Active Directory is Secret Server's native directory service.
Discovery		Discovery is the process where scans an environment to find accounts and associated resources called dependencies. Once accounts are found, you can use them to create associated new secrets in . Users with the "administer discovery" role permission can either manually import accounts or can create an automated process, called a discovery rule, to do so. Using discovery does not stop users from manually creating their own secrets.
Discovery Command Set		An SSH script that runs on Unix machines and produces a specific set of output to be consumed in a discovery source flow.
Discovery Scan Template		Defines an object and what properties the object contains. For example, a computer account has a name, machine, and domain. Think of a scan template as an interface that describes an object.
Discovery Scanner		A discovery scanner is a component of a discovery source that collects information during a discovery. There are four general types of scanners, called scan templates. Defines how to take that information and runs code to produce collection outputs. Scanners can be system out-of-the-box code that runs natively in the system or completely custom scripts that can do anything.
Discovery Script		A script for a discovery scanner.

Term	Definition	Description
Discovery Secret Search Filters		Certain scanners and import rules can use a filter that uses the name of the machine to find or use an associated Secret. For example, you may have a pattern of naming the local account on a machine including the machine name. A secret search filter allows you to find secrets using the name of the current machine in the pattern to find the matching secret.
Discovery Source		A discovery source is a named collective, ordered system that conducts discovery. There are five broad types: Active Directory, Amazon Web Services, Unix, VMware ESX\ESXi, and Google Cloud Platform.
Discovery Source Flow		A collection of scanners that work in a common pipe and filter architecture where each scanner inputs a certain type of item and then outputs a different type of item. For example, a scanner takes an input of a host IP range and outputs multiple computers that can then be consumed by another scanner which can input computer information and output computer accounts.
Distributed Engine		For smaller enterprises, Secret Server performs all functions on the Web server it is installed on. It is also scalable for large enterprises and scenarios demanding higher performance. We use remote distributed engines to accomplish this. You route high-demand processing and traffic operations through one or more of these to enhance 's capacity. For example, distributed engines can synchronize and authenticate for Active Directory. They can also perform remote password changing, heartbeat, discovery and more, all controlled by a single installation.
distributedengine		A Windows service that does a DE's actual work, such as password changing, heartbeat, discovery, and more. Each engine belongs to a site.
DKIM	DomainKeys Identified Mail	An email authentication technique that allows the receiver to check that an email was actually sent by the domain it claims to have been sent by and that it hasn't been changed in transit.

Term	Definition	Description
DLL	Dynamic-link library	A collection of small programs or routines designed to perform specific tasks and can be dynamically loaded into running programs.
DMZ	Demilitarized Zone	A physical or logical subnetwork that contains and exposes an organization's external-facing services to an untrusted network, usually the internet.
DN	Distinguished Name	A string used in the X.500 standard to uniquely identify an entity within a directory service.
DNS	Domain Name System	A system for converting human-friendly domain names into IP addresses.
DOM	Document Object Model	A programming interface that represents HTML and XML documents as a tree structure where each node is an object representing a part of the document.
DOS	Disk Operating System	A family of disk operating systems predominantly composed of MS-DOS and a rebranded version under the name IBM PC DOS.
DoubleLock		Secret Server's doublelock is a feature that provides an additional security layer by protecting secret data using asymmetric encryption (a public/private key pair) where the private key is a human-generated password. This feature is independent of regular Delinea permissions, Secret Server login access, or physical access to the machine running Secret Server. A shortcut way of thinking about doublelocks is as an extra password for secrets that is held by a set group of users. In addition, both the password and the group of users are reusable for other secrets.
DoubleLock Object		A named object that is associated with one or more secrets and one or more users (via password objects). DoubleLock objects, or simply doublelocks, point to secrets (what can be accessed) and doublelock password objects (who can access it).

Term	Definition	Description
DoubleLock Password Object		An encrypted password that is associated with one user. The same QuantumLock password object, or simply doublelock password, is used for all doublelocks to which a user has access. Once a user is assigned to a doublelock, that user has access to any secret using that doublelock, using a single password. A doublelock password has nothing to do with the user's Secret Server access password.
Download Automatic Export		Role permission: The user can view all of the automatic export tabs and download exports from cloud storage (cloud customers only).
Download Hash		Download hash codes or hashes are used to verify the integrity and authenticity of downloaded software. Hash codes are unique mathematical values that are generated based on the content of the software file and can be used to confirm that the downloaded file matches the original version and has not been tampered with. By comparing the hash code of the downloaded file with the hash code provided by the software developer, you can ensure that the software you downloaded is genuine and has not been corrupted during the download process.
DP	Delinea Platform	See Delinea Platform.
DPAPI	Data Protection API	A Windows API used by applications like Secret Server to encrypt sensitive data at rest.
DR	Disaster Recovery	The process, policies, and procedures related to preparing for and recovering from a serious negative event affecting information systems.
DRAC	Dell Remote Access Controller	A hardware and software solution for remote systems management.
DRP	Disaster Recovery Plan	A documented process or set of procedures that helps in the recovery or protection of a particular IT infrastructure in the event of a disaster.

Term	Definition	Description
DS	Directory Service	Software systems that store, organize, and provide access to directory information in order to reduce duplication of information.
DSA	Digital Signature Algorithm	A public-key algorithm used for digital signatures.
DSC	Desired State Configuration	A management platform in PowerShell that enables you to manage your IT and development infrastructure declaratively.
DSEE	Directory Server Enterprise Edition	An enterprise directory service product from Oracle, offering robustness and scalability.
DSOH	Directory Server On-Demand Hold	A feature in directory services that temporarily prevents specific changes from replicating to other servers.
DSS	Data Security Standard	Security standards designed to secure data through a network.
DSV	DevOps Secrets Vault	See DevOps Secrets Vault.
DUO	Duo Security	A company that provides multi-factor authentication services.
DWORD	Double Word (data type)	A data type that usually consists of 32 bits in a computer's memory.
EA	Early Availability	Refers to a beta version of software that is made available for testing before the official release.
EA	Enterprise Architecture	A conceptual blueprint that defines the structure and operation of an organization.
EAP	Extensible Authentication Protocol	A framework for transport of authentication protocols.
EAU	Endpoint Authentication	The process of authenticating devices that connect to a network.
EBS	Elastic Block Store (AWS)	Provides block storage volumes for use with Amazon EC2 instances.

Term	Definition	Description
EC2	Elastic Compute Cloud (AWS)	An AWS service that provides resizable computing capacity in the cloud.
ECC	Elliptic Curve Cryptography	An asymmetric key encryption technology.
ECDH	Elliptic Curve Diffie-Hellman	A version of the Diffie-Hellman protocol using elliptic curve cryptography.
ECDSA	Elliptic Curve Digital Signature Algorithm	A variant of the Digital Signature Algorithm (DSA) which uses elliptic curve cryptography.
Edit (Folder Permission)		Allows the user to create new folders in that folder, which forces the "Inherit Permissions from Parent" folder permission on the new folder, move secrets into that folder, and add new secrets into that folder.
Edit Secret		Role permission: Allows a user to edit secrets. Note that they still require the "Edit" or "Owner" permissions on the individual secrets they are editing.
EFS	Encrypting File System (Windows)	A feature of Windows that allows files to be transparently encrypted to protect confidential data.
EID	Endpoint Identifier	A unique ID that helps in identifying network endpoints.
EMEA	Europe, Middle East, and Africa	A commonly used regional designation.
Engine	Distributed Engine	An engine that spreads tasks across multiple servers or nodes to distribute the workload and improve performance.
ENU	English	One of the standardized set of codes used to represent the English language, such as "en" or "en-US".
ENV	Environment	In computing, refers to a specific set of hardware, software, and settings used for specific tasks.
EP	End Point	The point at which a data flow ends, like a destination IP address and port number in a network.
EPMD	Erlang Port Mapper Daemon	A service in Erlang programming for distributing and managing nodes.

Term	Definition	Description
Erase Secret		Role permission: Allows a user to permanently erase (as opposed to deactivate, which is reversible) a secret.
ERP	Enterprise Resource Planning	A software system that helps organizations manage and integrate their core business processes. It provides a centralized platform for various departments within an organization to collect, store, manage, and interpret data from different business activities
ESM	Enterprise Security Manager	A security module in SAP systems that helps in managing different security aspects.
EST	Enrollment over Secure Transport protocol	A protocol used for secure certificate enrollment.
ESX	Elastic Sky X	VMware project. Short for VMware ESXi hypervisor, a virtualization platform.
Event Pipelines		Event pipelines (EPs) are a named group of triggers, filters, and tasks to manage events and responses to them. Event pipelines themselves can be grouped into EP policies. The Secret Server EP system is essentially a flexible instruction set builder and manager for controlling events and responses.
Event Subscriptions		Event subscriptions trigger notifications of defined events within the system. These notifications are sent to the inbox and from there can be sent externally via email or Slack.
EVT	Event	An event log file extension for Windows.
EWSR	Enable Web Services Reporting	An option to activate reporting capabilities via web services.
EX	Export Policy	A set of guidelines or rules that govern how data or services can be transferred or accessed outside a particular environment.
Expire Secrets from Reports		Role permission: Allows a user to expire Secrets listed in a report.'

Term	Definition	Description
Extensible Discovery		Extensible discovery lets you extend the already powerful scanning abilities of Secret Server by creating custom scanners that run PowerShell. You can use either built-in or custom scanners and templates at each step of the discovery process in extensible discovery. If the built-in discovery sources, scanners, or input and output template, cannot you meet your needs, you can use PowerShell scripts to perform any part of discovery. Doing so requires that you define your own input and output templates and scanners and then add them to a new or existing discovery source.
FAU	Federal Agency Unit	A unit of the federal government responsible for performing government functions, ranging from intelligence and defense to public policy and regulations.
FIA	Financial Institutions Advisories	Advisories issued by the U.S. Treasury targeted at financial institutions to notify them of regulatory changes or security concerns.
FIDO2	Fast Identity Online 2	A set of standards that enable simpler and more secure user authentication experiences across many types of platforms and devices.
Field Slug Name		A field slug name in Secret Server is a unique human-readable identifier for a data field in a Secret Server template. The field slug name is available for integrating with third-party applications via API calls. Slug names are programmatically available for API calls but are not visible to template users (secret creators). Instead, they are displayed as references in secret templates.
FIPS	Federal Information Processing Standard	A set of U.S. government standards that define how various types of information are to be encoded. Secret Server's support for FIPS refers to its compatibility with FIPS 140-2 validated cryptographic modules.

Term	Definition	Description
Folders		Secret folders allow you to create containers of secrets based on your needs. They help organize your customers, computers, regions, and branch offices, to name a few. Folders can be nested within other folders to create sub-categories for each set of classifications. Secrets can be assigned to these folders and sub-folders. Folders allow you to customize Delinea permissions at the folder level, and all secrets within can inherit the folder's permissions. Setting permissions at the folder level ensures future secrets placed in that folder have the same Delinea permissions, simplifying management across users and groups.
Force Check In		Role permission: Allows a user to force a secret that is checked out by another user to be checked in.
FPS	Frames Per Second	A unit that measures display device performance or video/animation quality, indicating how many individual frames are displayed per second.
FPSE	Format Preserving Strong Encryption	Encryption that transforms plaintext into ciphertext of the same format and length, typically used in financial systems.
FQDN	Fully Qualified Domain Name	The complete domain name for a specific computer, or host, on the internet, often consisting of a host name and a domain name, like Example Domain .
FTA	Functional Test Associate	Typically a role or position involved in the functional testing of software or systems to ensure they meet specified requirements.
FTP	File Transfer Protocol	A standard network protocol used to transfer computer files from one host to another over a TCP-based network, such as the internet or an intranet.
GA	General Availability	The stage in a software's lifecycle where it is considered fully tested and reliable, often the first version available to the general public.

Term	Definition	Description
GCM	Galois/Counter Mode (cryptography)	A mode of block cipher operation providing both data authenticity (integrity) and confidentiality. Commonly used in cryptography.
GCM	Google Cloud Messaging	A messaging solution for sending information from servers to client apps. It is now replaced by Firebase Cloud Messaging (FCM).
GCP	Google Cloud Platform	A suite of cloud computing services that run on the same infrastructure that Google uses internally for its end-user products.
GDPR	General Data Protection Regulation	A regulation enforced by the EU to protect citizens' personal data and privacy, affecting businesses worldwide.
Generic Discovery Credentials		Built-in secret template.
Geo Replication		Server geo-replication is a technique used to distribute data across multiple geographic locations for the purpose of data redundancy, high availability, and faster access. It is commonly used in the context of database servers, web servers, and other types of infrastructure that require fault tolerance and quick recovery from hardware failures or other types of incidents.
Getting Started Tutorial		A introductory guide to Secret Server for technical users.
Global Banner		A multipurpose global banner for all users and used for maintenance, security, or policy notifications.
Google IAM Service Account Key		Built-in secret template.
GPO	Group Policy Object	A feature of the Microsoft Windows NT family of operating systems that allows administrators to implement specific configurations for users and computers within an Active Directory environment.

Term	Definition	Description
GPU	Graphics Processing Unit	Specialized hardware designed to accelerate rendering of images and videos to be output to a computer's screen.
Group		A collection of users managed together for administrative convenience. Users within a group inherit the Delinea permissions and roles attributed to that group, making it easier to manage security settings. Groups can also be synchronized with external services like Active Directory.
GSS	Generic Security Services	A software layer that provides a standardized interface for secure communication, often used to implement Kerberos mechanisms.
GUI	Graphical User Interface	A type of user interface that allows users to interact with computer systems through graphical elements like buttons and windows, as opposed to text-based interfaces.
GUID	Globally Unique Identifier	A unique reference number used as an identifier in computer software, ensuring that each object has a unique ID.
HA	High Availability	A system design approach aimed at ensuring a high level of operational uptime. It often involves redundant or failover components.
Healthcare		Built-in secret template.
Heartbeat		Secret Server's heartbeat feature allows secrets to have their entered credentials automatically tested for accuracy at a given interval. Using heartbeat on secrets ensures those credentials are up-to-date and can alert administrators if the credentials are changed outside of Secret Server. Heartbeat helps manage secrets and prevent them from being out of sync.
HMAC	Hash-based Message Authentication Code	A specific type of message authentication code that uses cryptographic hash functions and a secret key for data integrity and authentication.

Term	Definition	Description
HP	Hewlett-Packard	An American multinational information technology company that produces hardware and software solutions.
HPE	Hewlett Packard Enterprise	Hewlett Packard Enterprise Servers are robust and scalable servers designed to meet the complex demands of modern business computing, offering advanced features for virtualization, high-performance computing, and cloud-based environments.
HP iLO Account (SSH)		A built-in secret template.
HSM	Hardware Security Module	Physical computing devices that safeguard digital keys and perform cryptographic functions.
HSTS	HTTP Strict Transport Security	A web security policy mechanism that helps to protect websites against man-in-the-middle attacks by enforcing secure (HTTPS) connections.
HTML	Hypertext Markup Language	The standard markup language for documents designed to be displayed in web browsers.
HTTP	Hypertext Transfer Protocol	The fundamental protocol used for transferring data over the web.
HTTPAPI	HTTP Application Programming Interface	A set of API calls for HTTP, allowing for programmatic interaction with web services.
HTTPS	HTTP Secure (SSL/TLS encryption)	An extension of HTTP, secured with SSL/TLS encryption.
IAM	Identity and Access Management	A framework for business processes that facilitates the management of electronic identities, allowing the right individuals to access the right resources at the right times for the right reasons.
IBM	International Business Machines Corporation	An American multinational technology and consulting company.
IBM iSeries Mainframe		Built-in secret template.
ICD	Interface Control Document	A document that describes the interface to a system or subsystem, providing details for ensuring compatibility.

Term	Definition	Description
ICT	Information and Communications Technology	An umbrella term that includes any communication device or application, encompassing radio, television, phones, computer and network hardware, etc.
ID	Identifier	A unique value used to identify a record or entity within a database or system.
IDEA	International Data Encryption Algorithm	A symmetric key block cipher that was once considered very secure but has since been superseded by newer algorithms.
Identity Bridge		A legacy Active Directory management product.
IDP	Identity Provider	A system that creates, maintains, and manages identity information and provides authentication services.
IDS	Intrusion Detection System	
IE	Internet Explorer	A discontinued web browser developed by Microsoft.
IIS	Internet Information Services	A web server from Microsoft used to host websites and other content on the web.
iLO	Integrated Lights Out	An embedded server management technology exclusive to Hewlett Packard Enterprise, which allows for remote control of HPE servers, providing powerful management capabilities irrespective of the server's operating status.
Inbox		The Inbox page shows notifications such as event subscription alerts, access requests and approvals, and other configuration alerts in a single interface. In addition to viewing notifications in the inbox, you can configure the inbox to forward them via email or Slack, subject to numerous configurable criteria. You can also customize the format of the email messages.
INTG	Integrations	Generally refers to the process of bringing together different computing systems and software applications physically or functionally.

Term	Definition	Description
IO	Input/Output	The collection of interfaces that different functional units of an information processing system use to communicate with each other.
IOS	Internetwork Operating System	The software used on a majority of Cisco Systems routers and switches.
iOS	iPhone Operating System	Apple smartphone OS.
IoT	Internet of Things	Refers to a network of physical devices that are embedded with sensors, software, and other technologies to collect and exchange data with other devices and systems over the internet. Secret Server can manage credentials for IoT devices.
IP	Internet Protocol	The principal communications protocol for relaying datagrams across network boundaries in the internet.
IPSec	Internet Protocol Security	A suite of protocols for securing internet protocol (IP) communications by authenticating and encrypting each IP packet in a data stream—a VPN tunnel.
IPV	IPv4	The fourth version in the development of the internet protocol (IP) and routes most traffic on the internet.
ISAPI	Internet Server API	An API developed by Microsoft that allows you to extend the functionality of an IIS web server.
ISE	Identity Services Engine	A security policy management and control platform from Cisco Systems.
ISO	International Organization for Standardization	An international standard-setting body composed of representatives from various national standards organizations.
ITSM	Information Technology Service Management	A set of policies, processes, and procedures for managing IT services.
IWA	Integrated Windows Authentication	An authentication method to securely store usernames and passwords, commonly used in intranet environments.
JAR	Java Archive	A package file format that aggregates many files into one, typically used to store Java classes.

Term	Definition	Description
JIRA	Jira	An issue and project tracking software developed by Atlassian.
JS	JavaScript	A high-level, interpreted programming language used for client-side web development.
JSON	JavaScript Object Notation	A lightweight data-interchange format that's easy for humans to read and write and easy for machines to parse and generate.
JWT	JSON Web Token	An open standard for securely transmitting information between parties as a JSON object.
KB	Knowledge Base	A database used for storing information, commonly in the context of technical support.
KBA	Knowledge Base Article	An individual document in a knowledge base, typically addressing a single issue or topic.
KBA	Knowledge-Based Authentication	A security measure that requires the user to answer a question only they would know.
KEM	Key Encryption Mechanism	An algorithm used to securely encapsulate (encrypt) cryptographic keys.
KEX	Key Exchange algorithm	Algorithms used to securely exchange cryptographic keys between parties.
KMS	Key Management Service	A service that manages cryptographic keys for encryption. It uses envelope encryption where the encryption key changes each time you make a request for a key.
Kyber-1024		A KEM specifically designed to resist quantum computing attacks.
LAN	Local Area Network	A network that connects computers within a limited area, like a home or office.
LCID	Locale Identifier	A unique identifier assigned to geographical or cultural regions for formatting purposes.
LDAP	Lightweight Directory Access Protocol	A protocol for accessing and maintaining a directory service, such as Microsoft's Active Directory.

Term	Definition	Description
LDAPS	LDAP Secure	LDAP over SSL/TLS, a secure version of LDAP.
LDP	Lightweight Directory Protocol	Usually a typo referring to LDAP.
LDS	Lightweight Directory Services	A subset of LDAP services that's lighter and easier to manage.
LM	LAN Manager	An outdated protocol suite by Microsoft used to provide file and print sharing services.
LPT	Line PrinTer (port)	Refers to the printer port used in older computer systems.
LSA	Local Security Authority	A Windows component responsible for enforcing security policies.
LTS	Long Term Support (version)	Software versions that are supported for a longer period than standard versions.
LWP	Libwww-perl	A Perl library for web-related activities.
Maintenance Mode		Maintenance mode allows you to temporarily prevent users from changing roles, secrets, or secret-related data such as dependencies, templates, and password requirements.
Master Encryption Key		The main key used in a cryptographic system, often used to derive additional keys. When Secret Server is first installed, a unique random AES256 Master Encryption Key (MEK) is generated and saved in a file, encryption.config. The MEK protects anything sensitive in Secret Server that is not associated with a specific secret, as well as each secret's unique AES256 key when an HSM is not used.
Master Encryption Key Rotation		For added security, you can rotate the MEK, re-encrypting protected data with the new key.
MD2-5	Message Digest 2-5	Cryptographic hash functions.
MEK	Master Encryption Key	See Master Encryption Key.

Term	Definition	Description
MemoryMQ	Memory Message Queue	A legacy built-in service developed by Delinea—replaced with RabbitMQ for production systems.
MFA	Multi-Factor Authentication	A security system that requires multiple methods of authentication.
Microsoft SQL Server		A relational database management system developed by Microsoft.
MMC	Microsoft Management Console	A framework for hosting administrative tools on Windows.
MOF	Managed Object Format	A language for describing instances of CIM (Common Information Model) classes.
MP4	MPEG-4 video file format	A digital multimedia container format most commonly used to store video and audio.
MPEG	Moving Picture Experts Group	A working group responsible for the development of video and audio encoding standards.
MQ	Message Queue	Middleware from IBM that helps to seamlessly connect different components of a business application.
MS	MicroSoft	An abbreviation for Microsoft Corporation.
MSADC	Microsoft Active Directory Connector	A way to integrate Microsoft Active Directory with other services.
MSDTC	Microsoft Distributed Transaction Coordinator	A component of Microsoft Windows that is responsible for coordinating transactions.
MSI	Microsoft Installer	A software component used for installing, maintaining, and removing software.
MySql Account		Built-in secret template.
NARTAC	NATO Communications and Information Agency	An agency responsible for NATO's IT and communication needs.
NAS	Network-Attached Storage	A dedicated file storage system that provides storage space over a network.

Term	Definition	Description
NAT	Network Address Translation	A technique of remapping an IP address space into another.
NATO	North Atlantic Treaty Organization	A military alliance of 30 countries.
NCO	NATO Consultation	Likely refers to the process or instance of consulting or collaboration within the context of NATO.
NCRYPT	Ncrypt	A library in Windows for handling cryptography functions contained in nncrypt.dll. It is an essential component of the operating system and is used by various programs to ensure the security of sensitive information. This DLL file provides encryption and decryption operations, helping to protect data from unauthorized access or tampering.
NDP	Network Device Enrollment Service	A Cisco service for secure distribution of certificates.
NET	Microsoft .NET Framework	A software framework developed by Microsoft.
NETBIOS	Network Basic Input/Output System	An API that augments the DOS API and provides network services.
NG	Next Generation	Generally refers to the next iteration or version of a product, technology, or methodology.
NIST	National Institute of Standards and Technology	An agency that develops and promotes measurement standards.
NNTP	Network News Transfer Protocol	An Internet application protocol for the distribution, retrieval, and posting of news articles.
NPL	National Physical Laboratory	The national measurement standards laboratory for the United Kingdom.
NSA	Network Security Appliance	The SonicWall Network Security Appliance (NSA) series is a line of advanced firewalls designed by SonicWall, targeted primarily at medium to large-sized businesses and distributed enterprise environments.

Term	Definition	Description
NSA	National Security Agency	A U.S. intelligence agency responsible for signal intelligence and information assurance.
NT	New Technology	Usually refers to a family of operating systems by Microsoft, starting with Windows NT.
NTC	National Transportation Commission	An organization that regulates transportation.
NTFS	New Technology File System	A file system used by Windows NT and its successors.
NTLM	NT LAN Manager	An authentication protocol used in various Microsoft network protocol implementations.
NTP	Network Time Protocol	A protocol used to synchronize computer clock times over a network.
OAEP	Optimal Asymmetric Encryption Padding	A padding scheme often used in RSA encryption.
OATH	Open Authentication	Standards for multi-factor authentication (MFA).
OAUTH	Open Authorization framework for API authentication	A framework for token-based API authentication.
Object Metadata		Object metadata allows you to store extended information on several Secret Server objects including users, groups, folders, dates, or secrets via the user interface or REST API. You can store most data types, including strings, Boolean values, numbers, dates, and users. You can combine this metadata into sections containing named fields of your defined types.
OCS	Office Communications Server	A Microsoft instant messaging platform.
ODAC	Oracle Data Access Components	Software components for connecting to Oracle databases.
ODBC	Open Database Connectivity	A standard API for accessing database management systems.

Term	Definition	Description
OEM	Original Equipment Manufacturer	A company that produces parts and equipment that may be marketed by another manufacturer.
OIDC	OpenID Connect	An identity protocol that is layered on top of the OAuth 2.0 protocol.
OKTA	Okta	A service providing identity management solutions.
OLDAP	OpenLDAP	An open-source implementation of the Lightweight Directory Access Protocol.
OOB	Out of Box	
OpenLDAP Account		Built-in secret template.
ORA	Oracle database	A database management system from Oracle Corporation.
Oracle Account		Built-in secret template.
Oracle Account (TCPS)		Built-in secret template.
Oracle Account (Template Ver 2)		Built-in secret template.
Oracle Account (Walletless)		Built-in secret template.
ORG	Organization	A group of people working together towards common goals.
OS	Operating System	Software that controls the computer hardware and provides services for computer programs.
OSX	Operating System X	A desktop operating system from Apple.
OTP	One-Time Password	A password that is valid for only one login session.
OU	Organizational Unit	A subdivision within an Active Directory into which you can place users, groups, computers, and other OUs.
Own Group		Role permission: Allows a user to be an owner of a group. This permission is in the default Group Owner role, which is automatically assigned when that user is set as owner of a group.

Term	Definition	Description
Own Secret		Role permission: Formerly "Share Secret", allows a user to share secrets with other users. Also allows users to perform more advanced tasks on secrets of which they are "Owners", such as configuring expiration schedules, configuring the web launcher, converting secret template, and copying secrets (when a user also have the Copy Secret role permission.)
Own User		Role permission: Allows the user to become a user owner, used to configure specific users without the Administer Users permission.
Owner (Folder Permission)		Allows the user to create new folders in that folder without forcing inheritance, move the folder, delete the folder, rename the folder, and change the Delinea permissions and inheritance settings on the folder.
PAM	Privileged Access Management	A solution that helps organizations restrict privileged access within an environment.
PAP	Password Authentication Protocol	A simple, clear-text authentication scheme.
Password		Built-in secret template.
PBA	Privileged Behavior Analytics	See Privileged Behavior Analytics.
PBKDF2	Password-Based Key Derivation Function 2	A key derivation function with a sliding computational cost.
PC	Personal Computer	A computer designed for use by one person at a time.
PCI	Payment Card Industry	A set of security standards designed to ensure that all companies that accept, process, store or transmit credit card information maintain a secure environment.
PCI DSS	Payment Card Industry Data Security Standard	A set of security standards for merchants and organizations that handle branded credit cards.
PDF	Portable Document Format	A file format used to present and exchange documents reliably.

Term	Definition	Description
Personal Folder		In Secret Server, a personal folder is a folder that one (and only one) individual has owner access to. No user can modify sharing permissions on these folders. User's can add subfolders to their personal folder. The purpose of this folder is to allow a user to securely store work-related secrets that other users do not require access to. Note that when in break-the-glass mode, an Unlimited Vault Access can access a user's personal folder in order to recover secrets if needed.
Personal Folders		Role permission: Allows a user to have personal folder when the global personal folders configuration options is enabled.
Personally Identifiable Information		Any data that could potentially identify a specific individual.
PFX	PKCS #12	A file format for storing server cryptographic keys.
PII	Personally Identifiable Information	Any data that could potentially identify a specific individual.
PIN	Personal Identification Number	A numerical code used for authentication.
Pin		Built-in secret template.
PIV	Personal Identity Verification	A standard for smart cards used for identification.
PKCS	Public Key Cryptography Standards	A set of cryptographic standards.
PKI	Public Key Infrastructure	A framework that manages digital keys and certificates.
PM	Project Manager	An individual responsible for planning, executing, and closing projects.
PM	Privilege Manager	See Privilege Manager.
PNG	Portable Network Graphics	A raster graphics file format that supports lossless data compression.

Term	Definition	Description
POC	Proof of Concept	A demonstration to verify that certain concepts or theories have the potential for real-world application.
PORT	Network port	A hardware or software interface for transferring data.
POSIX	Portable Operating System Interface standard	A family of standards specified by the IEEE for maintaining compatibility between operating systems.
POST	Power On Self Test	A diagnostic process that occurs when you start the computer.
PostgreSQL	An open-source database management system	A free and open-source relational database management system.
PQ	Post Quantum	An encryption or encapsulation algorithm that is resistant to quantum computing attacks.
Privilege Manager (PM)		Privilege Manager is an endpoint least privilege and application control solution for Windows, macOS, and Unix/Linux, capable of supporting enterprises and fast-growing organizations at scale. Mitigate malware and modern security threats from exploiting applications by removing local administrative rights from endpoints. The two major components are Local Security and Application Control.
Privilege Manager Administrator		Role permission: Allows the user to have the "Administrator" role for Privilege Manager, giving full access to the system.
Privilege Manager Helpdesk User		Role permission: Allows the user to have the "Help Desk" role for Privilege Manager, giving full access to approve or deny escalation requests.
Privilege Manager MacOS Admin		Role permission: Allows the user to have the MacOS "Administrator" role for Privilege Manager, giving full access to the system.
Privilege Manager Unix/Linux Admin		Role permission: Allows the user to have management permissions to Unix/Linux policies and machines.

Term	Definition	Description
Privilege Manager User		Role permission: Allows the user to have the "User" role for Privilege Manager, giving read and write permissions to most items, but not rights to modify security permissions. Administrators do not have this permission by default.
Privilege Manager Windows Administrator		Role permission: Allows the user to have the Windows "Administrator" role for Privilege Manager, giving full access to the system.
Privileged Behavior Analytics (PBA)		PBA works with Secret Server to improve enterprise system security by helping to visualize, detect, interrupt, and announce threatening activity and behavior.
Product License Key		Built-in secret template.
Protocol Handler		An application on an end-user's machine. It enables communication between Secret Server and that client machine. It also provides the files needed by launchers.
PS	PowerShell	A task automation and configuration management framework from Microsoft.
PSE	Personal Security Environment	A user-specific environment with customized security settings.
PUB400		Public access folders in an IBM i environment.
Public Worker		A role that utilizes a public bus for communication and is not intended for executing business application logic.
PuTTY	Popular SSH and Telnet Client (literally)	A free and open-source terminal emulator that supports various network protocols.
QA	Quality Assurance	The process of verifying or determining whether products meet or exceed customer expectations.
QR	Quick Response	A type of matrix barcode commonly used for storing URLs or other information.
QRTZ	Quartz enterprise scheduler	An open-source job-scheduling library.

Term	Definition	Description
RabbitMQ (RMQ)		RabbitMQ is an important component of Secret Server's on-premises environment, providing a robust framework for queuing messages between Secret Server and its Distributed Engines. RabbitMQ is an enterprise-ready software package that provides reliability and clustering functionality superior to other applications. RabbitMQ helper is Delinea's implementation of RabbitMQ.
RabbitMQ Durable Exchange		In RabbitMQ, an exchange is a routing mechanism that takes messages from producers and pushes them to queues based on certain rules, known as bindings. An exchange can be configured to be "durable," meaning it will survive server restarts.
RabbitMQ Helper		See RabbitMQ.
RACF	Resource Access Control Facility	IBM mainframe security module.
RADIUS	Remote Authentication Dial-In User Service	A networking protocol that provides centralized Authentication, Authorization, and Accounting.
RAM	Random Access Memory	A type of computer memory that can be read and changed in any order.
RAS	Remote Access Service	A service for remote computer access.
RBAC	Role-Based Access Control	A system for managing permissions based on roles within the organization.
RBS	Role Based Security	An approach to security that assigns permissions based on roles within the organization.
RCE	Remote Code Execution	The ability to execute code on a remote system.
RCP	Remote Copy Protocol	A protocol used for copying files over a network.
RD	Remote Desktop	A technology that allows users to connect to a remote computer.
RDBMS	Relational Database Management System	A database management system based on the relational model.

Term	Definition	Description
RDP	Remote Desktop Protocol	See Remote Desktop Protocol
Remote Desktop Protocol		A Microsoft protocol for remote control of computers.
RDPWin		The primary executable for SSPH.
Remote Desktop Services		Remote control services (using RDP) provided by a dedicated server or servers.
RDS	Remote Desktop Services	See Remote Desktop Services.
ReBAC	Relationship-Based Access Control	A type of access control based on relationships between entities.
REG	Windows Registry	A database to store settings and options for the Microsoft Windows operating system.
Remote Password Changing		A Secret Server feature that can automatically change passwords on various platforms including Windows, databases, and network appliances. Remote Password Changing (RPC) allows secrets to automatically update a corresponding remote account. You can set secrets for automatic expiration, followed by automatic strong password generation and a remote password update to keep the subject accounts synchronized with Secret Server.
REQS	Requirements	Specifications that must be satisfied by a system or component.
REST	Representational State Transfer	An architectural style for distributed hypermedia systems.
REST API	RESTful Application Programming Interface	An API using REST architecture. Used in Secret Server.
RFC	Request for Comments	A publication from the IETF and the Internet Society, the principal technical development and standards-setting bodies for the Internet.
RHEL	Red Hat Enterprise Linux	An enterprise-level Linux operating system.

Term	Definition	Description
RIPEMD	Race Integrity Primitives Evaluation Message Digest	A cryptographic hash function.
RIPEMD160	160-bit RIPEMD	A 160-bit cryptographic hash function.
RMQ	RabbitMQ	See RabbitMQ.
Role		Every user and group must be assigned to a role. uses role-based access control to provide very granular system access. ships with three roles: Administrator, User, and Read-Only User. Each role contains a set of permissions to match the job function of users with that role. See the Role Permissions List for details.
Rotate Encryption Keys		Role permission: Allows a user to start a process that rotates the Secret encryption keys.
RPC	Remote Password Changing	See Remote Password Changing.
RPC	Remote Procedure Call	A protocol for executing code on a remote server.
RPO	Recovery Point Objective	Maximum acceptable data loss in the event of a failure.
RSA	Rivest-Shamir-Adleman	A public key encryption technology.
RTO	Recovery Time Objective	The maximum amount of time for recovering data after a disaster.
RU	Request Unit	A unit of measure for system resources.
Run Automatic Export		Role permission: The user can view all of the automatic export tabs and run the export manually by clicking the Run Export button.
Run Disaster Recovery Data Replication		Role permission: Allows user to initiate or test Data Replication.

Term	Definition	Description
Run Scripts		Role permission: Separates privileges in script management. Holders of the "View Scripts" role permission cannot execute test runs of scripts, and this permission must be assigned to perform this task.Administer Scripts remains unchanged and allows view, edit, and run permissions.
S3	Simple Storage Service	AWS object storage.
SA	Systems Administrator	Person responsible for managing systems.
SALT		Random data added during password hashing.
SAM	Security Accounts Manager	Windows component for managing security accounts.
SAML	Security Assertion Markup Language	An open standard used by Secret Server to support SSO.
SAN	Storage Area Network	A network designed for storing data.
SAP	Systems Applications and Products	An ERP system and company.
SAP Account		Built-in secret template.
SAP SNC Account		Built-in secret template.
SAPNCO	SAP NetWeaver Component	A component of SAP NetWeaver, which is a software stack and technology platform developed by SAP SE. It serves as the technical foundation for many of SAP's enterprise applications
SAPSNC	SAP SNC	Cryptographic library for SAP.
SBS	Small Business Server	Windows server edition tailored for small businesses.
SCIM	System for Cross-domain Identity Management	Protocol for managing identities across domains.
SCP	Secure Copy Protocol	SSH file transfer protocol.
SDK	Software Development Kit	Toolkit for software development.

Term	Definition	Description
SDLC	Software Development Life Cycle	The phases involved in software development.
SEC	Security and Exchange Commission	U.S. government agency for regulating securities.
Secret		A piece of information that is stored and managed within is referred to as a secret. Secrets are derived from secret templates. Typical secrets include, but are not limited to, privileged passwords on routers, servers, applications, and devices. Files can also be stored in secrets, allowing for storage of private key files, SSL certificates, license keys, network documentation, Microsoft Word or Excel documents and more.
Secret Checkout		The Secret Server checkout feature forces accountability on secrets by granting exclusive access to a single user. If a secret is configured for check out, a user can then access it. If Change Password on Check In is turned on, after check in, Secret Server automatically forces a password change on the remote machine. No other user can access a secret while it is checked out, except Unlimited Vault Accesss. This guarantees that if the remote machine is accessed using the secret, the user who had it checked out was the only one with proper credentials at that time.
Secret Key Rotation		Secret key rotation is a somewhat similar process to RPC by which the encryption key, used for securing secret data, is changed and that secret data is re-encrypted. Each secret receives a new, unique AES-256 key. Secret key rotation can be used to meet compliance requirements that mandate encryption keys be changed on a regular basis.
Secret Launch		Role permission: Dictates whether or not a user can launch a secret. Previously, a user could launch a secret if their user's role had the "View Secret" permission. As of Version 11.5, a user needs this permission to launch. A user will also need the "Secret Launch Remote Access (Platform)" permission to be able to launch a Remote Session with (RAS)

Term	Definition	Description
Secret Launch Remote Access (Platform)		Role permission: Dictates whether or not a user can launch a secret. Previously, a user could launch a secret if their user's role had the "View Secret" permission. As of Version 11.5, a user needs this permission to launch a remote session with RAS.
Secret Launcher		A secret launcher launches applications on end-user machines and automatically logs on using credentials stored in Secret Server. In general, there are three types of launchers: RDP, SSH, and Custom. This provides a convenient method to open RDP and PuTTY connections, but it also circumvents users needing to know their passwords–a user can still gain access to a needed machine but it is not required to view or copy the password out of Secret Server. A Web launcher automatically logs into websites using the client's browser.
Secret Navigation Slideout		The Secret Navigation Slideout is a set of useful links to secret. Its tab appears on the right side of all top-level pages.
Secret Server		Delinea Secret Server is an enterprise-grade password management solution designed to help organizations securely store, manage, and control access to privileged credentials. It aims to improve the security of sensitive data, reduce the risk of data breaches, and streamline the password management process.
Secret Server Cloud Quick Start		A quick-start guide intended for business users of Secret Server Cloud.
Secret Server Migration Tool		A migration utility for importing secrets from other applications

Term	Definition	Description
Secret Server Mobile		Through the Secret Server Mobile application, users can connect from a mobile device to a Secret Server instance to view, manage, and use secrets stored there. The mobile application interface is similar to the Secret Server interface, which makes it easy for users to navigate to find secrets and secret folders. The mobile application offers useful functionality including multi-factor authentication, biometric authentication, autofill, online and offline caching, and advanced secret workflows.
Secret Template		Secret templates are used to create secrets and allow customization of the format and content of secrets to meet company needs and standards. Examples include: local administrator account, SQL Server account, Oracle account, credit card and Web password. Templates can contain passwords, usernames, notes, uploaded files, and drop-down list values. New secret templates can be created, and all existing templates can be modified.
Security Alarm Code		Built-in secret template.
Security Hardening Guide		A document that outlines security hardening for securing your Secret Server instance, whether it be installed on a single server or in a multi-clustered environment.
SEIM	Security Information and Event Management	System for security management.
SERPENT128	128-bit Serpent	A 128-bit encryption algorithm.
SERPENT192	192-bit Serpent	A 192-bit encryption algorithm.
SERPENT256	256-bit Serpent	A 256-bit encryption algorithm.

Term	Definition	Description
Server Suite		Server Suite is a comprehensive security solution designed to manage, secure, and audit both user and privileged account access across a wide range of servers, including Windows, Linux, and UNIX systems. The suite is particularly focused on minimizing the risk associated with privileged access, which can be a significant security vulnerability if not managed correctly.
Session Connector		Normally, Secret Server requires installing additional software such as Connection Manager or Secret Server Protocol Handler (SSPH) on the end-user computers to launch secrets, such as RDP, SSH, or custom, and optionally record the session. With Secret Server Session Connector (SSSC) installed on a Remote Desktop Services (RDS) server, anyone who can download and launch a standard Remote Desktop Protocol (RDP) shortcut file can have the same experience. The RDS server itself runs a special SSPH for RDS–SSPH (RDS) as a remote app to record the sessions, so end-users do not need to install any additional software.
Session Recording Auditor		Role permission: Grants access to the session recording of a secret to a user with at least "List Access" permission on the secret. Administrators do not have this permission by default.
SFTP	SSH File Transfer Protocol	Secure file transfer protocol.
SHA	Secure Hash Algorithm	A set of cryptographic hash functions.
SHA256	256-bit SHA-2 hash function	A 256-bit cryptographic hash function.
SHA384	384-bit SHA-2 hash function	A 384-bit cryptographic hash function.
SHA512	512-bit SHA-2 hash function	A 512-bit cryptographic hash function.
SID	Security Identifier	An identifier for security principles in Windows.

Term	Definition	Description
SIEM	Security Information and Event Management	System for security management.
Site (Distributed Engine)		A bucket of work items for a particular network area. Each engine is assigned to a single site, but each site can include multiple engines, significantly increasing throughput.
Site (Secret Server Cloud)		In Secret Server Cloud, the site serves as the designated location for storing secrets. Any operations necessitating a Distributed Engine (DE) will utilize the site specified, along with the DEs associated with that site.
Site Connector		A Windows service that holds the work items for a number of sites. The site connector can be either RabbitMQ or MemoryMQ (a built-in service developed by Delinea). Each site can only be assigned to a single site connector, but you can have multiple site connectors running on separate machines, each storing work items for multiple sites. Those sites, in turn, distribute the work items among multiple engines. The ability to add new Site Connectors, Sites, and Engines as needed makes Distributed Engine a highly-scalable solution.
SLA	Service Level Agreement	A contract for service quality.
SLO	Service Level Objective	Objective measurements for service quality.
SMB	Server Message Block	A network file-sharing protocol.
SMB Fallback		To maximize compatibility across versions of Windows when a heartbeat fails Secret Server makes a second attempt to use the Secret via SMB when Use SMB heartbeat fallback is checked. When Use SMB heartbeat fallback is not selected this second attempt will not be made.
SMS	Short Message Service	Text messaging.
SMTP	Simple Mail Transfer Protocol	Protocol for sending emails.

Term	Definition	Description
SNC	SAP NetWeaver AS for ABAP - Security Network Communications	Security component for SAP.
SNMP	Simple Network Management Protocol	Protocol for network management.
SOAP	Simple Object Access Protocol	Protocol for exchanging structured information.
SOC	Security Operations Center. Secret Server provides audit logs for SOCs monitoring security.	Center for monitoring and responding to security incidents.
Social Security Number		Built-in secret template.
SonicWall NSA Web Admin Account		Built-in secret template.
SonicWall NSA Web Local User Account		Built-in secret template.
SP	Service Pack	A set of updates for software.
SPN	Service Principal Name	Identifier for service instances.
SQL	Structured Query Language	Language for database queries.
SQL Server Account		Built-in secret template.
SRV	Server	Server.
SS	Secret Server	Server for managing secrets.
Secret Server Cloud	Secret Server Console	Console for managing Secret Server.
SSDE	Secret Server DevOps Edition	DevOps edition of Secret Server.
SSH	Secure SHell	Protocol for secure remote access.

Term	Definition	Description
SSH CA	SSH Certificate Authority	Secret Server can act as a CA for signing SSH certificates.
SSH Jumpbox Route		A series of regular Linux servers, accessible from the Internet, that is a gateway to other Linux machines on a private network using the SSH protocol. This topic and its subtopics address discuss using jumpbox routes.
SSH Key		Built-in secret template.
SSH Key Rotation		SSH Key Rotation allows you to manage your Unix account private keys and passphrases as well as their passwords. With key rotation, whenever the password is changed on the secret (manually, during a scheduled auto-change, or when checking in a secret that changes the password on check-in), the public/private key pair will be regenerated and the private key encrypted using a new passphrase. The public key will then be updated on the Unix machine referenced on the secret.
SSHD	SSH Daemon (server process)	Server process for SSH.
SSL	Secure Socket Layer	Protocol for secure communications.
SSMS	SQL Server Management Studio	Management studio for SQL Server.
SSO	Single Sign-On	Technology for allowing single sign-on.
SSP	Secret Server Provider	Provider for Secret Server.
SSPH	Secret Server Protocol Handler	See Protocol Handler.
SSPH (RDS)	Secret Server Protocol Handler, RDS Version	A special SSPH for use with SSSC that enables optional keystroke recording.
SSSC	Secret Server Session Connector	See Session Connector.
STIG	Security Technical Implementation Guide	Guidelines for securing systems.

Term	Definition	Description
SUDO	Substitute User DO command	Command for temporary superuser access.
SUPM	SAP User and Profile Management	User and profile management for SAP.
SUSE	SUSE Linux distribution	A distribution of Linux.
Sybase Account		Built-in secret template.
SYS	System	System.
SYSDBA	Oracle database superuser role	Superuser role for Oracle database.
T1	Thycotic One	See Thycotic One.
TCP	Transmission Control Protocol	Protocol for reliable data transmission.
TCP445	TCP port 445	Used by SMB for file sharing.
TCPS	TCP over TLS	TCP traffic over TLS encryption.
TDC	Tableau Data Connection file	File type used by Tableau for data connections.
TDE	Transparent Data Encryption. SQL feature used by Secret Server to encrypt database contents.	SQL feature used by Secret Server for database encryption.
Teams		See User Teams.
Thycotic One		A legacy access management product.
TID	Thread ID	Identifier for a thread in computing.
TLS	Transport Layer Security. Cryptographic protocol used by Secret Server for secure communications.	Cryptographic protocol for secure communication.

Term	Definition	Description
TMS	Ticketing Management System	System for managing tickets in IT support.
TNS	Transparent Network Substrate (Oracle networking)	Oracle networking component.
TOAD	Toad database admin tool	Database administration tool.
TOE	Target of Evaluation	Subject of a security evaluation.
TOP	TakeOut Point	Point where data is extracted.
TOTP	Time-Based One-Time Password	A type of one-time password that is time-based.
TPM	Trusted Platform Module hardware chip	Hardware chip for secure computing.
TRP	Trusted Realm Participant	Participant in a trusted security realm.
TS	Terminal Services	Services to enable multiple user access to Windows OS.
TSF	TOE Security Functionality	Security features in a TOE.
TSG	Technical Support Group	Group that provides technical support.
TSS	TOE Summary Specification	Summary of TOE security features.
TTL	Time to live	Time limit for data packets in a network.
TTLS	Tunneled Transport Layer Security	TLS within another protocol.
UAC	User Account Control	Windows feature for user permission control.
UDP	User Datagram Protocol	Protocol for simple, connectionless data transfer.
UI	User Interface	Visual interface of a software application.

Term	Definition	Description
UMAC	Universal Hashing Message Authentication Code	A type of message authentication code (MAC) calculated choosing a random hash function from a class of hash functions. The resulting digest or fingerprint is then encrypted to hide the identity of the hash function used.
UNC	Universal Naming Convention (Windows network paths)	Windows network path naming.
UNIX	Unix operating system	An operating system.
Unix Account (Privileged Account SSH Key Rotation - No Password)	Built-in secret template.	
Unix Account (Privileged Account SSH Key Rotation)	Built-in secret template.	
Unix Account (SSH Key Rotation - No Password)	Built-in secret template.	
Unix Account (SSH Key Rotation)		Built-in secret template.
Unix Account (SSH)		Built-in secret template.
Unix Account (Telnet)		Built-in secret template.
Unix Root Account (SSH)		Built-in secret template.
Unlimited Administration Mode		A legacy name for *Unlimited Vault Access* mode.
Unlimited Vault Access (UVA)		Role permission: Allows a user to view and edit all secrets in the system, regardless of permissions, when Unlimited Vault Access Mode is on. Note that another user with the "Administer Unlimited Vault Access Configuration" role permission would still need to turn this mode on.

Term	Definition	Description
Unlimited Vault Access Mode		An emergency, break-the-glass mode that gives administrators access to all content within the system, regardless of explicit permissions. Access to UVA mode is controlled using role permissions.
Unrestricted by Teams		Role permission: Users can view all users, groups, and sites, regardless of team affiliation. Essentially, teams do not exist for the users with this permission, and the Teams page is not available to them. The default user role has this permission.
UPN	User Principal Name	User identifier in a Windows domain.
URI	Uniform Resource Identifier	A unique sequence of characters that identifying a logical or physical web resource.
URL	Uniform Resource Locator	A type of URI that identifies a web address, including the protocol.
USB	Universal Serial Bus	A standard for connecting devices.
User		Users are 's representation of people—one person per user. Each user has a unique username, as well as other attributes. Users are assigned to groups, and roles are assigned to them, either directly or via groups.
User Audit Expire Secrets		Role permission: Allows a user to view the "User Audit" report, which shows all secrets that have been accessed by a particular user in a specified date range. Also allows the user to force expiration on all these secrets, which would make Secret Server automatically change the password.
User Group		Secret Server allows administrators to manage users through user groups. Users can belong to different groups and receive the sharing permissions, as well as roles, attributed to those groups. This setup simplifies the management of the permissions and roles that can be assigned to a user. Additionally, groups can be synchronized with Active Directory to further simplify management.

Term	Definition	Description
User Teams		With Secret Server teams, administrators can create special groups called teams to restrict what users can see. A team bundles users and groups to assign them the same rules as to what other users and sites are visible to them. For example, a managed service provider could isolate their customers from seeing other customer's user accounts or a large company could "firewall" their users by department. Site visibility can also be restricted by teams.
UTC	Coordinated Universal Time	Standard time.
UTCNOW	Current time in UTC	Current time in Coordinated Universal Time.
UTF	Unicode Transformation Format	Encoding for Unicode characters.
UTF8	Unicode Transformation Format 8-bit	8-bit Unicode encoding.
UTILS	Utilities	Utility tools or programs.
UX	User Experience	Overall experience of a user using a product.
View (Folder Permission)		Allows the user to see the folder and secrets in that folder that are inheriting permissions from their folder.
View About		Role permission: Allows a user to view the "About" page from the Help menu, which links to external resources such as Technical Support and the Delinea blog.
View Active Directory		Role permission: Allows a user to view, but not edit, the Active Directory settings in the system.
View Advanced Dashboard		Role permission: Allows a user to view advanced dashboard. Without this permission, users will only be able to view basic dashboard.
View Advanced Secret Options		Role permission: Allows a user to view the Remote Password Changing, Security, and Dependency tabs on a Secret they have access to.

Term	Definition	Description
View Automatic Export		Role permission: The user can view all of the automatic export tabs.
View Backup		Role permission: Allows a user to view, but not edit, the automated backup settings.
View Configuration		Role permission: Allows a user to view, but not edit, general configuration settings.
View Configuration Proxying		Role permission: Allows a user to view, but not edit, SSH Proxy settings.
View Configuration SAML		Role permission: Allows a user to view SAML integration settings on the Login tab of Configuration settings.
View Configuration Security		Role permission: Formerly "View Security Configuration," allows a user to view the security configuration of Secret Server.
View Configuration Session Recording		Role permission: Allows a user to view session recording settings on the Session Recording tab of Configuration settings.
View Configuration Two Factor		Role permission: Allows a user to view the configuration settings of the two factor authentication that are available for users logging into Secret Server.
View Configuration Unlimited Admin		Role permission: Formerly "View Unlimited Vault Access Configuration," allows a user to view the Unlimited Vault Access Mode configuration. Also allows a user to view the Unlimited Vault Access Mode audit log.
View ConnectWise Integration		Role permission: Allows a user to view, but not edit, the ConnectWise integration settings.
View Data Retention		Role permission: Can view retained audit data. This permission does not automatically come with the Administrator role.
View Deleted Secrets		Role permission: Allows a user to view Secrets that have been deleted in the system.

Term	Definition	Description
View DevOps Secrets Vault Tenants		Role permission: View (not edit) the DSV tenants set to synchronize with Secret Server.
View Disaster Recovery		Role permission: Allows a user to view configuration, logs and audits for Disaster Recovery.
View Discovery		Role permission: Allows a user to view, but not edit, computers and accounts that are found by Discovery.
View Distributed Engine Configuration		Role permission: Allows a user to view the Distributed Engine configuration.
View DoubleLock Keys		Role permission: Allows a user to view which DoubleLock keys exist in the system.
View Dual Control		Role permission: Allows a user to view configured Dual Control settings for reports and Secret sessions.
View Enterprise Objects		Role permission: Allows a user to view user and secret metadata.
View Event Subscriptions		Role permission: Allows a user to view event subscriptions.
View Export		Role permission: Allows a user to view the export log of the system to see when users exported secrets. Does not allow a user to export.
View Folders		Role permission: Allows a user to view, but not edit, folders in the system.
View Group Roles		Role permission: Allows a user to see which groups and users are assigned to which roles. Does not allow a user to change these assignments.
View Groups		Role permission: Allows a user to see which groups exist in the system. Also allows a user to see which users belong to each group.
View HSM		Role permission: Allows a user to view the Hardware Security Module (HSM) configuration settings.

Term	Definition	Description
View IP Addresses		Role permission: Allows a user to view IP Address Ranges that have been created to restrict access. Does not allow a user to edit these ranges.
View Jumpbox Route		Role permission: Allows a user to view the details of all jump server routes in the Admin Jumpbox Route page but not make any changes.
View Key Management		Role permission: Allows a user to view the Key Management settings (Secret Server Cloud only).
View Launcher Password		Role permission: Allows a user to unmask the password on the view screen of secrets with a launcher. Typically, this includes Web Passwords, Active Directory accounts, Local Windows accounts, and Linux accounts.
View Licenses		Role permission: Allows a user to view, but not edit, the licenses in the system.
View Lists		Role permission: View lists and list contents in Admin > Lists.
View Nodes		Role permission: Allows a user to view, but not edit, the Secret Server web server nodes.
View OpenID Connect		Role permission: View OpenID Connect integration settings in the Configuration Login tab. This replaces the Delinea One equivalent.
View Password Requirements		Role permission: Allows a user to view character sets and password requirements.
View Pipelines		Role permission: Allows a user to view event pipeline policies and policy activities.
View Platform Integration		Role permission: Allows a user to view the Secret Server connection to the Delinea platform.
View Remote Password Changing		Role permission: Allows a user to view, but not edit, Heartbeat and Remote Password Changing settings.
View Reports		Role permission: Allows a user to view, but not edit, reports. See "Browse Reports."

Term	Definition	Description
View Roles		Role permission: Allows a user to view roles in the system. Also allows a user to see which groups are assigned to which roles.
View Scripts		Role permission: Allows a user to view PowerShell, SQL, and SSH scripts on the Scripts Administration page.
View Search Indexer		Role permission: Allows a user to view, but not edit, search indexer settings.
View Secret		Role permission: Allows a user to only view which Secrets exist in the system.
View Secret Audit		Role permission: Allows a user to view Secret Audit.
View Secret Password and Private Key History	Role permission: Allows a user to see the history of passwords, private keys, or passphrases in both old and new UI.	
View Secret Policy		Role permission: Allows a user to view, but not edit, Secret Policies.
View Secret Templates		Role permission: Allows a user to view, but not edit, Secret Templates.
View Security Analytics		Role permission: Allows a user to view, but not edit, settings for Privilege Behavior Analytics.
View Security Hardening Report		Role permission: Allows a user to view the Security Hardening Report.
View Session Monitoring		Role permission: Allows a user to view active launcher sessions.
View Session Recording		Role permission: Allows a user to view recorded sessions within Secret Server.
View SSH Menus		Role permission: Allows a user to view existing SSH Menus, used in allow-listing commands that can be used on a SSH session.

Term	Definition	Description
View System Log		Role permission: Allows a user to only view the System Log, which shows general diagnostics information for Secret Server.
View Teams		Role permission: Users can view all teams. This is essentially a read-only Administer Teams.
View User Audit Report		Role permission: Allows a user to view, but not edit, the User Audit Report.
View Users		Role permission: Allows a user to view which users exist in the system.
View Workflows		Role permission: View (not edit) workflows used for multi-tier secret-access approvals and secret erase requests.
VIM	Vi improved text editor	Advanced text editor.
VM	Virtual Machine	Software emulation of a physical machine.
VMware ESX/ESXi		Built-in secret template.
VNC	Virtual Network Computing	A graphical desktop sharing system that is not unique to Windows.
VPC	Virtual Private Cloud	Isolated cloud resources.
VPN	Virtual Private Network	Secure network over the internet.
VRM	Virtual Resource Manager	Resource manager for virtual environments.
VTY	Virtual Teletype	Terminal emulation.
W3C	World Wide Web Consortium	Organization for web standards.
WAN	Wide Area Network	Network covering a large area.

Term	Definition	Description
WatchGuard		WatchGuard is a technology company that specializes in network security products and services, including firewalls, secure Wi-Fi, multi-factor authentication, and network intelligence solutions for small to medium-sized businesses and organizations.
WatchGuard		Built-in secret template.
WCF	Windows Communication Foundation	Framework for building connected systems.
Web Launcher		Web launchers are a separate login method from the Web password filler and provide a convenient click to automatically log on simpler websites. Web launchers do not work on complex login pages that rely on JavaScript. For those login pages, use the browser extension for the Web password filler. By default, Web launchers are enabled on the Web Password Secret template, but they can be enabled on custom templates as well, as described in Enabling Launchers.
Web Password		Built-in secret template.
Web Password Filler (WPF)		Web Password Filler provides easy password autofill and lifecycle management services for web applications and web sites. It allows browsers to find and enter credentials of users, when a Delinea Platform or Secret Server instance has secrets related to that website. Note that WPF has been replaced by Delinea Credential Manager (DCM) as the preferred solution for web password management. Users are encouraged to transition to DCM for enhanced security and functionality.
Web Services Impersonate		Role permission: Allows a user to send an approval request to act as another user within their organization when accessing Secret Server programmatically. Administrators do not have this permission by default.
WEBM	WebM open media format	Media file format.
Windows Account		Built-in secret template.

Term	Definition	Description
WMA	Windows Media Audio	Audio file format.
WMI	Windows Management Instrumentation	Windows management tool.
Workflows		Access Request Workflows are improved access requests that allow users to build more complex interactions based on events within Secret Server. The first release of workflows offers access requests. Workflow templates define the series of steps and reviewers required for an access request. You can assign workflows to secrets or secret policies. The original access requests are one level or step—anyone approving approves the request—no other input is required. Workflows allow up to 15 approval steps where approval by reviews in step 1 moves the request to step 2, approval at step 2 moves it to step 3 and so forth. Denial at any step denies the request.
WPF	Windows Presentation Foundation	UI framework for Windows.
WPF	Web Password Filler	See Web Password Filler.
WS	Web Service	Service available over the web.
WSDL	Web Service Description Language	XML-based language for describing Web services.
WSUS	Windows Server Update Services	Windows update management.
XML	Extensible Markup Language	Markup language for encoding documents.
XPM	EXtended Privilege Management	Management of extended privileges.
XSS	Cross-Site Scripting	Web security vulnerability.
XXE	XML External Entity	XML parsing vulnerability.
YAML	YAML Ain't Markup Language data format	Data serialization format.

Term	Definition	Description
z/OS	Zero Downtime Operating System	z/OS is a 64-bit operating system for IBM mainframes, designed for robust performance, advanced security, and superior scalability, primarily used in enterprise computing environments requiring high levels of processing power and reliability.
z/OS Mainframe		Built-in secret template.

Self-Help Resources

- Forums. Forums are oriented toward admins and other technical users.
- Delinea Blog
- "Secret Server Glossary" on page 4

Technical Support

To have access to Delinea Technical Support, you must have an equal number of unexpired user and support licenses. All support licenses expire 365 days after they are issued.

Technical Support Coverage

Please see our *Getting Technical Support* section below.

Please see the **Support** link on the menu above on delinea.com for details about our support policies.

Accessing Upgrades

Supported customers have access to all new releases (both minor and major). See .

Requesting New Features and Providing Feedback

We encourage customers with active support licensing to provide feedback on our Delinea Ideas Portal.

Getting Technical Support

Important: Please see the **Support** link on the menu above for details about our support policies.

Step One: Gather Information You May Need

Before you contact Support, gather the following information:

- Your Delinea Support username and password
- The email account already associated with your account (if using email)
- Your company name

- The technical contact name
- The technical contact phone number
- The product name
- Issue symptoms and details
- Any other relevant details, such as hours the technical contact is present

Step Two: Get a Mandatory Support PIN

Secret Server

The support PIN validates that your license includes support, and you must provide the PIN in your email or when you call. The PIN also makes it easier for Delinea Support to locate your customer records and give you better support.

To get your PIN:

1. Get the log on the credentials you received when you became a Delinea customer.
2. Log on the Support Portal using your credentials.
3. On the main page, click the large blue **PIN** bar to get your PIN. The PIN appears on the button.
4. Record your PIN.
5. If you want to use our ticketing system for support, leave the browser tab open, and return for step four.

Secret Server Cloud

The support PIN validates that your license includes support, and you must provide the PIN in your email or when you call. The PIN also makes it easier for Delinea Support to locate your customer records and give you better support. In addition, there is an additional "privileged PIN" for accessing your cloud instance.

To get your PIN:

1. Log on the Cloud Manager Dashboard.
2. Click the **Generate Tech Support** PIN button. A Tech Support PIN popup appears.
3. Record your PIN.
4. Click the Generate Privilege PIN button. Another Tech Support PIN popup appears.
5. Record your privileged PIN. Note that privileged PINs begin with "p"

   Important: Providing us a privileged PIN gives Delinea Technical Support write access to your cloud database for one day. Secrets and other sensitive data remain encrypted and unreadable.

Step Three: Choose a Support Method

Delinea customers have access to support by phone, email, and our support ticketing system (best for issue tracking). In all cases, **you must first obtain a support PIN**.

> For Severity 1 issues you **must** use phone support. Otherwise, use the method you prefer. Severity 1 means a critical problem that has caused *complete loss of service* and work cannot reasonably continue at your worksite.

Step Four: Contact Support

Click the **Support** link on the menu above for Support email addresses and phone numbers.

Using one of the below methods, contact Delinea Support.

Phone Support

Delinea delivers support by phone worldwide. Select the applicable number from the list on the **Support** link in the menu above.

Email Support

Send your email to support@delinea.com **with the PIN number as part of the subject line** of your email. For example: PIN 345 Workflow Stopped Unexpectedly. Include all the information listed in step one.

> You must send your email using an email address already noted in your account with Delinea. Otherwise, it might delay our response

Ticketing System Support

Open a support ticket and track your issue to resolution.

- Visit the Support Portal Login Page and login using the credentials you received when you became a customer.
- After logging on, click the **Log a Case** button to create a new case or click **Case Management > Cases** to manage an existing one.

Guides and Tutorials

> We also offer a range of training videos on the Delinea Training site. This is a subscription service. Please contact your account manager for details.

This section provides tailored information for specific groups. These include:

- The Secret Server Business User Guide: This guide is for regular, non-administrative, users of Secret Server. It is mostly a set of links to a subset of the greater corpus of Secret Server documentation.
- Getting Started Tutorial Overview: Secret Server is a powerful application with many facets. As such, approaching it for the first time can be daunting. To counter that, we created this section, which is an introductory guided tutorial for new technical users. The tutorial suggests an order in which to learn topics and points to specific sections of documentation for details.

- Secret Server Cloud Quick Start: Secret Server Cloud is a scalable, multi-tenant cloud platform that provides the same features as the on-premise Secret Server Professional edition. With the Secret Server Cloud, all backend services, databases, and redundancy are securely managed by Delinea and hosted on the Microsoft Azure platform. Customers do not have direct access to the databases or application file system.
- Product Overview: This is the landing page for Secret Server. It includes these topics:
  - Getting Started
  - Best Practices
  - Download Secret Server
  - Release Notes
  - Delinea Blog
  - Video Tutorials

Secret Server Business User Guide

This guide is for regular, non-administrative, users of Secret Server. It is mostly a set of links to a subset of the greater corpus of Secret Server documentation. For Secret Server Cloud, see the "Secret Server Cloud Quick Start" on page 1237.

Business users are also referred to as "end users."

What Is Secret Server?

Secret Server is a comprehensive Privileged Access Management (PAM) solution designed to protect, control, and manage privileged accounts and credentials within an organization. It offers a secure, centralized vault to store sensitive information, such as passwords, keys, and certificates, while ensuring that access to these critical assets is granted only to authorized personnel.

Equipped with advanced features like access control, auditing, and automated password rotation, Secret Server enables organizations to maintain a strong security posture, reduce the risk of data breaches, and comply with regulatory requirements.

What Is the Purpose of the Business User Guide?

Secret Server is a powerful, advanced product with a wide range of capabilities. Even so, it is very easy to use for regular day-to-day operations for non-technical people. The key to this is knowing what to ignore and understanding the bits you do need to know. This guide is designed to help you do just that. It provides links to only what you need to know. You can add other topics later as needed.

Getting Help

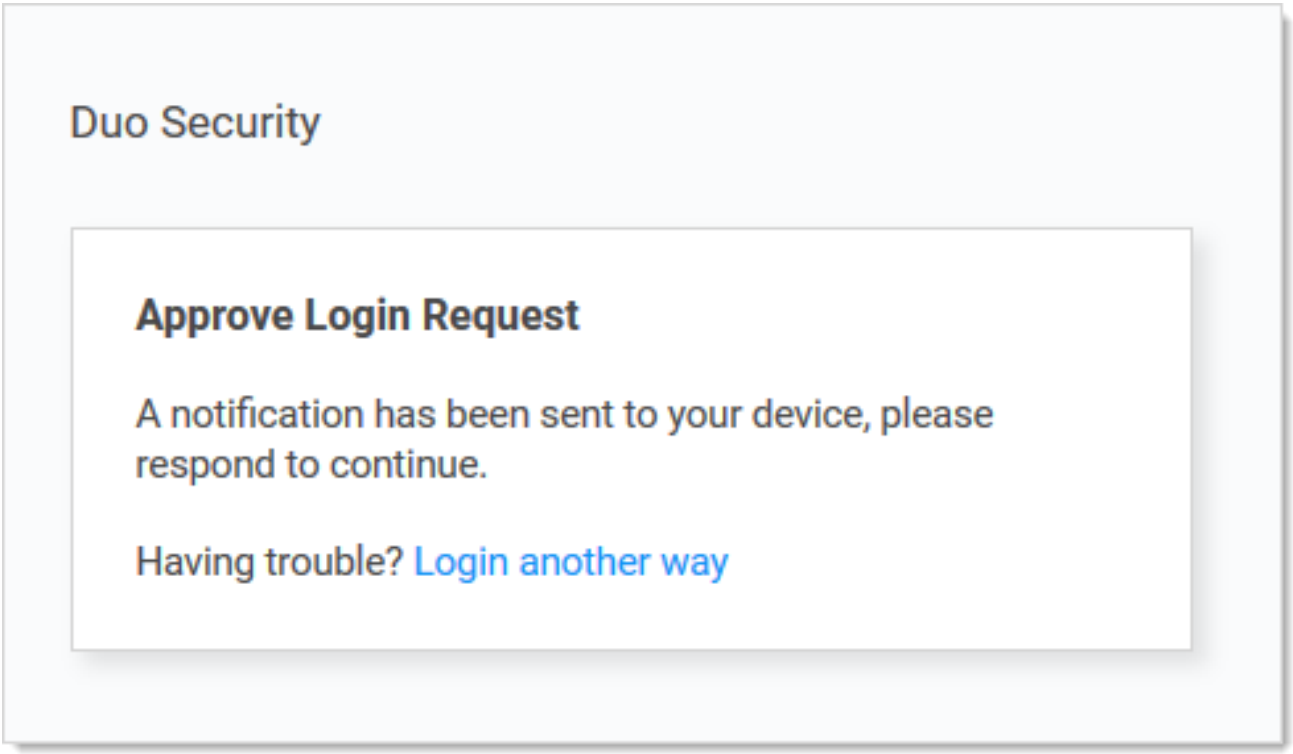
- Technical Support: Please contact your organization's help desk.
- "Self-Help Resources" on page 72
- "Document Conventions" on page 3

Important: When using this User Guide, it is easy to get lost in the ocean of Secret Server documentation. To avoid that, we recommend using **<Ctrl >** + click to access the links here. That way, the page you are going to will open to a new browser tab, leaving this one as is, making it much easier to get back to. You can also simply use the browser back button to return, but that can get tiresome because many pages link to others.

Logging on Secret Server

Depending on how your administrators configured Secret Server, you can log on with either your Active Directory account or a local account.

1. In your browser, go to the URL for your organization's Secret Server.
2. On the **Pick Your Account** popup, select your Active Directory account. The Enter Password popup appears. If you do not have an AD account, you may need to enter your local or domain information.
3. Click the **Sign In** button. If you have Duo two-factor authentication, this appears:



Your cell phone receives a notification you have to approve to access Secret Server.

> Secret Server also supports other two-factor authentication methods (depending on what your organization configured), such as text or email codes that Secret Server prompts you for.

> After you log on with your local account for the first time, you are immediately prompted to change your password .

4. Click the **Login** button. The Secret Server All Secrets page appears.

Secrets

Secrets are individually named packets of sensitive information, such as passwords. Secrets address a broad spectrum of secure data, each type represented and created by a *secret template* that defines the parameters of all secrets based on it. Secrets are very powerful and provide many ways of controlling and protecting their data, such as:

- Ensuring passwords are long, complex, and frequently changed.
- Relieving users of having to remember numerous complex passwords or when to change them. You only need to remember your password to access Secret Server. All of your secret passwords are managed for you.
- Automatically changing passwords at set intervals with no user intervention.
- Defining who has access to the secret.
- Ensuring the person accessing Secret Server or a secret is indeed you.
- Recording who actually accessed a secret.

All secret text-entry field information is securely encrypted before being stored in the database, including a detailed audit trail for access and history.

Some important basic information about secrets:

- "Viewing Secrets" on page 1165 (includes checking expiration and history)
- "Creating Secrets" on page 1146
- "Secret Configuration Options" on page 1166
- "Editing Secrets" on page 1153 (includes manually changing passwords, instead of waiting for expiration)
- "Deactivating and Reactivating Secrets" on page 1151

Secret Folders

Secret folders allow you to create containers of secrets based on your needs. They help organize your customers, computers, regions, and branch offices, to name a few. Folders can be nested within other folders to create sub-categories for each set of classifications. Secrets can be assigned to these folders and sub-folders. Folders allow you to customize Delinea permissions at the folder level, and all secrets within can inherit the folder's permissions. Setting Delinea permissions at the folder level ensures future secrets placed in that folder have the same permissions, simplifying management across users and groups.

- "Creating Folders" on page 1077
- "Moving Secrets Between Folders" on page 1082

Using Secrets on Websites (Web Password Filler)

Please set up Web Password Filler (WPF) in the following order:

1. Ensure you can log in to Secret Server the conventional way.
2. If necessary, create a folder in Secret Server where the WPF secrets will reside.
3. Install the WPF browser extension.

4. Configure WPF to point to Secret Server.
5. Login to Secret Server via WPF.

> WPF has been replaced by Delinea Credential Manager (DCM) as the preferred solution for web password management. Users are encouraged to transition to DCM for enhanced security and functionality.

> When creating or updating a WPF secret, ensure the URL is correct. If the site uses a redirect, modify the URL to the permanent one before saving. For example, change `https://login.microsoftonline.com/common/oauth2/authorize` to `https://login.microsoftonline.com`.

Checking out Secrets

The Secret Server *check-out* feature grants exclusive access to a single user. If a secret is configured for check out, a user can then access it. No other user can access a secret while it is checked out, except Unlimited Vault Accesss. This guarantees that if the remote machine is accessed using the secret, the user who had it checked out was the only one with proper credentials at that time. See "Checkout Overview" on page 1089 for details.

Getting Notified of Secret Events

Secret Server records specific events, including expired secrets, and optionally sends you alerts when they happen. See the "Notification Inbox Overview" on page 329 and "Creating Event Subscriptions" on page 321 for details.

Learning More About Secret Server—the Getting Started Tutorial

We created a "Getting Started Tutorial Overview" below for technical users. While it covers many things you do *not* need to know right now, you may later find it helpful if you want to get a deeper understanding of Secret Server.

Getting Started Tutorial Overview

Secret Server is a powerful application with many facets. As such, approaching it for the first time can be daunting. To counter that, we created this section, which is an introductory guided tutorial, for new users. The tutorial suggest an order to learn topics and points to specific sections of documentation for details.

> This tutorial is for system administrators of **Secret Server On-Premises** and other technical professionals. We recommend that non-technical users start with our "Secret Server Business User Guide" on page 75. For Secret Server Cloud, see the "Secret Server Cloud Quick Start" on page 1237.

Step 1: Trial Installation Prerequisites

> This topic only applies to **Secret Server On-Premises**

Below are our suggested guidelines for preparing to run a trial or proof-of-concept (POC) of Secret Server.

System Requirements

Please review the detailed "System Requirements for Secret Server" on page 94. The *Minimum Requirements* are for trial, sandbox, and POC environments. The *Recommended Requirements* are for production deployments.

Hardware Requirements

Secret Server can be installed on a physical server or virtual machine.

If you would like to set up front-end (application) clustering, you need to have two or more servers available.

For testing of high availability for the SQL Server, you can use either existing Microsoft AlwaysOn infrastructure or database mirroring. If you choose to test this, this is something your database team needs to prepare in advance.

Software Requirements

Checklist

- See System Requirements for Secret Server for details on supported Windows Servers (one server needed, minimum).

  Windows Server 2012 is a no longer supported operating system.

- SQL Server (one instance needed, minimum).
- Application server prerequisites.
- SSL certificate.

SQL Server

Delinea does not support using SQL Express in a production environment due to size and performance limitations.

You can create the SQL database in an existing SQL instance, or a new installation of SQL Server. For high availability, this needs to be a paid edition of SQL Server (not SQL Express). If you are using a new installation of SQL Server, please have this installed beforehand.

Detailed instructions for installation and configuration of SQL Server are included in one of the installation guides below (choose the guide matching the OS that SQL server will be installed on).

Application Server

We recommend installing Secret Server on Windows Server 2019 or greater. Include IIS, ASP.NET and .NET Framework. Refer to the System Requirements above to view prerequisite details.

Application Configuration

Service Account

Set up a service account:

1. Log on as a batch job (on the server that Secret Server runs on)
2. Modify Windows permissions to the Secret Server application directory (typically `C:\inetpub\wwwroot`) and `C:\Windows\temp`.
3. Provide access to your SQL Server instance by adding the db_owner permission to the Secret Server database.

For detailed instructions on how to configure Windows permissions for the service account, see "Running the IIS Application Pool As a Service Account" on page 63. The installation guides include instructions for assigning db_owner permission to the service account in SQL Server.

If you would like to test features that rely on Active Directory, such as AD group sync or discovery, you should also have accounts available with the appropriate AD permissions (described below). One option is to use the same account for both features.

Active Directory Group Sync

Active Directory group synchronization means that Secret Server can automatically add users and enable or disable them to log into Secret Server based off of their Active Directory group membership. You can choose which groups to sync. When configuring AD group sync in Secret Server, you are required to specify an account that can read the properties of users and groups. See "Active Directory Rights for Synchronization Account" on page 511 for a detailed list of required Active Directory permissions.

Discovery

To test discovery, please have some machines available for Secret Server to connect to for discovering accounts. An account is required to sync with AD and also scan the machines found for Windows local account and service account discovery. "Account Permissions for Discovery" on page 540 describes the permissions required for an AD account to be used for discovery.

Test Accounts

We recommend having a few test accounts available to represent the types of accounts you want to manage using Secret Server. These could be local Windows accounts, service accounts running scheduled tasks or services, SQL server accounts, and others.

Email Notifications

To test email notifications, which can be used for event subscription notifications or requests for approval to passwords, you need configuration information for the company SMTP server:

- Service account to run the application and connect to SQL
- Domain (test or production)
- Domain account to be used for AD sync and discovery
- Test machines (if testing discovery)
- Test accounts
- SMTP server settings

SSL Certificate

We recommend setting up SSL (or https) for access to Secret Server. To do so, you will need an SSL certificate. You may use an existing wildcard certificate, create your own domain certificate, or purchase a third-party SSL certificate for Secret Server.

Firewalls and Ports

Secret Server must connect directly to a target system to change its password. For devices that are firewalled off from Secret Server, remote agent can provide connectivity to them, but they also require connectivity from them to the target systems for password changing.

Please see "Ports and IP Addresses Used by Secret Server" on page 765 for a list of ports needed by Secret Server for password changing, discovery, and other features.

Step 2: Installation

This topic only applies to **Secret Server On-Premises**.

Process

Run the Installer: Secret Server comes with an installer that walks you through the entire process from start to finish. Once you have the prerequisites ready to go, download and run your installer, and the wizard will take you through the installation process. Please see our "Installation" on page 72.

Licenses

See the "Licensing" on page 88 section.

Step 3: Secret Server Dashboard

The Secret Server Dashboard is the main page for searching and viewing secrets. Nearly everything you do in Secret Server starts with the Dashboard. See "Application Dashboard" on page 182 for details.

Step 4: Security Best Practices

As you start using Secret Server, we strongly recommend configuring the following security settings. While these re optionl, setting them is a a best practice.

Local Admin Account Best Practices

Even if you plan to "Active Directory and Secret Server Overview" on page 509 to log into Secret Server, chances are you will need to use this account again. This is the first account you created during the installation process. Keep this account secure and avoid being locked out of Secret Server by following these suggestions:

- Store the credentials in a secure location that you can access if you lose all access to Secret Server.
- Enable the **Allow Users to Reset Forgotten Passwords** setting to provide a way of resetting the password if account is locked out or if the password is forgotten:

1. Select **Admin > Configuration**. The Configuration page appears.
2. Click the **Local User Passwords** tab to locate the setting.
3. Click the **Edit** button to edit the setting.
4. Click the **Save** button when finished.

This requires having an SMTP server configured.

- Configure the other **Local User Passwords** settings to enforce your password requirements, expiration, password history, and other password policies.

SSL (HTTPS) Best Practice

We recommend requiring SSL access to Secret Server. This requires setting up an SSL certificate for the website, preferably with a domain certificate. However, if you don't have a certificate, see "Installing Self-Signed SSL Certificates" on page 443. Once you have your certificate:

1. Configure the HTTPS binding for your Secret Server website using the certificate you choose.
2. Ensure your certificate is trusted on the Secret Server users' machines. See "Trusting an SSL Certificate on a Client Machine" on page 444 for instructions.
3. Enable **Force HTTPS/SSL** on the **Security** tab of the Secret Server**Configuration** settings.

Step 5: Backups

Configure backups to avoid losing your data. Secret Server provides the option to automatically take a backup on the interval you specify, sending the backups to a local or network location. There are two components of an entire backup of Secret Server: the Web application files and the database. Find these settings by selecting **Backup** from the **Admin** menu. See "Backup, Disaster Recovery, and Glass Break" on page 467 for more information.

To configure the backup paths, see "Backup Settings" on page 469 .

The file paths configured on this page by default need to be either changed or created on each server that the Secret Server application and database reside on.

Step 6: Active Directory Integration

This topic only applied to **Secret Server On-Premises**

Active Directory integration allows users to log in with their AD credentials and enables automated user management through group synchronization. This integration streamlines authentication and helps maintain consistent access control across your organization.

To integrate Active Directory with Secret Server, follow these steps in order:

Setting up Active Directory

Configure Active Directory - set up your AD domain connection and synchronization settings. See "Configuring Active Directory" on page 520

Enabling Active Directory Users

Enable AD Users - add individual users or synchronize entire groups. See "Enabling and Disabling Active Directory Users" on page 523

Managing Active Directory Users

Configure Automatic User Management - set up rules to automatically enable or disable users based on their AD status. See Active Directory Automatic User Management.

Step 7: Secret Server Framework

To try out Secret Server, you must have folders, roles, users, and secrets to operate on:

1. Setup some folders and roles: We encourage is for you to setup a folder structure and a few roles. The folder structure is how you will keep your secrets organized, and provide access to shared secrets. Additionally, roles ensure you are able to control access to different parts of Secret Server and assign Delinea permissions to view certain folders and secrets. See "Folders" on page 1075 and "Overview of Users, Roles, User Groups, and User Teams" on page 1302.
2. Add users if you have not already from AD. See "Creating Users" on page 1304 and "Creating User Groups" on page 1314.
3. Add an Active Directory or other secrets. If you plan on using discovery, the account will also need Windows/AD permissions to scan computers on the network for accounts. See "Secret Management Overview" on page 1131.

Step 8: Discovery

Secret Server has a discovery feature that can automatically find local Windows accounts, Active Directory service, Unix, VMware ESX/ESXi, and Active Directory domain accounts. Account and dependency types not supported out-of-the-box in Secret Server can still be discovered by writing PowerShell scripts that can be run as custom scanners. This allows administrators to quickly import accounts found by Secret Server on specified domains or IP addresses.

> Please see the "Discovery Overview" on page 534 for a comprehensive guide to configuring and using discovery.

To run discovery on a domain, IP address range, or a custom source, you need to first enable the discovery feature for Secret Server. Second, you must enable discovery for each discovery source you would like to be scanned.

Step 9: Remote Password Changing

Secret Server remote password changing (RPC) provides the ability to either start a password change manually or schedule automatic password changes to occur at a regular interval.

Enabling Remote Password Changing

See "Enabling RPC" on page 913.

Performing a Manual RPC

See "Running a Manual RPC" on page 914.

Common RPC Error Codes

See "RPC Error Codes" on page 951.

Step 10: Heartbeats

Heartbeat allows you to determine from Secret Server whether the credentials in a secret authenticate successfully with their target system. By default, heartbeat is turned off in Secret Server. See "Heartbeat Overview" on page 1058 for general information.

Enabling Heartbeat

See "Enabling Heartbeat in RPC" on page 1059.

Running Heartbeat

See "Running Heartbeat for a Secret" on page 1062.

Step 11: Audits and Reports

Before running reports and audits, you must create something to report on—to that end:

- Import a few accounts or create secrets manually
- Rotate passwords a few times
- View a couple of your secrets

This generates enough audit logs to provide meaningful outputs in your reports:

- Security Hardening Report
- What secrets have been accessed
- What secrets failed heartbeat
- Failed login attempts
- Secret activity

See "Built-in Reports" on page 882 for the most up-to-date list of reports included.

For details on using reports, see:

- "Creating and Editing Reports" on page 887
- "Viewing Reports" on page 900

Step 12: Secret Access and Workflow

Sometimes, depending on your scenario, you want to add extra protections to highly sensitive secrets. Secret Server has a access request and workflow features:

- "Checkout Overview" on page 1089: Grant access to a single user
- "Access Request Overview" on page 1085: Require approval prior to accessing a secret for a defined time period
- "Workflow Overview" on page 1101: Require multi-level and multi-user approval prior to accessing a secret for a defined time period
- "QuantumLock Overview" on page 1093: Add another security layer by encrypting secret data with a supplemental custom encryption key that is only accessible with an additional password, regardless of regular Delinea permissions.

Step 13: Secret Launchers

A secret *launcher* opens a connection to the remote computer or device or logs into a website using the secret's credentials directly from the Web page. While this provides a convenient method of opening RDP and PuTTY connections, it also circumvents users being required to know their passwords. A user can still gain access to a needed machine, but it is not required to view or copy the password out of Secret Server. A Web launcher automatically logs into websites using the client's browser. SS launchers, also called protocol handlers, come in three primary types:

- **Remote Desktop:** Launches a Windows Remote Desktop session and automatically authenticates the user to the machine.
- **PuTTY:** Opens a PuTTY session and authenticates the user to a Unix system.
- **Web Password Filler:** Uses a Chrome extension to automatically log the user into a website with secret credentials. See our separate documentation for Web Password Filler.

> When creating or updating a WPF secret, ensure the URL is correct. If the site uses a redirect, modify the URL to the permanent one before saving. For example, change `https://login.microsoftonline.com/common/oauth2/authorize` to `https://login.microsoftonline.com`.

> Note that WPF has been replaced by Delinea Credential Manager (DCM) as the preferred solution for web password management. Users are encouraged to transition to DCM for enhanced security and functionality.

- **Web Launcher:** An alternative method to automatically log on websites. See "Web Launchers" on page 707.

See "Overview of Secret Launchers and Protocol Handlers" on page 657 for more information.

Step 14: Recording Sessions

Session recording provides an additional level of security by recording a user's actions after a launcher is used. Session recording works for any launcher, including PuTTY and SSH, Windows Remote Desktop, Microsoft SQL Management Studio, and custom executables. The resulting recording is viewable from the Secret Audit. See "Session Recording Overview" on page 1256 for details.

Step 15: Secret Server APIs and CLI

You can access Secret Server without using the user interface for automation and integration purposes. Currently, there are two APIs:

- An asynchronous REST (representational state transfer) API for Web services, which is based on JSON (JavaScript Object Notation). This is the preferred method. It is faster and easier to read than the SOAP API and is still actively updated.
- A synchronous SOAP (Simple Object Access Protocol) for Web services, which is based on XML. This method is deprecated, but we still support it. It is based on an older technology, which has largely been replaced in recent years. There will be no enhancements to this API. There are, however, a few, rarely used capabilities that only our SOAP API has.

We offer a software development kit (SDK) that contains a .NET framework and a command line interface (CLI) for accessing the REST API with Windows applications or scripting languages.

Both APIs, the .NET framework, and the CLI support:

- GET Requests: Retrieve information from Secret Server, including entire secrets, individual secret fields, and security tokens
- POST Requests: Create Secret Server data
- PUT Requests: Update Secret Server data
- DELETE Requests: Remove Secret Server data
- Once-per-session Delinea API permissions (tested once and then based on the IP address), administered with a Secret Server rule

See the following sections for details on the API and CLI:

- APIs and Scripting
- SDK for DevOps
- SDK Integration Document

Step 16: Additional Resources for Secret Server

You have finished this "Getting Started" introduction to Secret Server. There is much more to explore within Secret Server, such as scripting, third-party Integrations (SIEM, CRM, HSM, and more), and connecting to Privilege Manager to monitor and protect endpoints. We look forward to working with you!

See "Help" on page 2 to learn more about Secret Server and other Delinea products.

Business Users vs IT Users

What is a Business User?

A Business User refers to someone who is not an IT user. These users generally utilize Secret Server to securely store credentials needed for accessing departmental websites, applications, and personal accounts within a highly secure enterprise vault. Business Users can:

Business users can:

- Access secrets: They can create, update, and delete their own secrets within Secret Server. For example, a user signing up for an online service can use our password generator to create a strong password, store that password in Secret Server, and later use Web Password Filler to access it when logging on.
- Request and approve access to secrets: Non-privileged secrets may need approval workflows. Business users can request access to these secrets and can approve access for others. For example, if access to an organization's social media accounts required authorization from a member of the marketing team, a business user could request access to the secret, and another business user could then approve access.
- Share secrets with other users: Business users can share non-privileged secrets with other users of Secret Server, either IT or business users.
- Access secrets using our mobile app: Business users can use the Delinea mobile application to access and manage their secrets.
- Use Web Password Filler: Business users can use our Web Password Filter (WPF) for accessing websites and auto-filling credentials from their secrets.
- View audits of their secrets: Business users can use auditing to see who accessed their shared secrets.

Administrators can restrict template visibility for Business Users. By default, all users have access to all templates, but business users typically need access to the following templates:

- Bank Account
- Combination Lock
- Contact
- Credit Card
- Healthcare
- Password
- PIN
- Security Alarm Code
- Social Security Number
- Web Password (Non-IT-related)

What is an IT User?

An IT user is someone accessing a vaulted credential that gives them privileged access such as root, domain admin, or any other administratively delegated privilege to the domain or anywhere in the corporate infrastructure.

The table below shows available actions to Business Users and IT Users:

Action	Business User	IT User
Approve access to secrets	•	•
Configure password rotation		•

Action	Business User	IT User
Configure security features for a secret		•
Create, delete, modify folders and add secrets to any folder		•
Create and delete personal folders	•	•
Create, update, and delete personal secrets	•	•
Create and manage Integrations, workflows, pipelines, discovery, sites, distributed engines, HA/DR, and more		•
Launch web password secrets	•	•
Request access to secrets	•	•
Share secrets	•	•
Use any administrative functions of Secret Server		•
Use any launcher including RAS (Platform)		•
Use Connection Manager to launch RDP or SSH sessions		•
Use the Delinea mobile app for access to secrets	•	•
Use the Secret Server SDK or API		•
Use Web Password Filler	For Non-IT-related tasks, websites or portals	For any tasks
Use Web templates in Secret Server	For Non-IT-related tasks, websites or portals	For any tasks
Utilize any templates including custom templates		•
View secret audits for their own secrets	•	•
View user audits for their own secrets	•	•

Secret Server Documentation

Introduction

Delinea Secret Server is an enterprise-grade password management solution designed to help organizations securely store, manage, and control access to privileged credentials. It aims to improve the security of sensitive data, reduce the risk of data breaches, and streamline the password management process.

Here are the key features of Delinea Secret Server:

- Secure Password Storage: Secret Server stores privileged credentials in an encrypted format, protecting sensitive information from unauthorized access.
- Access Control: Secret Server implements role-based access control, allowing administrators to set Delinea permissions and control who has access to sensitive information.
- Privilege Escalation Management: Secret Server integrates with Windows systems to provide privilege escalation management, helping to reduce the risk of data breaches.
- Auditing and Reporting: Secret Server provides detailed audit logs and reports, making it easier for organizations to track access to sensitive information and detect any unauthorized activity.
- Automated Password Management: Secret Server supports automated password management, helping to streamline the password management process and reduce the risk of manual errors.
- Multi-Factor Authentication: Secret Server supports multi-factor authentication, helping to improve the security of sensitive information.
- Integration with Other Tools: Secret Server integrates with a variety of other tools, including Active Directory, Microsoft Azure, and cloud-based applications, making it easier for organizations to manage their passwords and access controls.

This section of the Delinea documentation portal supports Secret Server.

> Navigate using the dynamic table of contents on the left, the page contents on the right, or by entering a search term above. Many pages in this documentation have sub-pages. The container (parent) pages can have introductory text or simply a heading with no text. Please click the table of contents on the left to see any sub-pages it might have.

Documentation

You are at the home page of the current Delinea Document Portal for Secret Server. It contains:

- New material.
- Links to legacy knowledge bases article that have yet to be converted or archived. There are very few of these left.
- Links to legacy PDF documentation. These are also rare, and if you do find one, its target is very likely out of date.

Delinea Blog

The Delinea blog offers cybersecurity insights and expertise from industry leaders. With a focus on zero trust, identity management, and privileged access, the blog provides practical advice and thought leadership to help organizations strengthen their security posture. As a trusted voice in cybersecurity, Delinea leverages the blog to empower customers embracing zero trust and demonstrate their commitment to innovation.

Video Tutorials

We offer a range of training videos on the Delinea training site. This is a subscription service. Please contact your account manager for details.

Developer Resources

"Developer Resources" on page 1494

Secret Server Cloud Quick Start

Overview

Secret Server is a scalable, multi-tenant cloud platform that provides the same features as the on-premise Secret Server Professional edition. With Secret Server Cloud, all backend services, databases, and redundancy are securely managed by Delinea and hosted on the Microsoft Azure platform. Customers do not have direct access to the databases or application file system.

End users are also referred to as "business users."

Cloud Versus On-Premise Secret Server

For documentation purposes, Secret Server Cloud is the same as the corresponding on-premise edition. However, there are some feature differences:

- **Site Connectors:** On-premise versions can use multiple site connectors to manage engine connections, such as RabbitMQ or MemoryMQ. The cloud version manages this for you as an Azure service and is not configurable.
- **CRM Integration:** On-premise versions can integrate with CRMs via direct database connections or the ConnectWise API. This is not currently available in Secret Server Cloud.

Getting Started

This section walks you through an initial configuration of your cloud instance. To see additional documentation for Secret Server Cloud features, please refer to the support resources section at the end of this document.

System Requirements

All cores are physical unless otherwise noted.

A distributed Engine server is required to communicate with Secret Server Cloud. Distributed engine server recommended specifications:

A distributed engine server is required to communicate with SSC. Distributed engine server recommended specifications:

- Windows Server 2016 or Above
- CPU: 4-core 2 GHz (minimum)
- Memory: 4 GB of RAM (minimum)

Engine Connectivity

Secret Server Cloud's Architecture Diagram shows the network topology of your cloud instance. Your on-premises distributed engines do not need any inbound TCP/IP ports open (unless using RADIUS authentication). If you do not have outbound firewall policies in place, no firewall configuration is necessary. If you do, the distributed engines need outbound access to:

- Secret Server Cloud's multi-tenant front-end Web server
- A shared service bus
- A customer-specific service bus
- A Content Delivery Network (CDN)

The protocols and endpoint details are in the architecture diagram mentioned above.

Initial Setup

After you sign up for a trial, you can choose your URL name and provision your instance:

> To see additional documentation for Secret Server Cloud features, please refer to the support resources section at the end of this document.

1. After you sign signed up for a Secret Server Cloud trial, you received an email from Delinea Sales. Click the **Cloud Portal** link in that email to begin your setup. The Setup Page appears in your browser.
2. Choose your location in the **Cloud Environment** dropdown list.
3. Click the **Continue** button. The Delinea One Portal appears.
4. Create the password for your first user account with administrator credentials. This account will be assigned to the email address you entered to request the trial.
5. After confirming the password, click the **Set Password and Login** button. The Delinea log on page appears.

   > This is the backup admin account that you may need in a "break the glass" or Unlimited Vault Access situation. Delinea recommends you store the password in a secured physical location such as a safe or locked file cabinet. You can reset the password using an email reset, but **if this password is forgotten or you no longer have access to the email account, Delinea cannot reset this password**.

6. Click the blue button that matches the location you just chose. A setup page appears.
7. Type a name for your subdomain. Do not use special characters or spaces.
8. Read the Business User (End User) License Agreement.
9. Click to select the check box to signify agreement.
10. From the dropdown, select **Yes** or **No** to signify your organization's oversight of EU information.
11. Click the **Accept** button. It may take several minutes for your new Secret Server Cloud to spin up.
12. When initialization is complete, click go to your Secret Server Cloud URL and click the **Login with Delinea One** button. You are automatically redirected to your new Secret Server Cloud dashboard.

> For information on how to install a distributed engine, please refer to "Distributed Engine Installation " on page 761.

Configure Active Directory Integration

Active Directory integration allows users to log in with their domain credentials. Connections to your domain are routed through the distributed engine service running in your network.

1. On the dashboard, create a new Active Directory secret from the create secret widget in the upper right hand corner.

> The domain account should be able to read users and groups from the domain you want to sync. For detailed information on the rights required, please see the "Active Directory Rights for Synchronization Account" on page 511.

2. Type the domain, username, and password in the **Create Secret** form.
3. Save the secret.
4. Search for **Active Directory**.
5. Click **Edit** and check the boxes for **Enable Active Directory Integration** and **Enable Synchronization of Active Directory**.
6. Click the **Save** button.
7. Click the **Edit Domains** button.
8. Click the **Create New** button.
9. Type your FQDN and a friendly domain name that users will see on the login page.
10. Click **Sync Secret** to select the secret you just created.

> The domain site is set to default. This means that the Active Directory authentication and synchronization will run through the distributed engine service installed on your network.

> Do **not** select "Enable Login from AD." If you do, you cannot set the domain groups later in this instruction.

11. Click the **Save and Validate** button.
12. Click the **Back** button.
13. Click the **Edit Synchronization** button. The Synchronization Edit page appears.
14. In the **Available Groups** list, click each domain group that you want to log on in Secret Server Cloud instance and click the **<** button to move the group to the **Synchronized Groups** list.
15. Click the **Save** button.
16. Click the **Synchronize Now** button to start the user and group synchronization immediately. The synchronization process runs automatically, but to get immediate results, you can start it manually.

Test Heartbeat and Remote Password Changing

Heartbeat ensures the secrets you have stored have the correct password, and Remote Password Changing (RPC) changes passwords on demand or a schedule.

1. Search for **Remote Password Changing**.
2. Click the **Edit** button.
3. Click to select the **Enable Remote Password Changing** and **Enable Heartbeat** check boxes.
4. Click the **Save** button.

5. Click the **Run Now** button in the **Remote Password Changing and Heartbeat Log** sections. This runs the heartbeat and RPC processes immediately.
6. Go to the secret you created for domain synchronization in the previous section or create a new test secret to use.
7. A brand new secret's **Last Heartbeat** status should be pending or processing. Once heartbeat completes you should one of these statuses:
   - **Unable to Connect:**Secret Server could not reach the target machine. This could be a firewall issue or the machine name or IP address is wrong.
   - **Failed:**Secret Server could connect but could not authenticate. This likely means the password on the secret is incorrect.
   - **Success:**Secret Server successfully connected with the username and password.
8. You can test password changing by viewing a secret and clicking the **Change Password Remotely** button.

   This will change the password on the target system.
9. You can view the status of password changes and heartbeats in the log at **Admin > Remote Password Changing.**

Next Steps

- Add another user to the Administrator role in Secret Server. This allows you to have another administrator besides the initial user account created. To assign roles, Search for **Roles** and click the **Assign Roles** button.
- Add a folder and share it with the group you synchronized from Active Directory. Create and edit folders from the Folder Tree View on your Dashboard.
- Create a secret in that folder for other users to see. When creating a secret, you can click the **Folder** link to save it to another folder.
- Have other users log on. Any users synchronized to Secret Server through the domain synchronization can log on with their domain credentials.
- Enable Google two-factor authentication by going to **Admin > Users**, editing the specific user, and assigning a two-factor option.

Troubleshooting and Resources

Get Error: "Site (Default) engines are not currently online" When Saving Domain

This can occur when Secret Server was not able to complete a round trip with the installed engine service. This validation may take several minutes for Secret Server to perform after the engine has been approved and assigned to the site. To address the issue:

1. On the server you installed engine on, check the logs in the install directory `C:\Program Files\Thycotic Software Ltd\Distributed Engine\log`.

2. If you see a message for "Could not configure, trying in 30 seconds" or a "Bus Broken Down Error" verify that the engine is approved and assigned to your default site.
3. Go to the site under **Admin > Distributed Engine > Manage Sites**.
4. Click the **Validate Connectivity** button.
5. If a success message appears and the engine status shows as online, try saving the domain again.

Secret Server Character Limits

Secret Server allows the following number of characters for the fields:

- Folder Name: 128. Error Message when exceeded - *The folder name must be 128 characters or less*.
- Group Name: 250. Error Message when exceeded - *Application Error*.
- Role Name: 255. Error message when exceeded - *Please choose a Role name with between 1 and 255 characters*.
- Secret Name: 1,992. Error Message when exceeded - *Invalid Secret Name*.
- Secret Text Fields: 9,999. Error message when exceeded - *Secret item value exceeds max length characters.*
- Secret Note Field: 9,999
- Request field 600 (This is a comment field used when requesting access to a secret). No error message given, it prevents exceeding 600 characters. If you paste in more than that it clips the text and still lets you save.
- Local User Username: 128
- Local User Display Name: 256
- Local User password: 500

Setup

Configuration Best Practices

Getting Started

Overview

This document was written after helping many customers successfully deploy Secret Server in their organizations. It covers the issues that most customers tackle as they consider which data to store, who needs access, what Delinea permissions to apply, and how to organize all their sensitive data. This document is not meant to cover everything

Think of Secret Server as a platform for your organization to store all of its passwords and sensitive data. This means that it can be configured to work in many different ways depending on your industry, compliance requirements, and ultimate end goals. The trick is to know your objectives and then match the capabilities and best practices to your situation.

Terminology

Throughout this topic, certain terms are used to refer to specific features or concepts within Secret Server. Some of these terms correspond to explicit roles defined within Secret Server that may be referenced, while others are broader terms that system administrators should be familiar with.

Administrator

Access to all the features within Secret Server can be granted to users by creating and assigning different roles. *Administrator* is one of the default roles that comes installed with Secret Server. By default, this role contains all Delinea role permissions, but it can be customized as well. In this guide, when it is used in the context of a Secret Server user, it is referring to the users who generally have most Delinea permissions and manage the system. Administrators have control over the global security and configuration settings.

> Administrators in Secret Server do **not** automatically have access to all data stored in the system—access to data is still controlled by explicit Delinea permissions on that data.

Basic User Role

The basic user role is a default role that comes installed with Secret Server. This role is a slimmed down version of the user role and primarily focuses on creating and modifying secrets, as well as limited "view" permissions. Users that have this role assigned to them also have their own personal folder.

Folder

A folder in Secret Server provides a hierarchical structure for organizing secrets. Some folders contain no secrets at all and may be used only to set Delinea permissions or policies on subfolders. Other folders may simply be a way to organize sub-folders that contain secrets. Folders are organized based on a "root" level folder structure, where "/" is the root level folder and any new folder created will be placed under that folder. Personal folders are unique and are created for each user, providing them the "personal folders" permission. Personal folders can contain sub-folders for the owner to organize their secrets.

Role Based Access Control (RBAC)

Secret Server role based access control (RBAC) is a mechanism that restricts system access to authorized users and defines what type of access a user has within the system. Often these roles correspond to features within the product and those features may give users greater privileges to make changes within the system. RBAC is a core Secret Server feature.

Secret

A secret is any sensitive piece of information (typically a password) that you would like to manage within Secret Server. Typical secrets include (but are not limited to) privileged passwords on routers, servers, applications, and devices. Files can also be stored in secrets allowing for storage of private key files, SSL certificates, license keys, network documentation, or even a Microsoft Word or Excel document.

Site

A site is a logical work container that can tell Secret Server which distributed engines should manage work associated with specific tasks. Sites are critical to ensuring that Secret Server can manage remote network segments, alternate locations, or even DMZs. By default, Secret Server comes with the "local" site. That site is unique as it is the only site that can be configured for "web processing" or "engine processing." When the local site is configured for Web processing, the Web servers themselves act as distributed engines and are responsible for all engine work processing, in addition to the Web Server role specific work that they may be configured for. Any additional sites that are user created may only be configured for Engine processing. The "Local" site comes with two free engines under any licensing model that may be used. Any additional sites and engines must be licensed separately and will incur additional licensing costs.

> If you are experiencing an issue with Local Site configured for web processing, Delinea recommends moving to DE processing for optimal performance and correct functional problems.

User

This is the default role for new users that are added to Secret Server. By default, this role contains several Delinea permissions that enable new users to interact with Secret Server. Many of these permissions are centered around creating and modifying secrets, as well as several "view" permissions to access audit information. Additionally, access to advanced secret options, assigning secret policies, and a few other advanced permissions are assigned to this role. It also gives each user their own personal folder that is accessible only by each individual user added to the system. Besides the owner, only the "Unlimited Vault Access" role can access these folders.

Know Your Edition

As you read through this guide, some features may be referenced that are only available in certain editions of Secret Server. To get an idea of what's available, you can reference the "Secret Server On-Premises Features by Version" on page 8.

Installation and Configuration

Before installing Secret Server, be sure to look at the "System Requirements for Secret Server" on page 94 The process for installing Secret Server is outlined in the "Installation" on page 72 matching the version of Windows Server you are using. If you have an active trial or have purchased Secret Server licenses, you can find your licenses by logging into your account through Cloud Manager.

Basic Configuration

Once Secret Server is installed, see the "Secret Server Business User Guide" on page 75 to begin setting up Secret Server right away. This covers:

- Adding your licenses
- Basic security settings
- Configuring automatic backups
- Basic security settings
- Heartbeat
- Basic security settings
- Setting up access for local and AD users

Advanced Configuration

Secret Server's Advanced Configuration page is intentionally hidden from casual access. You have to enter a URL—the page is not accessible by clicking a link. The URL format is:

```
https://<>/app/#/admin/advanced-config-settings
```

For example:

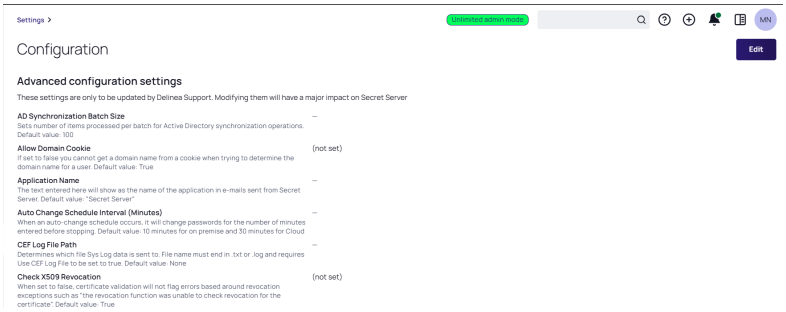
```
https://qa-test.acme-east.acmewidgets.com/app/#/admin/advanced-config-settings
```

The easiest way to get to the page is:

1. Open your Secret Server instance.
2. Navigate to the URL in your browser, remove everything after `admin/` and paste `advanced-config-settings`, so you will have something like `https://qa-test.acme-east.acmewidgets.com/app/#/admin/advanced-config-settings`.

   > Administrators in Secret Server do not automatically have access to all data stored in the system—access to data is still controlled by explicit Delinea permissions on that data.

3. Press **<Enter>**, and the (advanced) Configuration page appears:



4. Note the warning at the top of the page. It is serious, but it is also not *completely* correct. There are a few settings that may be important to your initial deployment. **Do not change any settings not directly discussed here without contacting Delinea Customer Service first**.

The following settings might need adjustment:

- **IP Address Header:** If you are using a load balancer and multiple Secret Server Web server nodes, it is important to set this header to `X-Forwarded-For`. That way, user audits reflect individual user IP addresses and not your load balancer IP address.
- **Secret Computer Matcher Once Per Discovery:** We mention this setting in the "Discovery Best Practices" on page 562 topic, where we recommend setting it to `yes` for large environment discovery. Otherwise, the matcher runs every five hours, regardless of how often discovery is configured to run.

Architectural and Design Considerations

You can view the Secret Server Architecture section. These reference architectures are, at minimum, refreshed every year and are created by our Professional Services Solutions Architect team. For this section, we provide some high-level architecture and design considerations that may help you design a more successful Secret Server or Secret Server Cloud installation.

> The following recommendations are primarily for Secret Server on-premises. For Secret Server Cloud customers, many of the recommendations are still relevant, even though you only have control over increasing distributed engines–the only Secret Server infrastructure you physically control when using Secret Server Cloud.

Consider some key questions about your SLA requirements for the application:

- What are the RPOs and RTOs for the application?
- Is high availability or disaster recovery required?
- Are you going to purchase Secret Server or Secret Server Cloud?

Answering these helps determine what initial infrastructure is needed for your environment. You can then look at the reference architectures to help select a variation of the reference architecture that works best for your requirements.

Many customers take a posted variation and alter it to meet their own needs.

When the Professional Services team works with our customers, we gather both architectural and stakeholder requirements to come up with a design that is sized correctly to meet all business needs. If you are planning to design Secret Server's architecture yourself, we suggest planning additional infrastructure based on feature utilization needs in the following order:

Session Recording

This is the most process- and memory-intensive feature of the product if it is used heavily. We recommend reviewing "Caveats and Recommendations" on page 1260 when planning to implement this feature, as it may require additional hardware or Web servers. Below are a few questions to ask yourself:

- Is the organization planning to use session recording and to what capacity?
- How many secrets may have session recording enabled?
- How many session recordings may occur concurrently?

We recommend only enabling session recording on secrets that absolutely need it–such as those with compliance or legal requirements. Otherwise, we recommend enabling session recording only on high value, high impact assets. This includes "global" admin accounts, domain administrator accounts, and other high-level privileged assets within your environment. This should minimize additional infrastructure just for session recording .

Discovery

This is another feature that can have a large impact on a Secret Server environment. A large enterprise discovering thousands of systems may require additional Web servers or distributed engines. Below are a few questions to ask yourself:

- How many systems do you intend to discover?
- How often should discovery run?
- How quickly does discovery need to complete?

We recommend using out-of-the-box discovery sources where possible. Since discovery cannot be scheduled to run at a specific time, consider enabling discovery for the first time during off-peak hours so it will run around the same time each day or week. If discovering a large number of systems, ensure you have ample Web servers and engines to handle the load. For example, increasing CPU count for each distributed engine can help distributed engines do more work in parallel.

Please see "Discovery Best Practices" on page 562 for details.

API Use Case

Employing multiple integrations with our product may impact a Secret Server environment. Below are a few questions to ask yourself:

- What integrations do you intend to use with Secret Server?
- What is the total number of API calls you anticipate per second, hour, or day?

We recommend that if you require several integrations with Secret Server where a high volume of API calls is anticipated, carefully consider how to configure your Web servers. You may want to have some Web servers dedicated to API use that have all Web roles explicitly disabled. You could place several such Secret Server Web servers in a load balancer configuration.

Remote Password Changes and Heartbeats

RPC and heartbeats may impact a Secret Server environment if used heavily. Below are a few questions to ask yourself:

- How many secrets RPC?
- How often should passwords be changed?
- How many RPC retries should be attempted?
- How often should we perform heartbeats?

We recommend carefully planning what types of secrets require different password changing schedules based on your company's information security policy. Generally, setting a large number of retry attempts for an RPC is not a good idea. The same goes for heartbeats. Match these settings to the business use case, such as 10 password retry attempts and having heartbeats occur once per day. These small refinements can greatly reduce the load on Secret Server. If you determine you need aggressive RPC and heartbeat schedules, consider having additional Web servers and distributed engines to handle the load.

Proxying

Heavy proxying can impact Secret Server infrastructure. Below are a few questions to ask yourself:

- How many systems are proxied?
- Are they SSH or RDP connections?
- What is the concurrent need?

We recommend proxy connections go through a distributed engine whenever possible. This offers a security advantage because ports, such as 3390 or 22, are not open inbound directly to your Web servers. You can review the "SSH Proxy Configuration" on page 833 section to size proxy requests.

General On-Premise Considerations

The areas mentioned below are often where we spend the most time with customers who have spent professional services time performing architectural health checks. These are the main areas we typically improve:

> For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments.

- Ensure that you have a database maintenance plan in place for Secret Server. It should be implemented or reviewed by your organization's DBAs. Adjusting the data retention settings is not enough and does not substitute for having a maintenance plan.
  - Ensure that you have a maintenance plan in place to detect and re-build Indexes that are fragmented. This should be implemented or reviewed by your organization's DBA.

> Note that your database maintenance plan may affect overall performance. See SQL Server Performance Improvement for more details.

- Ensure that RabbitMQ clustering configurations have work distribution policies in place. In most engagements, we use the AutomaticSyncMode policy.
- When designing multi-site, single-instance Secret Server implementations, be cautious when configuring Web servers and enabling roles on all Web server nodes when inter-location latency is high (50 ms or greater).
- When using the "local" site for Web processing when also using sites with distributed engine processing, consider using engine processing for the local site too. In most cases, when using both Web and engine processing, you are using both a built-in message broker (MemoryMQ) with (RabbitMQ).
- Consider having dedicated systems for Secret Server components, as proposed in our mid-range reference architectures. If using RabbitMQ, put it on a dedicated system that is not shared with the distributed engine service. Secret Server
- For large environments where discovery, RPC, and heartbeats will be used simultaneously, careful consider when to run discovery. Discovery can compete with RPC requests when both features are using the same site. For large environments, you may want to have a dedicated site and distributed engines for discovery and a separate dedicated site for secrets.

Securing the Encryption.config File

Security is a process—not a product. Take a look at the "Security Hardening Guide" on page 1419 to ensure your implementation of Secret Server has optimal security. The guide contains more in-depth recommendations for not only configuring the application in a secure manner but also hardening the server or servers Secret Server is hosted on. That guide complements the information provided here.

One of the most important areas for Secret Server hardening is protecting the `encryption.config` file that is created during installation. After the product is installed, this file exists in the main `\SecretServer\` directory. It is a very important file. This file (unencrypted), along with a backup of your Secret Server database, is all you need to get a Secret Server environment back up and running. Thus, it is imperative that you protect it. There are two ways to protect the `encryption.config` for on-premises Secret Server and two others for Secret Server Cloud.

Secret Server On-Premises

For an on-premise installation of Secret Server, we recommend protecting your `encryption.config` file with an HSM. When using an HSM, though, there are other things that you should be mindful of:

- Is the HSM highly available?
- Is the HSM capable of handling a high volume of access requests?
- What methods are available for retrieving the key from a backup if my HSM were to crash?

> If your HSM is down and you do not have backups, there is nothing we can do to help recover your data. Carefully consider the configuration of an HSM for protecting `encryption.config`.

A second, less secure, option for protecting the `encryption.config` file is to use DPAPI combined with EFS. DPAPI is a setting that is enabled on each Web server within your Secret Server cluster. EFS adds an additional password to the `encryption.config` file. It is worth noting that both protection mechanisms can be compromised if an attacker were to log on interactively to Secret Server's Web servers and become a local administrator. Give careful consideration to securing remote access to Secret Server when leveraging DPAPI and EFS.

We recommend storing an unencrypted copy of the `encryption.config` file for disaster recovery scenarios where the Secret Server Web server is irrecoverable. Make a backup of this file immediately after installation (before securing it with a HSM or DPAPI + EFS) and to store the file on one or more media devices such as a hardware encrypted USB drive. The device should then be placed in a secure location, such as a safe. Access to the device should go through a chain of custody process in the event of an emergency where the original file is needed.

Secret Server Cloud

If you are using Secret Server Cloud, there are two main methods for protecting your `encryption.config` file:

- Delinea owns your `encryption.config` file and is responsible for keeping it secure. We put internal mechanisms in place to ensure that Delinea does not have access to your data without your explicit permission. Refer to the Trust Center for more information.
- You configure a connection to AWS KMS to protect the `encryption.config` file. The master key is stored in AWS and under your complete control, inaccessible to Delinea staff

See AWS Key Management in Secret Server Cloud for more details.

Privileged Account Management Strategy

It is important to have a privileged account management (PAM) strategy that helps you determine which types of features to leverage for your various accounts and sensitive data you will be storing. Below are some suggested guidelines for creating a strategic plan. We recommend reading all sections of the guide for a comprehensive look at ways you can secure your Secret Server. However, these guidelines will also link to other parts of the guide so you can choose to jump to a specific section for more detail about a particular topic.

Identify Data at Risk

Consider all the types of sensitive data your team needs to be securely stored and managed. Where are the biggest risks and pain points in your current password management strategy? Data at risk also often includes more than just passwords.

To get started, think through these key accounts and principles:

- All shared privileged accounts: these are accounts that don't identify an individual (for example: administrator, root, enable, service accounts). All of these should have randomized passwords that are changed frequently.
- Do your users have individual privileged accounts? Maybe each user has—separate AD account for domain admin rights?
- Every password in your organization should be different.
- Do your users have individual privileged accounts? Maybe each user has—separate AD account for domain admin rights?
- What passwords could be needed in an emergency, outside of regular business hours, or when someone is on vacation?

Typical account passwords and sensitive data being stored in Secret Server:

- Active Directory domain administrator accounts
- Active Directory service accounts
- Application passwords (such as SAP and, custom apps)
- Cloud Administrative or Privileged Accounts
- Database accounts (such as MS SQL, Oracle, or MySQL)
- Network equipment passwords (such as router, switches, firewalls, phones, and appliances)
- Sensitive files (such as private key files, SSL certificates, and network documentation info)
- Software license keys, serial numbers, personnel data, and Wi-Fi passwords
- UNIX, Linux, Mac root, and local user accounts
- Website passwords (cloud services, DNS, Amazon AWS, vendors)
- Windows local administrator accounts

Who Accesses Secret Server?

After determining the data you will store in Secret Server, the next step is to decide who will use Secret Server to access and manage that data. A common approach is to begin by focusing on one group of users and the passwords they use on a regular basis, later expanding to other teams once a good strategy has been put in place. However, you may find it more beneficial to organize Secret Server for use by all of your users/teams at once so you can design an effective overall folder and policy structure that will work well across all teams.

What Privilege Levels Are Necessary?

Giving a user access to an account in Secret Server can entail different levels of privilege. Do you want a user to be able to edit the username, machine, or password of a secret, or only view the secret? Should they be able to share the secret with other users? Once you incorporate use of the Launcher into your users' workflow for authenticating to an application, do they really need to know a password, or can you mask it? The Workflow Security section can help you determine and implement key measures to ensure users have least privilege necessary.

What are your Password Requirements?

It's unlikely that all your accounts will have the same password complexity requirements and rotation schedule. In fact, for best security, you should have some variation. You can create sets of password requirements to control password length, characters, and complexity, then apply those to various account types using secret templates. Secret templates also allow you to set a default expiration period, which can translate to how often an account password will be changed automatically.

Evaluate your Existing Setup

While transitioning to using a new tool for managing your passwords, it is important to take into account how accounts are currently used in your environment. The following questions can help evaluate this:

- Do some of your users have their own, individual AD domain admin accounts, or are there only a few shared domain accounts?
- Do users use local administrator accounts or privileged domain accounts for admin access to systems?
- Are Active Directory permissions to resources (such as servers and applications) controlled using AD group policy?

Define Your Core PAM Strategy

There are a few different strategies that typically work best in Secret Server. Other methods of password management may work but require a more significant amount of time and effort to configure and maintain. The most commonly-used strategies are defined below.

Individual Privileged Domain Accounts

In this scenario, IT team members have their own domain admin accounts that are tied to their identity. They use these accounts to gain elevated privileges to resources such as production servers. Permissions to the various resources they're permitted to access are controlled by AD permissions.

To implement this in Secret Server, each account is stored as its own AD account secret. Only the user tied to that account is granted Delinea permissions to the secret. A security setting such as check out (one-time password) or hide launcher password is enabled so the user depends upon Secret Server to use the account. Therefore, all access to that account will be audited. When the IT admin needs elevated privilege to a box, they check out or view the secret and then use the launcher to access the machine.

A benefit of this strategy is that there is not conflict with multiple users trying to use the same account for access to one machine. This strategy provides great accountability—the security team knows the exact user accessing an account and the machine being accessed. The password is not shared among multiple users, and all privileged access is audited by Secret Server.

A pitfall of this strategy can be that there is more management of Active Directory permissions required in AD. While machines could be access or deny listed to force users to use the Secret Server launcher, thus controlling machine access through Secret Server, this can be tedious.

It is more secure, less work, and simpler to organize AD permissions for access to domain resources in Active Directory. This strategy works best for organizations that already use Active Directory heavily to control permissions of individual privileged users to domain resources. Ongoing maintenance will rely on updating Active Directory

permissions to resources in AD and ensuring that all new individuals' privileged accounts are being added for management under Secret Server.

Shared Privileged Domain Accounts

You may choose to have your users use shared privileged accounts to access resources. This strategy involves creating a few service accounts that have Active Directory permissions to OUs or groups of computers. In Secret Server, these accounts can be limited with the Launcher so they can only be used to Launch to certain computers. This means you can limit the number of domain accounts created and set Active Directory permissions more broadly (such as at OU level). These passwords could be changed on a schedule or, where possible, used with Check Out to change the password after each use. Using this setup, accounts can be designated for team or function and can have varying Check Out intervals set to ensure that only one person at a time is using each account.

A benefit of this strategy is if individuals do not already have their own privileged domain accounts in AD, then giving them access to shared accounts via Delinea permissions on the secret means less setup in AD while still maintaining accountability for who uses which account, and which machine they access.

A pitfall of this strategy can be that if the team (or function-specific accounts) cover a broad number of machines that can be accessed, it may be a lot of work to set up launcher allow/deny lists to control access through Secret Server. However, if these permissions are set only through Active Directory, it will be difficult to have the visibility into these limitations for an auditor.

Hybrid of Individual and Shared Accounts

Sometimes, your employees' roles may require longer, more specialized access. For those accounts, you can have individual privileged domain accounts, and for the other regular users you can use a few shared privileged domain accounts. All of these can be stored in Secret Server, but with different settings governing their usage. For example, the shared accounts would still have check out enabled, while the individual privileged accounts will simply have permissions limited to an individual user, possibly with the password hidden using hide launcher password.

What Is the Highest Risk?

Implementing a comprehensive PAM policy should eventually cover all of your privileged/shared accounts, but this can take some time. When looking at where to start, it is important to consider the areas of risk–where are the areas that need more immediate attention:

- Is it local Windows admin accounts all sharing the same password?
- Pass-the-hash vulnerability?
- Protecting your network equipment passwords?
- Avoiding fines for not meeting compliance mandates?
- Password misuse and auditing employee access to accounts?

Choose a starting point that gives your organization the most value, and then branch out from there.

Users and Groups

At minimum, the administrators who manage and use your organization's privileged passwords and data on a regular basis will need to access your Secret Server. Secret Server users can be defined in a few ways:

- Active Directory user accounts.
- Local Secret Server user accounts.
- User accounts from an Azure Active Directory tenant.
- User accounts from another OLDAP source (Basic/Kerberos).
- User accounts from SAML integration (often AD accounts). If local accounts are provisioned via SAML, they must correspond and match local user accounts that are within Secret Server.

  SS also has the concept of groups, which can be local (you create them in SS), AD-synced (security groups from AD), oLDAP groups, or AzureAD groups . Groups are a powerful tool for assigning and maintaining Delinea permissions to secrets, and therefore should be given careful thought and planning. Below we review the two most common account and group strategies our customers use. These same concepts can apply for other directory service accounts and groups other than Active Directory.

Local Secret Server Accounts

Local users and groups have to be created and managed manually in Secret Server, as they are not integrated with AD. The first account you create in Secret Server is an example of a local account. Local groups can include local users and AD accounts, and can have a user established as the group owner that is permitted to add or remove users to or from the group.

Active Directory Accounts

AD accounts can be added for access to Secret Server either manually (one by one) or by AD security group. When adding users by security group, you choose which groups Secret Server will synchronize with AD to update which users' access to Secret Server is enabled or disabled. AD group synchronization happens on a regular, customizable interval to keep group membership changes that happen in AD up-to-date in Secret Server as well.

Local or Active Directory Accounts?

We recommend using one of these options:

- Only local users and groups (best security)
- Only AD users and groups (most convenient)
- A hybrid of AD users and local groups (balance of security and convenience)

You need to choose an option that provides the levels of security and convenience that are acceptable for your organization. Using the AD accounts option is easy for user maintenance, but it limits the security of Secret Server to the level of security of your AD. This may be fine—just be sure to consider the question of domain admin access to AD in combination with Secret Server permissions.

Only Local Users and Groups

Creating local users and groups within Secret Server provides a lot of flexibility because you can tailor permission assignment by group to your exact needs. The major benefit of local users and groups is security: users and group membership can be controlled entirely by role-based access control (RBAC) within Secret Server. However, this approach requires more maintenance because creating or deleting users and managing group membership has to be controlled in Secret Server.

Only AD Users and Groups

If you are considering using AD users and groups for Secret Server access and Delinea permissions assignment, review your teams that need access to Secret Server. Compare them to the corresponding groups in your AD. If your AD groups map to ways you want to assign access to secrets, you can synchronize your AD groups with Secret Server and start assigning permissions to secrets (and levels of those permissions—View/Edit/Owner) by group. You can then effectively manage Secret Server access and secret permissions completely from AD by changing AD group membership.

Many customers choose this option because they can maintain control in AD and do not have to worry about any user or group maintenance within Secret Server. If you want to use this option but your AD groups don't match the way you want to assign secret permissions, you will need to create new AD groups to match this, or may want to consider the hybrid approach (below), using local groups instead.

This method, while more convenient, may require additional considerations:

- How are these AD groups being protected?
- Are there controls in place which require elevated or high privilege accounts to modify these AD groups?
- Are there alerts in place for when these groups are modified?
- Is the information security team closely monitoring these groups?

Hybrid of AD Users and Local Groups

A third option is to create local groups in Secret Server and add AD users to those groups for the purpose of organizing how Delinea permissions are assigned to secrets. Many customers who use this setup will create a single AD security group (for example, SecretServerUsers) to use to synchronize their AD users with Secret Server for log on. They then create additional local groups for their users to, which gives them permissions within Secret Server, such as to their teams folder. They may also be added to other Secret Server groups that provide them with other privileges within the environment.

This approach is more secure than using only AD groups and users, but if Active Directory were compromised, intruders may still be able to reset an account password and gain log in access to Secret Server. If secrets are stored in that user's personal folder, those secrets may be compromised which may lead to lateral movement elsewhere within the organization.

Business Users

A "business user” is a non-information-technology user. Business users typically use Secret Server for vaulting credentials for access to departmental websites, applications, and personal accounts in an enterprise-grade secure vault.

At Delinea, we strive to ensure that all Secret Server Enterprise Vault users get the maximum value possible from the product. Business users do not need all vault features, but they can benefit by securing their passwords and credentials to prevent abuse or malicious use.

Business users can:

- Access secrets: They can create, update, and delete their own secrets within Secret Server. For example, a user signing up for an online service can use our password generator to create a strong password, store that

password in Secret Server, and later use Web Password Filler to access it when logging on.

- Request and approve access to secrets: Non-privileged secrets may need approval workflows. Business users can request access to these secrets and can approve access for others. For example, if access to an organization's social media accounts required authorization from a member of the marketing team, a business user could request access to the secret, and another business user could then approve access.
- Share secrets with other users: Business users can share non-privileged secrets with other users of Secret Server, either IT or business users.
- Access secrets using our mobile app: Business users can use the Delinea mobile application to access and manage their secrets.
- Use Web Password Filler: Business users can use our Web Password Filter (WPF) for accessing websites and auto-filling credentials from their secrets. Note that WPF has been replaced by Delinea Credential Manager (DCM) as the preferred solution for web password management. Users are encouraged to transition to DCM for enhanced security and functionality.
- View audits of their secrets: Business users can use auditing to see who accessed their shared secrets.

A "non-privileged secret" refers to any secret stored within Secret Server that does not grant elevated access rights or Delinea permissions. The most common type is regular user-account passwords.

Table: Allowed Actions for Business and IT Users

Action	Business User	IT User
Approve access to secrets	•	•
Configure password rotation		•
Configure security features for a secret		•
Create, delete, modify folders and add secrets to any folder		•
Create and delete personal folders	•	•
Create, update, and delete personal secrets	•	•
Create and manage Integrations, workflows, pipelines, discovery, sites, distributed engines, HA/DR, and more		•
Launch secrets they have access to	•	•
Request access to secrets	•	•
Share secrets	•	•
Use any administrative functions of Secret Server		•

Action	Business User	IT User
Use any launcher including RAS (Platform)		•
Use Connection Manager to launch RDP or SSH sessions		•
Use the Delinea mobile app for access to secrets	•	•
Use the Secret Server SDK or API		•
Use Web Password Filler	For Non-IT-related tasks, websites or portals	For any tasks
Use Web templates in Secret Server	For Non-IT-related tasks, websites or portals	For any tasks
Utilize any templates including custom templates		•
View secret audits for their own secrets	•	•
View user audits for their own secrets	•	•

Administrators can restrict template visibility for Business Users. By default, all users have access to all templates, but business users typically need access to the following templates:

- Bank Account
- Combination Lock
- Contact
- Credit Card
- Healthcare
- Password
- PIN
- Security Alarm Code
- Social Security Number
- Web Password (Non-IT-related)

Authentication Strategy

Defining your authentication strategy ensures you have standardized authentication practices in line with your Secret Server RBAC scheme. Secret Server offers a wide variety of authentication options that can add flexibility and security to your business user's authentication process.

Strong Authentication

Protect the tool you are using to secure your privileged accounts by adding a second factor of authentication for users logging into Secret Server. Two-factor authentication can be added whether users are logging in with local or AD accounts. For more information about using two-factor authentication with Secret Server, see Best Practices in the "Security Hardening Guide" on page 1419.

SAML

If your organization is already using SAML for SSO across your organization, it might be a good option for Secret Server authentication too. SAML uses browser-based communication, between the service provider (Secret Server) and the identity provider (SSO providers) to broker authentication. For more information on configuring SAML with Secret Server, please see the. The major benefits SAML provides are:

- A consistent MFA strategy across all applications in your environment.
- Simplified authentication communication: The browser handles the process. For SSC, if the authentication strategy is to authenticate against the domain, that communication must flow from Secret Server Cloud to the distribute engine and finally to the domain controller and back for authentication. SAML shortcuts this by having the browser communicate to the service provider and identity providers, reducing authentication latency.
- Easy to configure, manage, and add new users.
- Supports multiple MFA options based on conditional access. For example, a user may only need to verify with one factor for accessing less critical apps, but Secret Server uses two-factor authentication.

Directory Services

Secret Server provides a multitude of authentication options through directory services. It can sync users into the application from various LDAP sources. It is important to use an outside authentication source to automate user provisioning. The User Account Options setting in the directory services configuration provides these options:

- Users are Enabled By Default (Manual)
- Users are Disabled By Default (Manual)
- User Status Mirrors Active Directory (Automatic)

There are benefits to each strategy, but the last one is usually best. Using a hybrid group structure prevents new users from gaining Active Directory permissions before they have been reviewed, and if they are disabled in active directory, they are automatically deprovisioned from the system. This provides automatic user management and easier offboarding strategies.

If you decide to use a manual strategy, we suggest using the automatic user management feature to disable users who have been inactive for a defined period of months. This can prevent long-inactive accounts from being compromised and keep your list of active users current.

Roles

Roles control which features of Secret Server a user is able to use, view, or administer. Existing roles can be customized, and new roles can be created as needed. Secret Server comes with several roles by default, including administrator, user, and read only. You should review the default roles and decide whether your organization needs further roles for various purposes such as third-party consultants or auditors.

> Users with the default administrator role (which contains all Delinea role permissions available) do **not** automatically have access to all data stored in your Secret Server. secrets are only visible to a user based on the explicit secret permissions assigned to them.

We strongly recommend pulling one or both role permissions pertaining to unlimited vault access mode out of the default administrator role. Unlimited Vault Access mode is a "break-the-glass" feature that allows a user to view all secrets in Secret Server. By splitting the Unlimited Vault Access Delinea permissions into separate roles, it ensures no one user can both turn on the feature and operate as the Unlimited Vault Access.

Commonly, operational employees are assigned to the "Unlimited Vault Access" role and a CISO or senior manager that is responsible for Secret Server is assigned the "configure Unlimited Vault Access" role.

> For more information about how unlimited vault access mode works and how to effectively control the relevant Delinea role permissions, see the "Security Hardening Guide" on page 1419 and "Unlimited Vault Access" on page 283.

Other sensitive roles you may want to directly assign to individuals include:

- Administer Role Assignment
- Administer Role Permissions
- Bypass SAML Login
- Create Root Folders
- Delete Secret

For administrator-related roles, we typically recommend having these associated to your planned internal Secret Server subject matter experts. Usually customers have a dedicated group or groups associated with administrator only roles and functions. You can create administrator tiers depending on the size of your organization and the tasks you expect the administrators to perform. This can reduce administrative overhead and provide a path for employees to gain further experience with the product.

We recommend creating AD groups for these administrative roles to ensure that these groups are protected and can only be modified by higher-privilege accounts. Ensure proper monitoring and alerting is in place when creating groups that are intended for high-privilege role access within Secret Server.

Role Definition and Assignment

Once you have defined your roles, they will seldom need to be changed. Access to modify and assign roles should be tightly controlled.

Group Assignment

If roles are assigned to groups, then assignment of the groups will also need to be controlled. Often very sensitive Delinea role permissions, such as Unlimited Vault Access, are assigned at the user level to limit the risk of granting group assignment Delinea permissions. Roles that are individually assigned should be routinely audited at least once a year to ensure users are only assigned the Delinea permissions needed for their job. See "Unlimited Vault Access" on page 283.

Delinea Permissions

You have different sets of passwords that should only be viewed by particular administrators. You may also have passwords that should be read-only to some administrators, editable by others, and not even visible to still others. All of these options are possible using the Delinea permissions within Secret Server.

Delinea Permissions can be allocated at the individual user level but it tends to be easier to manage over time if you allocate your permissions at the group level. You will need to decide if your existing AD groups could work for these permissions or if you need to create new AD groups or if you want to create and manage local groups in Secret Server.

For more information about what each level of Delinea permissions entails, see the "Secret Server Role Permissions List" on page 1288.

Folder Structure

Using Folders to Control Access (Inherit Permission)

You can apply Delinea permissions (View/Edit/Owner) at the secret level. This allows you to apply very granular Delinea permissions on a single secret if needed. Managing Delinea permissions on each secret is powerful for situations where you need that flexibility, but it tends to be harder to manage over hundreds or thousands of secrets. Instead, you should consider using folders to control permissions for most secrets. This can be done by creating a folder structure that best represents your organization, teams or data being stored and then applying permissions on the folders, using inheritance across folders where appropriate. Secrets placed in a folder can then inherit the permissions of the folder.

Deciding on your Folder Structure

The folder structure creates a hierarchy for organization and Delinea permissions. This means that folders near the root level need to break out access in high level terms and then get more specific permissions (typically breaking inheritance) as you move down to the "leaf level" sub-folders.

For example:

- Customers
- Human Resources
- Information Technology
  - Development Services
    - Programmers
  - Technical Services
    - Database
      - Oracle
      - SQL Server
  - Systems

    - Network Infrastructure
    - Unix
    - Windows
- Vendors

The most typical configuration is to break out the folders based on the teams that need to use those folders with the most restrictive Delinea permissions at the deepest subfolders of the tree.

For instance, an Oracle DBA might have the following permissions on the above folders:

- Information Technology (view)
  - Database (view)
    - Oracle (view/edit/owner)
    - SQL Server (view/edit)
- Technical Services (view)

> If the "Require view permission on a specific folder for visibility" setting (**Admin > Folder settings**) is enabled, a user cannot see the full folder structure unless they have view permissions on all the parent folders of a folder. For example, a user with view on the Oracle folder in our example, would also need view on Database, Technical Services, and Information Technology to see the full folder path.

There are settings to control whether inheritance on folders and secrets should be turned on and also whether users should always see all folders right click on a folder from the list, select View folder, select Permissions tab, click Edit and check or uncheck Inherit permissions. There are many ways to configure this for your organization.

The most common approach is:

- Use inheritance.
- Do not allow users to see folders unless they explicitly have view permission by enabling the "require view permission on a specific folder for visibility" setting.
- Require all secrets to have a folder.

> Consider using our "User Teams Overview" on page 1317 feature to align your groups within Secret Server to a team. This can help prevent users from sharing secrets with other individuals outside of their own team.

This approach allows different teams or even different departments within your organization to use the same Secret Server instance independently.

If a business need arises to break permission inheritance on a folder or secret, we recommend tracking or auditing those folders because manually applying permissions can increase your administrative overhead.

Secret Policy

A *secret policy* is a set of security and remote password changing settings that are normally applied to a secret on the Security or Remote Password Changing tabs. The benefit of using a secret policy is not only that settings can be applied in bulk to secrets (that is, by folder), but that these settings can also be enforced, preventing users from changing them.

Secret policies should be established to apply settings to secrets that are key to the workflow your organization is working toward. For example, if your primary concern is more detailed auditing around service account usage and you also have a requirement that all service account passwords change every 60 days at 2 A.M. on the next Tuesday, you can create a policy that includes these settings and apply it to the folders that will contain all of your service accounts. Whenever new accounts are added to the folder, such as when they are imported via discovery, the settings will automatically be applied and enforced.

Secret policies can also be updated after they have been assigned to folders. Therefore, if your password policy changes and you need your service account passwords to change every 30 days, you can update the policy and it will immediately apply to all secrets the policy is assigned to.

> Note: Secret policies do not apply to inactive or deactivated secrets. While a secret remains deactivated, policy enforcement (such as password requirements, expiration and other settings) is not active for that secret. If the secret is later reactivated, the assigned secret policy will be applied again.

As with Delinea permissions, secret policies can be inherited too. Be mindful of where you disable secret policy inheritance to ensure that exceptions to secret policies are tracked. Also, disabling secret policy inheritance may lead to increased administrative overhead.

Discovery

This section discusses some key best practices around using Secret Server's Discovery feature to find and manage accounts in your environment.

Discovery Workflow

While it may be tempting to immediately get started using discovery to get your accounts under control, there are a few things you can do ahead of time to make the enforcement of your organization's password policies more streamlined:

- Know which secret template you want to import accounts to. This can effect password changing and Launcher settings that are applied to your imported accounts.
- Have a folder structure established so you have folders appropriated for each type or category of discovered accounts.
- Apply a secret policy to the folders you import to.

Having these settings in place can save you the considerable amount of time it could take to have to re-organize all of your accounts and policies post-import.

Enterprise Deployment Considerations

We broadly recommend starting small and choosing specific objectives when working with discovery. If you are an organization that has 15 domains, for example, you may choose to first work with discovery within the domain you are most concerned about. Make the objectives even more specific where possible. An example first objective might be to configure discovery for finding all local administrator accounts on all your servers and creating discovery rules for ensuring that new servers have their password changed shortly after being built. Systems with internal elevated risk may also be a good place to start. Other examples are provided below.

Cloud Accounts

In more recent Secret Server versions, we support discovery of "Google Cloud Platform Discovery" on page 621 service accounts, VM instances, and "AWS Account Discovery" on page 611.

Local Windows Accounts

How many local Windows accounts in your environment use the same password? Are they local admin accounts? Use discovery to quickly mitigate the risk of pass-the-hash attacks by finding all of your local Windows accounts and setting their passwords to unique, strong passwords managed by Secret Server. Where your admins previously had to remember one password to access all machines with local admin rights, they now have to remember zero passwords because they can use Secret Server to find the machine and launch an RDP session using the local admin account without ever knowing, copying, or typing the password.

Find Backdoor Accounts

Ensuring that users are not creating backdoor administrative accounts on Windows machines is very important as these can compromise general security as well as open the potential for a user to access a machine directly without being audited. By running discovery on a regular interval and having discovery rules alerting you when new accounts are found, you can ensure that users any new local Windows account being created are identified in addition to being either removed or brought into Secret Server.

Service Accounts

Many organizations do not know where their AD service accounts are being used across the network. By using discovery to scan your network, you can find all of the Windows services, application pools and scheduled tasks that are run by AD service accounts. Once these accounts are found and brought into Secret Server, having discovery run on a regular basis will find any new locations where the account is being used since they were added to Secret Server. With discovery rules, those additional dependencies can be automatically added to the existing secrets. We recommend making sure that the service account discovery has run before using Secret Server to change the service account password.

Unix Accounts

When scanning for Unix accounts, we recommend using SSH key validation, as discussed in the "Security Hardening Guide" on page 1419. This ensures that you are only connecting and trying to authenticate to UNIX servers that have a valid and trusted SSH key.

ESX/ESXi accounts

Local accounts on ESX/ESXi systems should not change once the server is set up and configured. We recommend creating discovery rules that monitor your ESX/ESXi servers and email the proper teams to inform them of any new account found. These accounts really should not be created, so it is important to monitor them and ensure that no one is creating them maliciously.

Workflow Security

Often you will have situations in which you want users to have access to accounts, but only under certain circumstances, such as on a specific day or after the approval of a manager. Maybe your compliance requires that you have the ability to monitor an active RDP, or that you use a one-time password for certain accounts. This section examines best practices around workflow security settings in Secret Server as well as scenarios when these settings are commonly used.

Hide Launcher Password

Many times, giving an employee access to a resource through Secret Server does not require that he or she have access to the actual password for the account used. As long as the application a user needs can be started by the launcher, there is no reason the user needs to copy/paste or type the password. The hide launcher password setting implements the following:

- Users with access to the secret will see only asterisks (****) in the password field
- There will be no copy-to-clipboard, field history, or unmask icons next to the field

> Users with Delinea edit permissions to a secret with "hide launcher password" enabled can still view the password when editing the secret. To prevent all possible access to the password, limit users to view permission only.

This can be an important way to reduce exposure of your privileged account passwords. Hiding launcher passwords can be enabled for secrets under the Security tab of a secret or by applying a secret policy. You can also remove the ability for a user to see the password for any secret with a launcher by removing the "view launcher password" permission from their role.

Require Approval

The "requires approval for access" setting is typically employed in the following cases:

Simple approval workflows:

- When a user should be required to request access to a secret for a certain time period
- When an administrator would like to approve a user's access to a secret in advance for a time in the future (such as a maintenance period outside normal business hours)
- When a group of administrators would not like anyone to access a secret without the approval of another administrator

Advanced approval workflows:

- When requiring a multi-tier approval process that involves having more than one individual approve access to a secret
- When requiring multiple workflow steps, each with different reviewers and a varied number of required approvers
- When selecting "owners" as a review group

This setting can be turned on under the Security tab for an individual secret, but can also be applied via a secret policy. When enabling "requires approval for access," remember that users will still need to have at least view permission to the secret to request access to it. Once access has been granted to the secret, they have whichever level of permission was assigned to them for the secret (view, edit or owner). The approvers of the secret are specified when enabling the setting, and these individuals will be able to modify the time that the requestor originally submitted their access request for or deny the request altogether.

Please see our documentation on "Workflow Overview" on page 1101 for more advanced workflow use cases. For highly sensitive or privileged accounts, we do recommend implementing multi-tier approval processes where possible.

To require all approvers of a secret to also request access from another approver, be sure to enable the "owners and approvers also require approval" setting.

Require Comments

Requiring comments to be entered when viewing a secret can be an excellent way to ensure users are accessing a secret for legitimate reasons. You can even view the comments in the audit of the secret to historically track if a secret was accessed for the originally intended purpose. Managers can routinely review these comments and determine where employee training may be required.

A common example would be enabling require comments on a domain administrator account that is stored in Secret Server: A user may enter a comment that indicates he or she needs to use the domain administrator account to "perform adding a user to a group." In many cases, a domain administrator account should not be used for this purpose and often this work can be done with a lesser privileged account within the environment.

Requiring comments can also be combined with "Ticket System Integration" on page 238. This is a great way to align secret access with a valid ticket number and a comment. This can help with compliance and track usage of a secret tied to a specific task, which may provide more granular information as to why a secret is needed.

Check Out

There are times when users need to be able to access a password directly, but you still want to have control over how long they are able to use the account without the need to approve access each time. In this case, hiding the launcher password is not a possibility, but there is also concern about having the user know what the password is after they are done using it. Another concern if often the risk of the hash of the password being stored locally on remote devices after each use and potentially being vulnerable to a pass-the-hash attack.

"Check out" is a security setting that means:

- Only one user at a time has access to a secret
- A user can only access the secret for a predetermined check out interval, such as 30 minutes

- At the end of a check out interval (check in), or when a user manually checks in the account before the time is up, the secret is available for check out by another user
- When enabled, the password can also be changed automatically upon check in

Domain administrator accounts are a great example of a case in which using check out to change the password every time it is used can be extremely beneficial. This ensures that users are not copying the password to Notepad or writing it down for later use and also invalidates the hash that was stored on the remote machine after a remote desktop session.

Check out can be turned on under the Security tab for an individual secret, but can also be applied via a secret policy.

Session Monitoring

For critical systems and highly privileged accounts, sometimes simply having an audit trail showing when someone viewed the account in Secret Server is not enough. Maybe the auditor also wants to be able to review what was done with the account on a remote session. For these critical secrets, it is recommended to enable session recording for the secret. When session recording is enabled, all launcher sessions can be recorded for later viewing by the auditor or manager in the event they need to investigate the actions performed during a remote session.

What constitutes a "critical system" is subjective. Departments may define this differently, so having them involved in those discussions can be helpful. Some of these systems may be explicitly selected based on risk, compliance, or from the auditing team.

One of the most important things is to not consider all accounts or secrets critical, enabling session recording for them all. That can cause performance issues within your environment—session recording is the single most intensive feature of Secret Server.

Before enabling session recording, you may want to evaluate your users' roles to determine who can monitor real-time sessions and view recordings. The Delinea role permissions to look for are "administer session monitoring," "view session monitoring," and "view session recording."

Session monitoring can be turned on under the Security tab for an individual secret, but can also be applied via a secret policy.

Secret Templates

Secret templates in Secret Server define the types of data (secrets) that can be stored, and the settings for that data. You can store just about any type of sensitive data in Secret Server.

It is important to review the available templates and decide which ones should be available to your users as well as where you would like to make changes to the default templates included.

Configuring Templates

You can customize existing templates or create new templates if necessary. Many templates are included by default that cover common account types. For example, the AD Account template contains the following settings:

- Domain, username, password, and notes fields
- 30-day expiration period, applying to the password field
- RDP launcher, requiring user input for computer to connect to

- Password changing and heartbeat enabled
- AD password changer, with default password requirements

These settings are typically sufficient for most organizations to use out-of-box. However, you may wish to enable other settings or change settings such as enforcement of a naming convention or more complex password requirements. In this case, you have the flexibility to either modify the existing template, copy the existing template to use as a base for a new template, or create a new template from scratch. The following sections cover some fundamental template settings available for you to customize.

One best practice we often recommend is simply leaving default templates the way they are and duplicating the templates you plan to use. Then customize the newly duplicated templates as needed. Name them something your employees will recognize and readily use.

File Attachments

Do not forget files. You can have fields on your secret template attaching files. This can be used for storing license key files, private keys, SSL certificates, even Microsoft Word or Excel documents that contain sensitive data.

Naming Patterns

Secret Server supports enforcement of naming patterns for secret names. Naming patterns allow you to maintain consistency for secret names and can help ease both browsing and grouping secrets by name. Naming patterns use regular expressions and allow you to enter a descriptive error message to describe your naming standard to users. The most common naming standard used is RESOURCE\ACCOUNT (for example, server0001\administrator). You can find this setting by clicking Edit from the template designer page.

Password History

Secret Server automatically keeps all history on all fields on a secret template. This means that all previous values for machine, username, password and any other fields will be kept. This is helps ensure that previous passwords can be found if needed.

Password Requirements

Password Requirements determine the password compliance rules (for example, 16 characters, one uppercase, one lowercase, one symbol and one number). These can be customized and applied to passwords at the secret template level or per individual secret (under the Security tab). This controls the complexity of passwords generated by Secret Server. Password requirements can also be enforced when users try to edit or create new passwords, and can be viewed for password compliance in reports. This allows you to have different complexity rules for different types of passwords if needed (such as Oracle, SQL, Windows, and UNIX). You can choose to have Secret Server enforce the password requirements on add/edit by turning on validation on the secret template (click Edit from the template designer page).

We have added new password "Template Password Requirements" on page 1206 to recent versions of Secret Server, which further helps create unique passwords. We also added "Creating and Editing Custom Password-Exclusion Dictionaries" on page 1189 that can help personalize which words may never be used as part of a password that is generated.

Talk to your security management, auditors and industry experts to find out the best password complexity settings for your environment. Do not hesitate to stipulate complex passwords, such as 100-character random-generated

passwords with symbols, alphanumeric uppercase and lowercase)—using a platform like Secret Server makes it easy to work with passwords so complexity and length do not matter (for launchers, copy-to-clipboard, and auto change). In fact, very large passwords can add to security since administrators will be far less likely to remember them or write them down or want to type them.

Another thing to consider when creating password requirements is which character sets should be used. Some systems may not work well with certain characters. For example, underscores can be problematic in certain mainframe environments. You can create your own character sets (Admin > Secret Templates > Character Sets) for use in password requirements. These can then be used when passwords are generated by Secret Server.

Secret Expiration

Secret Server uses expiration to ensure that passwords are changed on a regular basis. Secrets can be set to expire on an interval such as 30 days (or other intervals as needed). Expiration is often combined with automatic password changing to control how often a password is changed (whenever it expires, Secret Server will queue the secret up for a password change).

You can also control which field is used for expiration. This does not have to be the password field—you could use expiration on a license key and set expiration to when the license is going to expire. When a secret expires, you can then update the expiration field (say license key) and it will no longer be expired. This is a generic way to ensure that a specific field on a secret is changed on a regular basis.

Session Launcher

The Launcher can be configured on the secret template to allow any tool to be launched using the secret such as Remote Desktop, PuTTY, Web launcher or a custom launcher you configure for a particular executable file, for example, MS SQL Management Studio, SSH clients, FTP tools and more. This can also be used with the "hide launcher password" setting to allow administrators to launch tools without revealing the password.

Template Management

It is worth spending time in the beginning to get your secret templates the way you want them before users start adding data. Therefore, when a user goes to create a new secret it will be clear which secret template to use instead of selecting the wrong one and attempting to fit account information into an unsuitable template. You can use an option on the secret called "convert template" to later convert a secret to another template, but it is much simpler to plan before your organization begins adding data.

Basic Configuration

When creating new secret templates, make sure you configure Remote Password Changing, password requirements, secret expiration and the launcher. Ensure your secret template names are descriptive and use terms your users understand. For instance, if you have one template that expires and one that does not, make sure it is clear from the name. If your organization does not use the term AD account, change it to match the organization's language.

Deactivate Unused or Retired Templates

Secret Server comes with many secret templates preconfigured. You should decide which you want to use and then deactivate the others. You can also retire secret templates if your requirements change over time—secrets remain when a secret template is deactivated but no one will be able to create new secrets for that secret template. Secret

Server SS uses soft deletes rather than hard deletes (data is marked as inactive rather than actually deleted), which is essential for auditing. Secrets and secret templates can be inactivated but not deleted.

Limit Secret Template Administrators

Changing secret templates should be limited to only a small subset of your Secret Server admins. Create a separate role that has the "administer secret templates" role permission and remove it from administrator if you have a lot of administrators. Once you have secret templates configured, it is unlikely they will need to be changed frequently so very few people should need access.

Override Settings at the Secret

Many of the settings at the secret template can also be overridden at a secret based on that template. For example, if you create a secret for your AD service accounts with a 30-day expiration but need 90 days for a specific AD service account, you can set it to 90 days for that one secret. This gives some flexibility for secrets that need to behave differently than other secrets using the same secret template.

Data Retention and Database Size Management

The "Audit Data Retention" on page 287 documentation may be helpful for very large environments where there is audit and log retention flexibility. For example, some of these tables within the database are sizeable, so if your environment exceeds 50,000+ secrets, it may be a good idea to make some adjustments. Similarly, you could have a smaller environment, say 25,000+ secrets, but if you are using all Secret Server features heavily, adjustment might be helpful.

Deleting the data within here should not substitute for a database maintenance plan and should be only considered complimentary to one. Lastly, individual audit tables, such as the "secret audit", cannot be managed independently outside of this configuration unless adjusting those tables directly within the database. Thus, we do not recommend doing unless under direct instruction of our support or professional services teams.

API and Extensibility

APIs and built-in extensibility features are one of the best ways to improve the automation and flexibility of Secret Server and address novel use cases. PAM Maturity relies on the consistent handling of credentials across your organization. Using the API is a great way to enforce consistency, without additional administrative overhead.

Features like event pipelines can help to organize secrets and users, as well as tweak some settings that are not enforced via policy. Additionally, you can discover and manage new device types using extensible discovery or custom password changers. This section covers some high-level best practices for these features and how best to employ them in your environment.

Running PowerShell with Secret Server

Secret Server's extensible features almost all use PowerShell from the Web servers or distributed engines to execute code. Create a service account for these tasks and store it in a secure location with the other Secret Server service accounts. Documentation for our "APIs and Scripting" on page 1487 components can be found in our Knowledge Base.

PowerShell Runspaces

Runspaces are instances of the PowerShell engine within a process. They define the context a PowerShell runs in and preserve session state using variables and functions that you define, including modules that you load.

For scripts executing on the local or default site, Secret Server generates a runspace to localhost on the Web server (Web site processing) or distributed engine (engine processing or Secret Server Cloud). For scripts running against a specified site, any engine associated to that site may run the script and accomplish the work. This means any dependent configurations need to be made across all Web servers or engines within a site.

This runspace is generated using a specified secret credential in all cases. The credentials used are critical in the operations of PowerShell in Secret Server and a least-permissioned approach should be used.

A domain account, that is, a member of the "remote management users" or "local admin" groups, on the engines or Web servers will have enough Windows permissions to generate the runspace Secret Server needs to execute code. Further restrictions to deny interactive log on can be applied; however, it is important to know what account to use for a least-permissions approach.

You can simplify the assignment of the privileged account in individual locations in Secret Server by specifying a "site run as" secret. This is a default secret for PowerShell running that prevents you from having to manually associate the secret in each place it is used. We highly recommend to configuring this setting on each site under the site's settings.

CredSSP

CredSSP is an authentication mechanism that is designed to delegate credentials across multiple sessions in PowerShell. By default, the runspace uses CredSSP authentication. This is not ideal as there are some security concerns with CredSSP. It is generally better to disable CredSSP authentication under all used sites, and instead implicitly pass credentials into the scripts. CredSSP does have dependent configurations that are required before it can be used.

However, If CredSSP is required, be very explicit with your delegate computer list. Allowlisting this option with an asterisk (*) may seem easy, but it allows an attacker to scale horizontally across your network.

API

The API is a powerful tool for improving automation and flexibility of your Secret Server deployment. Automation tools can pull dynamic credentials from the vault or leverage the API to create new secrets as part of an automation pipeline.

If your organization does not have script experts to improve your PAM program's flexibility, Delinea Professional Services can help to scope and create custom integrations to address your use cases. Contact your account manager or customer success manager to engage professional services.

API Authentication

Carefully consider your authentication strategy for the API when automating workflows. Authentication strategies that do not require hard coding a password into a configuration or script file are preferred. Secret Server Provides a few mechanisms to accomplish this:

Software Development Kit

The Secret Server Software Development Kit (SDK) is a mechanism to authenticate machines to a Secret Server instance, without having to pass implicit credentials into the system for each set of calls. To ensure proper RBAC, the SDK is associated to a specific API user in Secret Server. On the local system, once the SDK is initialized, it leverages DPAPI to encrypt the config files, tying it to the user who initialized it. You can use multiple SDK instances on the same machine; however, each instance needs its own directory.

Integrated Windows Authentication

You can enable Integrated Windows Authentication (IWA) in IIS to use native Windows authentication for API user authentication. This allows the domain to supply authentication between the Web server and Secret Server. This is a great option to remove credentials and automate authentication for automation processes in your environment.

> IWA is only available for Secret Server On-Premises.

Event Pipelines

"Event Pipelines" on page 295 are a powerful feature that configures tasks that run based on triggers and filters. If scripting is not an option for you, pipelines can be a script-free way to accomplish a lot of what the API provides. You can use event pipelines to build the core automation of a mature PAM deployment.

Distributed Engine and Protocol Handler Version Numbers

Secret Server Cloud

> This table is no longer updated. See the Secret Server Cloud Change Log for DE and PH updates.

Table: Secret Server Cloud Distributed Engine Versions

Secret Server Version	DE Version	PH Version	Date Published	Required Upgrade	Notes
2025-07-22	8.4.59.0	6.0.38.0	2025-07-22		**PH**: Fixed an issue with sessions not closing automatically when secret checkout expires. Enhanced parameter checking in install options to address CVE-2024-12908. Added support for keystroke-only recording in session connector.

Secret Server Version	DE Version	PH Version	Date Published	Required Upgrade	Notes
2025-01-23	8.4.45	6.0.3.33	2025-01-23		**PH**: With this version, protocol handler improvements include resolving an issue where all metadata was displayed when more than 10 fields were added to a secret, ensuring proper metadata management. Updating the heartbeat on a secret now generates an audit entry, providing clear documentation of whether the heartbeat was enabled or disabled. Large SSH keys can now be imported on Linux servers, enhancing compatibility and functionality for users managing SSH keys. When a secret is erased, the TOTP key and backup codes are also erased, ensuring complete removal of sensitive information. A cooldown period of 1 hour has been introduced for the Quantum Lock password, improving user experience by reducing the frequency of password entry. An issue with the Secret

Secret Server Version	DE Version	PH Version	Date Published	Required Upgrade	Notes
					Dependency Failure default report not running has been fixed, ensuring accurate reporting and monitoring.
2024-08-03	8.4.33.0	6.0.3.28	2024-08-03		**PH:**: With the previous version, protocol handler received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must manually redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before and upgrade to 6.0.3.28.

Secret Server Version	DE Version	PH Version	Date Published	Required Upgrade	Notes
2024-04-20	8.4.24.0	6.0.3.27	2024-04-20		**PH:**: With this version, protocol handler received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must manually redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

Secret Server Version	DE Version	PH Version	Date Published	Required Upgrade	Notes
2024-02-10	8.4.21.0	6.0.3.27	2024-02-10	PH: Yes	**PH:** With this version, protocol handler received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must manually redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.
2023-09-23	8.4.16.0	6.0.3.26	2023-09-23		**PH:** The legacy automatic update works up to this version. The next version will require a manual update. After that, the new automatic update will work. See the notes above.

Secret Server On-Premises

> This table is no longer updated. See the "Secret Server On-Premises Release Notes" on page 1589 for DE and PH updates.

Table: Secret Server On-Premises Distributed Engine Versions

Secret Server Version	DE Version	PH Version	Date Published	Required DE/PH Upgrade	Notes
11.7.000016	8.4.32.0	6.0.3.28	2024-06-12	DE: Yes	**DE:** Replacement for 11.7.000015. We pulled down version 11.7.15 (on-premises) to resolve a problem with older versions of RabbitMQ (before 3.10) impacting DE version 8.4.31, which is shipped with SS 11.7.15. This issue does not impact Cloud.
11.7.000015	8.4.31.0	6.0.3.28	2024-05-22		**DE:** Pulled down to resolve a problem with older versions of RabbitMQ (before 3.10) impacting DE version 8.4.31, which is shipped with SS 11.7.15. This issue does not impact Cloud.
11.7.000002	8.4.24.0	6.0.3.27	2024-05-15		
11.7.000001	8.4.24.0	6.0.3.27	2024-04-13	PH: Yes	**PH:** With this version, protocol handler received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must manually redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

Secret Server Download Hashes

This topic only applies to **Secret Server On-Premises**.

Download hash codes or hashes are used to verify the integrity and authenticity of downloaded software. Hash codes are unique mathematical values that are generated based on the content of the software file and can be used to confirm that the downloaded file matches the original version and has not been tampered with. By comparing the hash code of the downloaded file with the hash code provided by the software developer, you can ensure that the software you downloaded is genuine and has not been corrupted during the download process.

Downloading Secret Server

This topic only applies to **Secret Server On-Premises**.

To download Secret Server, navigate to Secret Server Download to get the latest .zip file. See the other topics in this section for installation or upgrade.

IIS and Secret Server

This topic only applies to **Secret Server On-Premises**.

Secret Server uses Internet Information Services (IIS) to run its web application, providing a secure and scalable platform for managing privileged credentials. Here are some key ways in which Secret Server uses IIS:

- Web Hosting: Secret Server is hosted on IIS, which serves as the web server to deliver the application to users. IIS handles HTTP/HTTPS requests, ensuring that the web application is accessible over the network.
- Authentication: Secret Server uses IIS to manage various authentication methods, including Integrated Windows Authentication (IWA). This allows users to authenticate using their Active Directory credentials without needing to re-enter them, enhancing security and user convenience.
- SSL/TLS Encryption: IIS is configured to use SSL/TLS to encrypt data transmitted between the client and the server. This ensures that sensitive information, such as passwords and secrets, is protected from eavesdropping and man-in-the-middle attacks.
- Application Pool Management: Secret Server runs in its own application pool within IIS. This isolates the application, ensuring that it has dedicated resources and can be managed independently of other applications on the server. The application pool can be configured to always run, preventing it from stopping due to inactivity.
- Logging and Monitoring: IIS provides logging capabilities that Secret Server utilizes to track access and activity. This includes logging user actions, system events, and errors, which are crucial for auditing and troubleshooting.
- Security Hardening: Secret Server employs various IIS security features to harden the application against attacks. This includes disabling unnecessary HTTP headers, configuring secure cipher suites, and ensuring that the application pool runs with the least privilege necessary.
- Session Management: IIS manages user sessions, ensuring that authenticated sessions are maintained securely. This includes handling session timeouts and ensuring that sessions are properly terminated when users log out.
- Load Balancing and Clustering: For high availability and scalability, Secret Server can be deployed in a clustered environment using IIS. This allows multiple instances of Secret Server to run simultaneously, distributing the load and providing redundancy in case of server failure.

Manual IIS Installation

This topic only applies to **Secret Server On-Premises**.

See "Advanced (Manual) Installation" on page 73 for more information.

IIS is an internal part of the Windows operating system, and only needs to be enabled. If IIS is not found, the Delinea Installer will install it for you. If you would prefer to install IIS manually, please refer to the instructions listed below for example steps in the Windows Server 2016 Operating System. For the most up-to-date setup instructions, see Microsoft's Technical Documentation.

Roles and Features

Delinea products recommend the following roles and features to be installed on the Secret Server IIS Server for maximum security and functionality options:

Roles

- Web Server (IIS)
- Web Server (IIS)\Web Server
- Web Server (IIS)\Web Server\Common HTTP Features
  - Default Document
  - Directory Browsing
  - HTTP Errors
  - Static Content
  - HTTP Redirection
- Web Server (IIS)\Web Server\Health and Diagnostics
  - HTTP Logging
- Web Server (IIS)\Web Server\Performance
  - Static Content Compression
  - Dynamic Content Compression
- Web Server (IIS)\Web Server\Security
  - Request Filtering
  - Windows Authentication
- Web Server (IIS)\Web Server\Application Development
  - .NET Extensibility 4.x
  - Application initialization
  - ASP.NET 4.x

    - ISAPI Extensions
    - ISAPI Filters
- Web Server (IIS)\Web Server\Management Tools
    - IIS Management Console
    - IIS Management Scripts and Tools

Features

- .NET Framework 4.x Features
    - .Net Framework 4.x
    - ASP.NET 4.x
    - WCF Services:
        - HTTP Activation
        - TCP Activation
        - TCP Port Sharing
- Windows PowerShell
    - Windows PowerShell 5.1
- Windows Process Activation Service
    - Process Model
    - Configuring APIs

Step One: Windows Server 2012-2019 IIS Installation

To install Internet Information Services (IIS) Manager on Windows Server 2016, you will need to give your server the Web Server (IIS) role using the following procedure:

> If this is *not* the first time you have run the wizard (that is, when first installing IIS), the Web Server Role (IIS) and Role Services windows will not appear, and the wizard order changes a bit. Instead, role services are selectable in the Server Roles window.

1. Click the **Server Manager** button on your server. The Server Manager Dashboard appears.
2. Click the **Add Roles and Features** button. The Add Roles and Features Wizard on the Before You Begin window appears.
3. Click the **Next** button. The Select Installation Type window appears.
4. Click to select **Role-based or feature-based installation** selection button.
5. Click the **Next** button. The Select Destination Server window appears.
6. Ensure the **Select a Server from the Server Pool** selection button is selected.
7. In the **Server Pool** section, click to select your server.

8. Click the **Next** button. The Select Server Roles window appears.
9. Click to select the **Web Server (IIS)** check box.
10. Click the **Next** button. The Select Features window appears.
11. In the **Features** list, Click to select the following checkboxes (If necessary, click the **Add Features** button when prompted):
    - .NET Framework 4.x Features > WCF Services > **HTTP Activation**
    - .NET Framework 4.x Features > WCF Services > **TCP Activation**
12. Click the **Next** button. The Web Server Role (IIS) window appears.
13. Click the **Next** button. The Select Role Services Window appears.
14. In the **Roles** list, click to select the following check boxes:

    Leave all the auto-selected check boxes as is.

    - Web Server (IIS) > Web Server > Common HTTP Features > **HTTP Redirection**
    - Web Server (IIS) > Web Server > Performance > **Dynamic Content Compression**
    - Web Server (IIS) > Web Server > Security > **Windows Authentication**
15. Click the **Next** button. The Confirmation window appears
16. Confirm your installation details.
17. Click the **Install** button. Wait for the installation to complete. The Results window appears.
18. Click the **Close** button. An IIS tile should now appear on your server.

We recommend you run Windows Update to install the latest security patches for IIS once you have IIS installed.

Step Two: Configure the IIS Website

Follow these steps to configure a website in IIS for Secret Server:

1. Extract the Secret Server files into `C:\inetpub\wwwroot\SecretServer`or your location of choice. If you rename`SecretServer`, do not use more than 20 characters.
2. Open Internet Information Server (IIS) Manager: On the taskbar, click **Server Manager > Tools > Internet Information Services (IIS) Manager**.
3. In the Connections pane, expand the server name.
4. Click on the **Application Pools** node. The Application Pools window appears.
5. Click the **Add Application Pool** link. The Add Application Pool dialog box appears.
6. Type `SecretServer` in the **Name** text box.
7. Click to select **4.x** in the **.NET Framework Version** dropdown list.
8. Click to select **Integrated** in the **Managed Pipeline Mode** dropdown list.

9. Click the **OK** button to save the new application pool. The dialog box closes.
10. (optional) Customize the Windows account Secret Server runs as:
    a. Right click the new application pool and select **Advance Settings…**
    b. Click the **Identity** setting in the **Process Model** section to select the desired account. Using this, you can, for example, set Secret Server to use IWA to connect to SQL.
11. Expand the **Sites** node on the **Connections** tree.
12. Click on the Default Web Site node.
13. In the **Actions** pane, click **Bindings** to set your desired website. The Edit Bindings dialog box appears.
14. Edit or add bindings as desired. We recommend using HTTPS with a real SSL certificate.
15. Click the **Close** button.
16. In the **Connections** tree, expand the **Default Website** node.
17. **Either**, If you see the default folder, **SecretServer**, which you created earlier:
    a. Right click the **SecretServer** folder and select **Convert to Application**. The Add Application dialog box appears.
    b. Click the **Select…** button to choose the pool you created earlier for Secret Server.

    Or, If you used a custom location instead:

    a. right click the Default Website. The Add Application dialog box appears.
    b. Type `SecretServer` in the **Alias** text box.
    c. Click **Select…** and pick the app pool created for Secret Server.
    d. Type the path where you extracted the Secret Server files in the **Physical Path** text box.
18. Click the **OK** button.

Step Three: Ensure IIS Does Not Stop the Worker Process

When using IIS version 7.0 and above, by default, the worker process terminates after an inactive period. If Secret Server is in its own application pool, that application pool will stop after a period of no requests. To ensure this does not happen, perform the following procedure. Additionally, by default, IIS launches a worker process when the first request for the Web application is received, so if the Secret Server application takes a long time to start, issues can result. Thus, we recommend launching the Secret Server application pool worker process as soon as IIS starts by setting the start mode to "AlwaysRunning."

Procedure:

1. Open **Internet Information Server (IIS) Manager**:
    - If you are using Windows Server 2012 or Windows Server 2012 R2: On the taskbar, click **Server Manager > Tools > Internet Information Services (IIS) Manager**.
    - If you are using Windows Server 2008 or Windows Server 2008 R2: On the taskbar, click **Start > Administrative Tools > Internet Information Services (IIS) Manager**.
2. In the **Connections** pane, expand the server name.

3. Click **Application Pools**.
4. Determine which application pool Secret Server is running as:
   a. Expand **Sites** at the left.
   b. Find the website Secret Server is running on.
   c. Click on the Secret Server website or virtual directory (if it is running on one).
   d. Click **Basic Settings** on the right panel. This indicates Secret Server's application pool.
5. Right-click the application pool and select **Advanced Settings...** The Advance Settings dialog appears.
6. In the **General** section, set **Start Mode** to **AlwaysRunning**.
7. In the **Process Model** section, set **Idle Time-out (minutes)** to **0**.
8. In the **Recycling** section, set **Regular Time Interval (minutes)** to **0**.
9. In the **Recycling** section, click the **>** next to **Specific Times** to ensure there are no times set. If there are, click the **...** to clear them.
10. Leave IIS Manager open—we will return to it below.

Step Four: Ensure the User Profile Always Loads

As of version 10.2, Secret Server requires its application pool "Load User Profile" setting enabled. Otherwise, Secret Server reports a critical alert to system admins.

> Even without the setting enabled, Secret Server loads to give access to secrets but many internal operations may malfunction, so we recommend resolving this issue as soon as possible.

Procedure:

1. Right-click the Secret Server application pool in IIS Manager and select **Advanced Settings...** The Advance Settings dialog appears.
2. Go to the **Process Model** section in the **Advanced Settings** dialog.
3. Set **Load User Profile** to **True**.
4. Preform an `iisreset` on the server (in an administrator command prompt).

Running the IIS Application Pool As a Service Account

> This topic only applies to **Secret Server On-Premises**.

> This configuration is not required for Secret Server Cloud as all web services are managed by the Delinea Operations team.

Overview

A domain service account should be used for the Secret Server application pool that can both access the Delinea product's SQL database and run the IIS Application Pool(s) dedicated to your Delinea product.

> A service account will usually need access to both the IIS resources and the database, but there may be cases when this may not be required.

> The service account created in this KB should **not** be the same account that is created during the installation of SQL and used to manage SQL as a whole.

To set up this service account correctly you will need to:

1. Create a service account in Active Directory that will be dedicated to your Delinea product (domain).
2. Granting the service account access to the SQL Server database.
3. Assign the service account as the identity of the application pool or pools in IIS.
4. Grant folder permissions for the service account on two folders.
5. Configure User Rights Assignment to the service account.

Procedure

> You must have IIS installed on your Web server before completing these steps.

Task 1: Creating a Domain Service Account

1. Create a local or domain user account (or identify one to use).
2. Open IIS (**Search > inetmgr**) on your Web server.
3. Open the **Active Directory Users and Computers** link from **Administrative Tools**.
4. Click to open the directory where you want to assign this account, such as testlab.com.
5. Select **Service Accounts**.
6. Right click and select **New > User**. The "New Object - User" wizard dialog box appears.
7. Type a name and logon name for the service account.
8. Click the **Next** button. The wizard advances to the next dialog box (same name).
9. Type a password in the Password and Confirm Password text boxes.
10. If necessary, click to deselect the **User must change password at next login** check box.
11. Click to select the **Password never expires** check box. Failing to do this could lock the account out of Secret Server.
12. " Check **Password never expires** or the account could lock you out of Secret Server.
13. Click **Next** button.
14. Click the **Finish** button. You can now give the account access to the database server and the application server.

Task 2: Granting Access to the SQL Database

> You must have SQL installed on your database server before completing these steps.

Grant access:

1. Open the SQL Management Studio on your database server.
2. Connect to your Delinea product's SQL database using an administrator account.
3. Click to select the Security folder in the Object Explorer.
4. Right-click the same folder and select **New > Login...**. A log on dialog box appears.
5. Ensure the **Windows Authentication** radio button is selected.
6. Click the **Search...** button. The "Select User, Service Account, or Group" dialog box appears.
7. Ensure that your domain or AD server appears in the **From this location** text box. If not, click the **Locations...** button and select it.
8. Type the login name you created for your Delinea service account, such as svc_thycotic, in the **Enter the object name to select** text box.
9. Click the **Check Names** button.
10. Click to select the correct account.
11. Click the **OK** button. The dialog box closes, returning you to the Login - New dialog box.
12. **Either**, if you have already created the database for your Delinea product:
    a. Click **User Mapping** in the **Select a page** list box.
    b. Click to select the check box for the database in the **Users mapped to this Login** list.
    c. Click to select the **db_owner** check box in the **Database role membership...** list.
13. **Or**, if you have not yet created the database:
    a. Click **Server Roles** in the **Select a page** list box.
    b. Click to select the **db_creator** check box.
14. Click the **OK** button.

Task 3: Assigning the Identity of Application Pools

1. Click the **Applications** node under the server name in the **Connections** tree.
2. Right-click the node and select **Advanced Settings...** The Advance Settings dialog box appears.
3. Click the **...** button for the **Identity** entry in the **Process Model** section. The Application Pool Identity dialog box appears.
4. Click to select the **Custom Account** selection button.
5. Click the **Set...** button. The Set Credentials dialog box appears.
6. Type your service account's name, such as test and password.
7. Click the **OK** button. The dialog box closes.
8. Open the command console as an Admin.

9. Change the directory to your .NET framework installation directory using the "cd" command, for example, `C:\Windows\Microsoft.NET\Framework\v4.0.30319`.
10. Type `.\aspnet_regiis -ga <domain name>\<username>`, replacing `<domain name>` and `<username>` with your information. For local accounts omit the domain name parameter.

Task 4: Granting Folder Permissions

> You must have the Delinea product application files installed (on your Web server) before completing this section.

Following the steps below, you give the service account "Modify" access to **two** folders:

- `C:\Windows\TEMP`
- The folder where your Delinea product's application files are located, such as `C:\inetpub\wwwroot\SecretServer`

Procedure (for each folder):

1. In a file manager, navigate to the Secret Server application folder.
2. Right-click the folder and select **Properties**. The Properties dialog box appears.
3. Click the **Security** tab.
4. Click the **Advanced** button.
5. Click the **Add** button. A permissions panel appears.
6. Click the **Select a Principal** link. The "Select User, Computer, Service Account, or Group" dialog box appears.
7. Ensure that your domain or AD server appears in the **From this location** text box. If not, click the **Locations...** button and select it.
8. Type the login name you created for your Delinea service account, such as svc_thycotic, in the **Enter the object name to select** text box.
9. Click the **Check Names** button.
10. Click to select the correct account.
11. Click the **OK** button. The dialog box closes, returning you to the permissions panel.
12. Click to select the **Modify** check box in the **Basic Permissions** section. Your service account should have the **Modify**, **Read & Execute**, **List folder contents**, **Read**, and **Write** permissions selected for this folder
13. Click the **OK** button.
14. Click the **Apply** button.

> If a Windows Security pop-up appears, click the **Yes** button. The service account will now be able to access this folder.

> The application folder only needs "Write" and "Modify" Windows NTFS permissions during the installation or during an upgrade. You can remove these once the installation process is complete.

> In order to encrypt the `encryption.config` file, the App Pool identity account needs Windows permissions on the file.

Task 5: Configuring User Rights

The following settings are required for DelineaSecret Server to function:

- "Log on as a batch job"
- "Impersonate a client after authentication"

You can adjust these settings either at the **Domain** level using group policy or locally on your IIS Web server using the Local Security Policy Console. See User Rights Assignment to learn more.

Option 1: Setting User Rights Assignment on the Domain

> This is an example of how to create a Group Policy Object (GPO), we recommend consulting with your organizational group policy administrator to create this policy.

> This overwrites any configuration in the local security policy. The local security policy is a safer option if you are not sure about usage across your domain.

1. Open the Group Policy Management Console.
2. Right-click the desired GPO folder (under the domain node) in the **Group Policy Management** Tree, and select **New**. The New GPO dialog box appears.
3. Type the name, such as " Delinea User Rights Assignment," in the **Name** text box.
4. Click the **OK** button. The dialog box closes.
5. Right-click the GPO you just created and select **Edit**. The Group Policy Object Editor appears.
6. On the **Computer Configuration** node, click to expand **Policies > Windows Settings > Security Settings > Local Policies**.
7. Click to select the **User Rights Assignment **folder.
8. Repeat the following procedure for the "Log on as a batch job" and "Impersonate a client after authentication" permissions (for this instruction we show the former):
    a. In the list on the right, right-click **Log on as a batch job** and select **Properties**. The "Log on as a batch job Properties" dialog box appears.
    b. Ensure that the **Define these policy settings** check box is checked.
    c. Click the **Add User or Group** button. A dialog box appears.
    d. Add your Delinea service account.
    e. Click the **OK** button. The dialog box closes. The new policy appears in the list.
    f. Click the **Apply** button.

9. Link your new GPO to the OU where your Delinea product machine accounts exist, that is, the Web and database servers.

Option 2: Setting User Rights Assignment Locally

1. On the Web server hosting IIS and your Delinea Application files, open the "Local Security Policy Console" as an administrator (Run as administrator).
2. On the Local Policies node, click to expand **Local Policies > User Rights Assignment**.
3. Click to select the **User Rights Assignment** folder.
4. Repeat the following procedure for the "Log on as a batch job" and "Impersonate a client after authentication" permissions (for this instruction we show the former):
   a. Right-click on **Log on as a batch job** in the list on the right and select **Properties > Add User or Group**.
   b. Click to select your Delinea service account.
   c. Click the **OK** button.

> If you get a "Service Unavailable" error after applying "Log on as a batch job" permissions, try updating your group policy settings: Open the **Command Console**, type in `gpupdate /force`**, and restart the **Windows Process Activation Service**.

Configuring gMSA Accounts – Application Pools

Configuring gMSA accounts for running Secret Servers application pool is possible by following the steps outlined below. While it may be possible to rotate the account used to run Secret Server's application pool with Secret Server itself, it may be preferable and less impactful to customers on their environment to simply create a gMSA (Group Managed Service) account. When the application pool password is updated with the new password via rotation through controlled by Secret Server, the application itself will restart. While this may be scheduled via Secret Server off-hours, this may impact the application unnecessarily. Having the application pool running as a gMSA would not impact the application in this way. Advantages to gMSAs are:

- Automatic Password Rotation that can be used on more than one server
- Minimize impact to application services by not requiring service restarts during password change
- The accounts cannot be used for interactive login (this makes it more difficult for an attacker to recover these credentials)
- The account cannot be locked out

For those wanting a GUI, you can use the tool found here.

Below are the steps you can follow for configuring Secret Server to run with a gMSA:

1. Create the KDS Root Key for the forest in which your Secret Server environment resides in an elevated powershell window. It may be required to perform this command from an elevated account within that forest/from a domain controller.

a. Add-KDSRootKey

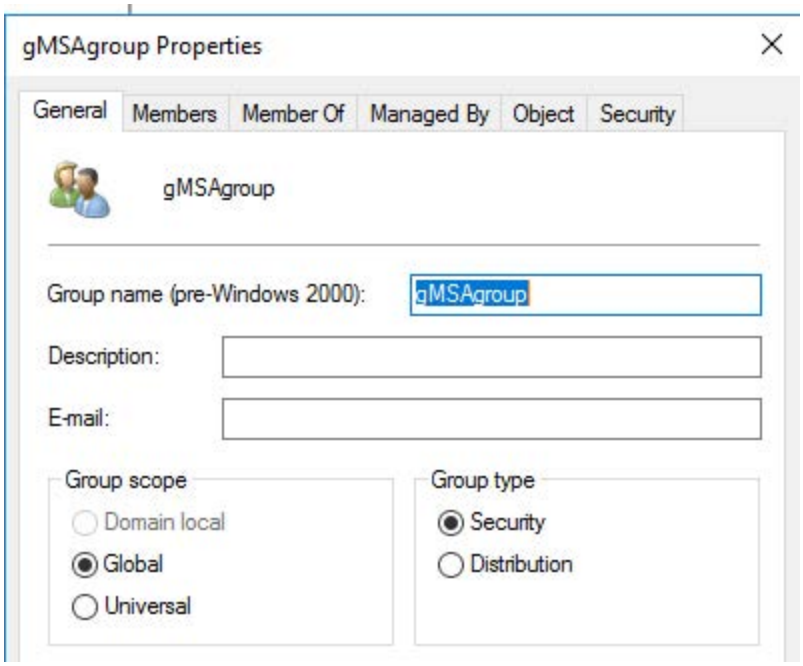
i. The -EffectiveImmediately switch doesn't actually make the account available immediately, there is a built-in 10 hour delay. This ensures AD replication is complete before you can use the accounts. You can alternatively add the switch -EffectiveTime ((get-date).addhours(-10)) to ensure the accounts can be used immediately. We suggest for production environments to simply wait 10 hours.

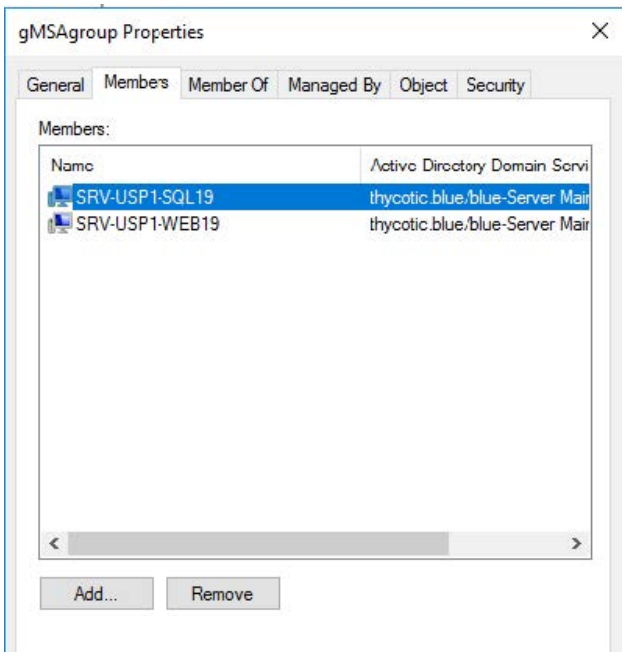
```
PS C:\Windows\system32> Add-KDSRootKey -EffectiveTime((get-date).addhours(-10))

Guid
----
0df16176-ce59-ed1a-519b-6de22ae91c34

PS C:\Windows\system32> _
```

2. Create a global security group that contains Secret Server web server node(s) and SQL server node(s).





3. Run the PowerShell to create the new gMSA account

   New-ADServiceAccount -name gMSA4-web19-iis -DNSHostName gmSA4-iis.pslab.com -PrincipalsAllowedToRetrieveManagedPassword gMSAgroup

```
PS C:\Users\Administrator.THYCOTIC.000> New-ADServiceAccount gMSA4-web19-iis -ManagedPasswordIntervalInDays 1  -DNSHostN
ame gMSA4-web19-iis.thycotic.blue -PrincipalsAllowedToRetrieveManagedPassword gMSAGroup
PS C:\Users\Administrator.THYCOTIC.000>
```

   By Default this password will change every 30 days. You can change this by using the -ManagedPasswordIntervalInDays flag to specify anything other than 30 days. I.e you could make this change every day if desired. Changes more frequently than once per day are not possible. It's also important to note that this cannot be adjusted after the command is run, so this is your only time to come up with this rotation schedule for this gMSA account without recreating the account. The password generated is a 120 character randomized password.

   You can verify this is set correctly by running the following command:

```
Get-ADServiceAccount -Identity gMSA4-web19-iis -Properties
passwordlastset,managedpasswordintervalindays
```

```
PS C:\Users\Administrator.THYCOTIC.000> get-ADServiceAccount -Identity gMSA4-web19-iis -Properties managedpasswordinterv
alindays,passwordlastset

DistinguishedName              : CN=gMSA4-web19-iis,CN=Managed Service Accounts,DC=thycotic,DC=blue
Enabled                        : True
ManagedPasswordIntervalInDays : {1}
Name                           : gMSA4-web19-iis
ObjectClass                    : msDS-GroupManagedServiceAccount
ObjectGUID                     : 50574bb5-0fba-4fb2-98b4-872bfbb9c6a8
PasswordLastSet                : 9/26/2019 11:25:41 AM
SamAccountName                 : gMSA4-web19-iis$
SID                            : S-1-5-21-1151005640-1597552947-4000691952-3101
UserPrincipalName              :
```

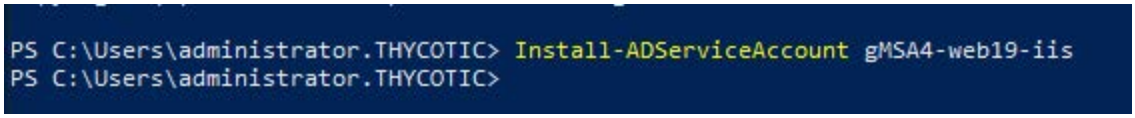
Reboot all systems that belong to the gMSA group after this step is completed.

4. Install Remote Server Administration Tools via Server Manager or PowerShell on all systems belonging to the gMSA group.

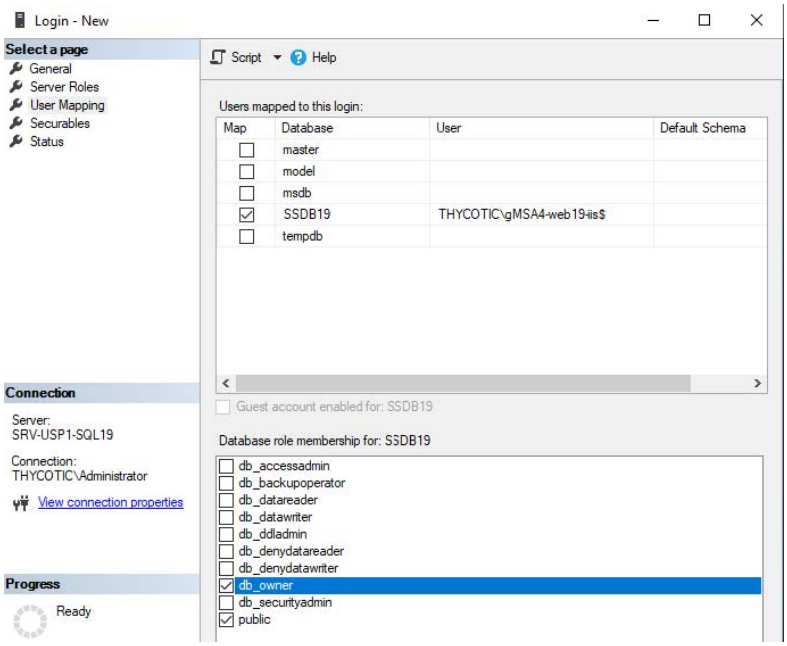
   ```
   Install-WindowsFeature -Name RSAT-AD-PowerShell
   ```

5. Install the gMSA account on each server belonging to the gMSA group

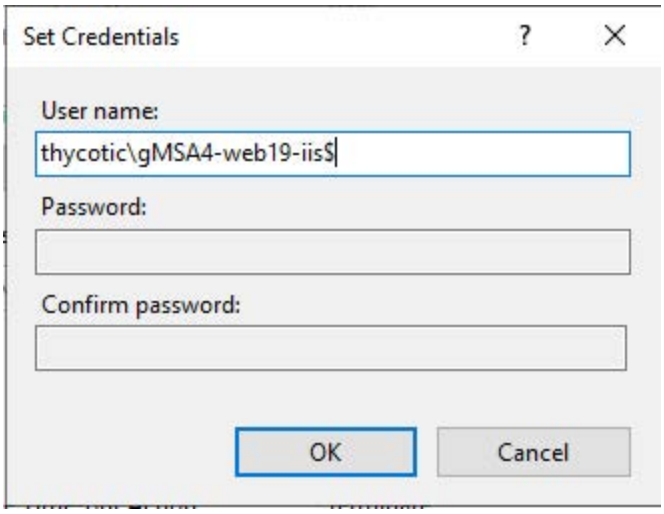
   ```
   Install-ADServiceAccount gMSA4-web19-iis
   ```



6. On the Secret Server Database Server, add the gMSA4-web19-iis account to be DBOwner of Secret Server database



7. On the Secret Server Web Server, switch the application pool account over to utilize the gMSA. When switching the account over, ensure you append $ to the end of the account name. This will grey out the requirement to supply a password.



8. Verify Secret Server is working and that you can still log in and access the database.

Lastly, there are still significant advantages to using Secret Server for rotating service account passwords within your environment:

- gMSA audit trail is not as comprehensive as Secret Server
- gMSA accounts can only have their password rotation schedule determined upon creation, which cannot be altered later. This can be changed as the need arises with Secret Server
- gMSA passwords are encrypted but also stored in local systems registry and there are scripts that can decrypt/retrieve this password if run in the context of LocalSystem.

We recommend this strategy above of using gMSAs for Secret Server Application Pool service accounts specifically for customers who have hard requirements on rotating the service account attached to the IIS application pool for Secret Server and do not want to cause downtime to the service.

We strongly encourage use of HSM as a best measure for protection of the encryption.config file. If utilizing EFS+DPAPI as a mechanism to protect Secret Server's encryption.config file, you will need to utilize a separate domain account to enable EFS. You will not be able to enable EFS with the gMSA account. In the context of this document, we would recommend having a separate domain account that is used for logging on to the system and enabling EFS protection on the encryption.config file. Lastly, It's important to note that this same Application Pool account requires to be provided dbowner access to the database. A skilled attacker would require multiple sets of credentials, an unencrypted encryption.config file, and a copy of the database in order to stand up a replica of the environment and gain access to any additional passwords.

Installation

This topic only applies to **Secret Server On-Premises**.

Please check the "Prerequisites" on page 93 and then select either our "Basic (Automatic) Installation" on page 75 or "Advanced (Manual) Installation" on the next page.

Advanced (Manual) Installation

This topic only applies to **Secret Server On-Premises**.

See "Manual IIS Installation" on page 59 for more information.

Procedure

For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.

Step 1: Downloading the Secret Server Application Files

Ensure you have the IIS, .NET Framework, and SQL Server prerequisites installed before following the steps below.

Go to the download page to get a .zip file that contains both Secret ServerandPrivilege Manager files in the manual installation section. Use this .zip file for the instructions below.

Step 2: Creating Folders and Extracting Contents

1. Extract the contents of the .zip file downloaded above (Right-click, **Extract All...**). The original file is named with the latest version number for Secret Server.
2. Extracting this file reveals a `nugetCache` folder, as well as another zipped folder named `ss\_update`. For a Secret Server-only install, you will not need the contents of the `nugetCache` folder.
3. Create a folder called `SecretServer` in the location `C:\inetpub\wwwroot\`.
4. Extract the contents of the `ss_update.zip` file (Right-click, **Extract All...**) to `C:\\inetpub\\wwwroot\\SecretServer`.

Step 3: Configuring IIS

Open Internet Information Services (IIS) Manager* and create a new application pool:

Our IIS installation sets the .NET trust level to "Full (internal), which may affect other applications on the server.

1. Right-click **Application Pools** and select **Add Application Pool...**
2. Type a name (for example, SecretServerAppPool).
3. Ensure that the highest .NET CLR version is selected.
4. Ensure the Managed pipeline mode is set to **Integrated**.
5. Click the **OK** button.

> The Secret Server installer sets the application pool to default to the system Network Service account. If you selected Windows Authentication Mode during the SQL Installation process, see "Running the IIS Application Pool As a Service Account" on page 63. To use Windows Authentication you must use an Active Directory service account to run the application pool in IIS. We recommend this as a security best practice.

6. See "Changing IIS to Not Stop Worker Process in IIS 7.0 and Later" on page 254 to set the Idle Timeout and Regular Timeout settings to 0 for the application pool in IIS.
7. Install Secret Server as either a virtual directory (4a) or as a website (4b):

Step 4a: Installing Secret Server as a Virtual Directory

1. Right-click **Default Web Site** and select **Add Virtual Directory...**
2. Select an alias for your Secret Server. The alias is appended to the website, and it is best to name it the name of your earlier unzipped folder. For example, SecretServer becomes `https://myserver/SecretServer`.
3. Select the physical directory for where you unzipped Secret Server, for example, `C:\inetpub\wwwroot\SecretServer`. Do not replace`SecretServer`with anything longer than 20 characters.
4. Click the **OK** button.
5. In the tree, right-click the new virtual directory and select **Convert to Application**.
6. Set the **Application Pool** to the same one you created in the Manual Installation section, for instance, SecretServerAppPool. Secret Server is now ready for installation. Skip to Step 5.

Step 4b: Installing Secret Server as a Website

1. In IIS, right-click **Sites** and select **Add Website...**
2. Type a site name.
3. Click **Select...** and choose the application pool you created in the Manual Installation section.
4. Click the **OK** button.
5. Click the **...** button beside the **Physical path** field and select the directory containing the unzipped Secret Server files, for example `C:\inetpub\wwwroot\SecretServer`.
6. Click the **OK** button.
7. Click the **OK** button at the bottom of the **Add Website** window to save your settings. Secret Server is now ready for installation.

Step 5: Completing Secret Server Installation from the Website

Your Secret Server advanced installation is now ready to complete:

1. "Installing and Configuring SQL Server" on page 123.
2. Open a browser and navigate to where your Secret Server is located, such as `http://localhost/secretserver`. You should arrive at a page that says "Secret Server (Not Installed or Unable to Access the Database)."

3. Click the **Install Secret Server** button.
4. On the **SQL Server Location** page, specify the server name of your SQL Database Server, `<DatabaseMachineName>\InstanceName` and then the database name that you created in SQL for Secret Server.
5. If you are using Windows authentication mode to access SQL (recommended), ensure the correct service account is listed.
6. If you selected mixed mode during the SQL install, select **SQL Server Authentication** and enter the SQL username and password you created for the SQL account. For information about adding a SQL Server user, see the "SQL Server 2016 Standard Edition Installation" on page 128.
7. Click the **Install Secret Server** button. Secret Server verifies it is able to successfully create the Secret Server database. If an error occurs no database changes will be made.

   Secret Server attempts to download and install the latest version from the Internet. If you do not have an active Internet connection on your Web server, Secret Server will continue to install the version from your downloaded application files.

8. The install may take a few minutes to complete. Once successful, click the **Return to Home** button.
9. Create a username and password for the administrator account for Secret Server and store these credentials in a safe location.
10. Click the **Create User** button and log on after entering the username and password.
11. Once logged on Secret Server, you are prompted with the Getting Started wizard. The wizard guides you through adding your Licenses, setting up an email server, and creating your first group.

    If you skipped the wizard and would like to return, go to **HELP > Getting Started** from the top menu.

Secret Server is now installed. See our "Getting Started Tutorial Overview" on page 78 or contact Delinea Support about training.

Troubleshooting Notes

- If the database name you provide does not yet exist in the specified instance of SQL Server, Secret Server attempts to create the database using the SQL or Windows account you have specified. For that account to create a database, it needs to have the dbcreator server role in SQL Server. Secret Server
- If using Windows authentication mode (recommended) you need to use a service account to run SS's application pools with appropriate Delinea permissions. See "Running the IIS Application Pool As a Service Account" on page 63.

Basic (Automatic) Installation

This topic only applies to **Secret Server On-Premises**.

Introduction

This is the installation guide for Windows Server 2012-2022 and Windows 10. For other operating system installation guides, please see "Technical Support" on page 72.

Secret Server Is an ASP.NET Website

Secret Server is installed as an ASP.NET website. The setup.exe file sets up the website with the correct Windows and IIS permissions and creates the settings in IIS.

SQL Server Is Usually Required

Secret Server requires an instance of SQL Server for the database backend and is installed by the setup.exe file, if missing. The SQL Server database will require a SQL account with *db_owner* permission to complete the installation.

> Delinea does not support using SQL Express in a production environment due to size and performance limitations.

Administrative Access

Throughout the installation, you will be required to be an administrator to perform most of these actions. Please ensure that you are logged onto your system with a Windows account that has administrative rights.

Review the Prerequisites

> Except for the operating system, the following prerequisites are installed automatically by our installer. If you already have some of them installed or wish to install them yourself, the installer will skip over them.

Please review the full list of system requirements and recommendations on the "System Requirements for Secret Server" on page 94 page.

Additional Recommendations

We suggest you:

- Use an SSL certificate for Secret Server.
- Run Microsoft Update on your server to make sure all components are up to date.
- For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.

Procedure

Step 1: Downloading the Latest Version of Secret Server

The latest version of Secret Server available for download . A setup.exe file is downloaded to your machine. We recommend running setup.exe as an administrator.

Step 2: Running the Installer

Welcome Page

The first installer page you are presented is the Welcome Page. The installer should detect whether the machine has Secret Server orPrivilege Manager for Windows and will declare which of those products it will install.

Database Page

The Database page allows you to choose to install SQL Express or connect to an existing SQL Server. If you select SQL Express, the installer requires Internet access to download the installation for SQL Server Express.

If Internet access is not available, a link to download SQL Server Express is presented. You are expected to install SQL Server Express and then restart the installer.

If Internet access is available, SQL Server Express is installed.

Prerequisites Page

The Prerequisites page ensures everything that is required to install Secret Server is setup correctly. Everything on this page *can* be installed outside of the installer. If not, the installer installs and configures them for you. This page is primarily for third party server configuration. If there are issues, please refer to support for the specific non-Delinea vendors.

Database Connection Page

The Database Connection page contains the connection information that Secret Server(and Privilege Manager) uses. You must click the**Test Connection** button and have a successful result before installation can continue.

Create User Page

The Create User page is where you enter the information for the initial Secret Server user.

Email Server Page

Enter connection information for the email server on this page. This is also optional and you can skip it and set it up later in Secret Server. This page will configures email for both Secret Server andPrivilege Manager for Windows.

Review Page

Review the, mostly default, settings on the Review page, and change them is needed. Some of the settings are validated before the install can begin.

Install Page

The Install page shows the status from log files as both Secret Server andPrivilege Manager are installed.

Step 3: Reviewing the Log Files (Optional)

After the applications are installed, the installer opens a Web browser to the Secret Server log on page. At this point, everything is installed to start using both Secret and Privilege Manager. If the installation failed or you wish you view the logs from the installation, click the **View Log Files** button.

Step 4: Opening Secret Server

If the setup.exe did not automatically open a browser, navigate to where Secret Server is located, for example: `http://localhost/secretserver`.

Step 5: Learning Secret Server

See our "Getting Started Tutorial Overview" on page 78 or contact Delinea Support about training.

Installing Secret Server via the Command Line

This topic only applies to **Secret Server On-Premises**.

Overview

ThycoticSetup.exe accepts command line arguments for a silent or automated installation. This topic discusses how to do that.

Basic usage:

```
ThycoticSetup.exe -q -s PARAMETER=<value> PARAMETER2=<value> (/nodetect) (/l <log file path>)
```

Important considerations:

- Always pass `-q -s` to `ThycoticSetup.exe` and then pass in your parameters or switches.
- There are two stages to the installer. The first (optional) stage is to install the prerequisites such as IIS and .NET 4.8. Then in a second stage, once all required prerequisites are present, you can install Secret Server or Privilege Manager (PM).
- The installer UI performs additional validation steps, such as testing the database connection information, that a silent CLI one does not. Thus, this install can fail if you provide incorrect settings.
- The installer checks to see if Secret Server and PM are already installed by default. It will install them if either is not found. If you would like to specify which applications to install, you must use the `/nodetect` switch to avoid the automatic detection, so the `InstallSecretServer` and `InstallPrivilegeManager` settings are respected.
- Due to how MSI installers work, if you need to pass in parameters that contain spaces, use the special `CMDLINE` parameter, using extra double quotes to delineate each parameter. For instance:

  ```
  ThycoticSetup.exe -q -s PARAM1=some_string PARAM2=1234 CMDLINE=" PARAM3=""Something with a space"" PARAM 4=""Another value with spaces"" "
  ```

  Note:

  - You can mix and match regular parameters (numerical values, or strings without spaces) with `CMDLINE`.
  - Any parameters sent inside of `CMDLINE` are treated as strings. Numerical parameters inside of `CMDLINE` are ignored.
- Be aware of how you call `ThycoticSetup.exe` and what special characters need escaping in your shell. This includes passwords containing symbols. What is required is shell dependent. For example, running the installer from PowerShell (or a .ps1 script) rather than an older command prompt (or a .bat file) would require escaping a different set of special symbols.
- We recommend using the `/l <logfile>` option to create a log file, which you can use to verify your parameters are correctly passed to the installer. This is especially useful when using `CMDLINE` for parameters with spaces, which is prone to mistakes.

For security, parameters involving passwords are not logged.

Install Prerequisites

As of Secret Server 10.11, you can silently install all required prerequisites. These are the same prerequisites the "Fix Issues" button in the installer UI fixes. The important difference is missing prerequisites are not auto detected–you must tell the installer which ones you want installed. Older versions will not do a silent command line installation unless these necessary prerequisites are already installed.

Parameters

Table: ThycoticSetup.exe Parameters

Parameter	Value	Required (if not present)	Purpose
`InstallPreReqs`	Boolean	Yes	Triggers the prerequisites installation. Enable this to install prerequisites with no application. This overrides `InstallSecretServer=1` and `InstallPrivilegeManager=1`.
`PRE_REQS_TO_INSTALL`	Comma separated list (see below)	Yes	Specifies which prerequisites to install.

Prerequisites

Table: Prerequisite (`PRE_REQS_TO_INSTALL`) Values

Prerequisite	Required (if not present)	Purpose
CONFIGURE_FIPS	No	Ensures the AES 256 and 128 ciphers are enabled in Windows.
ENABLE_FIPS	No	Enables FIPS mode in Windows. Generally, not needed, unless required by your environment.
INSTALL_HTTPS_BINDING	No	Enables HTTPS binding in IIS for the default website. Tries to pick an existing valid SSL certificate and creates a self-signed certificate if necessary for temporary use. Always use HTTPS with a valid certificate in production environments.
INSTALL_IIS	Yes	Installs the Web Server (IIS) Windows Role.
INSTALL_IIS_COMPS	Yes	Installs various required IIS features.
INSTALL_NET_WCF	Yes	Installs the WCF HTTP and TCP activation features.
INSTALL_NetFx48	Yes	Installs .NET 4.8. This **requires a reboot.**

Single-Line Example

```
ThycoticSetup.exe -q -s InstallPreReqs=1 PRE_REQS_TO_INSTALL=INSTALL_IIS,INSTALL_IIS_
COMPS,INSTALL_NET_WCF,INSTALL_HTTPS_BINDING,INSTALL_NetFx48 /l C:\temp\install-prereqs.log
```

Installing Applications

Secret Server or Privilege Manager can be installed and pre-configured using these parameters. If the required prerequisites are not already present, the installer exits. They can both be installed at the same time but will then share the same database and email settings.

If you need more control over configuring the website, you can create a site and configure it in advance (that is, using IIS's `AppCmd.exe`), and then pass the preconfigured website name as `SecretServerSiteName` or `PrivilegeManagerSiteName`.

Secret Server Parameters

Table: Secret Server Parameters

Parameter	Value	Default	Notes
CreateWebSite	Boolean	0	Required if the SecretServerSiteName website does not exist.

Parameter	Value	Default	Notes
`InstallSecretServer`	Boolean	1	Whether or not to install Secret Server. Must also use the `/nodetect` switch to avoid this being set to 1 if not already installed.
`SecretServerApplicationName`	String	`SecretServer`	Used for the application pool name as well as the website application or subfolder.
`SecretServerAppPassword`	String	Optional	Only required if you are configuring `SecretServerAppUserName`.
`SecretServerAppUserName`	String	`ApplicationPoolIdentity`	What identity to run the app pool as. The user must already exist.
`SecretServerConfigLogFile`	String	`<logname>_SS_Configuration.log`	Optional. The base `<logname>` is specified with the `/l` option.
`SecretServerDestinationFolderPath`	String	`C:\inetpub\wwwroot\SecretServer`	If you would like to use a directory containing spaces, see note above about how to use the `CMDLINE` parameter to pass it in. Do not replace `SecretServer` with anything longer than 20 characters.

Parameter	Value	Default	Notes
`SecretServerSiteHttpsPort`	Integer	Optional	HTTPS port. Always use HTTPS in production. If using the default website, this port is an additional HTTP binding, along with the default. If you use this option to bind HTTPS on another port, configure the HTTPS binding yourself and choose a certificate after the installer completes. `INSTALL_HTTPS_BINDING` only configures the certificate on the normal 443 binding.
`SecretServerSiteName`	Integer	Default website	Used by both Secret Server and PM. Must already exist, unless you also use `CreateWebSite=1` (see the Website Parameters section below).
`SecretServerSitePort`	Integer	Optional	HTTP port. If using the default website, this port HTTP binding is in addition to any defaults.
`SecretServerUserDisplayName`	String	None	The display name for `SecretServerUserName`.
`SecretServerUserEmail`	String	None	The email address for `SecretServerUserName`.

Parameter	Value	Default	Notes
SecretServerUserName	String	None	The initial Secret Server administrator user. If not set, once Secret Server is installed, the first person to visit the website will be able to pick the details on the "Create Initial Administrator" page.
SecretServerUserPassword	String	None	The password for SecretServerUserName.

Privilege Manager Parameters

Table: Privilege Manager Parameters

Parameter	Value	Default	Notes
CreateWebSite	Boolean	0	Required if the PrivilegeManagerSiteName website does not exist.
InstallPrivilegeManager	Boolean	1	Whether or not to install PM. Must also use the /nodetect switch to avoid this being set to 1 if not already installed.
PrivilegeManagerApplicationName	String	TMS, TMSAgent, TMSWorker	Used as the base name of the PM application pools (Regular, Agent, and Worker), plus the website application or subfolder.
PrivilegeManagerAppPassword	String	None	Only required if you are configuring PrivilegeManagerAppUserName.
PrivilegeManagerAppUserName	String	None	What identity to run the app pool as. User must already exist.

Parameter	Value	Default	Notes
`PrivilegeManagerDestinationFolderPath`	String	`C:\inetpub\wwwroot\TMS`	If you would like to use a directory containing spaces, see above on using the `CMDLINE` parameter.
`PrivilegeManagerLogFile`	String	None	Optional
`PrivilegeManagerSiteName`	String	Default website	`CreateWebsite=1` must also be set to customize this.

Required Database Parameters

Delinea does not support using SQL Express in a production environment due to size and performance limitations.

Table: Required Database Parameters

Parameter	Value	Default	Notes
`DatabaseConnectionTimeout`	Integer	15	Database connection timeout in seconds.
`DatabaseEnableMultiSubnetFailover`	Boolean	0	If your application connects to an AlwaysOn availability group (AG) on different subnets, setting `MultiSubnetFailover=true` provides faster detection of and connection to the (currently) active server. For more information about SqlClient support for AlwaysOn availability groups, see SqlClient support for High Availability, Disaster Recovery.
`DatabaseEnableSslEncryption`	Boolean	0	Whether or not to use SSL/TLS for the database connection.
`DatabaseFailoverPartner`	String	None	The name or address of the partner server to connect to if the primary server is down. Only used if `DatabaseEnableMultiSubnetFailover=1`.

Parameter	Value	Default	Notes
DatabaseIsUsingWindowsAuthentication	Boolean		Whether or not to use integrated Windows authentication for MSSQL access. If enabled, before running the install, you must configure your IIS application pool to run a Windows account permission to access the DatabaseServer, and the DatabaseUserName and DatabasePassword will not be used.
DatabaseName	String	None	Database name. Is created if it does not exist. Defaults to SecretServer if installing SQL Express.
DatabasePassword	String	None	Database SQL login password. Ignored if using Windows authentication.
DatabaseServer	String	None	Database server hostname or IP.
DatabaseTrustServerCertificate	Boolean	0	Only used if DatabaseEnableSslEncryption=1 is set. Do not enable in production if you are using SSL encryption; certificate trust validation is critical to security. Certutil.exe can be used to diagnose untrusted certificates. When TrustServerCertificate is set to true, the transport layer uses SSL to encrypt the channel and bypass walking the certificate chain to validate trust. If TrustServerCertificate is set to true and encryption is turned on, the encryption level specified on the server is used even if Encrypt is set to false. The connection fails otherwise.
DatabaseUserName	String	None	Database SQL login username. Ignored if using Windows authentication.
InstallSqlExpress	Boolean	0	Whether or not to install the free SQL Express to use as a database server. If enabled, none of the other database parameters are used. We only recommended this for testing. , do not use in production due to performance limits.

Email Parameters

You can set email parameter either in the UI after installation or by using these parameters at install time.

Table: Optional Email Parameters

Parameter	Value	Default	Notes
EmailDomain	String (optional)	None	Domain for SMTP credentials. Used if `EmailUseCredentials=1`.
EmailFromAddress	String (required)	None	The "from" address to use when sending emails.
EmailPassword	String (optional)	None	Password for SMTP credentials, used if `EmailUseCredentials=1`.
EmailPort	Integer	25	The TCP port used to connect to the SMTP server.
EmailServerName	String (required)	None	Hostname or IP of a SMTP server.
EmailUseCredentials	Boolean	0	Whether or not SMTP credentials should be sent when connecting.
EmailUseCustomPort	Boolean	0	Whether or not to use a custom port connecting to the email server.
EmailUserName	String (optional)	None	Username for SMTP credentials. Used if `EmailUseCredentials=1`.
EmailUseSSL	Boolean	0	Whether or not to use SSL/TLS when connecting to the email server

Single-Line Example

This example installs Secret Server and not PM, leaving variable for the database parameters:

```
ThycoticSetup.exe -q -s InstallSecretServer=1 InstallPrivilegeManager=0
DatabaseServer=<hostname> DatabaseName=<SecretServer> DatabaseUserName=<username>
DatabasePassword=<password> /l C:\temp\ss-install.log /nodetect
```

Moving Secret Server to Another Machine

This topic only applies to **Secret Server On-Premises**.

Always backup your data before performing this operation.

If you are moving/migrating Secret Server to a new machine and have installed IIS and .NET Framework as described in the Installation Guide on the new machine, you do not need to run the installer; you just need to follow the steps below:

1. If you use the "Force HTTPS/SSL" option, disable it by clicking **Configuration** from the **Administration** menu, and then click the **Security** tab, and **Edit**. You can re-enable the "Force HTTPS/SSL" option after you set up and install an SSL certificate on the new machine.

   > If you are also moving the SQL Server database, be sure to create a new backup of the database, as this setting is written to it. To move the database, follow the steps in "Moving the Microsoft SQL Server Database to Another Machine" on page 125.

2. If you have configured encryption of your key using DPAPI, you will also need to turn this off before continuing with Step 3. To do so, click **Configuration** from the **Administration** menu, then click the **Security** tab. Click **Decrypt Key** to *not use* DPAPI and enter your Secret Server account password.
3. Copy the folder that holds your Secret Server instance to the new computer.
4. Shut down the old web site and recycle its application pool as it is running background threads that are accessing the database.
5. Set up the new folder in Internet Information Server (IIS) as a virtual directory/application under the Default Web Site or as a separate Website. For detailed instructions, refer to "Advanced (Manual) Installation" on page 73 in the Installation Guide.
6. If your database server and credentials have not changed, skip this step. If they have changed, follow the steps below:
   a. Delete the database.config file from the secretserver folder (on the ASP.NET/IIS machine).
   b. Restart your new Secret Server website, so it is running.
   c. Browse to your Secret Server URL \ dbconnectionreset.aspx `http:\\secretserverurl\dbconnectionreset.aspx` and you will be prompted to enter your new database connection details.
   d. Enter your new SQL Server and the account information.
   e. Click **Next** and the site will connect to the new database. Your site is now pointing the new database.
7. Activate the licenses for the new server by going to the **Licenses** page.
8. If you are using certs, remember to set them on your new IIS, and then browse to Secret Server over HTTPS and re-enable force HTTPS if this was set on the original machine.
9. Re-enable DPAPI if this was disabled in the earlier step.

> If you are moving Secret Server web application from Windows Server 2008 to 2012 AND your Secret Server is below version 8.5, make sure that:

- .Net extensions 3.5 and ASP.Net 3.5 when adding the IIS role on the new server.
- Change the Secret Server application pool to 2.0 and recycle the application pool after running the installer.

Supported Software Versions

The following software versions are officially supported by Delinea:

- Microsoft SQL Server versions 2016-2022
- Windows Server versions 2016-2022
- TLS certificates versions 1.2 and newer
- NET 4.8 or newer
- RabbitMQ: Latest version
- PowerShell version 5.1 and newer

Licensing

> This topic only applies to **Secret Server On-Premises**.

The Secret Server licensing model allows for scalability and enhanced core functionality in the form of edition enhancements (Professional, Premium Edition) and user packs. Licenses can be purchased for these items as follows:

- **Users:**Secret Server ships with one free license for a single user. Additional user licenses can be purchased through https://delinea.com.
- **Support:** Support licenses allow you to receive technical assistance from the Secret Server support team, and software updates for installed versions of Secret Server. To be eligible for updates, the number of support licenses and user licenses must match.

After installation is complete, you need to enter your licenses using the Getting Started Wizard or from the Licenses Administration page. Entering your licenses allows you to add more users and enables additional features in Secret Server.

> For more information, see "Adding, Activating, Converting, and Deleting Licenses" on the next page.

Licensing Limited Mode

If you fail to activate your licenses, your system is placed in limited mode, which prevents the following actions:

- AD sync
- Creating and editing secrets
- Importing secrets
- Creating and editing secrets
- Web services (mobile applications)

Adding, Activating, Converting, and Deleting Licenses

> This topic only applies to **Secret Server On-Premises**.

This section explains how to add and activate Secret Server licenses (both online and offline) how to delete licenses, and how to convert from a trial license.

> For more information on understanding Secret Server licensing, see the "Licensing" on the previous page page.

Offline Activation

For offline activation, go to the License Activation Center.

Adding and Activating Secret Server Licenses Online or Offline

1. Log on to Secret Server as an administrator.
2. Search for **Licenses**. The Licenses page appears.
3. Click the **Install New License** button. The Install New License popup appears.
4. Click to select **Single Entry** in the **Entry Type** selection button.

   > If you have numerous licenses, you can click the license **Bulk Entry** selection instead. It allows you to paste an entire licensing email or a formatted list of licenses, adding all licenses in a few clicks. For a small number of licenses, especially if you are new to the process, we recommend using single entry, which provides better feedback on what you are doing.

5. Type (or paste) the **License Name** and **License Key** for the license that you received from your account manager.
6. Click the **Install** button. The License Installed Successfully popup appears.
7. If you have another license, click the **Install Another License** button to repeat the process.
8. Click the **Continue with Activation** button. The License Activation page appears.
9. Ensure your name, email address, and phone number are present and correct.
10. If you have an internet connection and want to activate **online**:
    a. Click the **Activation Type** dropdown list and select **Online**.
    b. Click the **Activate** button. An Activation Successful popup briefly appears and then disappears, and you are returned to the Licenses page where your new license now appears. The procedure is complete. **Do not do the remaining steps**.
    c. The endpoint called by Secret Server for posting data is: https://my.thycotic.com/LicenseActivation.ashx
11. If you do not have an internet connection on the Secret Server machine and want to activate **offline**:

a. Click the **Activation Type** dropdown list and select **Offline**. The Offline Activation section appears.
b. Click the **Copy to Clipboard** link to copy the text in the **Request** text box.
c. Copy the contents of your clipboard to a thumb drive or the like. Leave the Secret Server page open.
d. On another machine that does have access to the Internet, go to the License Activation Center.
e. Paste the copied text into the text box.
f. Click the **Activate** button. Activation Successful! appears at the top of the page and the text box now contains the activation confirmation.
g. Copy the entire text box contents.
h. Return to Secret Server and paste the response into the **Response** text area.
i. Click the **Activate** button. An Activation Successful popup briefly appears and then disappears, and you are returned to the Licenses page where your new license now appears.

For more information on activating Secret Server licenses, see the "License Activation FAQ" on the next page. Secret Server may be activated on an air gap network for both trials and licensed products. Please let your Account Manager know you will be using Secret Server on an air gap network for more information.

If you receive an error message, please take note of the error code and call the phone number contained in the message.

If an error message persists after successful activation, remove expired and invalid licenses from Secret Server by following the steps below, under **Deleting Secret Server Licenses**.

If you need help and your Secret Server has a current support license for each user license, please contact our technical support team.

For more information on Secret Server licensing and license activation, see "Licensing" on page 88 and the "License Activation FAQ" on the next page.

Converting Evaluation Licenses

If you had evaluation licenses initially and you recently purchased Secret Server, you need to remove all evaluation licenses before you install your purchased licenses. Follow the steps below, under **Deleting Secret Server Licenses**.

Deleting Secret Server Licenses

1. Log on to Secret Server as an administrator.
2. Search for **Licenses**.
3. Under the **Licenses** tab, click **Delete** next to the related license in the list.
4. Click **Delete** in the Delete license popup. The license information will remain available to you from your account.
5. Verify that the selected license key has been removed from the list.

License Activation FAQ

This topic only applies to **Secret Server On-Premises**.

What happens if we find that we had more named users than licenses after activation? Will the account lock us out? The user licenses are per named individual. You can simply disable any excess users so you are within your license count–these users can be re-enabled later and all audit log information is kept.

Why is license activation required?

Activation of license keys is standard practice in the software industry. We try to focus exclusively on implementing customer requests but occasionally we must spend time on licensing especially as Secret Server goes into new geographical markets.

Why does Secret Server On-Premises require annual license reactivation, even if my license term is longer than one year?

License activation and license renewal are separate processes that serve different purposes:

- **License renewal** determines how long your license is valid (its term).
- **License activation** verifies that your license has not been installed on more server instances than permitted.

Activation requests are valid for 13 months. This periodic reactivation ensures that licenses are not deployed to more environments than authorized. You will need to reactivate when:

- The 13-month activation period expires
- You add more server nodes to your environment
- You change database connection details

Is there a grace period before we must activate?

Existing customers have 30 days to activate their licenses after upgrading. New licenses must be activated immediately on adding them to Secret Server. Evaluation licenses do not require activation.

How is license activation implemented in Secret Server? Activation is per license and Web server (the combination of the two). Therefore, even if a Web server was already activated, if you bring up a new Web server, it also needs activation. The activation process gathers the name, email, and phone number of the individual activating, for internal purposes only. No other personal information is sent to Delinea.

What will happen if we don't activate our licenses?

Secret Server will go into limited mode if you do not activate your licenses. Limited mode allows you to view passwords, but many other features are disabled such as creating secrets, editing secrets, changing Delinea permissions, and using Web services. Activate your licenses to get out of limited mode.

We have several license keys. Do we need to activate each license key individually?

No, the license activation process will activate all license keys that are currently added to your Secret Server. However, additional license key for distributed engine may need to be activated individually if you receive the key after the other licenses.

What if we have been using our license keys on more than one instance of Secret Server?Secret Server software licenses (user, professional, enterprise, or enterprise plus edition licenses) may only be used on a **single**

production instance of Secret Server. You may use your same licenses for a single testing (non-production) environment. If you have used your licenses on multiple production instances of Secret Server, please contact us.

What information is collected and sent during license activation?

License Activation is required for each web server that will be running Secret Server. The request and the response to or from `delinea.com` are encrypted for added security.

The following information is sent to `delinea.com` when you activate:

- Name (user entered)
- Phone number (user entered)
- Email (user entered)
- All licenses (license name, license key)
- Hardware hash of each Web server

The following information is one-way hashed or omitted before it is sent to ensure it does not reveal any identifiable hardware information.

- Secret Server version
- An encrypted value to identify the instance
- Secret data or the `encryption.config` file (both omitted).
- The data that is gathered for is for contacting you if there is a licensing issue. Delinea will not sell or distribute the information provided during activation. The only information available to Delinea staff is the contact information for technical support and customer service.

Our Secret Server does not have outbound access to the Delinea.com Web site. Can activation be done while offline?

Yes, there is an offline option for activating licenses. See "Adding, Activating, Converting, and Deleting Licenses" on page 89.

If we have trouble activating our licenses, what should we do?

1. If your Secret Server is currently supported, with an equal number of current support licenses and user licenses, our technical support team can help you. Please contact us.
2. If an error message persists after successful activation, remove expired or invalid licenses from Secret Server by clicking the license name and then deleting it (License information will remain available to you from your account.)

My Server is a VM that moves to different hardware often. Will this cause me to need to reactivate over and over?

You do not need to reactivate over and over. When you activate, you can use Secret Server for a year without needing to reactivate, regardless VM hardware changes. However, if your machine name changes as well as your hardware, you will need to reactivate. If you are using a version older than 7.8.000000, you must reactivate when the VM moves.

Every time a customer switches Secret Server Databases the Secret Server license activation requirement appears. Is this now expected behavior?

Secret Server activation is now based on the Secret Server database name instead of the host name, hence, you can add or change nodes to a Secret Server cluster without reactivating. Activation requires both the license and Secret Server database. Therefore, even if you already activated a Secret Server Web server, when you install another, it too requires activation.

> The activation process gathers the name, email, and phone number of the individual activating Secret Server for internal use. Delinea gathers no other personal information.

Why do I have to do an offline activation?

If you are using Secret Server On-Premises, you will need to activate it to become a user. This can be done via the following URL: https://my.thycotic.com/LicenseActivation.ashx

Viewing Your License

To view your current license for Secret Server cloud version Search for **Licenses**. All your active subscriptions are listed here with the License name, License key, and License description.

The purchased version is not yet available in Secret Server On-Premises. Contact the purchaser at your company to inquire which version of Secret Server you purchased (this is listed in the executed order form from Delinea).

Prerequisites

The Secret Server Prerequisites page outlines the essential requirements needed before installing Secret Server on-premises or using Secret Server Cloud. It covers supported operating systems, hardware specifications, software dependencies (such as .NET and IIS), database requirements, and network considerations. This guide ensures that your environment is properly prepared for a successful Secret Server deployment, helping to avoid common setup issues and streamline the installation process.

- "Browsers Supported By Secret Server" below
- "System Requirements for Secret Server" on the next page

Browsers Supported By Secret Server

Secret Server can accommodate most major browsers available today. This covers each major browser and version supported by Secret Server, as well as support for the copy-to-clipboard feature.

> For the best security, always keep your browser updated to the latest version.

The following browsers are supported by Secret Server version 10.8 and newer:

- Chrome
- Edge
- Firefox
- Safari

- Opera

> Internet Explorer is not supported.

Language Support

Secret Server natively supports the following languages:

- Dutch
- English
- French
- French, Canada
- German
- Italian
- Japanese
- Korean
- Mandarin, simplified, China
- Mandarin, traditional, Taiwan
- Polish
- Portuguese
- Spanish

Using Chrome to Access Secret Server

The Chrome extension prompts users for "tabs" permissions, which Chrome uses to detect your browsing history, including what tabs you open and the URLs they open to. Secret Server uses the tabs permission function only to clear passwords on exit. No history is recorded.

System Requirements for Secret Server

> Most of this topic applies to Secret Server On-Premises. Subtopics, such as Distributed Engine Requirements, that also apply to Secret Server Cloud appear in a separate section.

> All cores are physical unless otherwise noted.

> Please read the notes at the bottom of this article.

Secret Server On-Premises Only

> As of August 31, 2025, Microsoft retired TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net now requires TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

Minimum for Basic Deployments

Minimum requirements to use any Secret Server On-Premises features.

Web Server

- 4 CPU cores
- 16 GB RAM
- 25 GB disk space
- Windows Server 2019-2023. Windows Server 2025 is pending.

  > Windows Server 2025 has not been fully validated with Secret Server. A known issue concerning Remote Password Changes for Windows Local Accounts may affect installations or upgrades using Windows Server 2025. For details and a workaround, see KB 1747412551367.

- IIS 7 or newer (64-bit applications only)
- .NET 4.8 or newer

Database Server

- 4 CPU cores
- 16 GB RAM
- 100+ GB disk space
- Windows Server 2019 or newer. See the note above for more details.

  > If you use Microsoft User CALs, you cannot use Windows Server 2019, you must use Windows Server 2012 or 2016. See the Secret Server On Premises Only section for more details.

- SQL Server 2016-2022
- Collation SQL_Latin1_General_CP1_CI_AS on both SQL Server and the database.

  > Using the SQL_Latin1_General_CP1_CI_AS collation is super important to avoid issues after installation.

Minimum for Advanced Deployments

For organizations deploying significant discovery, session recording, event pipelines, syslog, or many distributed engines:

Web Server

- 8 CPU cores
- 16 GB RAM
- 25 GB disk space
- Windows Server 2019-2023. Windows Server 2025 is pending.

  > Windows Server 2025 has not been fully validated with Secret Server. A known issue concerning Remote Password Changes for Windows Local Accounts may affect installations or upgrades using Windows Server 2025. For details and a workaround, see KB 1747412551367.

- IIS 8 or newer (64-bit applications only)
- .NET 4.8 or newer

Database Server

- 8 CPU cores
- 16 GB RAM
- 100+ GB disk space
- Windows Server 2019 or newer. See the note above for more details.

  > If you use Microsoft User CALs, you cannot use Windows Server 2019, you must use Windows Server 2012 or 2016. See the Secret Server On Premises Only section for more details.

- SQL Server 2016-2022
- Collation SQL_Latin1_General_CP1_CI_AS on both SQL Server and the database.

> Using the SQL_Latin1_General_CP1_CI_AS collation is super important to avoid issues after installation.

> Windows Server 2022 is supported by Secret Server 11.0 or later. It may work with earlier versions, but that has not been officially confirmed.

RabbitMQ Requirements

- 4 CPU cores
- 4 GB RAM

- 40 GB Disk Space

> Although these may be the minimum requirements, the way you utilize the product will influence the resource needs, and you may require additional resources.

For scalability and reliability, Delinea strongly recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but should not be used for production environments.

Further adjustments to system requirements for both RabbitMQ and distributed engines are at the discretion of Delinea Professional Services engineers.

For RabbitMQ, there is not an officially supported set of versions. Installation is only supported using the latest RabbitMQ Helper, which will install the latest versions. Any version of RabbitMQ available since the introduction of durable queues will work. If you wish to install an older version you can at your own discretion. Please note they might be prone to certain errors in functionality.

SQL Server Is Required

Secret Server requires an instance of SQL Server for the database backend for both basic and advanced deployments.

While the Secret Server `setup.exe` does install SQL Express on the server if no other Microsoft SQL server is available, this is not sufficient for most production workloads and is not supported by Delinea for any production work. To create a database, you need to have the **db_creator** permission. After the database has been successfully created, **db_owner** permissions are needed to manage it. The installer automatically grants you **db_owner** permissions, if you created the database.

> Delinea does not support using SQL Express in a production environment due to size and performance limitations.

System Requirements for Virtual Machines and Processors

A vCPU is a virtualized CPU core assigned to a virtual machine (VM) from the physical CPUs available on the host server. The following are some key points. Please see What is a vCPU and How Do You Calculate vCPU to CPU? for details.

Key points:

- vCPUs allow multiple VMs to share the physical CPU cores on a host through time-slicing and context switching.
- The ratio of vCPUs to physical cores determines CPU oversubscription. An oversubscribed CPU is shared among too many vCPUs, leading to potential performance issues.
- There is no fixed ratio for calculating optimal vCPU to physical core mapping. It depends on the specific workloads and resource demands of each VM.
- Monitoring CPU utilization for the VMs and host is crucial to identify performance bottlenecks and adjust vCPU allocations accordingly.

- Using too many vCPUs unnecessarily can increase licensing costs for some software that charges per vCPU.
- It is important to understand application resource needs, monitoring performance metrics, and adjusting vCPU allocations to strike the right balance between oversubscription and performance for cost optimization.

Secret Server On-Premises and Cloud

Session Recording Requirements

See "Basic Session Recording Requirements " on page 1260 and "Advanced Session Recording Requirements" on page 1259.

Distributed Engine Requirements

On the DE host:

- 4 CPU cores
- 4 GB RAM
- 25 GB disk space
- OS requirement of at least Windows Server 2019 or newer.

> Although these may be the minimum requirements, the way you use the product influences resource needs, hence you may require additional resources.

Further adjustments to system requirements for distributed engines are at the discretion of Delinea Professional Services engineers.

The latest Distributed Engine supported version is always the latest current version. Older versions can also be run if they are up to date or if the version used is just behind the latest. If there are breaking changes, an update will be forced.

Protocol Handler Requirements

- Any Microsoft-supported version of Windows.
- .NET 4.8 support

> Performance will vary with the specs of the machine and the functionality being performed.

Important Notes

Secret Server Cloud Only

Secret Server Cloud requires an on-premise machine to use a Distributed Engine.

Secret Server On-Premises and Cloud

- The use of Server Core for Secret Server installations is not recommended; All QA and testing is based non-core versions of Windows Server.
- System Requirements apply to both physical and virtual machines.
- For best performance, we recommend using dedicated (clean) servers for hosting Delinea products.

Secret Server On-Premises Only

> This section contains caveats potentially having a significant effect on any installation.

- For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.
- To comply with Microsoft licensing requirements, there is an additional constraint on which Microsoft Windows Server version you can use as the RDS server for session connector.

  > If you use Microsoft User Client Access Licenses (CALs), you cannot use Windows Server 2019. You must use Windows Server 2012 or 2016. If you use Microsoft Device CALs, you can use any supported version of Windows Server.

- Secret Server requires that Microsoft SQL Server and its database be set to the collation SQL_Latin1_General_CP1_CI_AS. See Microsoft SQL collation requirements and check your server collation settings before upgrading.

  > Using the SQL_Latin1_General_CP1_CI_AS collation is super important to avoid issues after installation.

- If .NET or IIS features are not already installed on the web server, the Delinea Installer will add and configure them automatically.
- If SQL is not already installed on a database server, the Delinea installer can setup SQL Express on the web server; however, SQL Express is intended for trials and sandbox environments **only**. Delinea **does not support it** because of performance issues due to the memory and product limitations.
- A link to Microsoft documentation on the use and limitations of SQL Express can be found here.
- Installing Secret Server with Azure SQL:

  Delinea recommends the Azure SQL Database and the web node be located in the same region because excess latency harms application performance.

  According to Microsoft, applications such as Secret Server, that use frequent, high-volume, ad hoc queries, use substantial response time on network communication between the application and Azure SQL database tiers. Hence, network latency with many data access operations across datacenters can become an issue.

- Unsupported Web Servers: Small Business Server (SBS), The Essentials Edition, Any client OS, domain controllers, SharePoint servers.
- SQL launchers do not support SSMS 18.0 or higher for SQL local accounts. AD authentication method is possible.
- Discovery scanning for Windows Server 2016 scheduled tasks requires that either the Secret Server node or the Distributed Engine that is executing the scan, must run on Windows Server 2016 or later. This is due to changes in Windows Server 2016 API used for scheduled task dependency scans.

  Compatibility issues with Microsoft libraries are likely if the Distributed Engine or Secret Server node operates on a version of Windows Server that is older than the version on the target server it is attempting to scan, for instance, a DE on 2016 scanning a machine running 2019. To ensure successful scans, we recommend that the DE or node runs on the same or a newer version of Windows Server as the target machine.

- AWS RDS: Currently, we do not recommend using Secret Server with AWS Relational Database Service when the Web host and the SQL instance are in different datacenters. Applications, such as Secret Server, that use frequent, high-volume, ad hoc queries depend on fast network communication response time between the application and SQL database. Thus, network latency with many data access operations across datacenters can become an issue.
- Secret Server requires the application pool to have the "load user profile" setting enabled. Secret Server will report a critical alert to notify admins if this setting is not enabled.
- Supported Web browsers: See "Browsers Supported By Secret Server" on page 93.

Proxied Environments

This topic only applies to **Secret Server On-Premises**.

If your Secret Server has outbound access through a proxy, its web.config must be modified to specify the proxy configuration.

If Secret Server is also clustered and has multiple worker roles enabled, the web.config must be updated for each Secret Server in the cluster.

See Microsoft documentation for more information.

The other option in a clustered environment is to specify a remote site for the data upload, and upload data through a Distributed Engine. If the distributed engine's host server is also behind a proxy, however, the engine's Delinea.DistributedEngine.Service.exe.config must be modified similarly to the `web.config` in order to specify the proxy settings.

For Secret Server v10.4 or later, the web-proxy.config can be uncommented and updated to specify the proxy settings.

For Secret Server v10.3.000015 or earlier, you must add proxy-related XML to the `web.config` file immediately following the file's closing `\</configSections\>` tag, as depicted here:

```
</configsections>
    <system.net>
        <defaultproxy enabled="true" usedefaultcredentials="true">
             <proxy
usesystemdefault="false" proxyaddress="https://proxy:port" bypassonlocal="true"/>
        </defaultproxy>
    </system.net>
<configuration type="thycotic.foundation.configuration, thycotic.foundation">
```

Using Webnode with Proxied Environments

If using a webnode you will need to add the following code:

```
<system.net>
    <defaultProxy configSource="web-proxy.config" />
</system.net>
```

DE Configuration

> Configuration files for proxy settings on web nodes and DEs will retain custom changes after product updates.

When Secret Server and distributed engines are behind a proxy, certain settings need to be added to web nodes and DEs if they exist in the environment.

To use the Distributed Engine through a proxy on DE versions older than 8.4.29.0, add proxy info to `Delinea.DistributedEngine.Service.exe.config`, located in the `C:\Program Files\Delinea\Distributed Engine\` folder. Insert the code between `</system.serviceModel>` and `</configuration>`. You may need to refer to the article below for other proxy-related settings.

Element (Network Settings)

```
<system.net>
    <defaultProxy>
        <proxy usesystemdefault="true" />
    </defaultProxy>
</system.net>
```

You will need to restart the DE service afterwards and the setting will need to be reapplied after any Distributed Engine upgrade.

Webnode Configuration

Main Proxy settings for DE versions 8.4.29.0 and newer, are stored in the `web-proxy.config` file in the Secret Server folder on each webnode. Microsoft's article on Proxy configuration explains all settings.

Element (Network Settings)

A few examples below:

Example #1

```
<?xml version="1.0" encoding="utf-8" ?>
<defaultProxy enabled="true">
<proxy
    usesystemdefault="true"
    proxyaddress="http://192.168.1.1:8080"
    bypassonlocal="true"
  />
</defaultProxy>
```

Example #2

```
<defaultProxy enabled="true">
    <proxy proxyaddress–"http://proxy.domain.com:80" bypassonlocal-"true" / >
</defaultProxy>
```

Now the following files need to be edited to point to the `web-proxy.config` file.

- `web-embeddedRole-backgroundScheduler.config`
- `web-embeddedRole-backgroundWorker.config`
- `web-embeddedRole-engineWorker.config`
- `web-embeddedRole-messageBroker.config`
- `web-embeddedRole-sessionRecordingWorker.config`

The code used in these files can be as follows:

```
<system.net>
    <defaultProxy configSource="web-proxy.config" />
</system.net>
```

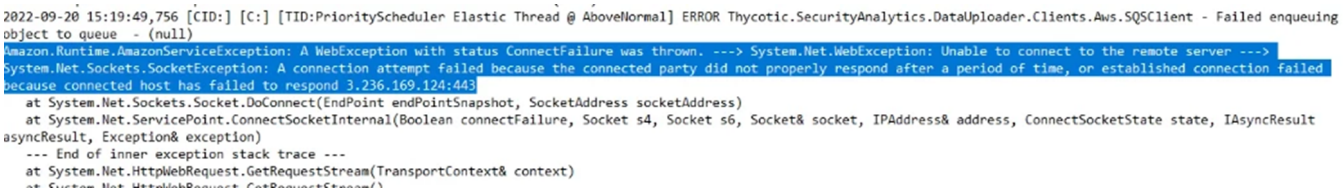
Placement of this setting may affect connection. Successful operation has been confirmed when the code is placed before the `<runtime>` section.

Troubleshooting Tips

Distributed Engines

Check the SSDE.log file.

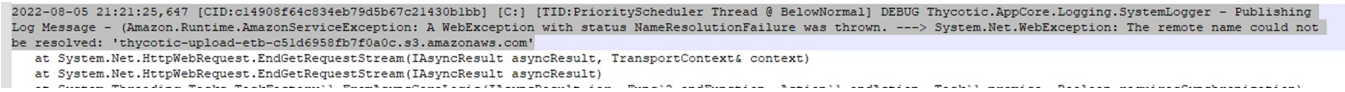
Example:



Webnodes

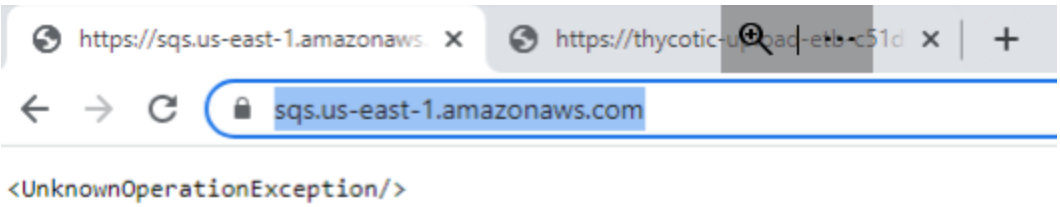
Check the SS-BWSR.log file

Example:

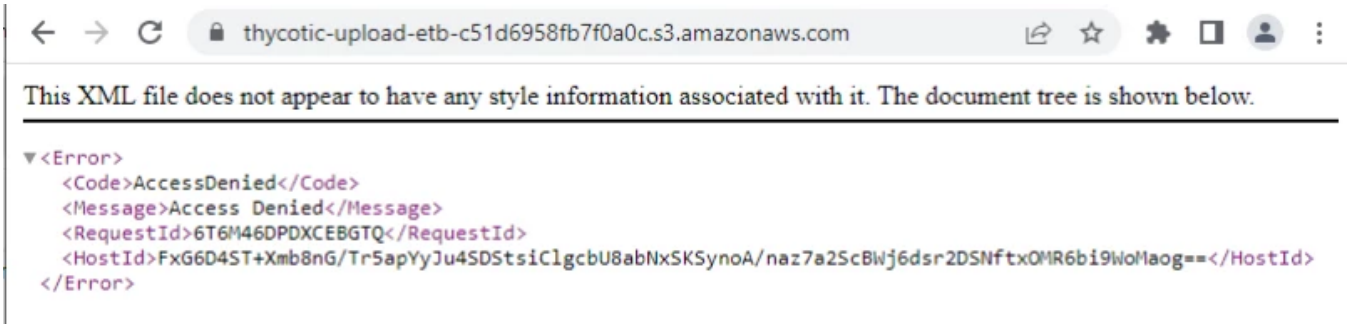


Check to see if the machine can pull up the IP/URL in the logs in web browsers. While these do not specifically show full communication between systems, they can help narrow down the issue.

Example #1:



Example #2:



RabbitMQ and Secret Server

> This topic only applies to **Secret Server On-Premises**.

Secret Server uses RabbitMQ as its message bus or broker to facilitate efficient and reliable message traffic between various components. This asynchronous message-based system ensures that operational instructions and data are passed back and forth seamlessly, enabling tasks such as password changes, discovery, and other background operations to be processed efficiently. RabbitMQ's robust framework supports clustering and high availability, making it ideal for large-scale deployments. All messages transmitted via RabbitMQ are encrypted, ensuring secure communication. Using RabbitMQ, Secret Server can handle large volumes of messages, maintain high performance, and ensure that critical operations are executed reliably.

Clearing RabbitMQ Message Queues

> This topic only applies to **Secret Server On-Premises**.

Some users note that older RabbitMQ message queues in Ready state are not clearing as expected, so messages accumulate. To clear the message queues, use the procedure below.

1. On the machine where RabbitMQ is installed, download the utility for removing old RabbitMQ queues.

   ```
   SHA1(RMQ_QueueRemoval.zip)= B8EE3CD2488AF2D7A42421B870EB8041434245C8
   SHA256(RMQ_QueueRemoval.zip)=
   B9AF3BF51B0E1E6E937830A6CF0974D3546183B78E1E86F6C8563E5E7243146A
   ```

2. Extract the zip file.
3. Open Windows PowerShell.
4. Navigate to the directory where you extracted the zip file.
5. Load the file by typing the following command:

   ```
   . .\RMQ_QueueRemoval.ps1
   ```

6. Run the commands below in the order shown:
   a. `ShowAllQueues`
   b. `ShowQueuesNoConsumer`
   c. `DeleteQueuesNoConsumer`

Installing RabbitMQ

> This topic only applies to **Secret Server On-Premises**.

Overview

What is RabbitMQ?

RabbitMQ is a robust message queuing software package that Secret Server uses to communicate with its distributed engines. For detailed information about RabbitMQ, go to the RabbitMQ website.

Why Install It?

RabbitMQ is an enterprise-ready alternative to MemoryMQ. While MemoryMQ is sufficient for basic and prototyping installations, RabbitMQ is the preferred messaging framework when the need for greater reliability and clustering arises.

> For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.

RabbitMQ and Encryption

All data sent from or read by Secret Server from RabbitMQ is encrypted. If you would like to add SSL despite the data already being encrypted, please follow the Advanced installation of RabbitMQ with TLS use case. Please note that Delinea Support can help with non-SSL installations. For SSL installation, configuration, troubleshooting, and RabbitMQ clustering, please contact Delinea Professional Services to learn more about our Professional Services rates.

Downloading Delinea's RabbitMQ Helper

Please go to Installing RabbitMQ with RabbitMQ Helper to download the most recent version.

Prerequisites

> Secret Server only supports RabbitMQ on Windows operating systems. Secret Server is incompatible with the RabbitMQ Federation plugin.

RabbitMQ requires:

General Requirements

See the Software Downloads and Requirements section in Installing RabbitMQ with RabbitMQ Helper section of RabbitMQ documentation.

SSL Certificate

- A server certificate of the PFX type and a root authority certificate of the CER type.
- The PFX certificate should have:
  - A name that matches the RabbitMQ Fully qualified machine name.
  - If you plan on making a RabbitMQ cluster, add DNS names (SANs) to your certificate.
  - Your certificate must be a RSA certificate. CNG is not supported and will cause the installation to fail.
- If you do not have an internal PKI and prefer not to use a public certificate, you can use a self-signed certificate.

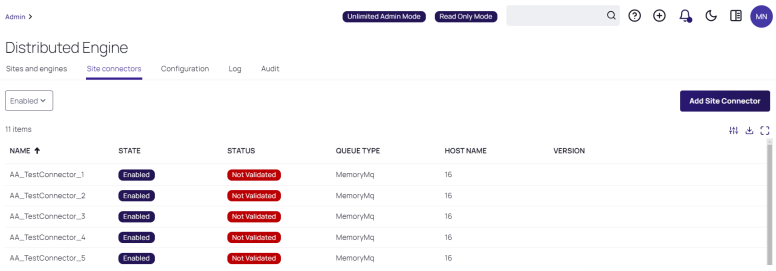
> Delinea will not assist with creating or troubleshooting self-signed certificates.

Installation

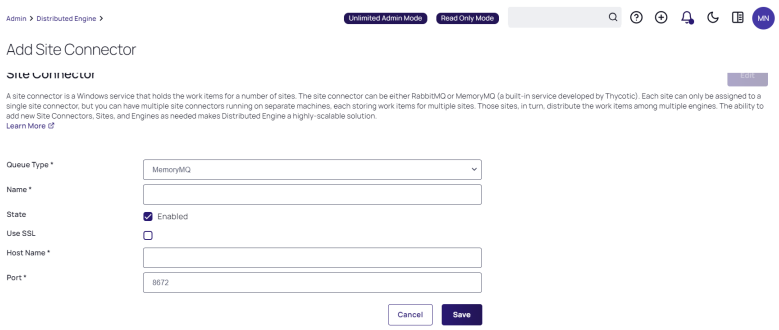
Task 1: Secret Server

In the Secret Server UI:

1. Navigate to **Admin** > **Distributed Engine**.
2. Access the **Site Connectors** tab and select **Add Site Connector**:



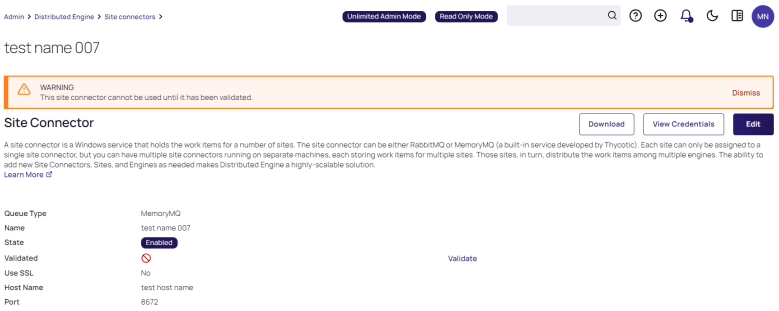
3. On the **Add Site Connector** page, select either **RabbitMQ** or **MemoryMQ** in the **Queue Type** drop-down list. If at least 3 RabbitMQ nodes have been set up in a clustering setup, choose MemoryMQ (see the Cluster section in the RabbitMQ Helper documentation for more information):



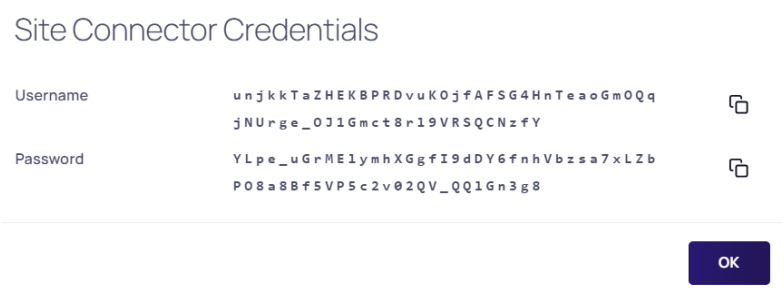
4. Type a name for your new site connector in the **Name** text box.
5. Select the **Enabled** check box.
6. Type the host name of the machine where you plan to install RabbitMQ, in the **Host Name** text box.

> The Engines need to be able to resolve this host name or the connection will fail. Inbound firewall rules must be created on the machine that is hosting the connector as well.

7. Type either port 5672 (non-SSL) or 5671 (SSL) in the **Port** text box.
8. Click the **Save** button.
9. After the site connector is created, click the site connector's link. The **Site Connector Details** will page appear:



10. Select the **View Credentials** button to retrieve the automatically generated credentials. The **Site Connector Credentials** pop-up will appear:



You can ignore the informational message that the connectivity has not been validated for now, as you will be doing so after you install RabbitMQ on the host you have selected.

11. Select the copy icons for both the **User Name** and **Password** values, to copy and store them for use in the next section.
12. Select the **OK** button.

Task 2: RabbitMQ Host

See RMQ Helper Installation for details.

Troubleshooting

Please refer to Troubleshooting for RabbitMQ Helper for details.

Secret Server Cloud Offboarding

This topic only applies to standalone **Secret Server Cloud**.

Privacy Policy

See the Delinea Privacy Policy for details on how your data is safeguarded.

Data Protection

At all times, even after your license expires, Delinea maintains strict security controls of your data. Only a tiny group of operations staff can access it and only with approval from at least one other person. You can get a SOC2 audit report for your instance, which requires an NDA, by emailing the RFP Helpdesk. The NDA is required because proprietary Delinea information is present in the report.

Refer to additional documentation on "Removing Deactivated User PII" on page 1306.

Your Data When Your Subscription Ends

Once your subscription ends:

1. Your instance enters a two-week grace period.
2. After the grace period expires, the instance is scheduled for deletion two weeks in the future. Your instance is inaccessible but all data is retained.

3. Once the deletion date arrives, your instance is eligible for deletion and can be deleted at any time at Delinea's discretion. In most cases, Delinea retains customer data substantially beyond the deletion date.

If desired, you can request that Delinea deletes your instance right away, and we will promptly respond. **Once deleted, your instance is not recoverable and your data is gone.**

Delinea Secret Server Performance and Sizing Guide

Last updated: 2026-92-25

Introduction

This guide provides updated recommendations for designing and scaling your Secret Server deployment. Using your recent performance benchmarks, this document offers insights and guidance, helping you design an environment that meets your needs.

> This guide uses a lot of technical jargon. If you experience "acronym failure" or wonder what the codes mean, see "Supplemental Information" on page 118, which includes an introduction to "Amazon EC2 Instance-Type Identifiers" on page 118 and a "Glossary" on page 119 of terms in this document.

Performance Testing Overview

Most, but not all, recommendations in this guide are supported by dedicated performance testing conducted in controlled environments.

Test Environment Setup

We set our performance benchmarks using clean, isolated infrastructure provisioned in Amazon Web Services (AWS) with no competing workloads. Each test environment was provisioned via Terraform, ensuring consistency, eliminating resource contention, and facilitating rapid deployment. This included adjusting computing resources, instance types, and endpoint volumes. We used AWS user-data scripts to automate endpoint configuration, enabling comprehensive testing from a single command.

Test Design Benefits

- Consistency and accuracy: Reliable, repeatable results improved the accuracy and trustworthiness of performance benchmarks.
- Cost efficiency: Lowered costs compared to physical data-center setups, enabling frequent and extensive testing to replicate enterprise-scale scenarios.
- Scalability: Flexibly scaled endpoints and computing resources for varied test scenarios.
- Versatility: Reduced setup time with an adaptable environment that is ready for future performance evaluations.

Core Sizing Principles

Component Roles

- Application servers (web nodes): Handled UI and API requests, orchestrated workflows, and published tasks to RabbitMQ.
- Distributed Engines (DEs): Consumed tasks from RabbitMQ and executed operations like discovery, heartbeats, remote password changing (RPC), and proxying.
- Database server: Stored all Secret Server data where performance is critical.
- RabbitMQ: Message queue facilitated asynchronous task processing between web nodes and DEs.

General Recommendations

Redundancy

We implemented N + 1 redundancy for all critical components (web nodes, DEs per site, database, and RabbitMQ) that ensured high availability and minimized downtime.

Engine Task Allocation

- Deployed at least two DEs per site for high availability.
- Limited discovery tasks to 50-60% of DE capacity to ensure resources for heartbeats, RPC, and other operations (see Engine Sizing per Site).
- If a specific workload is restricted to only one DE, you may need to add more DEs for redundancy of that workload, assuming that the task is critical enough to warrant redundant design. See Distributed Engine Job Function Optimization for more information on DE workloads and performance benefits.
- Example: Scanned 50,000 machines for local accounts (≈7,500 endpoints per hour with dual c5a.2xlarge DEs, ≈6.6 hours) every 24 hours yields ≈28% Discovery occupancy (6.6 ÷ 24). Scanning every 8 hours increases occupancy to ≈83% (6.6 ÷ 8), requiring 1-2 additional DEs per site.

For workload-specific DE sizing, see Heartbeats and Remote Password Changing.

Instance Selection

For dedicated hardware and software specifications, refer to "System Requirements for Secret Server" on page 94. Prioritize compute-optimized instances (for instance, AWS c5a series) for distributed DEs handling CPU-intensive tasks like discovery and RPC. Web nodes can use our minimum recommended system requirements unless handling proxying or session recording, which benefit from a more capable CPU (for instance, c5a.2xlarge).

For environments deploying both Secret Server and Privilege Manager on the same web nodes, use higher-spec instances. Combine disk-space requirements for both applications.

Database Performance

The database is often a key performance influence. Ensure adequate CPU, RAM, and high IOPS. Address database performance before extensively scaling web or DE tiers. Ensure dedicated database resources to avoid contention.

Session Recording

For basic session recording requirements, refer to the Basic Session Recording Requirements. For advanced session recording requirements, refer to the Advanced Session Recording Requirements.

Environmental and Compliance Considerations

Environments with stringent auditing, extensive SIEM integration, or data-at-rest encryption may introduce performance overhead. Apply a compliance overhead buffer (for instance, +10–15% of resource calculations) in such scenarios.

Workload-Specific Sizing Guidance

Discovery Operations

For environments with significant or time-sensitive discovery requirements we recommend dedicated DEs, potentially within a distinct "discovery site." Endpoint count is the primary driver of scan duration, each endpoint requiring individual connection and processing. Performance metrics assume low-latency (<20ms) connections to endpoints. Higher latency (for instance, >50ms) may reduce throughput, requiring additional DEs or regional sites. Web servers with the DE worker server role enabled can process discovery responses, enhancing efficiency. However, these nodes also handle other tasks (such as UI and API), so you cannot dedicate them solely to discovery. For high discovery loads, prioritize dedicated DEs (see Engine Sizing Per Site and Distributed Engine Job Function Optimization).

- **Guidance**: For quick discovery sizing, estimate DE needs as follows:
  - Local accounts: one DE ≈3,600 endpoints per hour; each additional DE ≈1,800 per hour.
  - Local accounts + dependencies: one DE ≈1,800 per hour; each additional DE ≈900 per hour.
- **Example**: 25,000 endpoints in 8 hours (local accounts) requires ≈3,125 per hour. One DE (3,600 per hour) is sufficient. For 4.5 hours, use two DEs (≈5,400 per hour). Use detailed metrics (see Discovery Sizing Considerations) for precise sizing with specific instance types (for instance, c5a.2xlarge).

Discovery Sizing Considerations

Accurate discovery sizing requires understanding customer requirements and environmental constraints. Ask the following questions to validate inputs.

Considerations:

- Scan frequency: How often must discovery run (hourly, daily, or weekly)?
- Completion time: How quickly must scans complete (for instance, <8 hours)?
- Endpoint count: Is the total number of systems accurate? Will discovery scale gradually (for instance, in a phased rollout)?
- Contention: Are other features (for instance, heartbeats, RPC, or proxying) heavily used, potentially impacting DE capacity?

Guidance: Verify endpoint counts with customers, because initial estimates may include future growth. For phased rollouts, start with fewer DEs and scale as endpoints increase. Ensure discovery occupancy remains <50–60% to avoid contention with other tasks (see Engine Sizing per Site).

Discovery Sizing Reference Table

The table below provides approximate discovery times for Windows local account discovery across enterprise scales, assuming dual c5a.2xlarge DEs (≈7,500 endpoints per hour) and additional DEs for faster completion.

Enterprise Size	Endpoints	Time (one DE, ≈3,750 endpoints per hour)	Desired Time	DEs Needed (Total)
Small	2,000	≈0.5 hours	<1 hour	1
Medium	25,000	≈6.7 hours	<4 hours	2 (≈3.3 hours)
Large	50,000	≈13.3 hours	<8 hours	2 (≈6.7 hours)
Massive	100,000	≈26.7 hours	<12 hours	3 (≈8.9 hours)

Guidance: Use this table for initial sizing estimates. Adjust based on specific requirements (for instance, scan frequency or dependency discovery) and environmental factors, such as latency).

See these sections for site-level sizing:

- Active Directory Computer Object Discovery
- Discovery Sizing Considerations
- Engine Sizing per Site
- Unix Computer Scan (Account Enumeration)
- Unix Network Discovery (Endpoint Identification)
- Windows Local Accounts and Dependency Discovery
- Windows Local Account Discovery

Active Directory Computer Object Discovery

Discovery efficiently queries Active Directory (AD) via LDAP for computer objects. Having no endpoint operations, it produces minimal load.

Guidance: A single DE (for instance, c5a.2xlarge) can handle thousands of AD computer objects in minutes. This is not a sizing constraint.

Windows Local Account Discovery

This discovery connects to Windows endpoints (RPC or WMI) to enumerate local accounts. Endpoint count drives scan duration due to connection or query overhead. Benefits from parallel processing with multiple DEs:

- **Performance** (endpoints per hour):
  - Dual c5a.2xlarge (16 total vCPUs, 2 DEs): ≈7,500 endpoints per hour (for 507 endpoints, 1,506 accounts).
  - Single c5a.2xlarge or c5a.4xlarge (8 or 16 vCPUs, 1 DE): ≈3,700 endpoints per hour.

- **Guidance**: Use 2+ DEs for >500 endpoints to reduce scan time. Engines with 8 vCPUs (for instance, c5a.2xlarge) are optimal—scaling out is more effective than scaling up beyond 8 vCPUs.

Windows Local Accounts + Dependency Discovery

Extends local account discovery to identify application and service dependencies, adding processing per endpoint. Endpoint count remains the primary driver.

- **Performance** (endpoints per hour):
  - Dual c5a.2xlarge (16 total vCPUs, 2 DEs): ≈6,900 endpoints per hour (for 507 endpoints, 1,506 accounts).
  - Single c5a.4xlarge (16 vCPUs, 1 DE): ≈3,400 endpoints per hour.
- **Guidance**: Use multi-DE configurations for large endpoint counts. Expect ≈10–15% throughput reduction compared to local accounts-only discovery due to dependency processing.

Unix Computer Scan (Account Enumeration)

This discovery establishes SSH sessions to Unix endpoints to retrieve local accounts. Endpoint count drives duration due to SSH connection overhead.

- **Performance** (endpoints per hour):
  - t2.xlarge (3 DEs, 4 vCPUs each): Up to 90,000 (for 100 endpoints).
  - c5a.4xlarge or c5a.2xlarge (1 DE, 16 ÷ 8 vCPUs): ≈30,000–40,000 (for 500 endpoints).
- **Guidance**: Throughput scales with DE count. For small to moderate counts (<1,000), t2.xlarge is cost-effective. For larger volumes (>1,000), we suggest c5a.2xlarge or c5a.4xlarge for sustained throughput.

Unix Network Discovery (Endpoint Identification)

Sweeps subnets (for instance, /22, /24) via SSH to identify responsive hosts and gather metadata without login. IP range size and host density drive duration.

- **Performance** (endpoints per hour):
  - c5a.2xlarge (1/22 subnet, 1 DE, 8 vCPUs): ≈36,700 endpoints per hour.
  - c5a.2xlarge (2/24 subnets, 2 sources, 2 sites, 2 DEs, 8 vCPUs): ≈45,000 endpoints per hour.
  - c5a.2xlarge (2 /24 subnets, 1 source, 1 site, 2 DEs, 8 vCPUs): ≈26,000 endpoints per hour.
  - Larger ranges (for instance, 10 x /22, single site): ≈4,100 endpoints per hour.
- **Guidance**: Use a single c5a.2xlarge for a large segment. For multiple segments, create separate sources and sites with dedicated DEs to scan in parallel, as additional DEs on a single segment yield diminishing returns.

Heartbeats

Heartbeats verify stored credentials against target systems. Target system responsiveness and network latency primarily influence performance with DE CPU as a secondary factor.

Performance metrics (per t2.xlarge, 4 vCPUs):

- Windows local accounts: ≈9–10 secrets per sec (≈32,400–36,000 secrets per hour).
- Unix: ≈8 secrets per sec (≈28,800 secrets per hour).
- Dual DEs: ≈14–20 secrets per sec (≈50,400–72,000 secrets per hour, mixed targets).
- Capacity insight: DEs are capable of >100 secrets per sec with RabbitMQ backlog and fast target responses, indicating DEs often wait in steady-state operation.

Guidance:

- Calculate hourly heartbeat load: Divide total secrets by heartbeat interval (for instance, 8 hours). For 25,000 Secrets, ≈3,125 heartbeats per hour.
- Engine requirements: DEs required = (heartbeats per hour, ≈36,000 secrets per hour per t2.xlarge). Round up and add one for redundancy. A single t2.xlarge handles ≈3,125 heartbeats per hour with spare capacity.
- Redundancy: Deploy 2+ DEs per site for N+1 redundancy.
- Performance optimization: If queues grow or completion times lag, investigate target system performance (for instance, latency, timeouts) before adding DEs.
- Workload balance: Heartbeats are rarely the primary driver for DE count, as discovery is more resource-intensive (see Engine Sizing per Site).

Example scenario: Customer needs to validate 75,000 credentials across three regions in <2 hours.

- Calculation: 75,000 heartbeats per 2 hours = 37,500 heartbeats per hour. Per t2.xlarge: ≈36,000 heartbeats per hour. DEs required: 37,500 ÷ 36,000 ≈1.04, round up to 2. For three regions: Site 1 (3 DEs, high-density), Site 2 (2 DEs), Site 3 (1 DE) = 6 DEs total.
- Recommendation: Deploy 6 DEs across three sites, with 2+ DEs per site where possible. Monitor RabbitMQ queue depths and target latency.

Remote Password Changing

Remote Password Changing (RPC) automates password rotation on target systems. RPC is more CPU-intensive than heartbeats due to authentication, password generation, and updates. Performance varies based on target system policies (for instance, password complexity, change propagation).

- **Performance** (per t2.xlarge, 4 vCPUs):
  - Unix: ≈1.8 secrets per sec (≈6,480 secrets per hour).
  - Dual DEs: ≈3.3 secrets per sec (≈11,880 secrets per hour).
  - Three DEs: ≈5.0 secrets per sec (≈18,000 secrets per hour).
  - Mixed workload (Windows and Unix): ≈2–4 secrets per sec (≈7,200–14,400 secrets per hour).
- **Guidance**:
  - Calculate Hourly RPC Load: For monthly schedules, divide secrets by 720 (24 hours × 30 days). For 25,000 Secrets, ≈35 password changes per hour.
  - Engine requirements: Engines required = (password changes per hour per ≈7,200 secrets per hour per t2.xlarge). A single t2.xlarge handles ≈35 per hour easily.

- Redundancy: Deploy 2+ DEs per site for N+1 redundancy.
- Emergency rotations: For rapid rotations (for instance, post-breach), assume ≈2 secrets per sec per DE and add +1-2 DEs buffer for latency or target issues.
- Workload balance: RPC is rarely the primary driver for DE count. Monitor RabbitMQ queues and target response times during rotations.

Example scenario: Customer needs to rotate 50,000 secrets (Windows and Unix) in <1 hour post-breach.

- Calculation: 50,000 secrets per 1 hour = 50,000 secrets per hour. Per t2.xlarge: ≈7,200 secrets per hour. DEs required: 50,000 ÷ 7,200 ≈6.94, round up to 7. Add 1-2 DEs buffer = 8-9 DEs.
- Recommendation: Deploy 9 DEs across sites, with 2+ DEs per site. Monitor DE CPU and RabbitMQ queue depths.

SSH and RDP Proxying

Securely tunnels SSH and RDP sessions, enabling controlled access. Proxy sessions can be handled by web Servers or DEs, with no inherent capacity difference. Sessions are assigned round-robin. Performance varies by activity and environmental factors.

- **Performance** (per node, web Server or DE, Intel 3.7 GHz Quad Core, 16 GB RAM equivalent):
  - SSH: ≈300 concurrent sessions (standard activity, for instance, file navigation, editing on Linux).
  - RDP: ≈100 concurrent sessions (standard activity, for instance, opening MMC snap-ins, editing files on Windows).
  - Heavy data transfer: ≈150 combined sessions (SSH + RDP) for large file transfers or high-bandwidth activities (for instance, video streaming).
  - Light activity: May exceed 400 combined sessions for minimal operations (for instance, basic commands).

> Proxying via DEs is less efficient if session recording is enabled (see Session Recording), due to traffic capture and RabbitMQ queuing overhead.

- **Guidance**:
  - Node selection: Prefer web servers if DEs are busy with session recording, discovery, or other tasks. Ensure DEs have sufficient CPU and memory for combined workloads.
  - Dedicated nodes for high loads: For 1,000 concurrent SSH sessions, deploy dedicated web servers or DEs: 1,000 per ≈200-250 sessions per node with ≈4-5 nodes.
- **Key performance factors**:
  - Latency: Minimize end-user-to-node latency. Lower latency to web servers vs. DEs may improve efficiency.
  - CPU resources: Proxying is CPU-intensive, especially for RDP. Scale to higher-core instances (for instance, c5a.2xlarge) if needed.
  - Network bandwidth: Ensure 100 MB/s for standard activity, 1 GB/s for heavy transfers.

- Troubleshooting: If performance degrades: reduce latency, increase CPU (for instance, c5a.4xlarge), test web server proxying if DEs show contention, and monitor CPU, network, and session latency.
- Redundancy: Deploy 2+ proxy-enabled nodes per site for N+1 redundancy.
- SSH public address: Multiple web servers' SSH public addresses impact routing or firewall configurations.

- **Example scenario**: 1,000 concurrent SSH sessions with standard activity, minimal recording.
  - Calculation: capacity: ≈200–250 sessions per node. Nodes required: 1,000 ÷ 250 ≈4. Add 1 for redundancy = 5 nodes.
  - Recommendation: Deploy 5 dedicated web servers (for instance, c5a.2xlarge, 100 MB/s bandwidth). Ensure low latency. offload recording to separate nodes. Monitor CPU or network metrics.

Heavy API Use

Consider API (nonhuman) interaction with Secret Server.

- **Performance**: A single web node (for instance, m5.large, 2 vCPUs, 8 GB RAM) handles ≈500–1,000 API requests per sec for lightweight calls (for instance, secret retrieval). Resource-intensive calls (for instance, bulk updates) reduce throughput by 50–70%.
- **Guidance**:
  - Allocate 2+ dedicated web nodes for API traffic, with a separate load balancer endpoint (for instance, AWS ELB, F5).
  - Encourage API clients to cache authentication tokens.
  - Be mindful of resource-intensive calls (for instance, bulk updates or broad searches). High-impact API calls include:
    - Authentication requests (cache tokens to reduce frequency).
    - File Uploads (for instance, secret attachments).
    - Downloading session recording videos (offload to dedicated storage).
    - Update operations (for instance, bulk updates, folder moves, more taxing than Get calls).
  - Optimize these calls through caching, batching, or isolating to dedicated nodes.
  - Monitor Application Server CPU and RAM and database performance under API load.

Session Recording

Session recording records proxied sessions for audit or review.

- **Guidance**:
  - Client session launching: ≈100 sessions per web node.
  - Video encoding (transcoding): Default 2 concurrent transcodes per session recorder worker role-enabled web node. Scale horizontally.
- **Processing Capacity**:
  - Standard node: ≈400–450 hours of video per day.

- Intel quick sync node: ≈1,500–2,000 hours per day.

> It's likely cheaper for you to buy additional web node licenses than it would be to buy hardware dedicated for this function.

- **Storage:** ≈15 hours per GB (≈27 GB per day for 400 hours). Use high-performance, SSD-backed file shares (for instance, AWS EFS, or NetApp). To manage storage costs, archive session recordings to slower and cheaper storage (for instance, AWS S3, cold storage). For encrypted recordings, restore to the original high-performance file share for playback in Secret Server. Plan archival strategies to balance cost and compliance requirements.
- **Sizing Equations**:
  - Web nodes for launching = (maximum concurrent per 100).
  - Session recording worker nodes = (total daily video hours per 400 or 1,500).
  - Dedicate web nodes with a session recorder role. The CPU is primary for transcoding. Deploy 2+ nodes per site for N+1 redundancy.

For additional recommendations and session recording capacities, refer to the Session Recording Caveats and Recommendations and System Capacity Specifications.

Web UI Traffic

Interactive user sessions.

- **Performance**: A single web node (for instance, m5.large) handles ≈1,000–2,000 UI requests per sec for light use (for instance, credential vault). Heavy feature use (for instance, reports, searches, dashboards) reduces throughput by 30–50%.
- **Guidance**:
  - A single web node supports 5,000+ concurrent UI sessions for light use.
  - For active environments with heavy feature use, start with 2 web nodes for HA and load distribution.
  - Isolate UI traffic to dedicated web nodes if impacted by API or background processing. Monitor CPU and RAM use.

Engine Sizing per Site

DEs handle discovery, heartbeats, RPC, and other tasks. Sites are logical groupings of DEs, often aligned with geographical or network boundaries. Proper sizing ensures balanced workloads and high availability.

Guidance:

- Workload balance: Limit discovery to 50–60% of DE capacity for heartbeats, RPC, and more.
- Redundancy: Deploy 2+ DEs per site for N+1 redundancy.
- Discovery-driven sizing: Calculate DEs based on discovery needs. Estimate occupancy: discovery scan duration or scan interval). If >50–60%, add DEs.
- Multi-site considerations: Create sites with dedicated DEs to minimize latency for regional endpoints.

Example scenario: Scanning 25,000 machines for Windows local accounts every 24 hours, <50% occupancy.

- Calculation: Dual c5a.2xlarge (≈7,500 endpoints per hour): 25,000 ÷ 7,500 ≈3.33 hours. Occupancy: 3.33 ÷ 24 ≈14%. Every 8 hours: 3.33 ÷ 8 ≈42%.
- Recommendation: 2 DEs per site (redundancy, low occupancy). For 8-hour scans, consider 3 DEs. Monitor CPU and RabbitMQ.

Large-scale example: 75,000 endpoints every 8 hours, 3 sites.

- Calculation: Dual c5a.2xlarge: 75,000 ÷ 7,500 ≈ 10 hours. For <8 hours, use 3–4 DEs per site (75,000 per ≈ 11,250 ≈ 6.67 hours). Occupancy: 6.67 ÷ 8 ≈ 83%. Add 1–2 DEs per site = 4 per site, 12 total.
- Recommendation: Deploy 4 DEs per site (12 total), ensuring <50% occupancy. Adjust for heartbeats and RPC.

Combined Use Cases and Example Scenarios

Prioritize sizing for the most resource-intensive or time-critical workload (for instance, session recording, discovery, or RPC with tight deadlines), then layer other requirements.

- **Example 1** (discovery, proxy, recording): 50,000 systems (Windows local accounts, 8-hour target) discovery, 500 concurrent SSH sessions, 200 concurrent recordings.
  - Session recording launching: 200 ÷ 100 = 2 web nodes with session recording worker role enabled.
  - Session recording processing: 8 hours per day × 200 sessions = 1,600 hours per day. 1,600 ÷ 400 = 4 standard worker nodes (or ≈ 1 quick sync node).
  - SSH proxy: 500 ÷ 200 = 2–3 dedicated web nodes.
  - Discovery: 50,000 endpoints: ≈ 7 DEs (50,000 per ≈ 7,500, dual c5a.2xlarge).
  - Additional: 1–2 web nodes for UI or API if not covered.
- **Example 2** (large discovery, recording, heartbeat or RPC, growth): 75,000 accounts discovery, 100 concurrent recordings, heartbeat and RPC for all, user growth from 500 to 2,000.
  - Initial:
    - UI web nodes: 2 (m5.large). For 2,000 users, assume 1–2 UI sessions per user (≈2,000–4,000 sessions). Assess if 2 nodes suffice or add 1–2.
    - Session recording launching: 100 ÷ 100 = 1 web node.
    - Session recording processing: 800 hours per day (8 hours × 100): 800 ÷ 400 = 2 worker nodes.
    - Discovery, heartbeat, or RPC DEs: 75,000 accounts in 10 hours (≈4 DEs, c5a.2xlarge). Add capacity for heartbeat or RPC (14 hours free; start with 4–6 DEs and monitor).
  - 3-Year growth (15,000 accounts, 150 recordings):
    - Session recording: ≈2 more worker nodes.
    - Discovery, heartbeat, or RPC: ≈1–2 more DEs.

Addressing Large-Scale Sizing Questions

While Secret Server is built for enterprises, we have not had many customers with environments exceeding the conditions above. Sales engineers, partners, and consultants should work directly with Delinea solutions architects to properly size Secret Server environments fitting at least one of the following parameters:

- 100,000+ secrets
- 500+ concurrent session recordings
- 5,000+ simultaneous active UI web sessions
- 50,000+ systems for frequent, full discovery
- 1,000+ simultaneous SSH or RDP proxy sessions

> Please do not directly contact developers to help with sizing requests. Solution architects will directly work with R&D if necessary to help size environments exceeding any of these numbers.

Monitoring and Iterative Sizing

Sizing is iterative. Continuously monitor:

- RabbitMQ: Queue depths, message rates.
- Distributed DEs: CPU use, task processing times, error logs.
- Application servers: CPU and RAM, request latencies, API metrics.
- Database server: CPU and RAM, Disk I/O (IOPS, latency, queue depth), and query performance.
- Secret server application logs: Performance insights, errors. Adjust resources based on observed performance, changing requirements, and user feedback to maintain optimal performance.

Supplemental Information

Amazon EC2 Instance-Type Identifiers

Overview

Amazon EC2 instance type identifiers are simple labels for virtual hardware. They tell you exactly what computer specs you are renting. By learning to read them, you can pick the best machine for your workload and budget.

The name follows a standard formula:
Family + Generation + Attribute + . + Size.

The first letter is the family. This tells you what the server is good at. For instance, c stands for compute-optimized, which is great for high-performance processing. An r stands for RAM, meaning it is memory-optimized for databases.

Next is the generation number. This indicates the age of the technology. A higher number means newer hardware. For example, an m6 instance uses newer chips than an m5.

You might see extra letters before the dot. These are attributes for special features. A g indicates AWS Graviton processors, while d means the server has fast local storage disks.

Everything after the dot represents the size. This defines how much memory and how many virtual CPUs you get. Sizes usually double as they go up; an xlarge has twice the power of a large.

Here is an example using m6gd.xlarge:

- m: General purpose family.
- 6: Sixth generation (newer tech).
- g: Graviton processor.
- d: Includes local disk storage.
- xlarge: The specific capacity.

Not Just AWS

Amazon EC2 instance type identifiers have "leaked" into other areas:

- **Other cloud providers** have adopted similar naming conventions. Azure and Google Cloud use their own schemes, but documentation and architecture discussions often reference AWS instance types as a shorthand for describing compute requirements—"this workload needs roughly a c5.2xlarge equivalent"—even when the actual deployment is elsewhere.
- **Infrastructure and DevOps tooling** frequently uses EC2 instance type identifiers in configuration files, Terraform scripts, Kubernetes node selectors, and cost-optimization tools regardless of whether the author is explicitly discussing EC2. They've become a de facto unit of compute specification.
- **Benchmarking and performance documentation** often cites instance types as a reproducible way to describe the test environment—"tested on a c5a.2xlarge"—so readers know the exact CPU, memory, and network baseline without a lengthy hardware description.
- **Job postings and architecture docs** sometimes use them loosely to communicate scale, as in "this service runs on a handful of m5.xlarge nodes," where the instance type doubles as a concise spec sheet.

So while the identifiers are formally AWS terminology, they have spread into general cloud infrastructure discourse as a convenient shorthand for describing compute resources precisely.

Glossary

Acronyms and Initialisms

AD: Active Directory. A Microsoft directory service used to manage users, computers, and other objects on a network. Secret Server queries AD via LDAP to discover computer objects.

API: Application Programming Interface. A set of protocols that allows software to interact with Secret Server programmatically. API calls include secret retrieval, bulk updates, and authentication requests.

AWS: Amazon Web Services. A cloud computing platform used in Delinea's performance testing to provision controlled test environments.

CPU: Central Processing Unit. The primary processor in a server. CPU capacity is a key sizing factor for DEs, web nodes, and database servers.

DE: Distributed Engine. A Secret Server component that consumes tasks from RabbitMQ and executes operations such as discovery, heartbeats, remote password changing, and proxying. DEs are deployed across sites for workload distribution and redundancy.

EFS: Elastic File System. An AWS managed file storage service. Referenced as an option for high-performance, SSD-backed file shares used in session recording storage.

ELB: Elastic Load Balancer. An AWS service that distributes incoming traffic across multiple targets, such as dedicated web nodes handling API traffic.

HA: High Availability. A system design approach that minimizes downtime by deploying redundant components. The guide recommends N+1 redundancy for all critical Secret Server components.

IOPS: Input/Output Operations Per Second. A performance metric for storage devices. High IOPS is critical for Secret Server database performance.

LDAP: Lightweight Directory Access Protocol. A protocol used to query and manage directory services such as Active Directory. Secret Server uses LDAP for AD computer object discovery.

MMC: Microsoft Management Console. A Windows administrative tool that hosts management snap-ins. Referenced as an example of standard RDP session activity.

RAM: Random Access Memory. Volatile memory used for active data processing. Adequate RAM is recommended for database servers and web nodes.

RDP: Remote Desktop Protocol. A Microsoft protocol for remote graphical access to Windows systems. Secret Server can proxy and record RDP sessions.

RPC: Remote Password Changing. A Secret Server feature that automates password rotation on target systems. RPC is more CPU-intensive than heartbeats due to authentication, password generation, and update operations.

S3: Simple Storage Service. An AWS object storage service. Referenced as a cold-storage option for archiving session recordings to reduce costs.

SIEM: Security Information and Event Management. A system that aggregates and analyzes security event data. Extensive SIEM integration may introduce performance overhead in Secret Server environments.

SSH: Secure Shell. A protocol for encrypted remote access to Unix/Linux systems. Secret Server uses SSH for Unix discovery, proxying, and session recording.

SSD: Solid-State Drive. A high-performance storage device. SSD-backed file shares are recommended for session recording storage.

UI: User Interface. The web-based graphical interface for interacting with Secret Server. UI traffic is handled by web nodes and can support thousands of concurrent sessions.

vCPU: Virtual CPU. A virtualized processor core allocated to a virtual machine or cloud instance. vCPU count is a key factor in DE and web node sizing.

WMI: Windows Management Instrumentation. A Windows infrastructure for managing data and operations. Secret Server can use WMI (or RPC) to connect to Windows endpoints during local account discovery.

Terms

Compliance overhead buffer: An additional resource allocation (typically 10–15%) applied to sizing calculations for environments with stringent auditing, SIEM integration, or data-at-rest encryption requirements.

Computer object discovery: The process of querying Active Directory via LDAP to identify computer objects on the network. This produces minimal load and is not typically a sizing constraint.

Dependency discovery: An extension of local account discovery that also identifies application and service dependencies on each endpoint. It adds roughly 10–15% processing time per endpoint compared to accounts-only discovery.

Discovery occupancy: The percentage of a DE's available time consumed by discovery tasks, calculated as scan duration divided by scan interval. Delinea recommends keeping occupancy below 50–60% to reserve capacity for heartbeats, RPC, and other operations.

Heartbeat: A Secret Server operation that verifies stored credentials against target systems by periodically checking that passwords remain valid. Performance depends primarily on target system responsiveness and network latency.

Intel Quick Sync: A hardware-accelerated video encoding technology built into Intel processors. Nodes with Quick Sync can process approximately 1,500–2,000 hours of session recording video per day, compared to 400–450 hours on standard nodes.

N+1 redundancy: A high-availability strategy where one additional component is deployed beyond the minimum required. For example, if three DEs are needed for workload, four are deployed so that one can fail without service disruption.

RabbitMQ: An open-source message broker used by Secret Server to facilitate asynchronous task processing between web nodes and Distributed Engines. Monitoring RabbitMQ queue depths and message rates is important for performance tuning.

Session recording: A Secret Server feature that captures proxied SSH and RDP sessions for auditing and review. Recording involves client session launching, video transcoding, and storage management.

Site: A logical grouping of DEs in Secret Server, often aligned with geographical or network boundaries. Each site should have at least two DEs for redundancy.

Terraform: An infrastructure-as-code tool used by Delinea to provision consistent, repeatable test environments in AWS for performance benchmarking.

Transcoding: The process of encoding recorded session video into a storable and playable format. By default, each session recorder worker role-enabled web node handles two concurrent transcodes.

Web node: A Secret Server application server that handles UI requests, API traffic, and workflow orchestration. Web nodes can also be configured with worker roles for session recording launching and processing.

SQL Server and Secret Server

This topic only applies to **Secret Server On-Premises**.

Secret Server utilizes Microsoft SQL Server as its backend database to store and manage all its data securely and efficiently. SQL Server provides a robust and scalable platform for handling the extensive data operations required by Secret Server, including storing secrets, audit logs, user information, and configuration settings. The database is configured to use the SQL_Latin1_General_CP1_CI_AS collation to ensure compatibility and optimal performance.

Using the SQL_Latin1_General_CP1_CI_AS collation is super important to avoid issues after installation.

Secret Server supports various editions of SQL Server, including Express, Standard, and Enterprise, allowing organizations to choose the edition that best fits their needs. For high availability and disaster recovery, Secret Server can leverage SQL Server's advanced features such as mirroring, clustering, and AlwaysOn Availability

Groups. Additionally, Secret Server can be configured to use Integrated Windows Authentication (IWA) for secure and seamless access to the SQL Server database.

Choosing a SQL Server Edition to Use with Secret Server

This topic only applies to **Secret Server On-Premises**.

Choose the Microsoft SQL Server edition to work with Secret Server that best supports the functionality you wish to achieve.

The brief guide below should help you decide which licensing model best suits the needs of your organization.

SQL Server Express Edition

SQL Server Express is a free version of SQL that is sufficient to run most of the functionality within the Secret Server application itself.

However, advanced functionality like mirroring and clustering is not available.

Delinea does not support using SQL Express in a production environment due to size and performance limitations.

SQL Server Standard Edition

SQL Server Standard provides most of the functionality administrators typically want, including the most common type of mirroring, and clustering up to two cluster nodes.

SQL Server Enterprise Edition

SQL Server Enterprise provides all of the functionality found in the Standard Edition, plus the ability to cluster up to eight nodes and to perform asynchronous mirroring.

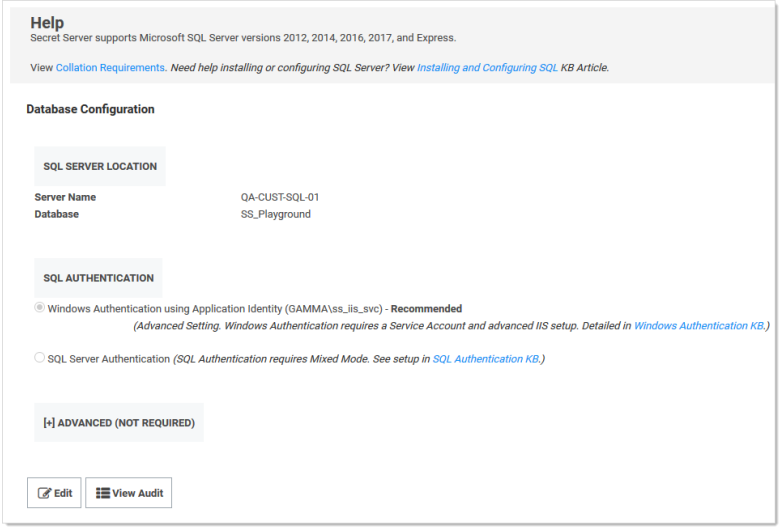
For more information on the different editions of SQL Server, see the Microsoft SQL Server 2022 Licensing Guide.

Enabling SQL Server Encryption

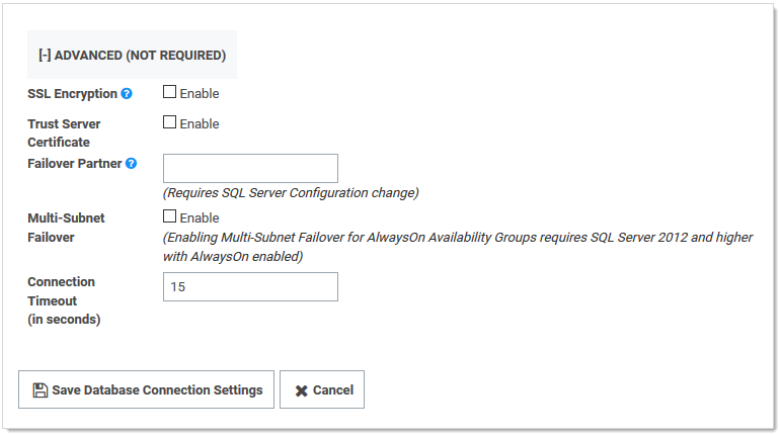
This topic only applies to **Secret Server On-Premises**.

Administrators can enable end-to-end encryption with the SQL database by using an Encrypted connection. This is a feature that is built into Microsoft SQL Server and Secret Server supports. To enable encryption:

1. Search for **See All**. The admin panel appears.
2. Type Database in the **Search** text box and select **Database**. The Database Configuration page appears:



3. Click the **Edit** button.
4. Click the **Advanced (Not Required)** link. A new section appears:



5. Click to select the **SSL Encryption** check box.
6. Click the **Save Database Connection Settings** button.

> SQL Server must be pre-configured to support encryption. This Microsoft TechNet article explains how to configure the SQL Server environment for encryption. The SSL encryption used for communicating with SQL Server is either 40 or 128 bit, depending on the Windows operating system used.

> Using this setting can adversely affect performance. See this TechNet article for additional information.

Installing and Configuring SQL Server

> This topic only applies to **Secret Server On-Premises**.

For step-by-step instructions on how to install SQL 2016, see "SQL Server 2016 Standard Edition Installation" on page 128.

Secret Server requires Microsoft SQL Server as the back-end database. All editions, including the Express version, of 2016-2022 are supported.

> Delinea does not support using SQL Express in a production environment due to size and performance limitations.

Setting up SQL Server requires:

- Installing an SQL Server
- Creating an SQL Account
- Configuring database access in Secret Server
- Installing SQL Server

> If you are using SQL Express make sure to get the edition with tools that will include SQL Management Studio. Follow the link in the .

> Before installing the SQL server, please make sure that the "no count" SQL Server connection property is turned off. If this setting is turned on, no Secret Server jobs will execute.

Creating an SQL Account

SQL Authentication

The fastest method to get started with Secret Server is to create a SQL Authentication account. Follow the instructions in the Database section of the "Basic (Automatic) Installation" on page 75.

For troubleshooting and configuring SQL installation on a different server that the application server see "SQL Server Authentication Configuration" on page 127 article.

Windows Authentication

A more advanced way to have Secret Server access the SQL server would be through a service account and using Windows Authentication. Because of the requirement of a service account and added IIS settings, we only recommend this for non-evaluation setups. See instructions in "Configuring Integrated Windows Authentication" on page 389.

Configuring Database Access in Secret Server

Once the account has been created and SQL server installed with the MSI. The third step of the Web installer will ask for database access information.

SQL Location

- **Server Name or IP**: If it is a local machine the server name will be (local) or localhost for the default instance, or if a named instance such as SQL Express it would be `localhost\SQLExpress`. If you are unsure, copy the value from the "Server name" text box when connecting through SQL Management Studio.
- **Database Name**: If you have created a database, enter the name. If you have given the SQL account dbCreator permission, enter a database name for Secret Server to create.

SQL Authentication

- **SQL Server Authentication**: Implies a SQL account has been created that exists only with SQL Server. The account will need to be dbOwner on the database or need dbOwner permission to create the database. This is recommended for quickest setup. For more detailed information and troubleshooting see "Installing and Configuring SQL Server" on page 123 .
- **Windows Authentication**: The identity of the application pool will access the database. This requires a domain Service account that has been granted access to run ASP.Net and the database. This is an advanced setting that is not recommended for evaluations. Follow the instructions on using a service account in "Configuring Integrated Windows Authentication" on page 389.

We suggest to setup the database maintenance to regularly backup the transaction log for the Secret Server database to prevent system down issues. Once the log fills up, it may cause Secret Server to go down. Check Managing Full SQL Server Transaction Logs for more details.

Azure AD password authentication depends on a deprecated Microsoft library and is not recommended for production use. Refer to the above authentication methods for supported alternatives.

Moving the Microsoft SQL Server Database to Another Machine

This topic only applies to **Secret Server On-Premises**.

This article only applies if your MS SQL Server database is only for Secret Server.

Follow the steps below for moving MS SQL Server database for Secret Server.

Task 1: Backing up and Restoring the Database

To back up your Secret Server installation:

1. Enable the maintenance mode.
2. Stop the Secret Server site in Internet Information Server (IIS) to prevent any changes to the database.
3. Navigate to the directory where Secret Server is installed.
4. Copy the folder (holding the application) to your back up location.

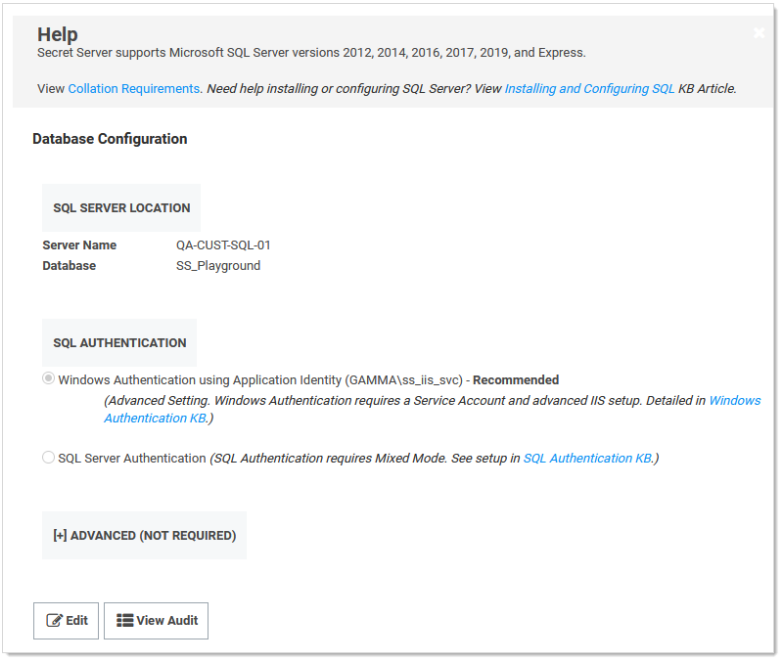
5. Open your SQL Server Management Studio.
6. Right click the database your Secret Server is running on, and select **Tasks > Backup**.
7. Click the **Add** button. You are prompted to enter a file path for the `.bak` file. This can be the final destination (not recommended) or a temporary one (for later moving to a back up location).
8. Make sure SQL Server has permissions for this location. That is, create (if needed) and or grant access to the account that will access the database (see the "Installation" on page 72 for account creation instructions). See "Running the IIS Application Pool As a Service Account" on page 63 (Task 2) for details.
9. Copy the resulting database backup file (`.bak`) to your backup location.

> You can also automate steps 2-4 using the command: `osql -S myserver\SQLEXPRESS -E - Q "BACKUP DATABASE SECRETSERVER TO DISK = 'c:\backup\ss.bak'.`

> We recommend taking the old database offline after all steps are complete.

Task 2: Connecting Secret Server to the New Database

1. Restart your Secret Server website in IIS.
2. Log on Secret Server as a local admin.
3. Navigate to `https://<your_SS_URL>/Setup/Database`. The Database Configuration page appears:



> The setting here are stored in `C:\inetpub\wwwroot\Secretserver\database.config`. You can back that file up to revert or simply return to this page to reset the connection again. See the Privilege Manager documentation if you need to change its configuration too.

4. Click the **Edit** button. The page becomes editable.
5. Type your new SQL Server location (server name) and database.
6. Click the **Save Database Connection Settings** button, and the site will connect to the new database.
7. Your site is now pointing the new database.

> To roll back changes and restore the original database, complete both tasks again to move the database back to the original database server.

> If you are also moving the Secret Server application to another server, see "Moving Secret Server to Another Machine" on page 86 for more information.

> The steps in Task 2 should be performed for each web node in a deployment. Making the change on one node only will not propagate to the other nodes.

SQL Server Authentication Configuration

> This topic only applies to **Secret Server On-Premises**.

SQL Authentication requires:

- Creating a new SQL account
- Enabling mixed mode
- Enabling named pipes and SQL Browser a non-local SQL Server

Creating a new SQL Account

See the Creating an SQL Account section on the "Installing and Configuring SQL Server" on page 123 page.

Enabling Mixed Mode

1. Connect to SQL Server in SQL Management Studio.
2. Right click on the instance node and select **Properties**.
3. Go to the **Security** tab.
4. In the **Server Authentication** section, select **SQL Server and Windows Authentication Mode**.
5. Click the **OK** button.
6. Restart the SQL Server, by right clicking on the instance node and selecting **Restart**.

If your SQL server is running on a separate machine, you need to turn on named pipes and SQL browser to ensure the SQL server can be accessed from an external machine.

Enabling Named Pipes and SQL Browser

1. Open SQL Server Configuration Manager.
2. Click the **SQL Server Network Configuration** node.
3. Select **Protocols for MSSQLSERVER**.
4. Enable the following:
   - Shared memory
   - Named pipes
   - TCP/IP
5. Enable **SQL Browser**.
6. Click to select the **SQL Server Services** node.
7. Right click **SQL Server Browser** and select **Start**.

SQL Server 2016 Standard Edition Installation

This topic only applies to **Secret Server On-Premises**.

Overview

The following steps walk you through setup and configuration for SQL Server 2016 Standard Edition as an example. For the most up to date resources on installing SQL see Microsoft SQL Technical Documentation for more information.

At the completion of this article you will have:

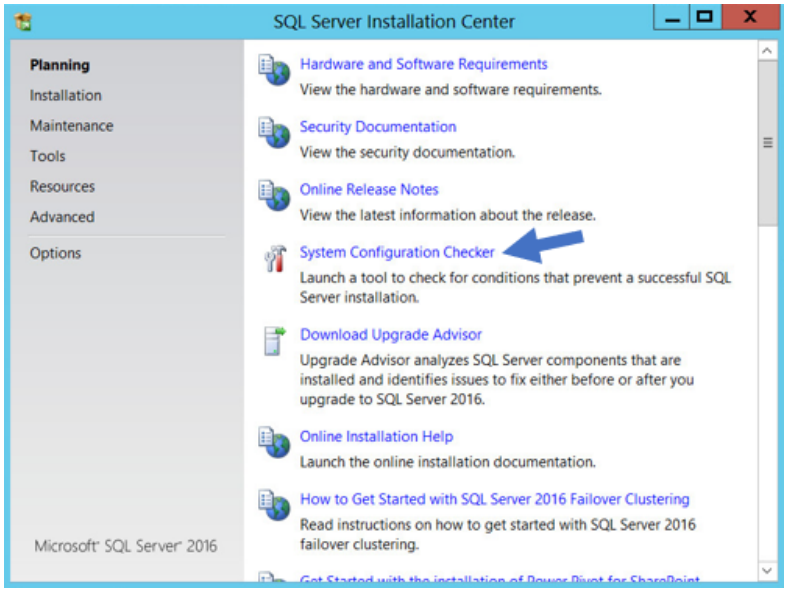
- Installed a basic stand-alone instance of SQL Server 2016 Standard with the minimum features necessary for SQL Server.
- Installed SQL Server Management Studio for managing the local database.
- Created a database in SQL for your Delinea product
- Created a new SQL Server user login for your SQL database

This document uses Delinea's Secret Server product as example in the instructions, but the same steps apply for Privilege Manager advanced installs.

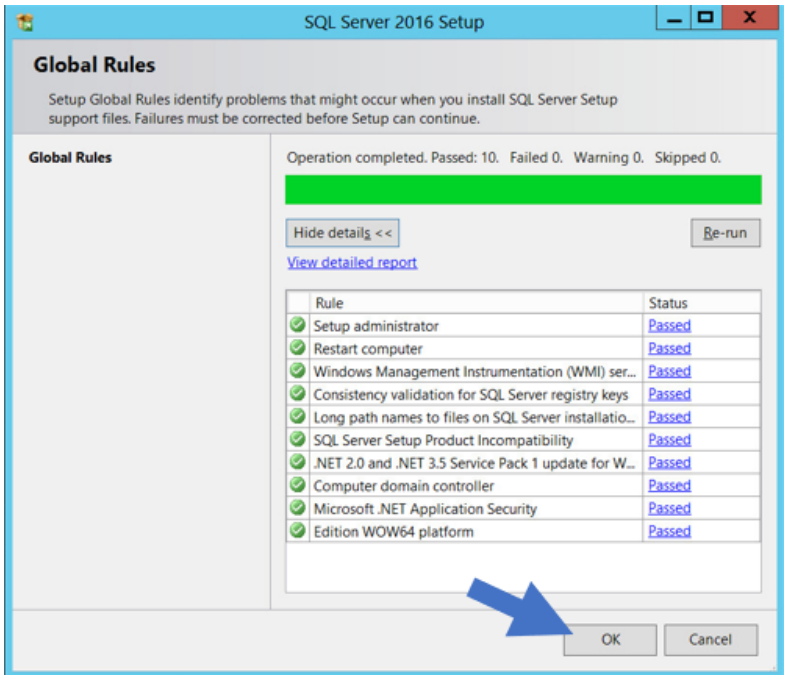
Procedures

Installing SQL Server 2016

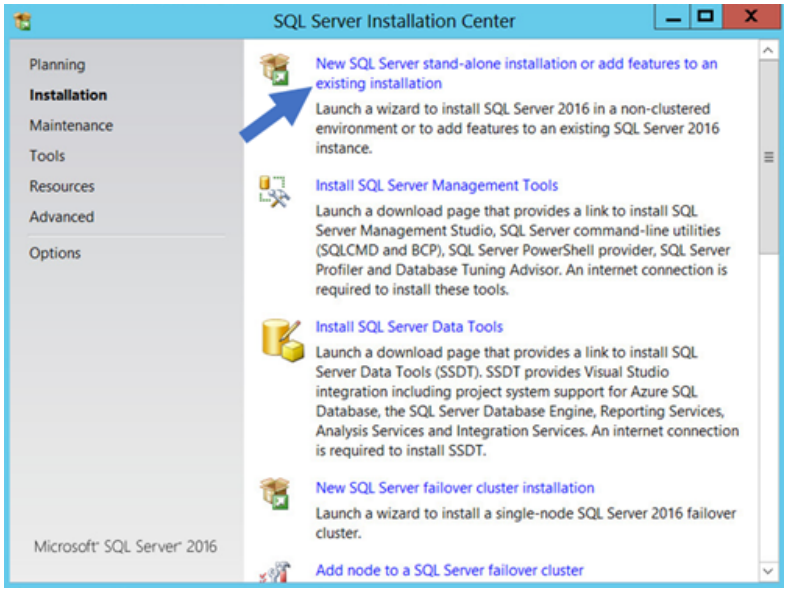
1. Launch the SQL Server installer from CD or file download. The SQL Server Installation Center opens to the Planning window:



2. Click the **System Configuration Checker** link. This runs a tool that checks for conditions on your server that could prevent SQL Server from installing.
3. When the tool launches, click the **Show details** button. A successful scan should look like the one shown below. If you encounter any issues, look at the detailed report, resolve the reported issues, and rerun the scan.

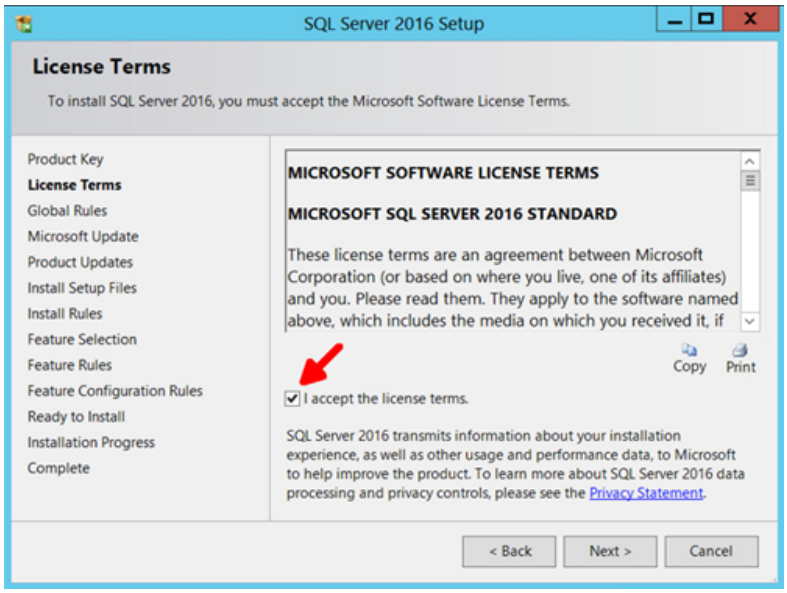


4. Click the **OK** button when done to return to the "SQL Server Installation Center" window.
5. In the SQL Server Installation Center window, click the **Installation** link. The Installation Window appears:

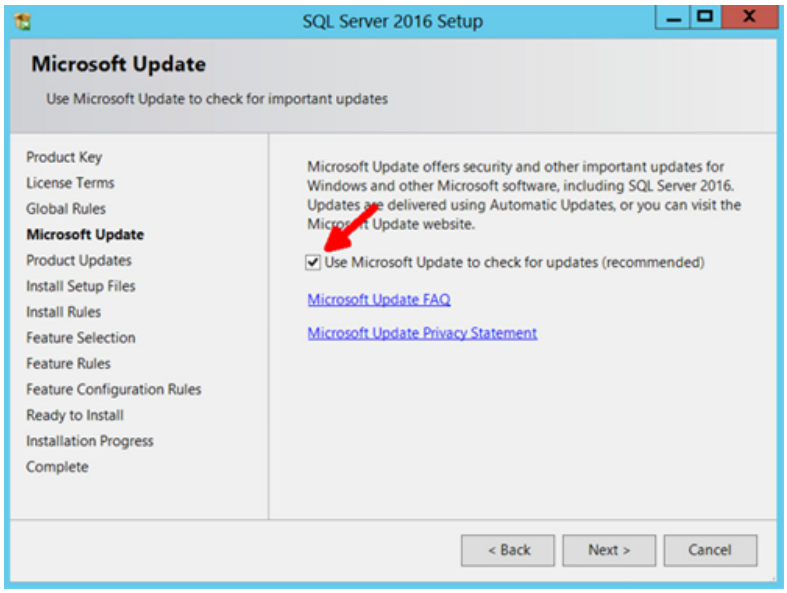


6. Click **New SQL Server stand-alone installation…** link. The Product Key page appears:

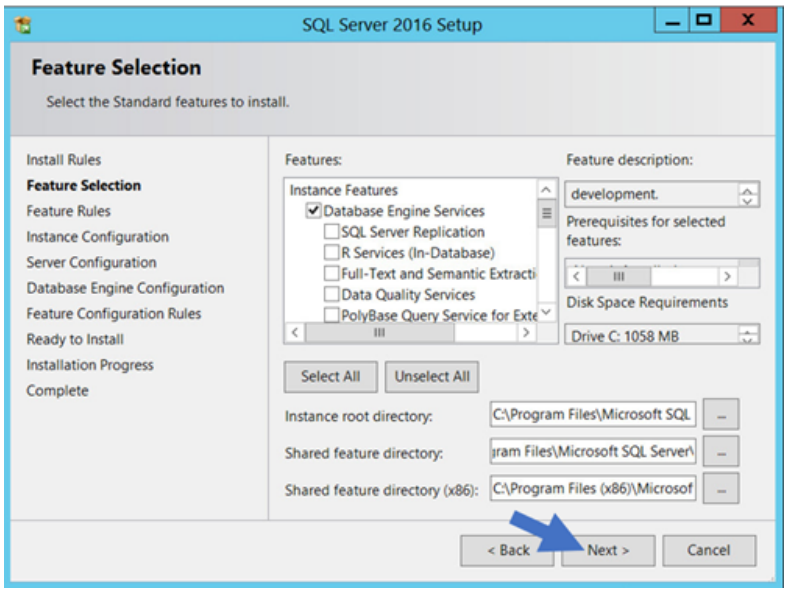
7. Click to select the **Enter the Product Key** selection button.
8. Type your product key in the **Enter the Product Key** text box.
9. Click the **Next >** button. The License Terms page appears:



10. Click to select the **I accept the license terms**. check box.
11. Click the **Next >** button. The Global Rules page appears (not shown) after the rule check runs.
12. Click the **Next >** button. The Microsoft Update page appears:



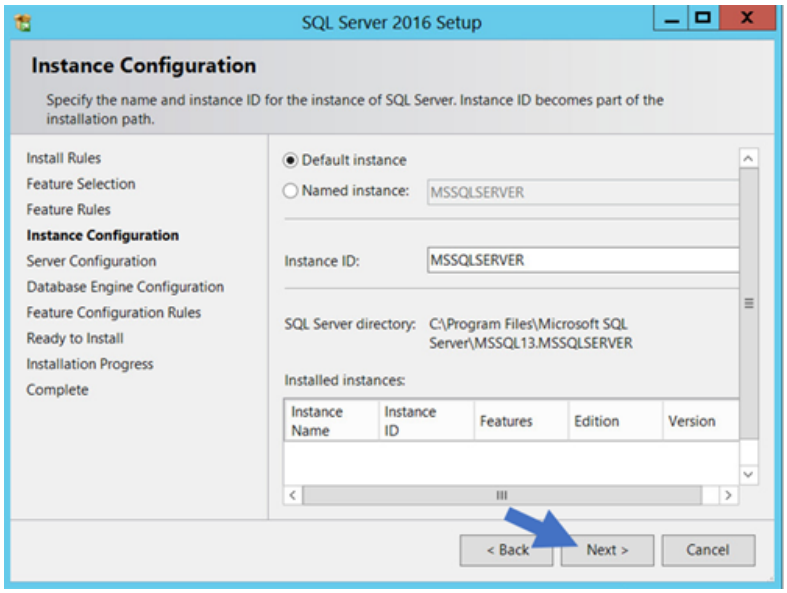
13. Click to select the **Use Microsoft Update...** check box to check for updates (recommended), unless your software update process does not use automatic updates from Microsoft
14. Click the **Next >** button twice to bypass the Product Updates page. The Install Setup Files page appears.
15. Wait for the installation to complete.
16. Ensure that all operations pass.
17. Click the **Next >** button twice to bypass the Install Rules page. The Feature Selection page appears:



18. Ensure the **Database Engine Services** check box is selected. This is the only feature necessary for Secret Server. Unless you are using Geo-Replication, you can leave everything else unchecked. Leave the directory

locations unchanged.

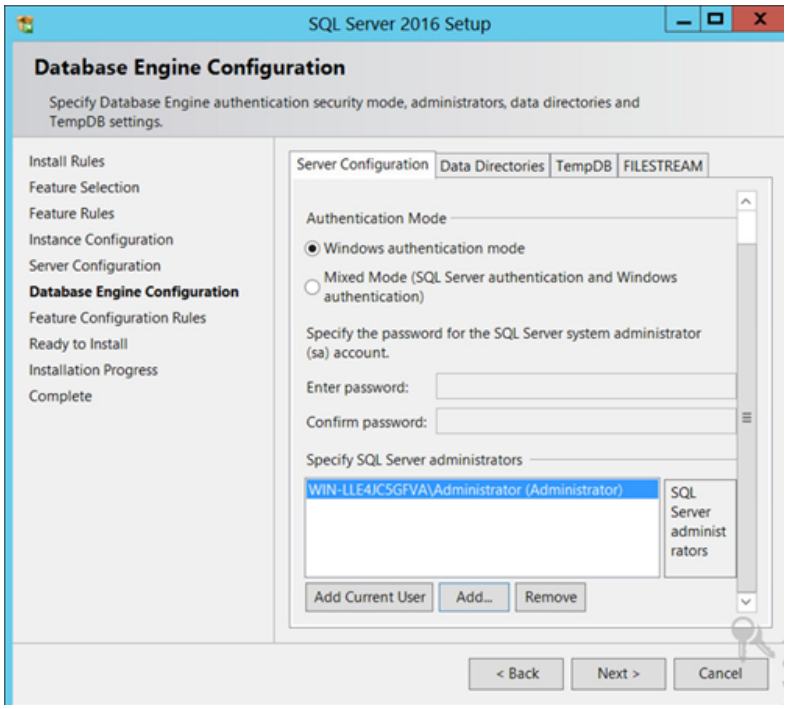
19. Click the **Next >** button twice to bypass the Feature Rules page. The Instance Configuration page appears:



20. Ensure the **Default Instance** selection button is selected.
21. Type a name for your SQL Instance in the **Instance ID** text box.

> Note: Before completing Step 22, confirm that the required SQL Server collation is set correctly at both the server and database levels.

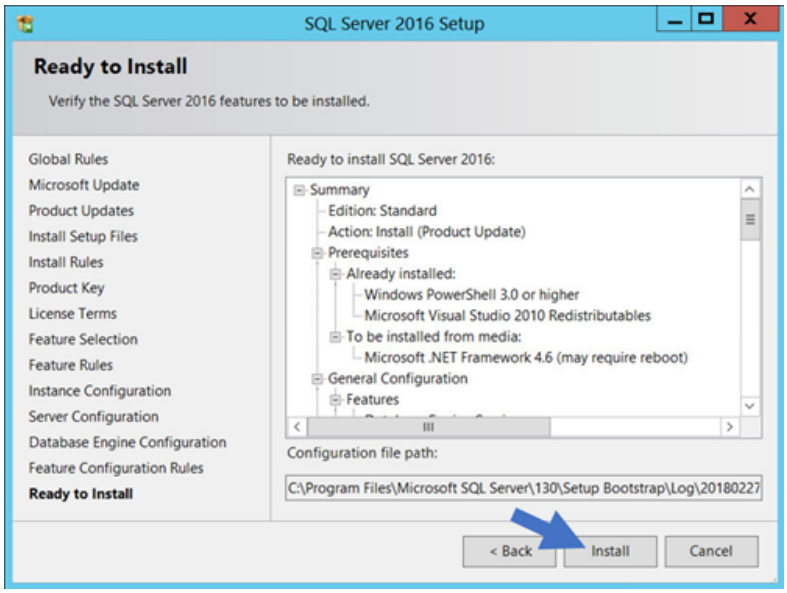
22. Click the **Next >** button twice to bypass the Server Configuration page. The Database Engine Configuration page appears:



23. You have the choice to select either **Windows Authentication Mode** or **Mixed Mode**. Select the option that will work best for your environment:
    - **Mixed Mode (for easiest configuration)**: This mode is required if you intend on using a SQL Server account to authenticate Secret Server to your SQL Server instance. We recommend using mixed mode if you are setting up a test or demo environment. Selecting this option will also require you to set a password for the SQL Server system administrator (sa) account. See **Adding a SQL Server User** below for instructions on adding more users.
    - **Windows Mode (recommended for best security)**: This mode prevents SQL Server account authentication. We recommend using Windows mode for production environments. Whatever user or group assigned will have administrative access to your SQL instance. According to best security practices, limit this number to as few users as possible.

    > If choosing **Windows Mode** you will also need to "Running the IIS Application Pool As a Service Account" on page 63 later in the installation process.

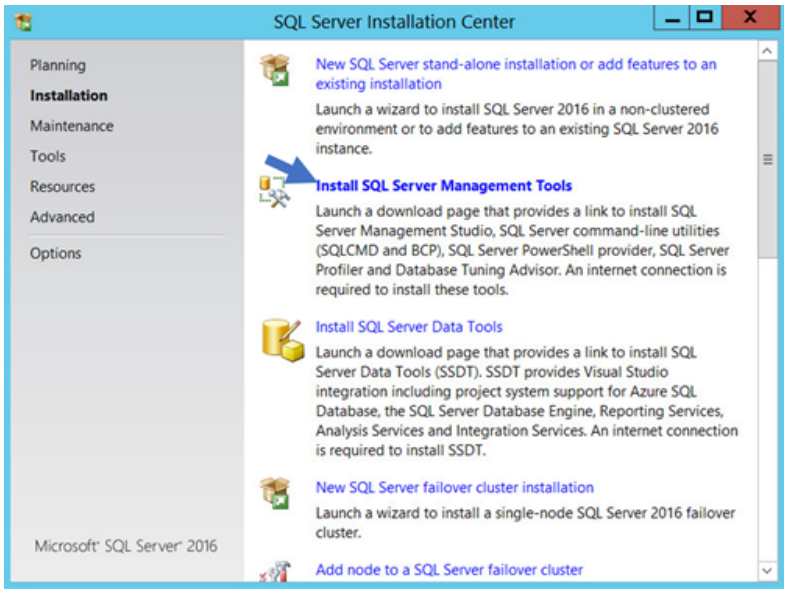
24. You can leave the options in the remaining tabs at their default values or change the file locations in the **Data Directories** and **TempDB** tabs if you wish to store the database and log data in a different drive or directory.
25. Click the **Next > button** twice to bypass the Feature Configuration Rules page. The Ready to Install page appears:



26. Click the **Install** button.
27. Wait for installation to complete. This may take several minutes.
28. Click the **Close** button.

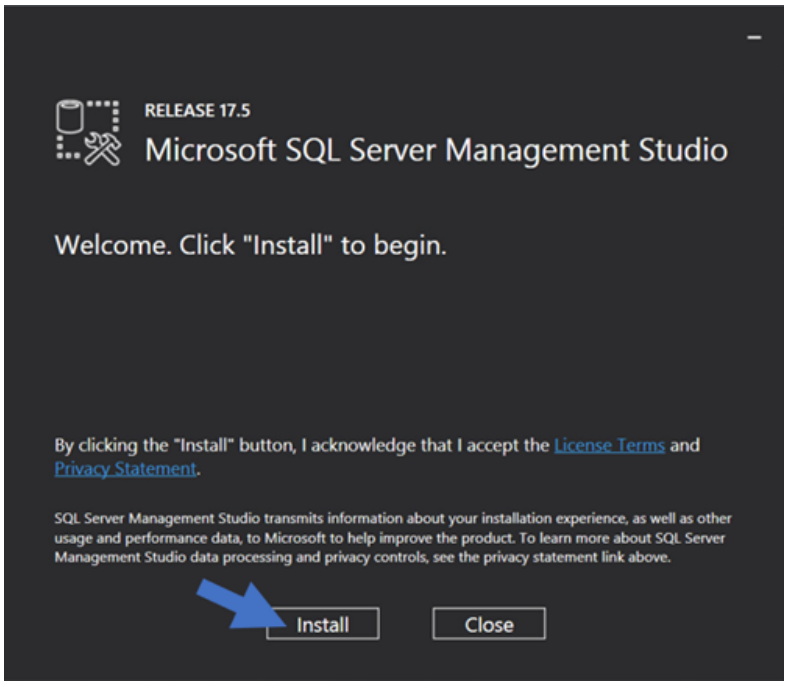
Installing SQL Server Management Studio

1. In the "SQL Server Installation Center" window, click the **Installation** menu item. The Installation page appears:

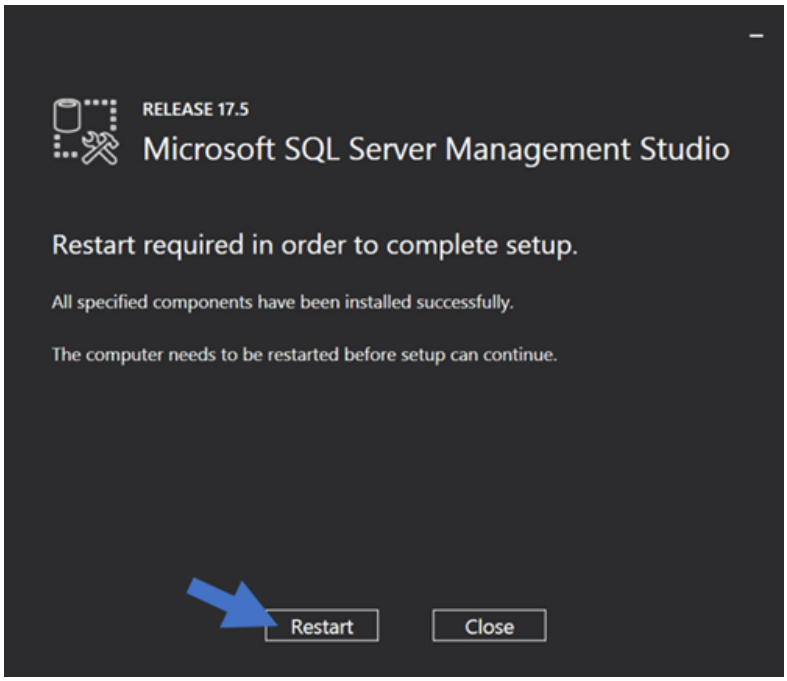


2. Click the **Install SQL Server Management Tools** link.

3. Wait for the Web page to load then click the **Download SQL Server Management Studio...** link. A file downloads.
4. Run the downloaded file (varies by browser). The SQL Server Management Studio installer starts.



5. Click the **Install** button.
6. Wait for the installer to complete. This may take several minutes.



7. Click the **Restart** button if prompted. Otherwise, click the **Close** button.
8. Close "SQL Server Installation Center."

Creating the SQL Server Database

To install Secret Server, the Delinea installer creates the SQL database for you if it does not exist and if the user account has Microsoft SQL Server permission to create a new database, which requires the dbcreator server role.

If not using the Delinea Installer, use the following steps to create a database manually through SQL Server Management Studio:

1. Open SQL Server Management Studio.
2. Connect to your SQL Server instance.
3. Right click the **Databases** folder and select **New Database...** The New Database page appears.
4. Type a name for your database in the **Database Name** text box.
5. Click the **OK** button.

Adding a SQL Server User to Secret Server

According to security best practices, limit the number of users with access to your SQL database as much as possible. Use the following instructions to add a SQL Server account for Secret Server to use to access the SQL database:

1. Open SQL Server Management Studio.
2. Connect to your SQL Server Database.
3. Expand the **Security** folder.

4. Right-click the **Logins** folder and select **New Login...**
5. Select a method of authentication:
   - **SQL Server Authentication**: Use this option to create a new SQL Server account (this requires mixed mode to be enabled). To create the account, enter a new username and password and then deselect the **Enforce Password Policy** check box to prevent the account from expiring.
   - **Windows Authentication**: Use this option to add access to SQL Server for an existing Windows account. To add the account, enter the login name or click **Search** to find the account. It is recommended to use a domain account rather than a local Windows account.
6. **Either**, if you have already created the database for your Delinea product:
   a. Click **User Mapping**in the**Select a page**list box.
   b. Click to select the check box for the database in the**Users mapped to this Login**list.
   c. Click to select the**db_owner**check box in the**Database role membership...**list.
7. **Or**, if you have not yet created the database:
   a. Click**Server Roles**in the**Select a page**list box.
   b. Click to select the**db_creator**check box.
8. Click to select the check box next to your Secret Server database.
9. In the **Database Role Membership** window, click to select the **db_owner** check box.
10. Click the **OK** button.

SQL Server Performance Improvement

This section provides insights and recommendations for improving SQL Server performance, focusing on reducing blocking and optimizing database operations.

Recommendations

Snapshot Isolation

We highly recommend enabling both `ALLOW_SNAPSHOT_ISOLATION` and `READ_COMMITTED_SNAPSHOT` in your database settings. This configuration allows transactions to work with a consistent snapshot of the data, significantly reducing blocking. While writers will still block other writers, most read operations will not be blocked.

To enable snapshot isolation, execute the following commands:

```
ALTER DATABASE MyDbName SET ALLOW_SNAPSHOT_ISOLATION ON;
ALTER DATABASE MyDbName SET READ_COMMITTED_SNAPSHOT ON;
```

This change allows sessions in the `READ_COMMITTED` isolation mode (the default) to automatically use snapshot isolation, requiring no application changes.

Using READ_UNCOMMITTED

For many application workflows that do not require strict transaction isolation, using `READ_UNCOMMITTED` mode can eliminate most blocking. This mode allows reading uncommitted changes, which can be suitable for scenarios where absolute accuracy is not critical.

HADR_SYNC_COMMIT Considerations

HADR_SYNC_COMMIT waits can occur during indexing operations. The ALTER INDEX ... REBUILD command is an offline operation, making the table inaccessible during the process. It is recommended to perform such operations during off-hours.

Troubleshooting

Analyzing Blocking

To get a sum of all blocking, use the following query:

```
SELECT OBJECT_NAME(o.object_id), i.name, row_lock_wait_in_ms + page_lock_wait_in_ms AS
"milliSecondsBlockedSinceRestart"
FROM sys.dm_db_index_operational_stats (DB_ID(), NULL, NULL, NULL) o
JOIN sys.indexes i ON i.object_id = o.object_id AND i.index_id = o.index_id
ORDER BY row_lock_wait_in_ms + page_lock_wait_in_ms DESC
```

This query provides a detailed view of blocking times for each index, helping identify potential bottlenecks.

Understanding SLEEP_BPOOL_FLUSH

The SLEEP_BPOOL_FLUSH wait type should generally be ignored. It is part of SQL Server's mechanism to categorize session blocking. This wait type is not necessarily indicative of a user transaction waiting.

The buffer pool is used for caching database pages. When a page is updated, it is marked as dirty and eventually written back to disk. If the disk response time exceeds 20ms, the process throttles itself. A response time of 24ms, for example, is not considered excessive.

HADR_SYNC_COMMIT Considerations

HADR_SYNC_COMMIT waits can occur during indexing operations. The ALTER INDEX ... REBUILD command is an offline operation, making the table inaccessible during the process. It is recommended to perform such operations during off-hours.

For on-hours work, consider using online index operations, which take short-lived locks, allowing the table to remain accessible. If the HADR_SYNC_COMMIT waits are still unsatisfactory, consider discussing asynchronous commit mode.

By implementing these strategies, you can enhance SQL Server performance, reduce blocking, and ensure smoother database operations.

Uninstalling Secret Server

This topic only applies to **Secret Server On-Premises**.

Following these instructions ensures there is absolutely no residue or trace of Secret Server on the server.

Uninstalling Secret Server is a quick, three-step process:

1. Delete the database.
2. Delete the virtual directory.
3. Delete Secret Server files.

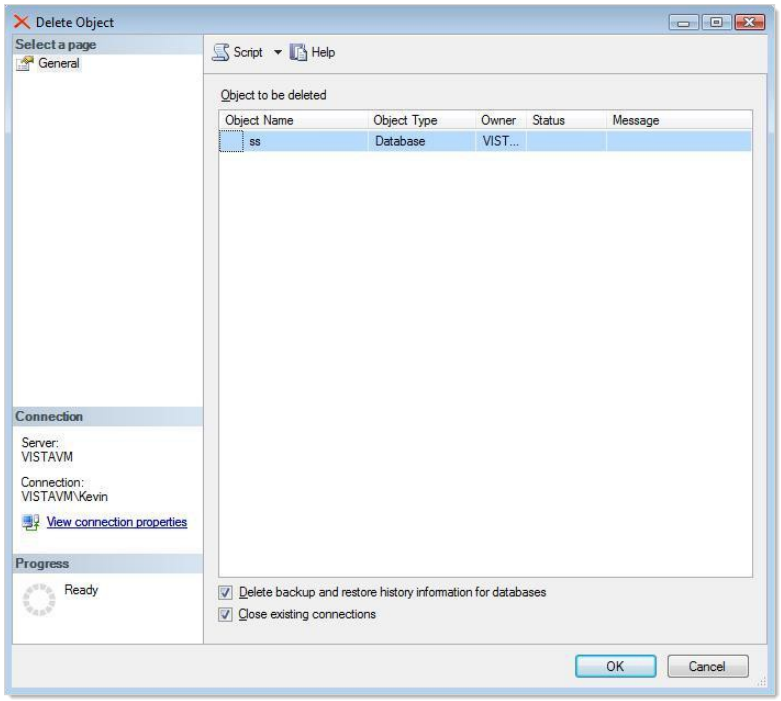
Task 1: Deleting the Database

Dropping the database deletes all of your data.

> You cannot undo this procedure once you are done. We strongly suggest backing up the installation first in case you need to restore it.

Procedure:

1. Open the Microsoft Management Studio.
2. Connect to the database.
3. Locate your Secret Server database in the object explorer, which is normally in the **Databases** folder. If necessary press F8 to show the object explorer.
4. Right click the database and select **Delete**. The Delete Object dialog appears:

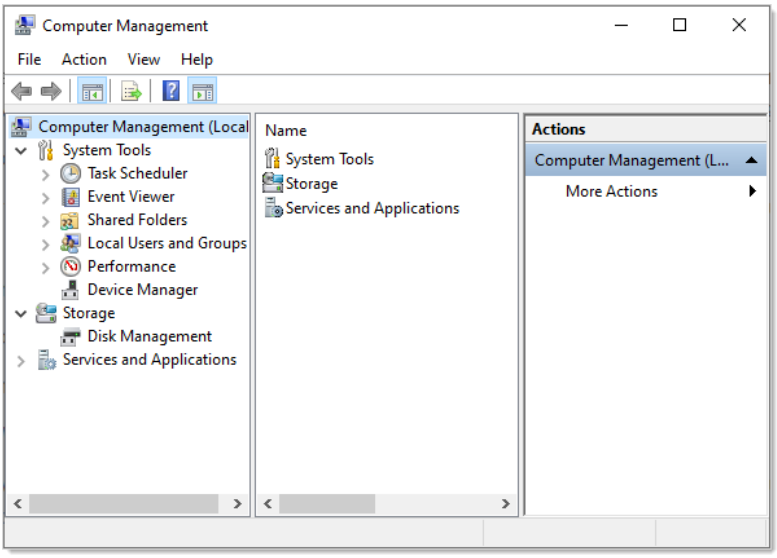


5. Ensure the **Drop Existing Connections** check box is selected. This disconnects all connections to the Secret Server database.
6. Ensure the **Delete backup and restore history information for databases** check box is selected.
7. Click the **OK** button. The database is permanently deleted.

Task 2: Deleting the Virtual Directory

If you installed Secret Server as a virtual directory, the virtual directory must be deleted first. If Secret Server is not configured as a virtual directory, skip this task.

1. In the search text box in your **Start Menu**, type `Computer Management`.
2. Click the **Computer Management** result. The Computer Management Console appears:



3. Click to expand the **Services and Applications** node.
4. Click the **Internet Information Services (IIS) Manager** node.
5. Click to expand the **Web Sites** subfolder.
6. Click to expand the Secret Server Web site.
7. Right click the virtual directory and select **Delete** or **Remove**. The directory is deleted.
8. (Optional) Delete ASP.NET's cached version of Secret Server:
   a. Open the directory `C:\Windows\Microsoft.NET\Framework\<version number>\Temporary ASP.NET Files`, substituting your ASP.NET version number.
   b. Delete the subfolder with the same name as your virtual directory.

> These files are not a security risk, but removing them eliminates any evidence that Secret Server was installed.

Task 3: Deleting Secret Server Files

> The `encryption.config` file is crucial to restoring any backup. Ensure this file is backed up if you may want to restore Secret Server.

1. Locate the directory where Secret Server is was installed.
2. Click to select it.
3. Press **<Shift>** + **<Delete>** to **permanently** delete the files. Holding shift bypasses the recycle bin. Secret Server is now permanently removed from the system.

> Even "permanently" deleted files can sometimes be recovered with special tools. If that is a concern, we suggest using a file shredding application to delete the folder.

Upgrading

> This topic only applies to **Secret Server On-Premises**.

> As of August 31, 2025, Microsoft retired TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net now requires TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

- Secret Server and Secret Server Cloud .NET Framework 4.8 Mandatory Upgrade
- "Upgrading Secret Server" on the next page
- "Upgrading Secret Server Without Outbound Access" on page 167
- "Upgrading Secret Server with Web Clustering" on page 144
- Secret Server Upgrade Checklist

Ensuring Upgrade Security

> This topic only applies to **Secret Server On-Premises**.

We take the following measure to ensure the upgrade is secure:

Secret Server on-Premises upgrades are packaged in a wrapper zip file for delivery. These upgrade zip files are named with the release version, such as `version_11_1_000006.zip`. Each wrapper zip file contains two files, a security catalog file named `hashes.crt` and yet another zip file named `ss_update.zip`.

The `ss_update.zip` file holds the changes for the new Secret Server version (database and file changes). The `hashes.crt` file is a signed security catalog containing the hash of the `ss_update.zip` file, which is used to ensure the authenticity and integrity of the `ss_update.zip` file.

A hash is a long string of characters that represents a unique digital "fingerprint" of any file the hash function is run on. Any change to a hashed file causes future hashes of the altered file to differ from the original hash, proving the file is different.

When the upgrader processes `ss_update.zip`, the following occurs:

1. The `hashes.crt` file is validated to ensure that its digital signature is the original produced by Delinea.
2. The same hash function that created the original hash is run on the `ss_update.zip` file, creating a new hash.
3. The original hash is compared to the new hash, ensuring the two match and `ss_update.zip` has not been tampered with.
4. The original wrapper zip file is inspected to ensure it does not contain any unexpected, likely malicious, files.

As a result of this inspection process, the upgrader is positive both `ss_update.zip` and `hashes.crt` are genuine and there are no foreign files present.

Upgrading Secret Server

This topic only applies to **Secret Server On-Premises**

For manual upgrades, please see the Secret Server On-Premises Upgrade Checklist prior to upgrading.

If you have Privilege Manager installed, the Secret Server upgrade process will begin an upgrade for Privilege Manager as well.

How Standard Upgrades Work

Secret Server periodically polls the update server to detect new updates. If the "Allow Automatic Checks for Software Updates" option is enabled in the Admin > Configuration menu, you will see the "An update is available (xx.x.xxxxxx)" link after logging in with an administrator account.

Before You Begin

1. Ensure you will have access to account credentials for the server hosting Secret Server AND the SQL Server instance hosting your Secret Server database.
2. Ensure you have a recent backup of the application files and database available.
3. If you use clustering, stop the application pools on all of the servers except the one that is currently the "primary."

How to Upgrade

1. From a computer that has outbound network access, in your Secret Server search for **Upgrade Secret Server**. The Upgrade Secret Server page appears.
2. Enable Maintenance Mode.

> Note that it is recommended to enable Maintenance Mode before upgrading Secret Server to ensure limited downtime during the upgrade process. You cannot make changes to the database while in Maintenance Mode, this includes changing Secrets or Secret-related data.

a. Click **Enable Maintenance Mode**, and in the Enable Maintenance Mode popup click **Enable**.

b. Otherwise, click to select **Do not put Secret Server in Maintenance Mode during the upgrade process** to skip this step.

3. Ensure your install is backed up:

> All your data is encrypted using the `encryption.config` file in your Secret Server application folder. **Your data cannot be decrypted without it**. Thus, it is critical that you backup the application folder and its contents before proceeding.

a. Click the **Backup** button. The **Backup** tab appears. Here you can configure and then run a backup of the SQL Server database and the web application. You can save backups to local folders or network folders through configuration. The AppPool running Secret Server must be configured to not shut down. The IIS Application pool will need Full Control to the backup folder specified for this user. Click the links on the tab to learn more before continuing.

b. Click the **Run backup now** button.

c. When finished backing up both, return to the Upgrade Secret Server page and click to select the **The Secret Server database and application folder have been backed up** check box.

4. Click the **Continue** button. The Upgrade Secret Server page appears.
5. Click the **Download Latest Version** button to download Secret Server. Wait for the download to finish. The Install Secret Server button appears.
6. Click the **Install this Version** button. The upgrade starts. When it is finished, the Secret Server Upgrade Installation Status page appears.
7. Click the **Return to Home** button to return to the dashboard. The upgrade is complete.
8. If you intend to use Web clustering, proceed to "Upgrading Secret Server with Web Clustering" below.

Upgrading Secret Server with Web Clustering

> This topic only applies to **Secret Server On-Premises**.

Introduction

Secret Server has a built-in Web installer. The Web installer is a series of pages inside Secret Server that allow you to download and run updates. Secret Server is accessible to users for most of the upgrade process. You can bring down outside access to the site if you want to prevent users from making changes during the upgrade. Preventing user access makes restoring the database and site backups simpler if you decide to roll back the upgrade immediately afterward.

> You do not need to download the installer or `setup.exe`.

Please see the Secret Server On-Premises Upgrade Checklist prior to upgrading. Back up your Secret Server folder and database before performing the upgrade.

Never overwrite or delete your `encryption.config` file.

Distributed engines automatically upgrade.

Before Beginning

- Ensure that you have account credentials information and access for the server hosting Secret Server*and* the SQL Server instance hosting your Secret Server database.
- Have a recent backup of the application files and database available.
- If you use clustering, stop the application pools on all of the servers.

Upgrading a Clustered Environment

1. Follow the instructions in "Upgrading Secret Server" on page 143 or "Upgrading Secret Server Without Outbound Access" on page 167 as applicable to upgrade one server.
2. Once upgraded and working, copy the Web application folder (without the `database.config` or the `encryption.config` files) to all secondary servers, and replace the content of the existing Web application folder with the new version.
3. If the Delinea Management Server is installed and clustered, you need to copy the Delinea Management Server directory to the secondary servers as well. This directory is included by default for new installs of Secret Server 10.2 and above. The Delinea Management Server is used by advanced session recording and Privilege Manager. If the Delinea Management Server folder and site do not exist in IIS, then no additional actions are needed beyond copying the Secret Server directory.
4. Start secondary servers and confirm they still work.

When copying the application files of the upgraded node, the log folder is optional.

EFS and DPAPI Encryption

When upgrading, after the initial cluster configuration, you do not need to copy the `database.config` or `encryption.config` files to the other servers. If you need to copy those files because the database configuration changed and uses DPAPI, disable DPAPI encryption in Secret Server by going to **Admin > Configuration** and clicking **Decrypt Key to not use DPAPI**, located on the **Security** tab, before copying those files to secondary servers.

EFS encryption is tied to the user account running the Secret Server application pool, so it is not machine specific. Copying EFS encrypted files between Secret Server instances will not result in errors, but is not needed.

Upgrading Database Mirroring

1. If there is more than one Web server running Secret Server, ensure all instances are pointing to the same database.
2. Stop all but one of the web servers.
3. Perform the upgrade on that single instance.
4. Once upgraded and working, copy the Web application folder to all secondary servers.
5. Start the secondary servers, and confirm they work.
6. Ensure all instances are properly activated.
7. Ensure that the database changes have been replicated to the mirror database.
8. If the secondary Web server was pointing originally to the secondary database, adjust it to point back to the secondary database.

Upgrading Remote DR Instances

1. Perform the upgrade on one instance.
2. Backup that instance.
3. Copy the database backup to the remote DR instance.
4. Restore the database.
5. Once the instance is upgraded and working, copy the Web application folder (but not the `database.config` or the `encryption.config` files) to the remote DR instance (overwriting the existing files).
6. Restart IIS or recycle the application pool running Secret Server on the remote DR instance.
7. Confirm that the remote DR instance is working correctly.

Error Conditions

Error(s) that may arise if the following condition(s) exist:

The version does not match: If a node is not properly updated from the source node after an upgrade, that node will not run because the application version does not match the database. The solution is to copy the application folder (minus the `database.config` or `encryption.config` files) and to replace the files on the secondary server.

Minimizing Upgrade Downtime

This topic only applies to **Secret Server On-Premises**

Introduction

Large enterprise Secret Server customers with clustered environments often have a strong interest in minimizing downtime during their upgrade process. This document details our recommendations for accomplishing that.

> This strategy may require close coordination between networking, server administration, and SQL DBA teams. We recommend they are available at the same time during the upgrade to minimize downtime. This procedure works best for those upgrading from the prior most recent version of Secret Server.

We recommend that you have a QA or test environment mirroring your production environment and that you first run this procedure through that environment to ensure the desired results occur, prior to attempting this in a production environment. As with any third-party application upgrade, we strongly recommend taking snapshots or virtual machine backups of your web, Secret Server distributed engine, and database servers so you can easily revert to a pre-upgrade state if issue arise during the upgrade.

> Distributed engines auto-upgrade as part of the upgrade process to the latest release. It is possible that you will have up to 10 minutes of downtime while the engines upgrade, regardless of this procedure.

> Customers using IWA and upgrading from 10.6 or lower to 10.6 or greater need to follow the steps in "Configuring Integrated Windows Authentication" on page 389 to configure their distributed engines.

Procedures

Load Balanced Configuration Upgrade

Prerequisites

The upgrade procedure requires that you do these steps outside of the Secret Server install.

- Download the upgrade package (step 1)
- Backup your database (step 2)
- Obtain the database upgrade script from support (step 4)
- Backup any customized web.config or web-appsettings.config files (step 10)

Procedure

1. Download the latest version of Secret Server from the Support Website.
2. Perform a full backup of your Secret Server database using the preferred backup method used by your company. For a quicker recovery procedure in case of disaster, we recommend creating a local SQL backup, engaging your SQL DBA team as needed. If you use an AlwaysOn configuration, perform the backup from your primary node. If desired, you can choose the option to do a "copy only" backup to avoid interrupting any log truncation performed by your enterprise backup tool.
3. Restore the database onto a separate SQL server or separate instance within your environment. This restored backup is used to test the upgrade process. For this instruction, we call this server the "Test SQL Server."

> Depending on your circumstances, you might want to provision a standalone SQL server to accommodate this need in the future.

4. Request a database upgrade script from the Delinea Support team. You must provide them the current **exact** version of software you are on. The script can **only** be provided by Delinea. You can be request it prior to your upgrade.
5. Run the upgrade script on the Test SQL Server to verify the upgrade script runs without errors. If the upgrade script completes without errors, you can proceed.
6. Remove the database from the Test SQL Server. This may require your restarting SQL Server Engine services prior to removal.
7. Choose one of the web servers in a load balancer pool. For this instruction, we call this the "Target Web Server A." The pool has three servers total (Target Web Server A, B, and C).
8. Stop IIS on Target Web Server A. That server will appear offline in the pool list on your load balancer configuration application. For now, leave the other target web servers as is.
9. Temporarily remove Target Web Server A from the load balancer pool using your load balancer configuration application. Leave the server itself running. For example, on a F5 Big-IP load balancer:
    a. Click Local Traffic.
    b. Click Pools.
    c. Click to select the desired pool.
    d. Click Advanced in the Configuration section.
    e. Ensure Reject is selected for Action on Service Down.
10. Copy the Secret Server application files you downloaded to Target Web Server A. Copy all files in the SS_update.zip file into Secret Server directory on Target Web Server A. This typically takes less than five minutes, depending on VM resources.

> If you have any customized settings that are per-node-specific in the existing web.config or web-appsettings.config files on the target servers, consider whether you want to protect those changes from being overwritten during the upgrade. Because the default contents of those files might change with the upgrade, we strongly recommend copying any customizations line-by-line to the new files, rather than simply replacing the new files with your customized ones. We suggest running a diff or comparison operation on the file pairs to see what, if anything, was customized in the existing files or changed in the new files.

11. When you are prompted, instruct the system copy dialog to overwrite all files.
12. (Optional) When the Secret Server files are finished copying, enable maintenance mode on Target Web Servers B and C to eliminate the possibility of password changes occurring during your database upgrade. The Secret Server read-only vaulting function is still possible from these nodes.

> See "Maintenance Mode FAQ" on page 234 for more on maintenance mode.

14. Start IIS on Target Web Server A. Wait until the site fully loads. This may take some time.

> Once the site loads, when you locally access that web server, you will see a Secret Server error message saying your database does not match your Secret Server. You can ignore that and click the Continue button.

15. Run the script you modified on the Production SQL Server.
16. Once the script completes, disable Target Web Servers B and C on your load balancer pool.
17. Enable Target Web Server A on your load balancer pool.
18. Access the web server through the load balancer URL. The Secret Server Login page should appear, and you should be able to log on immediately.

> If the warning message about the database not matching Secret Server appears, ignore it and click the Continue button.

19. Make Target Web Server A the primary load balancer node in the load balancer pool until the other target web servers are upgraded and online.
20. Disable IIS on Target Web Servers B and C.
21. Manually upgrade the Secret Server application files as previously discussed.
22. Enable IIS on Target Web Servers B and C.
23. Enable Target Web Servers B and C in the load balancer pool.
24. If you earlier put any of the target web servers in maintenance mode as a precaution, return them to normal function.

Manual Rolling Upgrade

Introduction

The manual rolling upgrade provides a way to upgrade Secret Server with little to no downtime. That is, users will continue to have secret access during the upgrade.

> This procedure only applies to clustered (multiple Web node) Secret Server environments environment.

Prerequisites

The administrator role needs the following Delinea permissions:

- Administer Configuration
- Administer Nodes
- Administer Backup

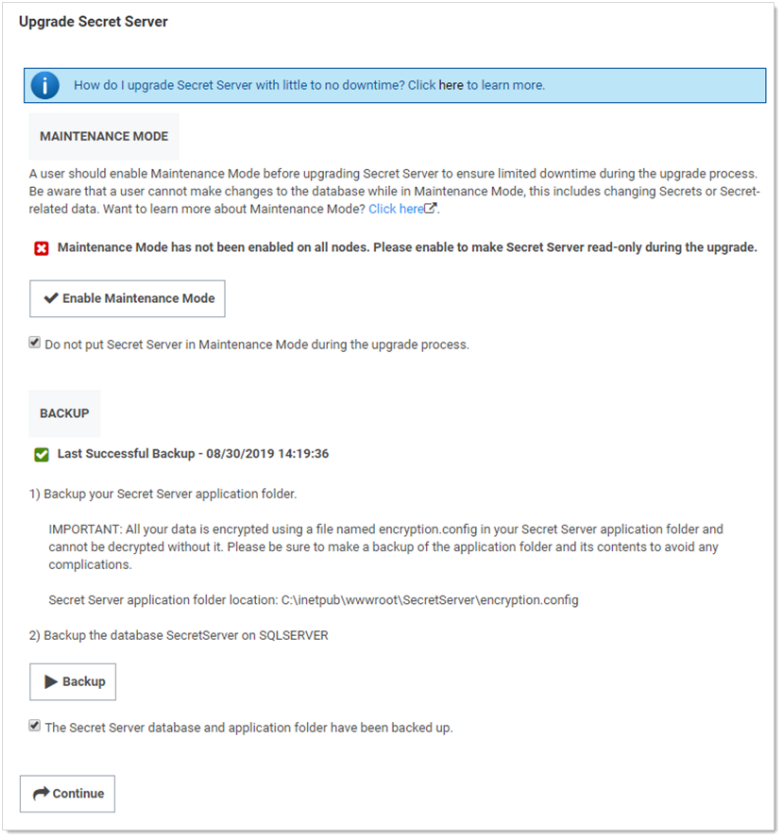
In addition, the role:

- Needs a database login with permission to change the database
- Requires access with permission to update files on web servers
- Must go through the current upgrade process
- Must not turn on maintenance mode until needed

Procedure

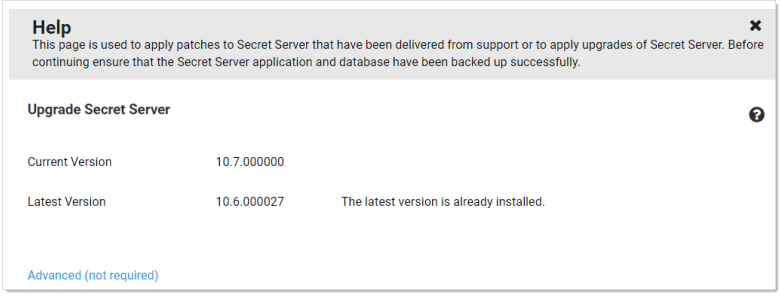
Task One: Uploading the Upgrade

1. Download the latest version of Secret Server.
2. Search for **Upgrade**:

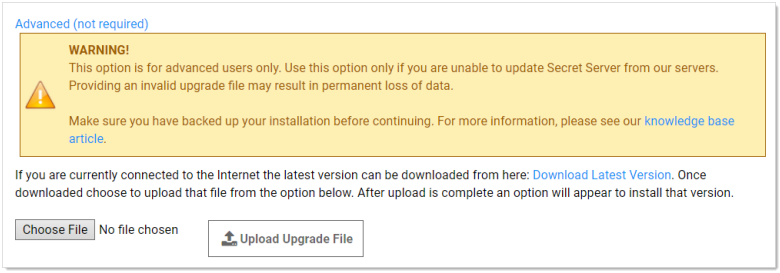


3. **Important:** Click to select the **Do not put Secret Server in Maintenance Mode during the upgrade process** check box.
4. Backup the Secret Server application folder.

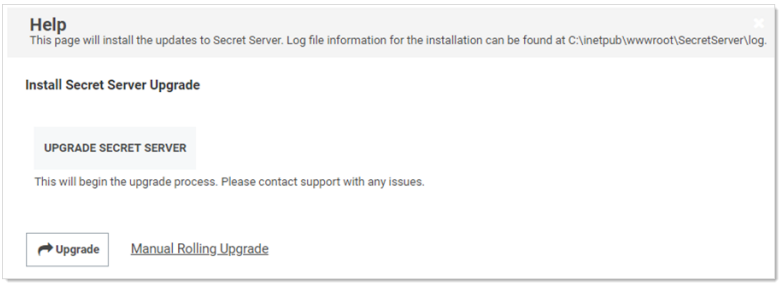
   Important: Ensure the encryption.config file is backed up. It is located at `c:\inetpub\wwwroot\SecretServer\encryption.config`.
5. Click the **Backup** button to back up the Secret Server database.
6. Click the **Continue** button. The Upgrade Secret Server page appears:



7. Click the **Advanced (not required)** link. The Advanced section appears:



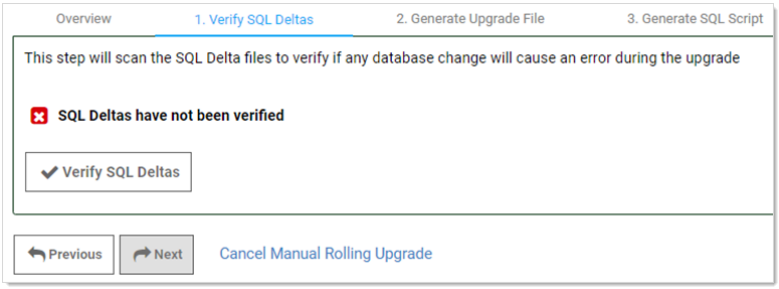
8. Click the **Choose File** button, and select the zip file you downloaded earlier to upgrade to.
9. Click the **Upload Upgrade File** button. The new version appears as available for installation:



10. Click the **Manual Rolling Upgrade** link. The Manual Rolling Upgrade wizard appears.

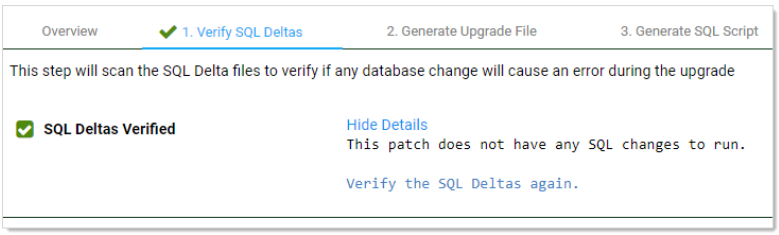
Task Two: Verifying SQL Changes (Wizard Step One)

1. Click the **Next** Button. The Verify SQL Deltas tab appears:



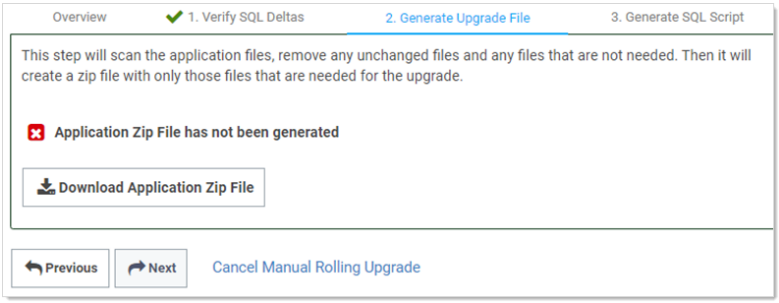
> Clicking the "Cancel Manual Rolling Upgrade" link, at any time, will take you to the Install Secret Server Upgrade page.

2. Click the **Verify SQL Deltas** button. This tests the prospective changes to see if errors result. If errors result, please contact Delinea Technical Support. If the verification succeeds:



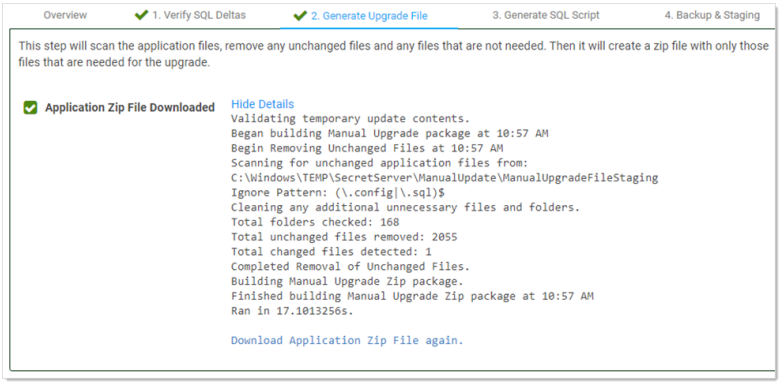
Task Three: Generating the Upgrade File (Wizard Step Two)

1. Click the **Next** button. The Generate Upgrade File tab appears:



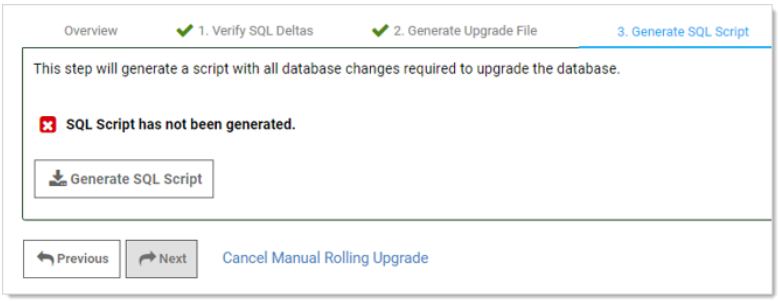
2. Click the **Download Application Zip File** button. This generates a zip file with only the changed files needed to upgrade the application files on the Web server nodes.

> This may take a few minutes to generate and download.

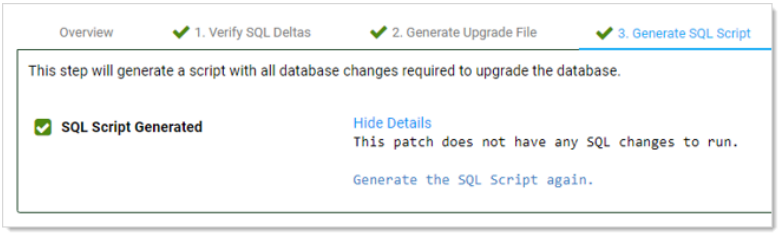


Task Four: Generating the SQL Script (Wizard Step Three)

1. Click the **Next** button. The Generate SQL Script tab appears:

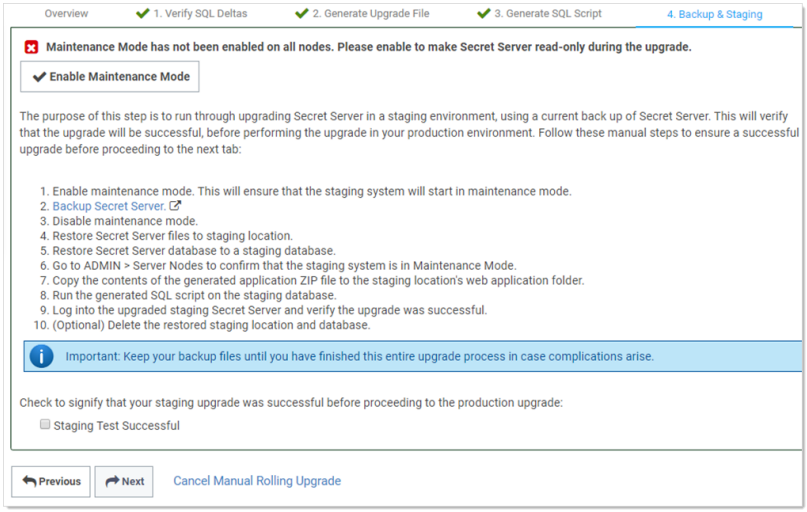


2. Click the **Generate SQL Script** button. This generates script file with all the database changes needed to upgrade the database. When finished:



The wizard proceeds to step four:

Task Five: Backing up and Staging (Wizard Step Four)



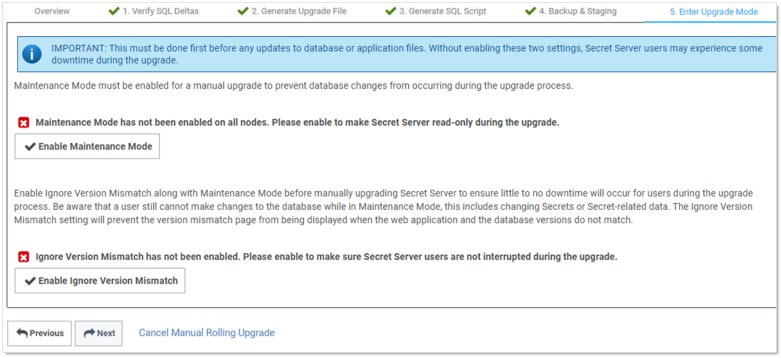
1. Click the **Enable Maintenance Mode** button.
2. Back up Secret Server: Type "backup" in the Admin search text box, and click the item that appears in the dropdown list to access the Backup Configuration page. Click the **Backup Now** button.

3. Click the **Disable Maintenance Mode** button.
4. Restore Secret Server files to the staging location:
   a. Copy the backup zip file to the staging location.
   b. Unzip the backup file.
   c. Copy the files to the web application folder.
5. Restore the Secret Server database to a staging database:
   a. In SQL Server Management Studio, right click on **Databases**.
   b. Click **Restore Database**.
   c. In **Source**, select **Device**.
   d. Select and add the backup database file location.
   e. Click **Ok**.
6. Search for **Secret Nodes** to confirm the staging system is in maintenance mode.
7. Copy the contents of the generated application Zip file to the staging location's web application folder. Typically, this is `C:\inetpub\wwwroot\SecretServer`.
8. Run the generated SQL script on the staging database.
9. Log on the upgraded staging Secret Server to verify the upgrade was successful.
10. (Optional) Delete the restored staging location and database.

    Important: Keep the backup files till you verify the upgrade was successful. You may need them if an issue develops.
11. Click to select the **Staging Test Successful** check box to confirm your staging upgrade was successful. This is your confirmation that there were no errors before performing the actual upgrade in your production environment. The confirmation is recorded.

Task Six: Starting Upgrade Mode (Wizard Step Five)

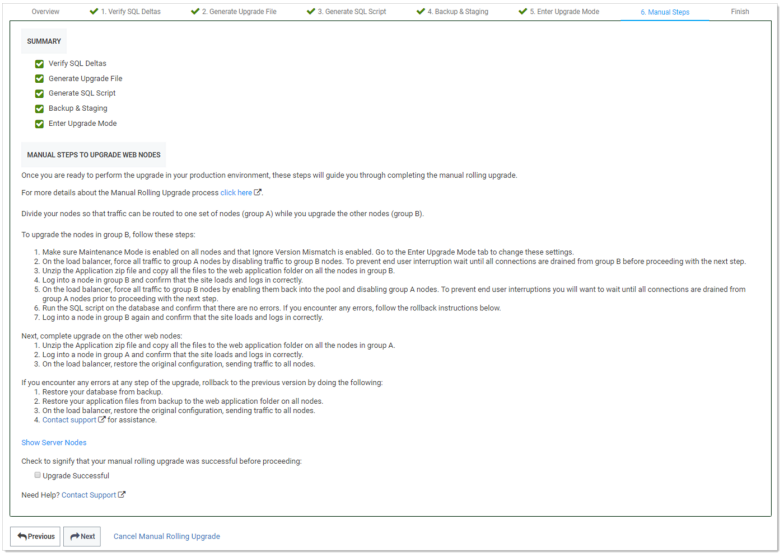
1. Click the **Next** button. The Enter Upgrade Mode tab appears:



2. Click the **Enable Maintenance Mode** button. This mode limits the activities of users on secrets, secret templates, password requirements, and others and can take several minutes to start. A confirmation popup

appears.

3. Click the **Enable** button to confirm the mode change. The popup disappears.
4. Click the **Enable Ignore Version Mismatch** button. This prevents users from being redirected to the Version Mismatch page. A confirmation popup appears.
5. Click the **Enable** button to confirm the setting change. The popup disappears.
6. Click the **Next** button. The Manual Steps tab appears:



Task Seven: Upgrading Web Nodes (Wizard Step Six)

To upgrade Web nodes:

1. Split your nodes into two approximately even groups (A and B) so that one group can service traffic while the other is upgrading.
2. Ensure "maintenance mode" and "ignore version mismatch" are enabled on each node. You can change them from the Enter Upgrade Mode tab.
3. On the load balancer, disable traffic to group B. To prevent traffic interruptions, ensure those nodes are all completely disabled before proceeding to the next step. Group A, alone, now handles the traffic. For example, on a F5 Big-IP load balancer you:
   a. Select the Members tab on the pool page.
   b. Select the node to disable.
   c. Click Force Offline.
4. For each node in group B:
   a. Navigate to the Downloads folder.
   b. Extract all the files from the application zip file downloaded earlier.

c. Copy the extracted files to the Web application folder.

d. Log onto the node to ensure the site correctly loads and logs on.

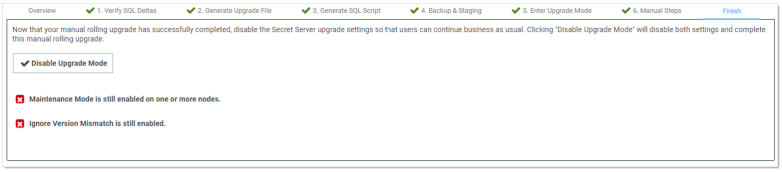
5. On the load balancer, enable the group B nodes to return them to the pool.
6. Disable traffic to group A. To prevent traffic interruptions, ensure those nodes are all completely disabled before proceeding to the next step. Group B, alone, now handles the traffic.
7. Execute the script you created on the database, confirming there are no errors. If there are errors, follow the rollback instructions.
8. Log onto each group B node again to ensure the site correctly loads and logs on.
9. For each node in group A:

   a. Navigate to the Downloads folder.

   b. Extract all the files from the application zip file downloaded earlier.

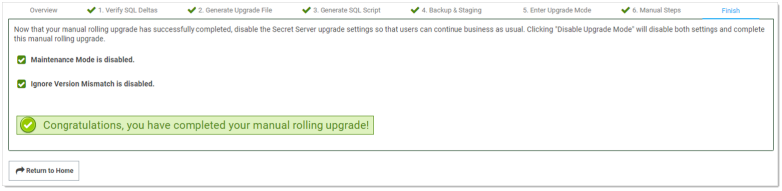
   c. Copy the extracted files to the Web application folder.

   d. Log onto the node to ensure the site correctly loads and logs on.
10. On the load balancer, enable the group A nodes to return them to the pool, restoring the original configuration and returning traffic to all nodes.
11. Click to select the **Upgrade Successful** check box.
12. Click the **Next** button. The Finish tab appears:



Task Eight: Finishing up (Wizard Step Seven)

1. Click the **Disable Upgrade Mode** button. A Finish Manual Rolling Upgrade popup appears. This popup both disables maintenance mode and disables the ignore version mismatch setting.
2. Click the **Disable** button. The popup disappears, and a completion message appears:



Troubleshooting and Notes

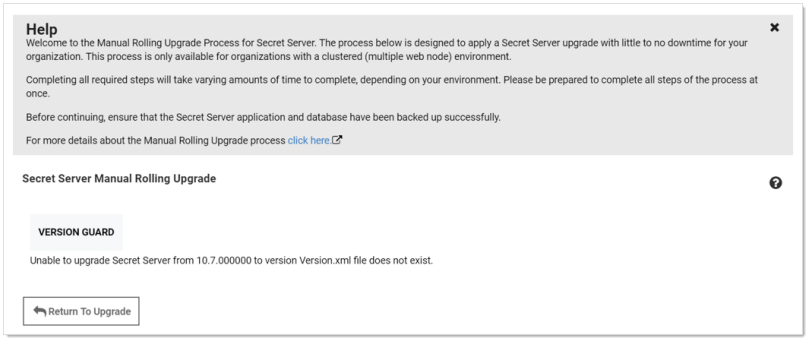
Rolling Back to the Previous Version

If you encounter errors at any step of the upgrade, rollback to the previous Secret Server version:

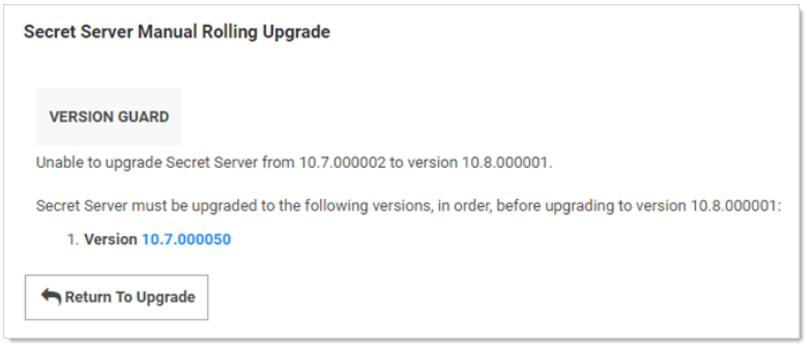
1. Restore the database from the backup.
2. Restore the application files from the backup files to the Web application folder on all nodes.
3. On the load balancer, restore the original configuration, sending traffic to all nodes.
4. For assistance, contact us.

Version Guard

If an uploaded upgrade file cannot be used to upgrade the current version of Secret Server, then "Version Guard" will block the upgrade and provide instructions on how to continue:



This usually occurs when not completing the perquisite steps in order. Click the **Return To Upgrade** button to return you to the first upgrade page to remedy the situation.



This page also list the blocking versions that you must upgrade to prior to running the manual rolling upgrade.

New Advanced Configuration Setting

There is a new setting called "Manual Upgrade: Allow version mismatch while in Maintenance Mode." This setting, which only applies in maintenance mode, prevents Secret Server from redirecting users to the version mismatch message page.

New Audit Type

To support the manual rolling upgrade, there is a new audit type–ManualUpgrade. Its audits are stored in the tbAudit table and record the following actions:

- CANCEL
- COMPLETED
- GENERATE DB SCRIPT
- GENERATE UPGRADE ZIP
- STAGING TEST
- STARTED
- VERIFY DELTAS

Manual Rolling Upgrade

This topic only applies to **Secret Server On-Premises**.

Introduction

The manual rolling upgrade provides a way to upgrade Secret Server with little to no downtime. That is, users will continue to have secret access during the upgrade.

This procedure only applies to clustered (multiple Web node) Secret Server environments environment.

Prerequisites

The administrator role needs the following Delinea permissions:

- Administer Configuration
- Administer Nodes
- Administer Backup

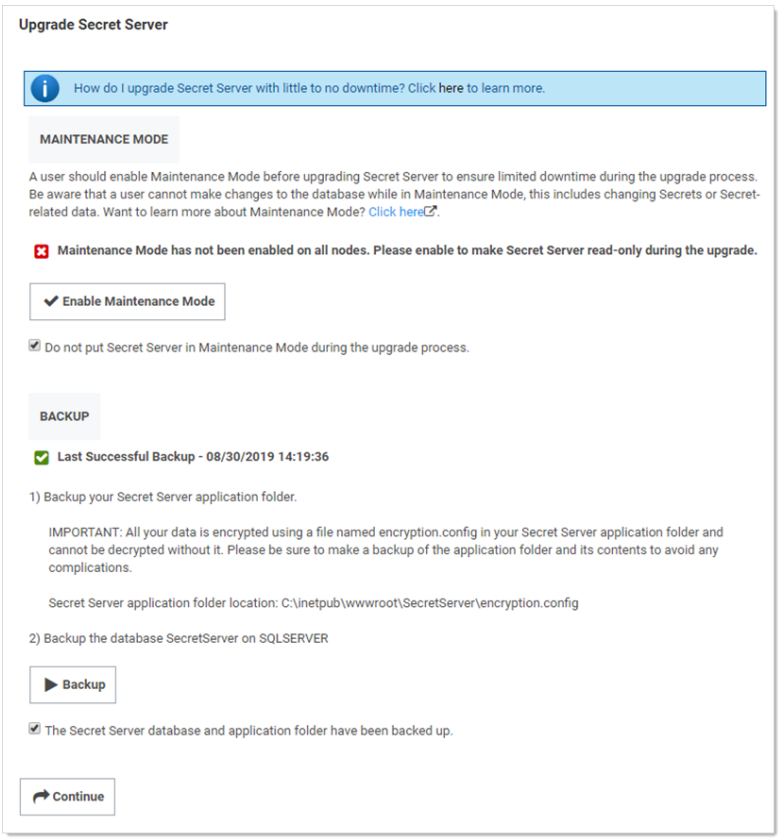
In addition, the role:

- Needs a database login with permission to change the database
- Requires access with permission to update files on web servers
- Must go through the current upgrade process
- Must not turn on maintenance mode until needed

Procedure

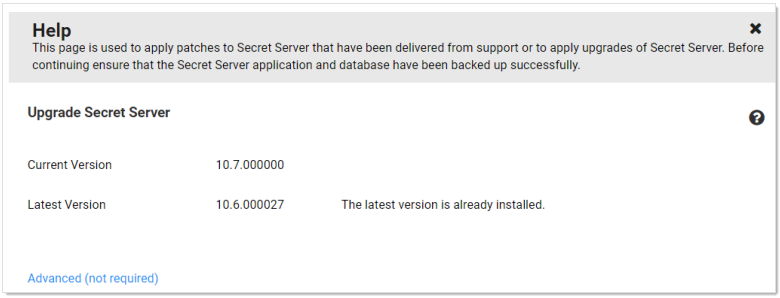
Task One: Uploading the Upgrade

1. Download the latest version of Secret Server.
2. Search for **Upgrade**:

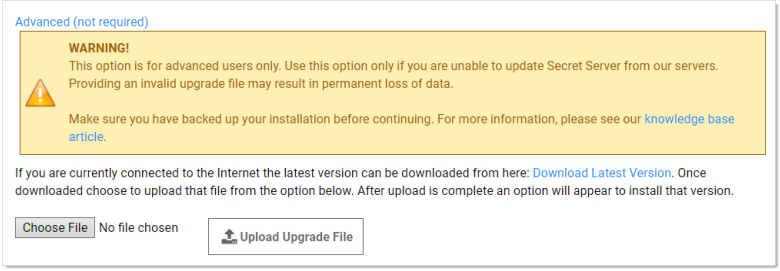


3. **Important:** Click to select the **Do not put Secret Server in Maintenance Mode during the upgrade process** check box.
4. Backup the Secret Server application folder.

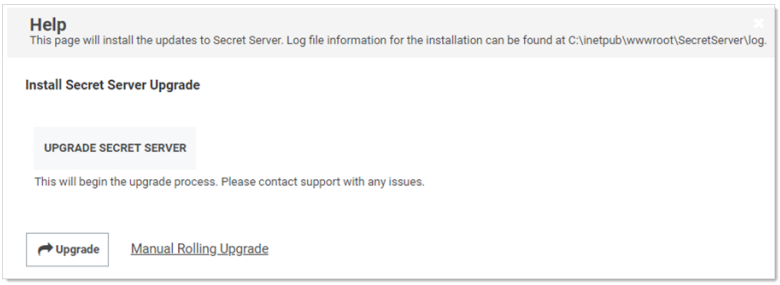
   Important: Ensure the encryption.config file is backed up. It is located at `c:\inetpub\wwwroot\SecretServer\encryption.config`.
5. Click the **Backup** button to back up the Secret Server database.
6. Click the **Continue** button. The Upgrade Secret Server page appears:



7. Click the **Advanced (not required)** link. The Advanced section appears:



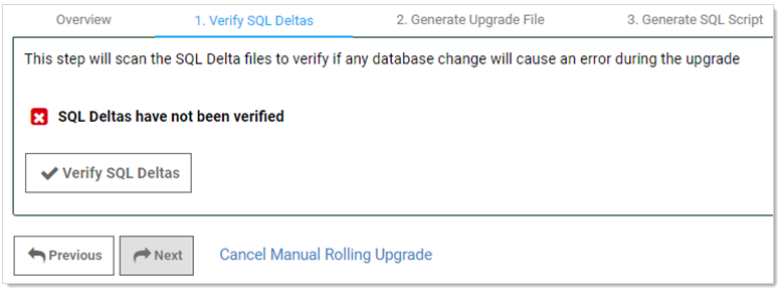
8. Click the **Choose File** button, and select the zip file you downloaded earlier to upgrade to.
9. Click the **Upload Upgrade File** button. The new version appears as available for installation:



10. Click the **Manual Rolling Upgrade** link. The Manual Rolling Upgrade wizard appears.

Task Two: Verifying SQL Changes (Wizard Step One)

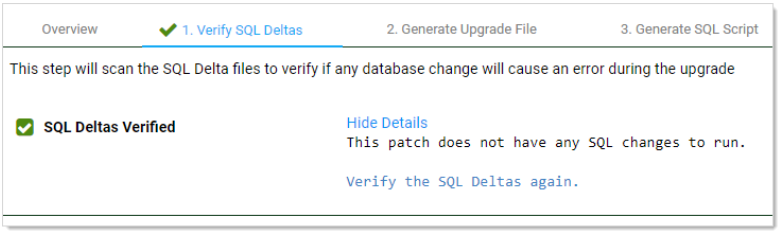
1. Click the **Next** Button. The Verify SQL Deltas tab appears:



> Clicking the "Cancel Manual Rolling Upgrade" link, at any time, will take you to the Install Secret Server Upgrade page.

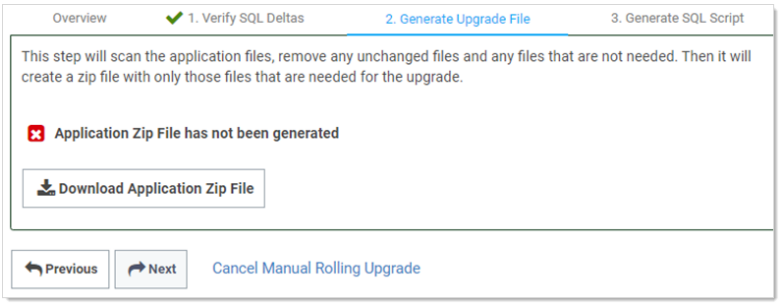
2. Click the **Verify SQL Deltas** button. This tests the prospective changes to see if errors result. If errors result,

please contact Delinea Technical Support. If the verification succeeds:



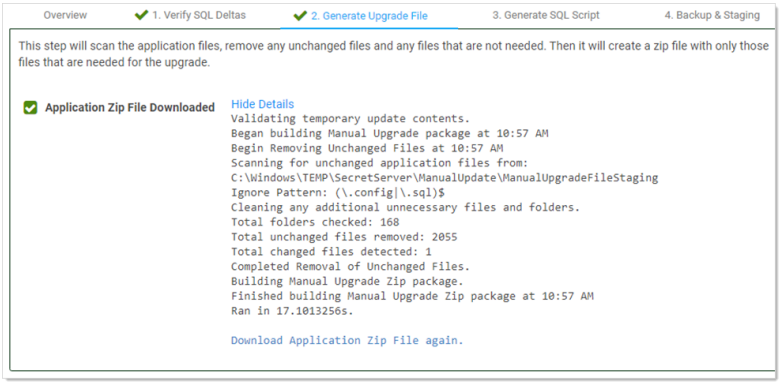
Task Three: Generating the Upgrade File (Wizard Step Two)

1. Click the **Next** button. The Generate Upgrade File tab appears:



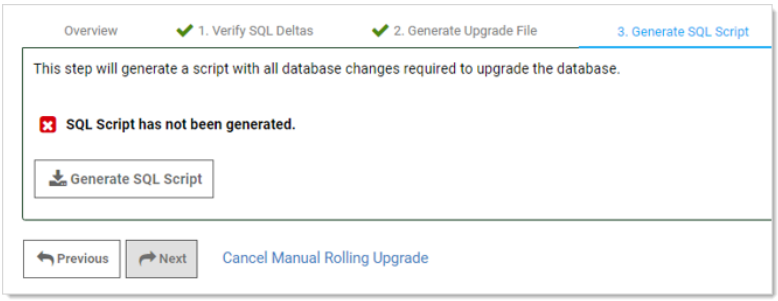
2. Click the **Download Application Zip File** button. This generates a zip file with only the changed files needed to upgrade the application files on the Web server nodes.

> This may take a few minutes to generate and download.



Task Four: Generating the SQL Script (Wizard Step Three)

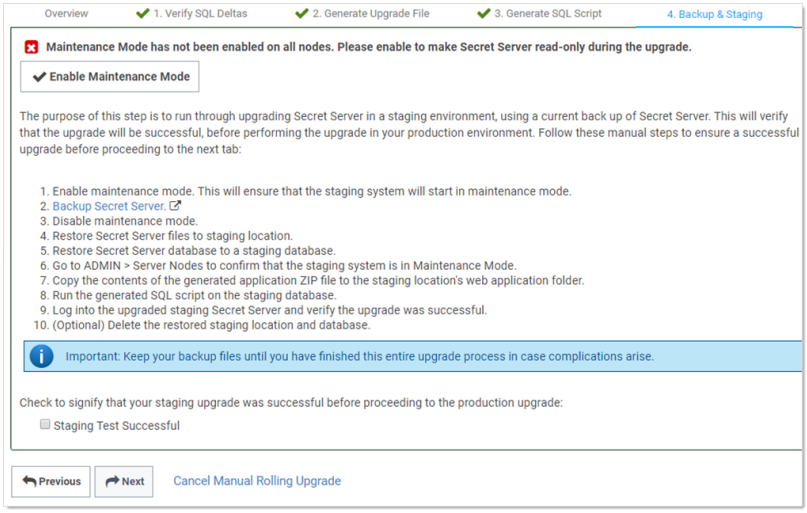
1. Click the **Next** button. The Generate SQL Script tab appears:



2. Click the **Generate SQL Script** button. This generates script file with all the database changes needed to upgrade the database. When finished:

   The wizard proceeds to step four:

Task Five: Backing up and Staging (Wizard Step Four)



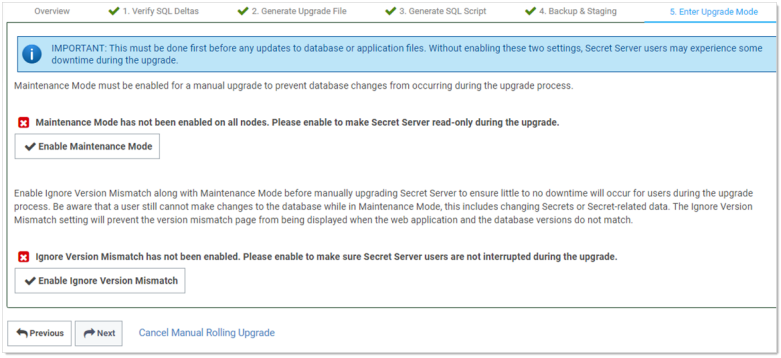
1. Click the **Enable Maintenance Mode** button.
2. Back up Secret Server: Type "backup" in the Admin search text box, and click the item that appears in the dropdown list to access the Backup Configuration page. Click the **Backup Now** button.

3. Click the **Disable Maintenance Mode** button.
4. Restore Secret Server files to the staging location:
   a. Copy the backup zip file to the staging location.
   b. Unzip the backup file.
   c. Copy the files to the web application folder.
5. Restore the Secret Server database to a staging database:
   a. In SQL Server Management Studio, right click on **Databases**.
   b. Click **Restore Database**.
   c. In **Source**, select **Device**.
   d. Select and add the backup database file location.
   e. Click **Ok**.
6. Search for **Secret Nodes** to confirm the staging system is in maintenance mode.
7. Copy the contents of the generated application Zip file to the staging location's web application folder. Typically, this is `C:\inetpub\wwwroot\SecretServer`.
8. Run the generated SQL script on the staging database.
9. Log on the upgraded staging Secret Server to verify the upgrade was successful.
10. (Optional) Delete the restored staging location and database.

    Important: Keep the backup files till you verify the upgrade was successful. You may need them if an issue develops.
11. Click to select the **Staging Test Successful** check box to confirm your staging upgrade was successful. This is your confirmation that there were no errors before performing the actual upgrade in your production environment. The confirmation is recorded.

Task Six: Starting Upgrade Mode (Wizard Step Five)

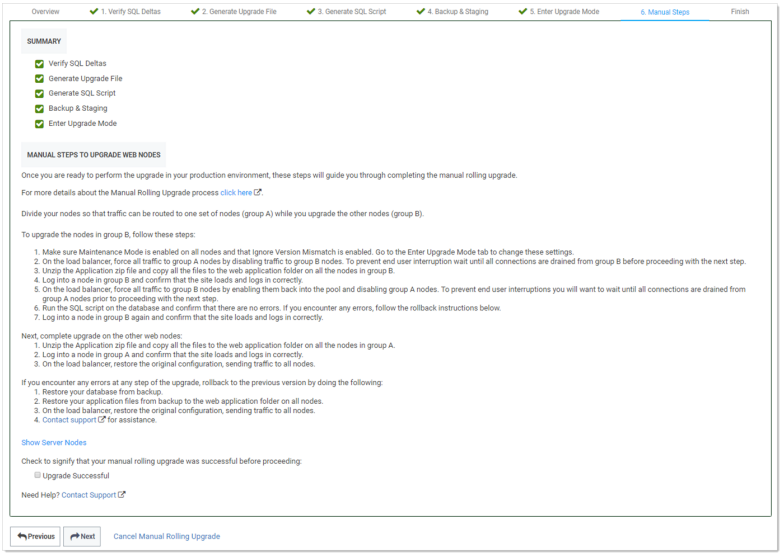
1. Click the **Next** button. The Enter Upgrade Mode tab appears:



2. Click the **Enable Maintenance Mode** button. This mode limits the activities of users on secrets, secret templates, password requirements, and others and can take several minutes to start. A confirmation popup

appears.

3. Click the **Enable** button to confirm the mode change. The popup disappears.
4. Click the **Enable Ignore Version Mismatch** button. This prevents users from being redirected to the Version Mismatch page. A confirmation popup appears.
5. Click the **Enable** button to confirm the setting change. The popup disappears.
6. Click the **Next** button. The Manual Steps tab appears:



Task Seven: Upgrading Web Nodes (Wizard Step Six)

To upgrade Web nodes:

1. Split your nodes into two approximately even groups (A and B) so that one group can service traffic while the other is upgrading.
2. Ensure "maintenance mode" and "ignore version mismatch" are enabled on each node. You can change them from the Enter Upgrade Mode tab.
3. On the load balancer, disable traffic to group B. To prevent traffic interruptions, ensure those nodes are all completely disabled before proceeding to the next step. Group A, alone, now handles the traffic. For example, on a F5 Big-IP load balancer you:
   a. Select the Members tab on the pool page.
   b. Select the node to disable.
   c. Click Force Offline.
4. For each node in group B:
   a. Navigate to the Downloads folder.
   b. Extract all the files from the application zip file downloaded earlier.

c. Copy the extracted files to the Web application folder.

d. Log onto the node to ensure the site correctly loads and logs on.

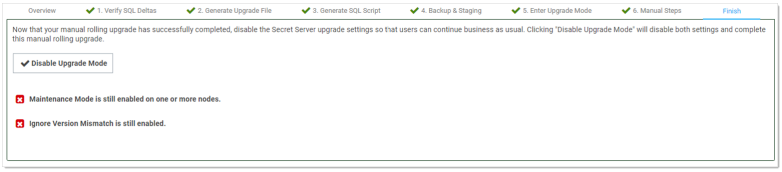
5. On the load balancer, enable the group B nodes to return them to the pool.
6. Disable traffic to group A. To prevent traffic interruptions, ensure those nodes are all completely disabled before proceeding to the next step. Group B, alone, now handles the traffic.
7. Execute the script you created on the database, confirming there are no errors. If there are errors, follow the rollback instructions.
8. Log onto each group B node again to ensure the site correctly loads and logs on.
9. For each node in group A:

   a. Navigate to the Downloads folder.

   b. Extract all the files from the application zip file downloaded earlier.

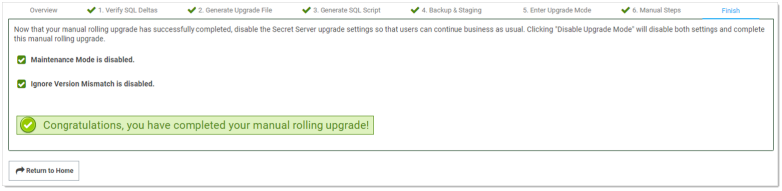
   c. Copy the extracted files to the Web application folder.

   d. Log onto the node to ensure the site correctly loads and logs on.
10. On the load balancer, enable the group A nodes to return them to the pool, restoring the original configuration and returning traffic to all nodes.
11. Click to select the **Upgrade Successful** check box.
12. Click the **Next** button. The Finish tab appears:



Task Eight: Finishing up (Wizard Step Seven)

1. Click the **Disable Upgrade Mode** button. A Finish Manual Rolling Upgrade popup appears. This popup both disables maintenance mode and disables the ignore version mismatch setting.
2. Click the **Disable** button. The popup disappears, and a completion message appears:



Troubleshooting and Notes

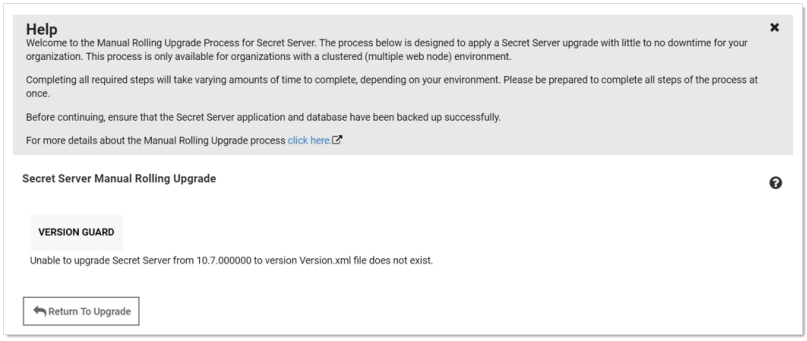
Rolling Back to the Previous Version

If you encounter errors at any step of the upgrade, rollback to the previous Secret Server version:

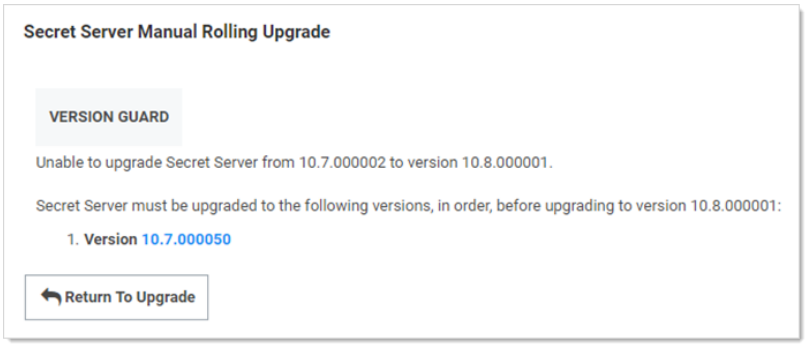
1. Restore the database from the backup.
2. Restore the application files from the backup files to the Web application folder on all nodes.
3. On the load balancer, restore the original configuration, sending traffic to all nodes.
4. For assistance, contact us.

Version Guard

If an uploaded upgrade file cannot be used to upgrade the current version of Secret Server, then "Version Guard" will block the upgrade and provide instructions on how to continue:



This usually occurs when not completing the perquisite steps in order. Click the **Return To Upgrade** button to return you to the first upgrade page to remedy the situation.



This page also list the blocking versions that you must upgrade to prior to running the manual rolling upgrade.

New Advanced Configuration Setting

There is a new setting called "Manual Upgrade: Allow version mismatch while in Maintenance Mode." This setting, which only applies in maintenance mode, prevents Secret Server from redirecting users to the version mismatch message page.

New Audit Type

To support the manual rolling upgrade, there is a new audit type–ManualUpgrade. Its audits are stored in the tbAudit table and record the following actions:

- CANCEL
- COMPLETED
- GENERATE DB SCRIPT
- GENERATE UPGRADE ZIP
- STAGING TEST
- STARTED
- VERIFY DELTAS

Upgrading Secret Server Without Outbound Access

This topic only applies to **Secret Server On-Premises**.

Upgrading to Secret Server version 10.0.000000 and above will require configuring integrated pipeline mode on the Secret Server Application Pool. Please see "Changing IIS to Not Stop Worker Process in IIS 7.0 and Later" on page 254 for details on configuring integrated pipeline mode in IIS. If you use Integrated Windows Authentication you will also need to update IIS authentication settings as detailed in "Configuring Integrated Windows Authentication" on page 389. If you are at version 9.1.000000 and below, you will need to first upgrade to 9.1.000001 before you can upgrade to 10.0.000000 and above.

How Upgrades Work

Secret Server periodically polls our update server to detect updates. If your Secret Server instance is on an internal network that has no outbound access or goes through a proxy, Secret Server will not be able to perform updates automatically.

If this is the case, outbound access is needed to the following connections in your firewall if you want automatic updates:

- `d36zgw9sidnotm.cloudfront.net:443`
- `updates.thycotic.net:443`
- `updates.thycotic.net:80`

The following steps can be used to perform an upgrade for versions 7.1.000015 and higher. If you have an older version of Secret Server, please contact Delinea technical support for assistance.

Procedure

Step 1: Open the Upgrade Secret Server Wizard

From a computer that has outbound network access and Secret Server access, follow these steps:

1. Open the Secret Server Upgrade page:
   a. In a web browser, go to: `http://<YourSecretServerURL>/Installer.aspx?patch=true`
   b. Replace `<YourSecretServerURL>` with your actual Secret Server URL.
   c. The upgrade wizard will appear.
2. Enable Maintenance Mode:
   a. Click **Enable Maintenance Mode**.

      This temporarily prevents users from changing roles, secrets, or secret-related data such as dependencies, templates, and password requirements.
   b. For more information, see Maintenance Mode FAQ.
3. Back up Secret Server:
   a. Back up the Secret Server application folder
   b. Back up the Secret Server database.
4. To confirm backup completion, on the upgrade page, select the checkbox labeled: **The Secret Server database and application folder have been backed up**.
5. Click **Continue**. The next page of the wizard will appear.

Step 2: Get and Upload the Latest .zip File

1. Download the latest version of the `.zip` file by clicking the **Download Latest Version** button on the installer page.

   Example file name: `Version_10_2_000000.zip`. Note where you save it. You also can find the downloadable update files below.
2. Click the **Choose File** button to add the Secret Server `.zip` file you just downloaded.

   > To verify the file hashes for the latest version using the posted hash values, refer to "Secret Server Download Hashes" on page 49.

   > Do **not** use the fresh-install `SecretServer.zip` file or `setup.exe` that is first downloaded from Delinea.com. Only use the **Get Latest Version** link–there are differences between the upgrade file and the fresh-install zip file.
3. Click the **Upload Upgrade File** button. You will see a message confirming the file was successfully uploaded, and the **Install This Version** button appears.
4. Click the **Install this Version** button. The Upgrade Secret Server page appears (not shown).

Step 3: Upgrade Secret Server

1. Click the **Upgrade** button. The upgrade automatically processes, and once it has finished you will see a confirmation page.
2. Click **Return to Home** to return to the dashboard.

Offline Installation Download Files

If you do not have access to another installation of Secret Server or you are upgrading from an earlier version, click one of the following links, depending on your *current* installed version:

- 8.4.000003 or earlier
- 8.4.000004 to 9.1.000000
- 9.1.000001 to 10.9.000003
- 10.9.000005 to 11.5.000002
- 11.5.000002 or later

Secret Server On-Prem Upgrade Checklist

1. Make sure the environment complies with Secret Server's system requirements.

- Run the PowerShell command below on each server node and confirm that it has .NET Framework 4.8 or newer:

  (Get-ItemProperty "HKLM:SOFTWARE\Microsoft\NET Framework Setup\NDP\v4\Full").version
- SQL Express is intended for POC environments only.
- SQL Server and the Secret Server database should be set to the collation SQL_Latin1_General_CP1_CI_AS.

> Using the SQL_Latin1_General_CP1_CI_AS collation is super important to avoid issues after installation.

- Run the SQL query below against the Secret Server database to confirm that the SQL compatibility level is 110 and above:

```
USE <YOURSECRETSERVERDB>; GO SELECT compatibility_level FROM sys.databases WHERE name =
'<YOURSECRETSERVERDB>'; GO
```

2. Check if DPAPI is enabled by navigating to the **Admin > DPAPI**. If yes, disable it by clicking on the Decrypt Key Using DPAPI button. Repeat and perform this step on each server node.

3. Check if **Integrated Windows Authentication** is enabled in Secret Server by navigating to the **Admin > Directory services configuration**. If yes, make sure that ONLY Windows Authentication is enabled, and all other authentication is disabled for the Secret Server site on all server nodes. Otherwise, both Forms and Anonymous Authentication should be enabled, and all other authentication is disabled. For steps on how to do so, click here.

4. Save a full back-up of the application files (C:\inetpub\wwwroot\SecretServer) of each server node. NOTE: The backed-up `encryption.config` file should be the unencrypted version.

5. Save a full back-up of the Secret Server database.

6. Make sure there is enough disk space on the database server, specifically the drive where the database and transaction log files are stored.

7. If the environment has SQL merge replication, be aware that support for this scenario is a deprecated feature no longer supported by Delinea with additional requirements around upgrades. Please review this documentation. In most scenarios, we would recommend AlwaysOn.

8. Get the current version of the Secret Server instance using the SQL query below, then request for the upgrade script from Delinea Support. Ensure to provide the exact current version of your Secret Server instance.

```
select top 1 VersionNumber as VersionString ,cast(SUBSTRING( VersionNumber ,0 ,CHARINDEX
('.',VersionNumber,0) ) as int) as Major ,cast(SUBSTRING( left(VersionNumber ,charindex('.',
VersionNumber, charindex('.', VersionNumber)+1)-1) ,CHARINDEX('.',VersionNumber,0)+1 ,LEN
(left(VersionNumber ,charindex('.', VersionNumber ,charindex('.', VersionNumber)+1)+1)) ) as
int) as Minor ,cast(SUBSTRING( VersionNumber ,LEN(left(VersionNumber ,charindex('.',
VersionNumber ,charindex('.', VersionNumber)+1)+1)) ,LEN(VersionNumber) - LEN(left
(VersionNumber ,charindex('.', VersionNumber, charindex('.', VersionNumber)+1)-1)) ) as int)
as Build from tbVersion order by Major desc, Minor desc, Build desc
```

9. Download the correct Secret Server application files and extract ss_update.zip to a temporary folder on each server node (e.g., Desktop, C:\Temp).

- For the latest release: https://updates.thycotic.net/secretserver/getlatestversion.aspx?alwayslatest=true

10. Make sure there is an account with the permissions below that can be used at the time of the upgrade:

- Administrator access on all server nodes or machines where Secret Server is installed.
- Can log in via SQL Server Management Studio, has Write/Alter SQL Server permission to the Secret Server database and has ability to restore from the full backup if needed.
- Local Account which can be used to log into the Secret Server application as an Admin.

> NOTE: Secret Server may be offline during the upgrade, so make sure the account's credentials are available outside the application.

11. Open Programs and Features on the server node and make sure Microsoft Monitoring Agent is not installed. Repeat and perform this step on each server node.

The APM feature in SCOM Agent on the server node causes the IIS application pool to crash. If it is necessary to have the SCOM Agent on the server node, reinstall it with the “NOAPM = 1” switch using msiexec.exe to exclude the APM feature.

12. Plan a sufficient change window, typically two hours, to accommodate the work needed for the upgrade, as well as any rollbacks that need to happen if errors are encountered. Although, the method of upgrade, size and complexity of the environment will determine the amount of actual service disruption to the end users.

Don'ts:

1. Do not proceed with the upgrade without a full back-up of the Secret Server application files with the unencrypted version of encryption.config and database.config files.

2. Do not proceed with the upgrade if you encounter any SQL error when running the upgrade script against the Secret Server database in SQL Server Management Studio. Take a screenshot of the error message, then rollback the transaction.

3. If the environment has a SQL High Availability setup, do not run the upgrade script against all databases. Run it on the primary database or listener.

Do's:

1. Stop the Secret Server application pool before starting the upgrade process. If it is a clustered Secret Server instance, the application pool can be stopped one at a time.

2. Add BEGIN TRANSACTION on top (Line 1) of the upgrade script, search for COMMIT TRAN at the end of the script and mark it as a comment (i.e., --COMMIT TRAN;). If the upgrade script ran successfully, proceed with commit by removing the comment tag (i.e., COMMIT TRAN;). Otherwise, take a screenshot of the error message in SQL Server Management Studio and run ROLLBACK TRANSACTION in the same query window.

3. After upgrading the database and overwriting the server node's application files, start the Secret Server application pool on it and perform an IISRESET. If it is a clustered Secret Server instance, make sure that Secret Server is accessible on the first server node, then proceed with overwriting the application files on the second node. Once done, make sure that Secret Server is accessible on the second node, then repeat the process on the remaining server nodes. Remember to stop the Secret Server application pool, overwrite the application files, start the application pool, and perform an IISRESET on each server node.

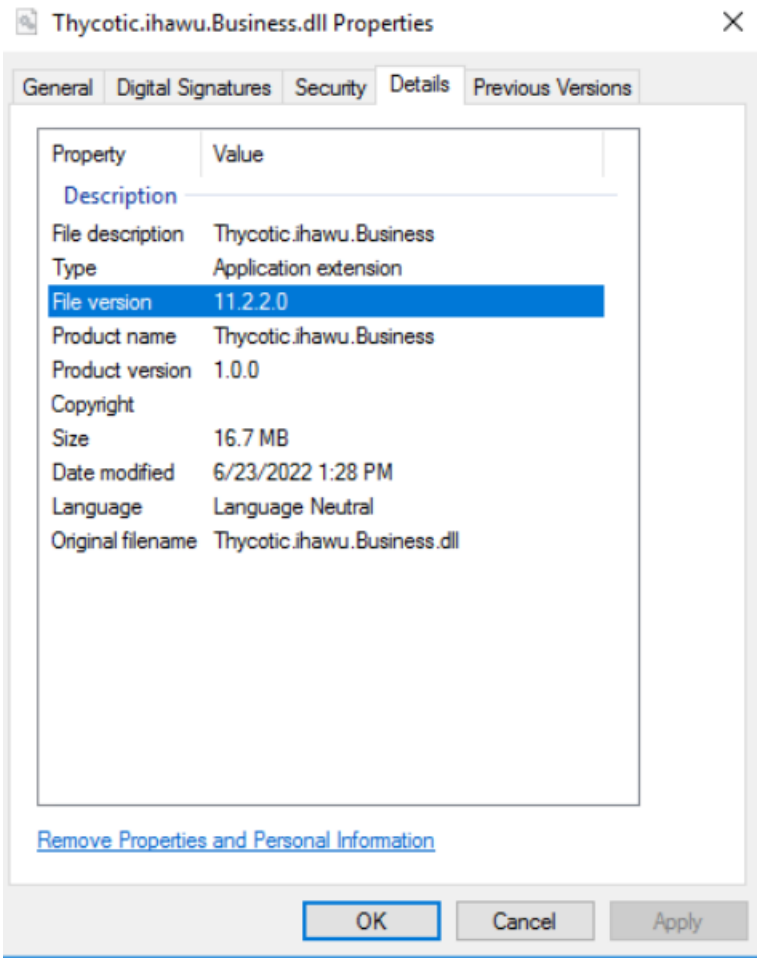
Post upgrade tasks & issues

1. For the "Binary Version Mismatch" error, make sure the Thycotic.ihawu.Business.dll file has the correct upgraded version.

a. Navigate to the C:\inetpub\wwwroot\SecretServer\bin folder of the server node/s.

b. Right-click on the Thycotic.ihawu.Business.dll file and select Properties.

c. Click on the Details tab and check the File Version.



d. If the version is incorrect, stop the Secret Server application pool and overwrite application files (C:\inetpub\wwwroot\SecretServer) with the same version as the database.

2. For “The version of your database does not match the version of your application” error, get the current version of Secret Server in the database by running the SQL query below:

```
select top 1 VersionNumber as VersionString ,cast(SUBSTRING( VersionNumber ,0 ,CHARINDEX
('.',VersionNumber,0) ) as int) as Major ,cast(SUBSTRING( left(VersionNumber ,charindex('.',
VersionNumber, charindex('.', VersionNumber)+1)-1) ,CHARINDEX('.',VersionNumber,0)+1 ,LEN
(left(VersionNumber ,charindex('.', VersionNumber ,charindex('.', VersionNumber)+1)+1)) ) as
int) as Minor ,cast(SUBSTRING( VersionNumber ,LEN(left(VersionNumber ,charindex('.',
VersionNumber ,charindex('.', VersionNumber)+1)+1)) ,LEN(VersionNumber) - LEN(left
(VersionNumber ,charindex('.', VersionNumber, charindex('.', VersionNumber)+1)-1)) ) as int)
as Build from tbVersion order by Major desc, Minor desc, Build desc
```

If the version is incorrect, please do the following:

a. Restore a working back-up copy of the Secret Server database.

b. Run the upgrade script provided by Delinea Support.

3. For IIS errors, make sure the Secret Server application pool on all server nodes has the following Advanced Settings:

- Managed Pipeline Mode: Integrated
- Start Mode: AlwaysRunning
- Identity: Should be the application pool service account running Secret Server
- Idle Timeout(minutes): 0
- Load User Profile: True
- Regular Time Interval (minutes): 0

4. The application pool service account should have the following required permissions:

- Modify Windows NTFS permission on the C:\Windows\Temp and C:\inetpub\wwwroot\SecretServer on all server nodes
- Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment > “Log on as a batch job” policy
- Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment > “Impersonate a client after authentication” policy

5. Re-enter the application pool service account credentials in case its password has changed.

6. If the server nodes are behind a load balancer and Secret Server is not loading via load-balanced URL, access Secret Server directly from each server node using localhost.

7. If issue persists, open a support case, and attach a zipped Secret Server logs located in

C:\inetpub\wwwroot\SecretServer\log of the server node(s) having an issue.

Navigation and Customization

The Navigation and Customization section of the Secret Server documentation provides comprehensive guidance on tailoring the user interface to enhance usability and efficiency. These features collectively empower users to customize their Secret Server experience, improving both the aesthetic and functional aspects of the platform to better align with organizational needs and personal preferences.

Navigation

- "All Secrets Page" on page 1131 This page serves as a master list of all stored secrets, allowing users to customize columns and access secret actions quickly.
- "Application Dashboard" on page 182 The main interface for searching and viewing secrets, offering customizable widgets and a centralized view of essential information.
- "Configuration Search" on page 184 A dynamic tool for locating specific configurations within Secret Server, streamlining administrative tasks.
- "Global Search" on page 184 A feature that provides a dynamic search experience across the platform, with filters for different categories like secrets and folders.

- "Main Navigation Drawers" on page 184 Enhanced navigation through drawer-style menus, offering quick access to various sections such as Home, Secrets, and Reports.
- "Secret Folder-Tree Panel" on page 1084 A panel that provides a hierarchical view of secret folders, allowing users to navigate and manage secrets efficiently.

Customization

- "Setting Color Modes" on page 177 Users can personalize the visual appearance of Secret Server by selecting different color modes, enhancing readability and comfort.
- "Configuring Custom Logos" on the next page Organizations can brand their Secret Server instance by uploading custom logos, ensuring a consistent corporate identity.
- "Configuring Global Banners" on the next page Administrators can set up global banners to display important messages or alerts across the platform, ensuring critical information is communicated effectively.
- "Enabling Login Banners" on page 176 Login banners can be configured to display messages or terms of use before users access the system, enhancing security and compliance.
- "Configuring User Experience" on page 177 : Focuses on tailoring the interaction between users and Secret Server.
-

Customization

The Customization section provides guidance on personalizing the user interface to align with organizational branding and user preferences. This section includes:

- "Setting Color Modes" on page 177 Users can personalize the visual appearance of Secret Server by selecting different color modes, enhancing readability and comfort.
- "Configuring Custom Logos" on the next page Organizations can brand their Secret Server instance by uploading custom logos, ensuring a consistent corporate identity.
- "Configuring Global Banners" on the next page Administrators can set up global banners to display important messages or alerts across the platform, ensuring critical information is communicated effectively.
- "Enabling Login Banners" on page 176 Login banners can be configured to display messages or terms of use before users access the system, enhancing security and compliance.
- "Configuring User Experience" on page 177: Focuses on tailoring the interaction between users and Secret Server.

Configuring Custom Logos

You can add your own branding by adding customized logos to Secret Server. The logos only apply to the current UI–the classic UI is not supported. The logos and their requirements are listed in the table below.

Table: Custom Logo Specifications

Mode	Format	Required Pixel Dimensions	Maximum File Size
Light	Full-sized	200×50	1 MB
Light	Icon	50×50	1 MB
Dark	Full-sized	200×50	1 MB
Dark	Icon	50×50	1 MB
Light	Login	400×400	1 MB
Dark	Login	400×400	1 MB

To use custom logos:

1. Create images for all six of the listings in the table above. The images can be svg, png, or jpg. The images must be the exact dimensions listed and not over the maximum file size.
2. Search for **User Interface**.
3. Click the **Edit** button. The page becomes editable.
4. For each of the listed custom logos:
   a. Click the **Change** link. A file selection dialog box appears.
   b. Navigate to and select the image matching the description.
   c. Hover over the logo description on the left to see the exact size requirements for the specific logo.
5. Click **Save**. The images appear in the listing, and the logos are deployed to the application at the top of the user's profile.

Configuring Global Banners

Overview

You can configure a multipurpose global banner for all users and use it for maintenance, security, or policy notifications. You can set the banner style, text, a hyperlink, and an in-theme color, which is determined by the style. The styles include:

- Caution
- Error
- Failure

- Information
- Status
- Success
- Warning

The settings are available in the User Interface section.

Configuration

1. Search for **User Interface.**
2. Click **Edit**. The page becomes editable.
3. Click to select the **Show Custom Banner** check box. New controls appear below.
4. Type or paste the desired text in the **Banner Text** text box.
5. Type or paste the desired URL, if any, in the **Banner View Link** text box.
6. Click the **Banner Style** dropdown list to select one of the following:
   - Caution
   - Error
   - Failure
   - Information
   - Status
   - Success
   - Warning
7. Click **Save**.
8. Click **Preview Banner** to see your new banner.

   The Preview button is primarily for when you have previously dismissed the banner. The first time you save a new banner, it automatically appears at the top of every page, including the one you are on.

9. Click the **View** button inside your banner to go to the URL you entered.
10. Click the **Dismiss** button to remove the banner from all pages for that session.

Enabling Login Banners

If your company requires the login banner for usage agreements and conditions to be visible when users log into Secret Server:

To enable the login banner, follow the procedure below:

1. Search for **Login policy** and click **Edit** at the top right.
2. Select the checkbox for **Enable Login Policy**. The Force login policy check box and Login policy window will appear.

   Check **Force login policy** to force the user to accept the login policy that is displayed.

   Edit the text in the **Login policy** window if needed and click **Save.**
3. Log out of Secret Server and re-try logging in.

   On the Secret Server Login page, users logging into Secret Server will see the default message provided in the login policy box.

> Note that enabling login policy will override the value in "policy.txt", and your changes will not be lost after the upgrades.

> The login policy is not applicable to the mobile app and will not be shown.

Setting Color Modes

Overview

> As of version 11.4, the classic UI is no longer available to anybody.

Color mode is a color scheme (skin) for the UI. The color modes are System Default, Light, and Dark. System default means whatever color was chosen on your system for the Windows application default.

Setting Your Default Color Mode

1. Click the user icon at the top right of any page and select **User Preferences**. The User Preferences Page appears.
2. Click the **Settings** tab.
3. Click the **Color Mode** dropdown list to select the desire color mode. Your choices are:
   - Light Mode
   - Dark Mode
   - System Default: The color chosen for your Windows default application color.

   The mode changes right away–no need to save the change.

Configuring User Experience

Overview

The **User Experience** page is a part of general application configuration that focuses on tailoring the interaction between users and Secret Server. It encompasses settings that define how users engage with the system, ensuring that their experience is both efficient and secure.

Key aspects of the **User Experience** page include:

- Performance and Responsiveness: Settings like Search delay and inactivity timeouts are configured to optimize the application's responsiveness and ensure that users receive timely feedback, while maintaining security through automatic log-outs after periods of inactivity.
- Localization and Formatting: By setting the time zone, date, and time formats, the application can present information in a way that aligns with the user's regional preferences, enhancing usability and reducing confusion.
- Security and Compliance: Options such as requiring folders for secrets and managing password history, are designed to enforce security policies and compliance requirements, ensuring that sensitive information is handled appropriately.
- User Roles and Permissions: The default role for new users and language settings help streamline the onboarding process and ensure that users have the appropriate access and interface language from the start.

The **User Experience** page is designed to create a seamless, intuitive, and secure environment for users, balancing ease of use with necessary security measures.

Settings

To configure User Experience settings, search for **User Experience**, and click **Edit**. The following settings are available for configuration:

- **Search delay**: Sets the number of milliseconds a search waits after a user stops typing.
- **Force inactivity timeout**: Sets a time limit on idle sessions. Once a session expires, the user must log in again with their username and password.
- **Force inactivity timeout minutes**: Sets the inactivity time limit on idle sessions.
- **UI inactivity timeout**: Sets time in minutes. After this time elapses, the new UI will show an overlay to indicate that it has stopped making server calls and refreshing data. This is to limit workload for browsers tabs that are not active.
- **Time Zone**: Select the appropriate time zone from the drop-down. The server will run schedules and show dates in this timezone by default.
- **Default date format**: Select the related date format from the drop-down. All dates will render in this format unless a user preference overrides it.
- **Default time format**: Select the related time format from the drop-down. All times will render in this format unless a user preference overrides it.
- **Require Folder For Secrets**: Select this checkbox to require that all secrets to reside in a folder. Folders can be designated per secret on the All Secrets page.
- **All Secret Password History**: Select this checkbox to prevent users from reusing old passwords. When using the change password or bulk change password action, this will enforce that no passwords will be able to be reused for the password change on a secret.
- **Secret Password History**: Sets the number of secret password changes. When using the change password or bulk change password action this will enforce uniqueness across a specific number of password changes.
- **Secret Password Displayed Interval Minutes**: Sets the interval in minutes which must pass between audit entries, when a secret password is viewed. If set to 0, every secret display event is audited (no debounce). The

default value is 5 minutes.

- **Secret View Interval Minutes**: This setting controls the minimum time between "View" audits. It acts like a debounce (rate-limiting) mechanism, with the default time being 5 minutes.
- **Secret Comment Interval Minutes**: The number of minutes for which a secret can be viewed after entering a comment. Applies only when "Requires Comment" is enabled, and has a default range of 5 minutes.
- **Include Session Info on Each Audit**: If a secret has the *require comment* checkbox enabled, the ticket number will be applied to every audit on the secret during that session.
- **Password mask timeout (seconds)**: Sets the seconds before the password mask returns after viewing the password. After this time period has elapsed, a password field will hide this password and remove it from browser memory. Viewing the password again after this time period will require a request for the password from the server. Setting this to 0 will disable the feature.
- **Separate secret audit for comment**: When this checkbox is selected, a secret that requires a comment will have a separate audit event instead of combining Comment and View. View will only occur if a user views the secret.
- **Separate checkout and comment action**: When this checkbox is selected, the inline action menu on the secret grid will show both checkout and comment instead of combining them.
- **Checkout notification threshold**: Sets the percentage of time-elapsed since a secret was checked out, for when the checkout notification will be sent. If set to 0 the feature is disabled.
- **Enable Secret Check Out Extension**: Select this checkbox to allow users to extend the remaining check-out time for secrets.
- **Enable icon gathering**: Select this checkbox to enable downloading of favicons for secret URL values.
- **Show icons for secrets**: Select this checkbox to enable the display of icons for secrets in the secret list and the secret details page.
- **Application Language**: Select the default language for users from the drop-down.
- **Default New User Role**: Select the related role from the drop-down. All new users will be given the selected role, if any, in addition to inheriting roles from any groups they are in.
- **Approval allow approver change request time**: When true, the approver of an access request can change the start and end times for the requests.
- **Approval allow custom duration**: Allows the access requestor to specify a custom duration for the access request.
- **Approval allow minute durations**: List of allowed minute durations that can be requested for approval for secret access requests. If custom duration is allowed, these are simply quick pick options on a request.
- **Disable legacy bookmark pages**: Select this checkbox to allow customers to choose whether legacy bookmark pages are disabled (made invisible) or not. The option is activated by default, marking these pages as disabled.

This option can be toggled to view those bookmark pages that are used by legacy versions of Web Password Filler.

- **Enable request force checkout**: Select this checkbox to enable a user without force-checkout permission to request a force checkout of a secret.

When done, click **Save**.

Navigation

The Navigation section outlines the key components that facilitate efficient and intuitive access to secrets and configurations within the platform.

- "All Secrets Page" on page 1131 This page serves as a master list of all stored secrets, allowing users to customize columns and access secret actions quickly.
- "Application Dashboard" on page 182 The main interface for searching and viewing secrets, offering customizable widgets and a centralized view of essential information.
- "Configuration Search" on page 184 A dynamic tool for locating specific configurations within Secret Server, streamlining administrative tasks.
- "Global Search" on page 184 A feature that provides a dynamic search experience across the platform, with filters for different categories like secrets and folders.
- "Main Navigation Drawers" on page 184 Enhanced navigation through drawer-style menus, offering quick access to various sections such as Home, Secrets, and Reports.
- "Secret Folder-Tree Panel" on page 1084 A panel that provides a hierarchical view of secret folders, allowing users to navigate and manage secrets efficiently.

All Secrets Page

All Secrets is a master table of the secrets stored on Secret Server. It is a one-stop, searchable location for examining the status and properties of secrets. It is a supplement to, not a replacement for, the "Folders" on page 1075. It lists and you can sort by secret template, heartbeat status, sync status, machine, access date, username, and much more.

Click the **Secrets** menu item in the left menu to see the All Secrets Page.

Secret Columns

You can customize which columns are displayed by clicking the on the right side of the title bar. The sortable columns available are (the ones displayed by default are bolded):

- Active
- Auto Change Enabled
- Checked Out
- Checkout Enabled

- Checked Out User ID
- Checked Out User
- Created
- Days until Expiration
- QuantumLock Enabled
- **Favourite**
- **Folder**
- Folder Path
- Heartbeat
- Hide Password
- Inherits Permissions
- Last Accessed (When the logged in user last accessed a secret, not the last time a secret was accessed by anyone)
- Machine
- **Name**
- Notes
- Out of Sync
- Requires Approval
- Requires Comment
- **Secret Template**
- Username

Quick Launch and Actions

You can quickly access several secret actions from the All Secrets table by hovering the mouse pointer over the secret's row:

- Quick Launch: Secrets that display a rocket icon have secret launchers associated with them. Click the icon and a Select Launcher page appears. Click on the desired launcher from the list.
- More Actions: Click the **...** icon to
  - Audit: Brings you to the Audit tab of the secret's page.
  - Details: Brings you to the General tab of the secret's page.
  - Share: Brings you to the Sharing tab of the secret's page.

Other Features

The All Secrets page also allows you to:

- Select multiple secrets for "Bulk Operations" on page 195 by clicking the secret's check box. You can also download multiple secrets in a CSV file by clicking the download icon at the top of the table.
- Select the secret as a favorite by clicking the star icon.
- View supplemental information about the secret by clicking any blank area on the secret's row.
- Click the secret's name to go to that secret's page.
- Filter the secrets shown in the table by template, search text, or activity status.
- Click the "Secret Navigation Slideout" on page 1172.

Application Dashboard

The Secret Server dashboard is the main page for searching and viewing secrets. You access it by clicking the **Dashboard** menu item from the Home menu, or by navigating to **Admin > Dashboard**.

Dashboard Components

Overview Tab

The Overview tab provides several fixed widgets for getting a quick understanding of your Secret Server installation:

- **Approvals:** Your current in-process approvals. See "Access Request Overview" on page 1085.
- **Engine Status:** A scrollable list of distributed engine connections and activation statuses.
- **Heartbeat Status:** A graphic of the current status of your heartbeats: success, pending, or failed. When you click on one of the statuses, you are brought to a report page for that status. For example, **Reports > Secrets Failing Heartbeat**. When you click the **Heartbeat Status by Day** link , you are brought to the **Reports > Heartbeat Status by Day** page. See "Heartbeat Overview" on page 1058.
- **Most Used Secrets:** A table of the most recently accessed secrets, listed by date and folder.
- **Password Rotation:** The state of your current password rotations. When you click the **RPC by Day for today** link you are brought to the **Reports > RPC by Day** report page. See "RPC Overview" on page 900.

To see an overview of incoming system and subscription alerts, see the "Notification Inbox Overview" on page 329.

Customized Tabs

Tab Management

The following operations are available for creating custom tabs:

- **Create:** Click the **+** icon to the right of the tabs to create a new empty tab.
- **Delete:** Click **Remove tab page** on a tab and select **Confirm remove tab** to delete a tab. You can cancel changes by clicking **Cancel**. A confirmation pop up page appears.
- **Rename:** Click **Rename** on a tab to change the tab name. You can cancel changes by clicking the `Cancel` button.

- **Sort:** Click **Sort:** on a tab, the Sort menu will appear. Drag the tab names up and down inside the Sort menu to change the sort order of the tabs. When done, click **Save tab order**.

Dashboard Widgets

By default, the Overview tab contains above mentioned widgets (function boxes). You can add these widgets on custom tabs:

- Expired Secrets
- Favorite Secrets
- Out-of-Sync Secrets
- Recent Secrets
- Reports
- Request Management

Widget Types

Table: Dashboard Widgets

Widget	Description
Expired Secrets	Displays expired secrets.
Favorite Secrets	Displays secrets marked as favorites. Also appears on the Secret Navigation Slideout.
Out-of-Sync Secrets	Displays secrets that are out-of-sync–the heartbeat or RPC have failed.
Recent Secrets	Displays the secrets viewed most recently. Also appears on the Secret Navigation Slideout.
Report	Displays a report. Click the **Report Category** list to select a report from the drop-down menu. One report can be displayed per widget. Click the title of the report to navigate to the Report View page.
Request Management	Displays any requests pending for the logged in user.
+ Add Widget	Default widget that appears on an empty custom tab. When clicked, adds a widget that is not currently displayed to the Dashboard. This widget's function is duplicated automatically when you add a new Dashboard tab. You cannot remove this widget.

The Search and Browse widgets cannot be rearranged. They always remain in the top left region of the tab.

Managing Widgets

The following operations are available (by clicking the **More Options** icon on a widget) for managing widgets:

- **Delete:** Delete the widget from this custom tab.
- **Refresh:** Update the information in the widget. This is not available for all widgets.

Configuration Search

The Configuration Search (also called the "configuration preview") is a dynamic, one-stop locator for Secret Server configurations. To use it:

1. Search for **Configuration Search**. The Configuration Search page appears.
2. Either choose a configuration section from the links at the bottom or type a configuration name in the dynamic search box. Either way, the matching configuration sections appear at the bottom (replacing the original links).
3. Refer to the documentation topics for the specific configuration you navigated to.

Global Search

Global search appears at the top of every page in Secret Server. When you click inside the search box, a search window appears.

The window dynamically changes as you type a search term. At the top of the window there are six filter buttons that tell you how many search hits in each category. There are five places within the application (contents) that contain the word that is searched. The categories are:

- **Content:** The application interface.
- **Favorite:** Secrets marked as favorites.
- **Folders:** Secret folders.
- **Recent:** Recent search terms.
- **Secrets:** Secret names.

Help Menu

The Help Menu is available via the question mark icon on the top right. It includes links to:

- About - direct links to Delinea Technical support, Blog, Feedback/Feature Request, Forums, Knowledge Base, and Mailing List.
- Secret Server REST API Guide - standard Swagger / Open API documents as well as interactive online documentation of the Secret Server REST API interfaces.
- User Guide - direct link to Secret Server documentation.

Main Navigation Drawers

Introduction

Since version 11.7, Secret Server's left navigation was greatly enhanced. The administration side panel was removed and replaced by a more all-encompassing drawer-like nested navigation panel.

You access it by clicking or hovering over the desired menu item or clicking the **>>** icon at the bottom. Clicking the **<<** icon closes the selected drawer.

Home Drawer

The home drawer contains the "Application Dashboard" on page 182.

Secrets Drawer

All Secrets

All Secrets displays all secrets that the user has permission to view. It provides a comprehensive list of all the secrets the user can access within Secret Server.

Quick Access

Quick access provides a convenient view of high-use secrets as well as keeping track of secrets that have been opened during the current session. It allows users to quickly find and access secrets they use frequently.

Favorites

Users can mark secrets as "Favorites" for easy retrieval. This feature allows users to quickly access secrets they use regularly without having to search for them each time.

Recent

This link shows the 15 secrets accessed most recently by the user. It helps users quickly return to secrets they have worked with in the near past.

Most Used

This link displays the secrets that the user has opened most often, providing quick access to the secrets that are most important or frequently needed in their daily tasks.

Shared with Me

This link shows the secrets that other users have shared with the user. It allows for collaboration and sharing of necessary credentials without compromising security, as permissions are still enforced.

Checked Out

The "Require Check Out" feature ensures that only one user at a time has access to a secret. When enabled, users must check out a secret before they can access it, preventing other users from accessing the secret while it is checked out.

Folders

The Folders section contains the "Folders" on page 1075

Discovery Drawer

Analysis

Opens the Discovery page to the Analysis tab. The analysis feature in Secret Server discovery provides a graphical summary of discovery activity, allowing users to manage discovered items effectively. It includes information about each item and is crucial for managing the discovered items. Items from disabled discovery sources will not be visible.

Network View

Opens the Discovery page to the Network View tab. The network view allows users to view the results of completed discovery after defining the discovery sources. It provides a graphical representation of the organizational structure and allows users to filter items by type, such as computers, computer accounts, public keys, service accounts, or directory accounts. Users can also initiate a rescan of certain items like computers by clicking the scan button.

Sources

Opens the Discovery page to the Sources tab. Discovery sources are the starting point for the discovery process. They define where and how Secret Server should look for accounts and dependencies.

Configurations

Opens the Discovery page to the Configurations tab. Contains the following settings that can be configured for Discovery:

- **Enable discovery:** Enabling discovery will allow scans to be run and resources discovered.
- **Discovery Interval Days:** Set the interval in days.
- **Discovery Interval Hours:** Set the interval in hours.
- **Ignore Cluster Node Objects:** If set to yes, Discovery scans will bypass machines identified as "msclustervirtualserver". Default value: No.
- **Discovery Scan Offset Hours:** Sets time offset in hours for discovery scan operations. Default value: 0.
- **Days to Keep Operational Logs:** Logs older than this value are removed from the system. This value is typically not modified.
- **Deactivate dependency not found threshold:** Threshold for number of times a dependency can be not found before being deactivated. (0 - Never)

Log

Opens the Discovery page to the Log tab. The discovery log provides a detailed record of the discovery process. It logs the activities and events that occur during the discovery scans, including the identification and categorization of computers, accounts, and dependencies within the network. The log is useful for troubleshooting, auditing, and understanding the actions taken by the discovery feature.

When a discovery scan is run, whether manually or automatically, the discovery log captures information such as:

- The start and end times of the discovery scan.
- Any errors or issues encountered during the scan.
- Details about the objects that were discovered, such as computers and accounts.
- Actions taken by the discovery process, such as creating new secrets for discovered accounts or linking discovered dependencies to existing secrets.

By reviewing the discovery log, administrators can gain insights into the effectiveness of the discovery scans, identify any potential issues that need to be addressed, and ensure that the discovery process is functioning as intended. It serves as a historical record that can be referenced to verify the discovery activities and outcomes.

Computer Scan Log

Opens the Discovery page to the Computer Scan tab. The computer scan log shows logs of the computer scanning process. This log provides details about the scanning of each machine found during the discovery scan to collect information configured to be collected by the discovery source.

Computer Scan Results

Opens the Discovery page to the Computer Scan Results tab. The computer scan results feature provides detailed information about the scanning process. It includes the results of the computer scan, which attempts to collect information such as local accounts, Windows services, scheduled tasks, and IIS application pools from each machine found during the discovery scan.

Reports Drawer

Report List

Opens the Reports page to the General tab, which contains the report list. The list provides a set of standard reports that include a variety of 2D and 3D charting and graphing components, as well as full grids of data. Some reports are purely data detailed and have no charts. Users can create custom reports based on Secret Server data such as user, audit, permissions, and folders. Reports can be organized into categories to aid in organization and access control.

Security Hardening

Opens the Reports page to the Security Hardening tab. The security hardening report checks aspects of Secret Server to ensure security best practices are being implemented. It identifies potential security issues within an installation and provides recommendations for hardening the security posture of the Secret Server environment.

User Audit

Opens the Reports page to the User Audit tab. The user audit report feature in Secret Server displays every password or secret accessed by a user within a specified period. This report is essential for assessing and controlling vulnerability risk when someone leaves the organization and for complying with regulatory requirements.

Schedules

Opens the Reports page to the Scheduled Reports tab that allows users to set reports to be generated on a regular schedule and sent via email to the management team or auditors. With the Health Check option, users receive an email only when a report has content, targeting unusual events for immediate alerts.

Audit

Opens the Reports page to the Audit tab. Secret Server maintains an immutable audit log of privileged user activity, which can be reviewed by the IT and security team. The audit feature includes customizable alerts (Event Subscriptions) that send email notifications when specified actions are performed or events occur. Audit reports provide accurate details on the secret itself, allowing users to monitor the level of activity on any secret they have access to.

Access Drawer

Users

Opens the Users tab of the User Management page. Secret Server supports both Local and Domain user accounts for authentication. Local user accounts are stored and managed by Secret Server, while domain user accounts are managed by Active Directory but subject to changes made in Secret Server. Administrators can create, edit, or remove local user accounts and configure account lockout settings to prevent repeated unsuccessful login attempts.

Groups

Opens the Groups tab of the User Management page. Secret Server allows administrators to manage users through user groups. Users can belong to different groups and receive the sharing permissions and roles attributed to those groups. This setup simplifies the management of permissions and roles that can be assigned to a user. Groups can also be synchronized with Active Directory.

Roles

Opens the Roles tab of the Roles Page. Role-Based Access Control (RBAC) in Secret Server enables IT admins to control what individual users can do within the application. Secret Server ships with out-of-the-box roles for common configurations and allows custom roles to be created that correspond to an organization's structure.

Directory services

Opens the Domains tab of the Directory Services page. Secret Server integrates with Active Directory, allowing administrators to automatically grant and revoke access to Secret Server with existing tools and policies. By assigning access based on security groups, manual permission granting is minimized, and users' rights in Secret Server change appropriately when their roles change.

IP address restrictions

Opens the Overview tab of the IP Address Management page. IP address restrictions in Secret Server allow administrators to control the locations and networks from which users can gain access. This feature enables limiting access to Secret Server to users who are "on network" and not accessing through VPN or other external networks.

Inbox Drawer

Secret Access Requests

Opens to Inbox > Secret Access Requests. The secret access requests feature in Secret Server allows a secret to require approval before access is granted. When a user requests access to a secret, an email is sent to the approval group(s), notifying them of the request. Members of the approval groups can approve or deny the request, and access can be granted for a set time period. This feature establishes a workflow model where users must request access, and approvals can be managed through the Secret Server interface or via email if configured.

Secret Erase Requests

Opens to Inbox > Secret Erase Requests. Secret erase requests are used when a secret needs to be permanently removed from Secret Server. This is typically done for regulatory compliance and is not intended for database cleanup. When a secret erase request is made, it must be approved by designated approvers before the secret can be erased after a specified date and time. The process ensures that irreversible actions are taken with proper authorization and for valid reasons.

Application Requests

Opens to Inbox > Secret Application Requests. Application requests are not explicitly mentioned in the provided documents. However, in the context of Secret Server, this could refer to requests related to application account secrets or requests for integrating applications with Secret Server. These requests would likely follow a similar approval process to ensure proper access control and security compliance.

System Alerts

Opens to Inbox > System Alerts. System alerts are notifications that inform administrators and users about important system events or conditions that require attention. These can include alerts about system health, configuration changes, heartbeat failures, or other significant system-related issues. Alerts can be customized and sent via email to ensure prompt awareness and response.

Notifications

Opens to Inbox > Notifications. Notifications can include alerts about access requests, system events, and other important information that users need to be aware of.

Rules (Management)

Opens the Rules tab of the Inbox > Notifications page. Inbox rules are used to trigger actions based on notifications and can send either an email or a Slack message to a specified group of users when certain conditions are met. These rules are primarily for non-admin end-user communications and event subscriptions. They are used to filter notifications and define who receives the email or Slack message when a notification arrives.

Templates (Management)

Opens the Templates tab of the Inbox > Notifications page. Inbox templates are used for formatting and populating the content of messages sent to users' inboxes and can also be used by event pipelines. These templates define the subject, language used, and the canned text for the message, which contains variables that are replaced by Secret Server when the message is sent. Inbox templates can be system templates, which are read-only and can be cloned to create custom templates, or they can be custom templates that users create and edit themselves.

Inbox templates are crucial for managing how email and notifications are sent and received by users. They allow for configuration of notification scheduling, collecting notifications into digest format, and creating message templates and rules. This customizable tool set helps reduce alert fatigue by enabling users to receive notifications in a way that is most relevant and actionable for them.

Resources (Management)

Opens the Resources tab of the Inbox > Notifications page. Resources associated with inbox templates are items, such as images, that go along with any email based on the template. These resources are included in the message to enhance the visual presentation and provide additional context or branding.

Settings Drawer

All settings

Opens the Admin > All Settings page in the alphabetical view. This page serves as a comprehensive list of all system settings, organized alphabetically for easy navigation. This page allows administrators to quickly locate and manage various configurations, from authentication methods to email settings, ensuring that they can fine-tune the Secret Server environment to meet their organization's specific security and operational requirements.

Configuration Search

Opens the Admin > Configuration Search page. This page is a utility within Secret Server that enables administrators to swiftly find any system configuration by entering search terms. This feature streamlines the process of locating specific settings among the multitude of configurable options, saving time and simplifying system management tasks.

Distributed Engine

Sites and Engines

Opens the Sites and Engines tab of the Distributed Engine page. This tab provides an overview and management interface for the distributed engines and their associated sites within Secret Server. This tab allows administrators to configure and monitor the engines that handle tasks such as remote password changing and discovery scans, ensuring efficient distribution of workload across the network.

Site Connectors

Opens the Site Connectors tab of the Distributed Engine section. The tab provides access to the list of all the existing site connectors with the option to enable, disable, edit or add new connectors.

Configuration

Opens the Configuration tab of the Distributed Engine page. This tab is where administrators can set up and modify the settings for distributed engines in Secret Server. This tab includes options for engine registration, task assignment, and communication settings, which are crucial for the engines to operate correctly and securely within the distributed architecture.

Log

Opens the Log tab of the Distributed Engines section. The tab provides the log of all engines' events with the exact date and time, and detailed event messages. Select the related site from the Sites dropdown on the top to view the log for the specific site.

Audit

Opens the Audits tab of the Distributed Engine page. This tab offers a detailed log of all activities related to distributed engines, providing administrators with a transparent view of engine operations. This audit trail is essential for security and compliance, as it records actions such as engine registration, task execution, and any configuration changes.

Proxying

SSH

Opens the SSH Proxy tab of the Proxying page. This tab allows administrators to configure the settings for SSH proxying within Secret Server. This tab includes options to enable the proxy, set the proxy port, and manage other related settings, which are vital for securely routing SSH sessions through Secret Server and protecting endpoint credentials.

RDP

Opens the RDP Proxy tab of the Proxying page. This tab is dedicated to configuring the RDP proxying feature in Secret Server. Administrators can enable the RDP proxy, define the proxy port, and adjust settings to ensure that RDP connections are securely routed through Secret Server, enhancing credential security and session management.

SSH Terminal

Opens the SSH Terminal tab of the Proxying page. This tab provides configuration options for the SSH terminal within Secret Server. This tab allows administrators to customize the terminal settings, such as enabling command menus and setting up session recording, to ensure a secure and controlled environment for SSH sessions.

Endpoint Configuration

Opens the Endpoints tab of the Proxying page. This tab lists all the server nodes, sites, and engines that can be configured as proxies for SSH and RDP sessions. Administrators can manage which nodes act as proxies and configure their public host and bind IP addresses, ensuring that sessions are securely routed through the designated endpoints.

Remote Password Changing

Configuration

Opens the Remote Password Changing page. This page is where administrators configure and manage the remote password changing feature in Secret Server. This page allows for the setup of password changers, scheduling of password changes, and monitoring of password change activities, which are critical for maintaining password security across the network.

Password Changers

Opens the Password Changers Configuration page. This page is a central location for setting up and managing the password changers used in Secret Server. Administrators can add, edit, and delete password changers, as well as configure their settings to ensure that passwords are changed according to organizational policies and compliance requirements.

Dependency Changers

Opens the Dependency Changers page. This page is designed for administrators to configure and manage the dependency changers in Secret Server. This page enables the setup of dependencies for secrets, ensuring that related credentials are updated in sync when a password change occurs, maintaining consistency and reducing the risk of service disruptions.

Heartbeat Log

Opens the Heartbeat Log tab of the RPC Logs page. This tab provides a log of all heartbeat activities within Secret Server. Administrators can review the log to monitor the health and accessibility of secrets, ensuring that credentials are valid and services are operational, which is essential for maintaining system integrity.

Password Change Log

Opens the Password Change Log tab of the RPC Logs page. This tab offers a detailed record of all password change activities in Secret Server. This log is crucial for tracking the success or failure of password changes, troubleshooting issues, and ensuring that password policies are enforced across the organization.

Diagnostics

System Log

Opens the Logs tab of the System log section. The tab provides the log of all the machines' events with the exact date and time, log levels, and detailed event messages. Select the related log level from the dropdown on the top to view the the specific log level events.

Server Nodes

Opens the Server nodes section that allows to edit nodes and filter them by workloads and clusters. See Secret Server Clustering for more info.

Diagnostics

Opens the Diagnostics section. Se Diagnostics for more details.

General

Secret Policy

Opens the Admin > Secret Policy page. This page is where administrators create and manage secret policies in Secret Server. These policies define sets of rules that can be applied to multiple secrets, such as remote password changing and security settings, to enforce consistent security requirements across the organization's secrets.

Secret Templates

Opens the Templates tab of the Admin > Secret Template page. This tab provides a list of all secret templates available in Secret Server. Administrators can create, edit, and manage templates, which dictate the structure and policies of secrets, ensuring that sensitive information is stored and handled in a standardized and secure manner.

Event Pipeline Policy

Opens the Policies tab of the Admin > Event Pipelines page. This page allows administrators to create and manage event pipeline policies in Secret Server. These policies define the workflows and actions triggered by specific events, enabling automated responses to activities within the system and enhancing operational efficiency.

Event Subscriptions

Opens the Subscriptions tab of the Admin > Event Subscriptions page. This tab is where administrators can set up and manage event subscriptions in Secret Server. This feature enables the configuration of notifications for defined events, which are sent to users' inboxes and can be further communicated externally via email or Slack, keeping stakeholders informed of critical activities.

Workflow

Opens the Admin > Workflows page. This page is dedicated to creating and managing workflows in Secret Server. Workflows allow for the setup of multi-tiered approval processes for secret access, providing a structured and secure method for sharing sensitive information within the organization while maintaining control and auditability.

Secret Folder-Tree Panel

The secrets menu item in the new UI has a collapsible secret folder-tree panel that occupies the full height of the page. This replaces the legacy folder tree at the bottom of the left navigation bar and delivers a significantly improved folder browsing experience. To view the panel, click the **>** icon on the bottom left of the page.

You can create folders, if you have permission to do so, by clicking the folder button on top of the folder panel.

Quick access provides a convenient view of high use secrets as well as keeping track of secrets that have been opened during the current session. Any pinned folder offers the same quick view but is scoped to the context of that folder. For example, only show me favorite or recent secrets from a single folder and its subfolders.

Direct links are available to common filtered views of secrets that allow for searching and advanced filtering within a specific context.

All folders to which you have access appear in the folder tree. A context menu offers options such as creating subfolders or pinning a specific folder. These options are also available when viewing a folder by clicking on the context menu next to the page title.

Secret Navigation Slideout

The Secret Navigation Slideout is a set of useful links to secret. It appears on the top navigation bar.

Click **Open secret panel** next to your user login button at the top right, and the slideout appears.

There are four dropdowns:

Favorites

These are the secrets you set as favorites by clicking the star icon on the secret's row on the All Secrets table.

Dropdown Quick List

When you click the dropdown, you see a list of your favorite secrets:

The initial view shows the folder path to the secret and a "favorite" toggle icon. You may need to hover over the blank space to see an unselected toggle.

> Some changes may require you to refresh the list by clicking the stacked dots icon.

Each list item has its own dropdown. When you click it, a set of information about the secret appears, including a list of users or roles with access to (shared with) the secret.

> You may also have to enter a comment or check out the secret.

Most of the datums can be copied with a single click of the copy icon next to each. You can hover the mouse pointer over the "Shared with" list to see the type of access for that user or role, or you can click "See All" to see the entire list.

Favorites Page

Alternatively, in the slideout, you can click the Favorites title to navigate to the full Favorites page.

Recent

These are the secrets you have opened recently. The dropdown provided for each list item is exactly the same as that provided in "favorites," as is accessing the Recent page via clicking the title.

Most Used Secrets

These are the secrets you have opened the most often. The dropdown provided for each list item is nearly the same as that provided in "favorites," as is accessing the Recent page via clicking the title. The only difference is each list item states the time since last access.

Shared with Me

These are the secrets others have shared with you. No folder path is provided.

The dropdown provided for each list item provides a shortcut to request approval for the secret:

Administration

The Administration section covers a comprehensive set of administrative tools and configurations for managing Secret Server. It encompasses a wide range of functions, including database management (with options for

changing SQL service account passwords and connections), security features (custom SSH cipher suites), service controls (enabling web services), data management (export and import settings), system integrations, maintenance capabilities, metadata handling, ticketing system integration, troubleshooting tools, and an unlimited vault access mode.

Secret Server Architecture

To view the architecture diagrams for Secret Server, see Platform Architecture.

Application Settings

Search for **Application** to get to the Application Settings page.

The Application Settings page allows configuring basic Secret Server settings. Here, you can enable automatic checks for software updates and gain early access to new features through the Early Adopter setting. You can also opt to send anonymized system metrics to Delinea for product improvement and enable webservices to allow other applications to interact with Secret Server. Additional settings include configuring offline access duration for mobile devices, setting session timeouts for webservices, and managing token refreshes. Furthermore, you can enable Syslog/CEF Log Output, configure WinRM settings, and obfuscate personally identifiable information in audits.

Click **Edit** to enable, disable or set the desired configurations.

When done, click **Save** to save your settings.

Click **Test system log** to test your configurations.

The following configurations are available here:

- **Automatic checks for software updates**: Enable to be notified at the top of each page with a link to the latest update.
- **Early Adopter**: Enable to have access to the early adopter release - access, use, and benefit from the latest features, enhancements and improvements as soon as they are available. It is recommended to evaluate them in your test environment before an organization-wide rollout.
- **Send anonymized system metrics to Delinea**: Enable to sent anonymized data about your configuration and usage of Secret Server for the further product improvement. See Anonymized system metric information for more details.
- **Enable webservices**: Enable to allow other application to interact with Secret Server (requires to log in with the Secret Server credentials).
- **Maximum Time for Offline Access on Mobile Devices (days/hours)**: The maximum time for offline access on mobile devices setting in the server determines how long to cache secret data on the mobile device. Once the device is not in contact with the server for longer than the specified amount of time, the device removes its cache of the stored secrets. The only way to view secrets on the device once the cache is cleared is to connect to SS again so that the secrets can be re-downloaded. See Maximum Time Offline Explanation for more details.
- **Session timeout for webservices (days/hours/minutes)**: Set a Session time limit on Webservices API. Once Webservices expires, the user must log in again with their username and password.

- **Enable refresh tokens for webservices**: Tell OAuth2 to send back a refresh token during Authentication. This token will allow the user to get a new access token without having to enter credentials.
- **Maximum token refreshes allowed**: Set the maximum amount of times a user can refresh an access token.
- **Prevent direct API authentication**: Prevents non-Application Account users from directly authenticating against the API. It requires obtaining a token through the UI for authentication. Additionally, there is a bypass RBAC role available that allows to circumvent this restriction. When this setting is enabled, access to the SSH terminal is blocked. Note that while the restriction is intended to prevent direct API authentication, it also impacts SSH login capabilities. Adding the Bypass direct API authentication restriction role permission will allow logging on despite the restriction.
- **Prevent Application from Sleeping When Idle**: A keep alive thread will run in the background pinging the web URL to make sure IIS does not stop running due to inactivity.
- **Enable Syslog/CEF Log Output**: Check to enable Syslog/CEF Log Output. See Syslog/CEF Logging Advanced Settings Information for more details.
- **Syslog/CEF Server *** : Enter Syslog/CEF Server Address.
- **Syslog/CEF Port ***: Enter Syslog/CEF Server Port.
- **Syslog/CEF Protocol**: Select Syslog/CEF Protocol to use when sending logs.
- **Syslog/CEF Time Zone**: Select Time Zone to use when sending Syslog/CEF Protocol log entries.
- **Syslog/CEF DateTime Format**: DateTime Format for Syslog/CEF Protocol log timestamps. Syslog: Jun 23 2022 11:22:33; ISO 8601: 2022-06-23T11:22:33.000.
- **Syslog/CEF Site**: This is the site that the CEF/Syslogs will run on.
- **Write Syslogs As Windows Events**: When enabled, Audits and Event Subscriptions will be written out to the Windows Event Log of the server.
- **WinRM Endpoint URL ***: The URL of the Windows Remote Management listener that will be used to run PowerShell scripts.
- **Enable CredSSP Authentication for WinRM**: Enable to allow a client to delegate credentials to a target server. See How do I configure CredSSP for WinRM? for more details.
- **Max Secret Log Length**: Enter the maximum Secret Log Length.
- **Custom URL**: The custom-set external binding for the server.
- **Privilege Manager Installation URL**: The custom-set location for Privilege Manager.
- **Obfuscate Personally Identifiable Information**: Delimit personally identifiable information (PII) in Audits. If obfuscate is selected, then it will automatically remove PII data from Audit exports. Note: This will only export data from the last enabled date.

Bulk Operations

Running Bulk Operations

You can perform bulk actions on multiple secrets in a folder:

1. Navigate to the folder containing the secrets you wish to perform a bulk actions on.

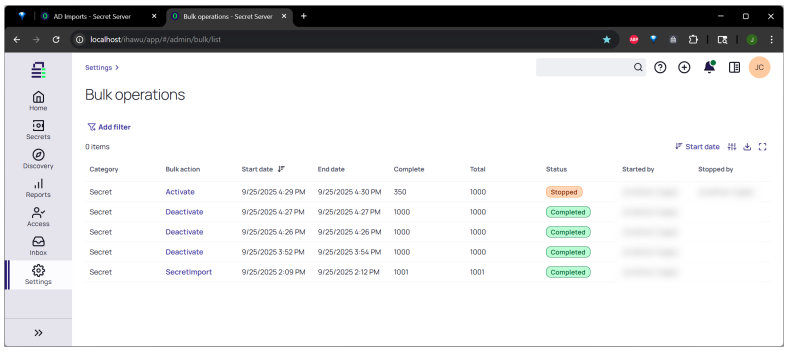
   You can also run bulk actions from the All Secrets page and other locations–wherever there is a

2. In the **Folder Scope** dropdown select to display the secrets in the current folder only or in the subfolders too.
3. Click to select the secrets you wish to include. To check them all, check the check box in the column header row. The **Bulk actions** button appears at the top. Click **Bulk actions** to select the action. The unlabeled bulk actions popup appears.
4. Available bulk actions include:
   - Activate
   - Assign jumpbox route
   - Assign secret policy
   - Assign to site
   - Change password remotely
   - Change security options
   - Change share permissions
   - Convert secret template
   - Deactivate
   - Erase secrets
   - Heartbeat
   - Move to folder
   - Request access
   - Set privileged account
   - Toggle autochange
   - Update associated secrets
   - Update password requirements

Bulk actions may differ by Secret Server version.

Accessing the Bulk Operation Dashboard

1. Go to **Settings** and click on **Bulk Operations** in the **Secrets** section. The Bulk Operations Dashboard appears:



2. Click the **Add Filter** button and select **Bulk Status**. A dropdown list appears.
3. Select one of the following:
   - Running: Bulk operations currently running or in the queue to run.
   - Completed : Bulk operations that completed successfully.
   - Error: Bulk operations that failed to complete for any reason other being stopped.
   - Stopped: Bulk operations that were stopped by the owner or someone with the "Administer Bulk Operations" role permission.
   - The X button to remove all filtering. Without filtering, you can still see what the status is of each operation by viewing the Status column.

   Secret Server only retains the past 30 days of bulk operations.
4. Click individual rows to see details for that bulk operation.

Stopping Bulk Operations

Overview

Bulk operations enter a queue for execution. You can clear that queue, stopping any pending operations before they happen.

Stopping a bulk operation does not undo any completed task.

For performance reasons, the bulk-operation process only checks for a stop instruction every tenth item. This means that if you are, for example, moving 1000 secrets to a folder, and you click the stop button on the active processes popup after 71 have been moved, the actual number moved may be 80 or even 90.

Bulk Operations can be stopped from:

- The Active Processes "toast" dialog in the top right corner.
- The Bulk Operation Dashboard page. See "Accessing the Bulk Operation Dashboard" on the previous page.

A bulk operation can always be stopped by the person who started it. It can also be stopped from the Bulk Dashboard page by any user with the "Administer Bulk Operations" role permission.

Note that when first loaded, the Bulk Dashboard page by default is filtered to running operations only. This is because in most cases users want to see the status of a current operation. The Bulk operations table, tbBulkOperations, is included in data retention by default. It is set to keep the past 30 days of bulk operations.

The active processes popup appears when:

- Running an import
- Running a bulk operation
- Running heartbeat now

Initially, the popup only shows the current operation. Click **See All** button to see the entire set. The popup also has a **Stop** button to stop the current queue from executing, with the limitation mentioned above.

Changing SQL Server Connection Parameters

This topic only applies to**Secret Server On-Premises**

Once Secret Server is installed, it may be necessary to change the connection string that Secret Server uses to connect to its database. You must be authenticated to access Secret Server and have the Administer Configuration role permission.

1. Search for**Database**to get to the Database Configuration page.
2. Click **Edit**. The page enters edit mode.
3. Edit the parameters as desired.
4. Click the **Save Database Connection Settings** button. A confirmation message appears. Secret Server recycles its application pool (needed to clear the connection string cache), and then returns you to the Secret Server dashboard.

Custom SSH Cipher Suites

Overview

You can configure a custom cipher suite to assign to a site. The cipher is used for SSH client and server operations for that site, including SSH proxy, SSH terminal, discovery, remote password change, heartbeat and SSH scripts. Each cipher in the suite is prioritized by order used. Each one is tried before moving on to the next lower one if unsuccessful.

Please see "SSH Cipher Support" on page 874 for a listing of the default cipher suites.

Configuring Custom SSH Cipher Suites

Currently, you can only configure one custom SSH cipher suite.

To configure a custom SSH cipher suite:

1. Search for**Custom SSH Cipher Suite**to get to the Custom SSH Cipher Suite page.
2. The default **Details** tab provides a brief summary of the cipher suite. You can edit the name and description for the suite, as well as view the currently enabled algorithms.
3. Use the **Encryption Algorithms**, **Key Exchange Algorithms**, **MAC Algorithms**, and **Public Key Algorithms** tabs to enable, disable, and prioritize a list of each type of algorithm for the cipher suite.

   You can also check **FIPS** compliance for each of the algorithms. The types include encryption, key exchange, MAC, and public key algorithms.
4. To add algorithms to the list, click one of the algorithm tabs.
5. Select the **Edit** button on the top right of the algorithm page. The tab becomes editable.
6. Select the algorithms that you would like to add or uncheck to remove. When done, click **Save**.
7. To prioritize the algorithms, click **Reorder ciphers** on the algorithm page.
8. Drag the algorithms in the desired order. When done, click **Save Field Order**.
9. Select the **Audit** tab to display a list of actions taken with the cipher suite.

Using Custom SSH Cipher Suites

To enable the feature for a distributed engine:

1. Search for**Distributed Engine**. The Distributed Engine page appears.
2. Click the desired site name in the list. Its configuration page appears.
3. In the **Advanced site configuration** section click **Edit**.

   If you cannot edit the page, you may need the "administer distributed engines" permission.
4. For the **SSH Cipher Suite** option, select **Use Custom Cipher Suite**.
5. When done, click **Save**.

Secret Server Database Maintenance

This topic only applies to **Secret Server On-Premises**.

Purpose

This topic, *Secret Server Database Maintenance*, is intended to share, at a high-level, information around best practices and recommended practices as it pertains to the Delinea product database hosted in Microsoft's SQL Server. The primary focus will be around SQL Server hosted on a physical or virtual machine.

However, a customer can choose *under specific architectures* to host the database within cloud-based SQL Server Platform-as-a-Service (PaaS) offerings such as Azure SQL DB or AWS RDS.

Customers and partners may use this document for reference with any version of SQL Server. Where there are differences in edition or limitations within PaaS services will be noted.

Implementation of database maintenance is not within the scope of Delinea Support.

Please note references or links provided to third-party or open-source tooling is not a direct endorsement by Delinea.

When using Azure SQL with Entra ID authentication, database role assignments must be made directly to the Entra ID user account. Group-based role assignments (where an Entra ID security group is granted database permissions) are not supported due to Azure AD token limitations in non-interactive authentication scenarios. While tools like SQL Server Management Studio may work with group-based permissions, Secret Server will experience permission failures.

Intended Audience

SQL Server is a vast product with multiple components and configurations that Database Administrators can spend years to understand fully. This document is intended as a guide to get started; it is not a one-stop-shop for all the answers. Any job role can utilize this document as a reference for Delinea application databases.

Cloud Providers

The following providers will be considered and noted in this document:

- Azure: Azure SQL DB
- AWS: SQL Server on AWS RDS
- GCP: Cloud SQL for SQL Server

Azure SQL includes SQL Server services on Azure VMs and Azure SQL Managed Instance (MI). This document considers those services to be in parity with SQL Server running on-premises in the area of database maintenance.

Cloud provider information is subject to change by the specific provider and is out of the control of Delinea. This document will be maintained for significant changes, but advise consulting the provider's documentation to verify updates to those services.

Required Maintenance

SQL Server can be installed without much difficulty. Going through the wizard, you can do "next, next, next" and have SQL Server running on any server or desktop (even IoT devices). However, the wizard installation does not set up maintenance on the application databases you add. The application may work well initially; it starts with a small amount of data in the database. As your user base or usage grows, so will the database.

Ensuring proper maintenance is set up for the application database(s) is essential for the application and the business. As the enterprise expands the use of Delinea products, the hosted database expands and grows with data. Proper maintenance can ensure as the amount of data grows, the database is maintained correctly for the best performance possible.

The following sections will be the focus of this document. Links will be provided as needed to given additional resources to expand or research further with a given feature or concept of SQL Server.

Backups

If the application database is "lost" for whatever reason, how much data can you lose? This question needs to be answered by your backup plan and determines how you configure it within SQL Server. Backups in SQL Server serve the role of recoverability but also with database space management.

This section will go over the available backup types and how they offer recoverability. Additionally, some tools and options for automating those backups will be provided as examples.

Database Integrity

One of the most primary causes of data loss is hardware failures. Some hardware failures can cause SQL Server databases to become corrupt and unrecoverable without a backup being restored.

Detecting these scenarios will ensure your application and business continue operating or can recover safely.

An important note is that some database corruption can follow your database backups, so it is crucial to perform.

Indexes and Statistics

Users are starting their day, and the help desk begins to get calls that the application is not responding, or pages are taking ages to load. On average, the performance issues with application databases come down to two objects: indexes and statistics. The query optimizer in SQL Server is the piece that ensures the queries from the application run as efficiently as possible. A central part of that work is the indexes and statistics of the tables referenced in the query. Ensuring proper maintenance is performed regularly will help the query optimizer with its goal of efficient query processing.

Database File Size

The files of a database themselves do not require direct maintenance. This section focuses on the configuration of database files and how some maintenance tasks mentioned previously can help you manage the physical file size.

This will not apply to any PaaS offering of SQL Server; the cloud-provider maintains the files and underlying storage.

The Database

This document is focused on maintenance for Delinea database(s), but before we get to that, we need to get on the same page with what makes up a database in SQL Server. At a high overview, databases contain the following:

- Collection of **tables**
- The tables have **rows** that include various **columns**
- Those **columns** store certain types of data: dates, strings, binary, numbers, etc.
- The data is persisted to **database files** on a file system

While data is persisted to the database files, it will exist within memory when applications reference and manipulate it. SQL Server manages that memory and how/when that data gets persisted to those database files.

Additional objects you find in a database that are directly associated with the tables for performance are the following items:

- Indexes
- Statistics (index and column)

Physical Files

There are two types of database files with SQL Server:

- Data files (**.mdf* or **.ndf*)
- Log files (**.ldf*)

As mentioned previously, mechanisms within SQL Server handle persisting transactions that have written new data or modified current data into the data file. The log file stores a history of those transactions until the change has been persisted in the data file. If SQL Server crashes, that log file's job is to help get the database back to a consistent state.

Recovery Model

A central area to understand with database maintenance is the recovery model of the database. The recovery model will play a role in how SQL Server manages transactions being written between the log file (history of transactions) and the database's data file. Transactions being the meat of an application database, it plays a significant role. For example, the backups occur within the context of the recovery model. A database can only be set to one of three recovery models:

- Full
- Simple
- Bulk-logged

The default recovery model in SQL Server for new user databases is **Full**. Any new database that is created will be set to full recovery. There are possible model Database (system database in SQL Server) configurations that can change this. The below sections provide a bulleted list of points to be aware of with each recovery model type and how the log file space is managed.

Full

- Can recover to a specific point in time (minimal data loss)
- Log backups **are required**
- All transactions are fully logged
- Manage log space via backup and maintenance

Simple

- Recovery only to the end of the last backup (data loss greater)
- Log backups **are not allowed**
- Some transactions **will not** be fully logged
- Automatic log space management, handled by SQL Server
- Many HA features do not support use with this model (Log shipping, Availability Groups, etc.)

Bulk Logged

- Recovery to the end of the last backup (point-in-time recovery not supported)
- Log backups **are required**
- Bulk operations are minimally logged
- Manage log space via backup and maintenance

Additional details on SQL Server recovery modules can be found at Recovery models (SQL Server).

Cloud Providers

The database's physical files and the recovery model setting are areas of database management that the cloud provider maintains and controls. The databases are operating under the full recovery model for PaaS offerings of SQL Server.

Backups

Backups are always a best practice, even when you do not think you will need to restore from them. The unknown, after all, is unknown, and backups can always help plan around the unknown. Three types of backups can be taken in SQL Server.

Backup Types

Full

A full backup contains the full extent of data within the database and the transaction log to recover the database to a consistent state. This backup is required as a minimum before the other backup types can be done. During recovery, the full backup is the first backup type that has to be applied.

Differential

The differential backup contains all changes in the database *since* the last full backup. As databases grow, the time required for a full backup may extend, and it may not be reasonable to frequently take a full backup. A differential can be used to continue the frequency within a shorter time window. Additional differential backups will grow based on data changes since the last full that was taken.

Log

This backup contains changes logged in the database transaction log file that is not persisted in the database files. The size of these backups will vary based on the activity that has occurred in the database.

Recoverability

A backup strategy or schema should focus on the need for recoverability. A backup's primary purpose is to recover data. Delinea's database(s) recovery needs are purely based on the business requirements of a customer. A disaster recovery plan should account for and determine the backup scheme chosen based on those requirements.

Example

A retail company utilizes Secret Server and has labeled it a business-critical system. The product is only used by their users during regular operating hours of 7:00 AM to 5:00 PM Monday through Friday.

The business requirements for databases with systems labeled as business-critical have an RPO (recovery point objective) of 10 minutes. An example database configuration and backup scheme recommended in this situation that would meet the RPO would be as follows:

1. The database recovery model is set to full.
2. Backups are taken:
   - Full: weekly, every Monday @ 4:00 AM
   - Differential: twice daily, Monday - Friday @ 5:00 AM and 1:00 PM
   - Log: daily, Monday - Friday every 10 minutes between 5:00 AM - 6:00 PM

On Wednesday at 3:45 PM, the disk hosting the database server for Secret Server goes offline. When the disk and server are brought back online, the database is corrupt and cannot be brought online. The following backup files are needed to meet the RPO of recovering the data within 10 minutes of the time the database went offline at 3:45 PM:

- Full backup from Monday
- Differential backup from 1:00 PM on Wednesday
- All log backups from Wednesday at 1:00 PM to 3:40 PM

The above recovery meets the RPO as there is only a data loss potential of 5 minutes.

Backup Automation

Backup Types

Delinea products, such as Secret Server, offer the ability to schedule *full* backups daily. That option can be used if the recovery limitations around that schedule and backup type meet your business need. When you need to get more granular with the backup type and schedule, SQL Server does offer two options:

SQL Server Maintenance Plans

- These offer a "quick-and-dirty" method of getting backup jobs in place
- It can be difficult at times to troubleshoot issues with them.
- They do not offer much control; as databases are added or removed, you have to adjust the backup task manually.

SQL Agent Jobs

- These offer a more robust method
- Does require scripts be written to perform the backup
- Some tooling is available with prewritten scripts (see more below)

Ola Hallengren's Backup Script

This script is a standard tool used by many in the SQL Server community. You can download the script and find full details at SQL Server Backup. The stored procedure offered allows you extreme granular control over the backup type, what flags are used in the backup command, cleaning up old backup files, and stripping backups for performance improvements.

The scripts provided below can be used in a SQL Agent Job to be scheduled on the frequency required to meet your recovery needs.

Full Backup

```
EXECUTE dbo.DatabaseBackup @Databases = 'SecretServer',
@Directory = '\\backups\SQLServer\dbserver1', @BackupType = 'FULL',
@Verify = 'Y', @Compress = 'Y', @CheckSum = 'Y', @CleanupTime = 504,
@CleanupMode = 'AFTER_BACKUP'
```

The above command will take a full backup of the *SecretServer* database and write it to the network share `\\backups\SQLServer\dbserver1`. Also, backup verification and compression will be used, along with a checksum performed. If the backup is successful, full backups older than three weeks (504 hours) will be deleted from the network share.

Log Backup

```
EXECUTE dbo.DatabaseBackup @Databases = 'SecretServer',
@Directory = '\\backups\SQLServer\dbserver1', @BackupType = 'LOG',
@Verify = 'Y', @Compress = 'Y', @CheckSum = 'Y', @CleanupTime = 336,
@CleanupMode = 'AFTER_BACKUP'
```

The above command will take a log backup of the *SecretServer* database and write to the same network share. The same actions will be performed with backup verification, compression, and checksum. Log backups that are older than two weeks will be deleted.

Application Impact

Backups overall will not impact or impede the application from being able to perform write and read operations. You may observe spikes in resource usage on the database server under certain circumstances when the full backup is being run, but it should not be excessive.

It is advised to monitor performance during backup processing to ensure any performance issues or adjustments to schedules are addressed. As the database grows, it may require adjusting the backup scheme to meet the RPO without affecting the application's performance during business hours.

Cloud Providers

The cloud provider controls backups and the frequency of them. Specific controls around retention are specific to the cloud provider.

Azure SQL DB

- Azure SQL performs automatic backups (Automated backups in Azure SQL Database).
- Backup frequency is **full** every week, **differential** every 12-24 hours, and **log** backups every 5-10 minutes.
- Log backup frequency can also be based on computing size and amount of database activity.
- Backup storage is configurable, but the default configuration will replicate to another datacenter within that region.
- By default, backup retention can make a point-in-time recovery seven (7) days (configurable to a maximum of 35 days).
- Long-term backup retention is possible for up to 10 years.

AWS RDS - SQL Server

- Support for automated and manual backups
- "Backup window" is configured for the instance to include all databases, defaults to a 30- minute window
- Various situations cause the backups not to occur during the window. See AWS's Introduction to backups.
- Backup retention is configurable; the default depends on how the instance was created in RDS

GCP Cloud SQL

- Support for automated and manual backup
- The backup window is a 4-hour window, not configurable
- Recommended to perform manual backups on a more frequent schedule
- Reference documentation. See Google's About Cloud SQL backups.

Database Integrity

Various types of corruption can occur with databases, logical or physical. The corruption can be captured and travel with the backups of the databases as well. Corruption in the backup will cause issues when the need arises to implement a recovery plan, and there is no viable backup to use.

Identifying issues around database integrity early ensure the application's database stays online and backups are not affected.

Types of Corruption

Logical

This corruption involves consistency errors being found in the page-level structure of the database. Depending on where that page is found can determine how much effort is required to correct it or what amount of data recovery can be done.

Physical

This level of corruption is critical and will affect the uptime of the database. Physical corruption tends to be a hardware-level issue in most situations. In most cases, a backup has to be performed to recover.

Physical Corruption Warnings

There are two errors that SQL Server will write to the Windows Application event log that are excellent precursors to know physical corruption is possible.

Table: Corruption-Related Errors

Error 824	Error 825
This event occurs when data is read by the application and requires SQL Server to retrieve it from the physical file (data file). A consistency check is done when this process occurs, and if SQL Server detects an error, it will cause this event to generate. The event message will be similar to: *SQL Server detected a logical consistency based I/O error* You can find more details about this error at MSSQLSERVER_824 .	This error is more critical and should raise alarms (if being monitored). When the application queries data and SQL Server has to retry multiple times to retrieve it from the physical file, this event can be triggered. The event message will be similar to: *A read of the file '%ls' at offset %#016I64x succeeded after failing %d time(s) with error: %ls.* You can find more details about this error at MSSQLSERVER_825.

DBCC CHECKDB

CHECKDB is the command used for running integrity checks on any SQL Server database, including the system databases. You can review the syntax for the command at DBCC CHECKDB (Transact-SQL).

Execution Performance

Running an integrity check against a database is a process that can require additional resources compared to other maintenance tasks. Some tweaks can be done based on the version and edition of SQL Server to improve the performance. In Standard Edition, the CHECKDB command is a single- threaded operation, meaning as the database grows, the process will take longer to complete. In Enterprise Edition, the same command utilizes parallel processing. In Enterprise Edition of SQL Server 2016, an option to configure the MAXDOP for the command is offered, allowing control of how many CPUs are used.

Additional details: CHECKDB From Every Angle: How long will CHECKDB take to run?

Application Impact

Internally when CHECKDB is executed against a database, it will utilize a snapshot of that database; this causes it to be an OLINE operation. This snapshot allows the operation to run without directly affecting on-going application activity against the database.

However, this task is an I/O intensive operation and should be done during minimal user activity in the application. While it won't directly affect the application, the overall high I/O activity may affect SQL Server's overall performance based on the resources the server is provided.

The CHECKDB command performs multiple operations, and those can be broken out (see documentation) and ran individually. An alternative that can allow less performant impact is to run those individual commands. A production database may only have CHECKDB run the physical checks only (*WITH PHYSICAL_ONLY*). It will allow the physical structure of the database to be verified for consistency. It is a low overhead check and will still check for common hardware issues that could cause data loss.

It is still recommended to perform a FULL run of CHECKDB on your production servers to ensure no type of corruption is found. Running this process on a restored database on a different server is fine, but it will not find corruption that may exist on that production server. If you restore a backup and run CHECKDB against that restored database, it merely verifies the backup you restored has no corruption in it.

Integrity Check Automation

Ola Hallengren's DatabaseIntegrityCheck Script (stored procedure)

This script is a standard tool used by many in the SQL Server community. You can download the script and find full details at SQL Server Backup. It will support the flags and options of CHECKDB by the version of SQL Server and is Availability Group aware.

The script below is commonly used for small databases, where integrity check is under an hour run time (total for all user databases).

```
EXECUTE \[dbo\].\[DatabaseIntegrityCheck\] @Databases = 'USER_DATABASES', @LogToTable = 'Y'
```

If the database is extensive in size, then a dedicated job for each database would be recommended. The script above can be updated for this purpose by replacing *USER_DATABASES* with the specific database's name.

Scheduling these jobs to run at least weekly is recommended.

Cloud Providers

Azure SQL DB

Azure utilizes various techniques to assist in managing data integrity. The Azure SQL engineering team provides more details at Data Integrity in Azure SQL Database. The article states running CHECKDB is unnecessary. The "what if" can still exist. Performing this maintenance is allowed on Azure SQL DB.

AWS RDS - SQL Server

The customer is responsible for running data integrity tests. The information above would be applied in the same way to the database hosted on AWS RDS SQL Server.

GCP Cloud SQL

The customer is responsible for running data integrity tests. The information above would be applied in the same way to the database hosted on GCP Cloud SQL for SQL Server.

Index and Statistics

The query optimizer lives to have good indexing and statistics in a database. An index strategy for a database will ensure the application performs optimally, at any size. Several chapters can be dedicated to indexing and statistics with SQL Server; it is a big topic for performance tuning. This section is going to cover a few areas to provide an overview.

Index Types

Index types vary on availability based on the version of SQL Server installed. The most common index types found in Delinea databases will be clustered and non-clustered indexes. If SQL Server 2016 SP1 is being utilized, then

columnstore indexes may be found in the database.

The index and type found in a database can be gathered using the following query:

```
SELECT o.name, i.name AS indexName, i.type_desc, o.type_desc, ps.row_count FROM sys.indexes i
INNER JOIN sys.objects o ON i.object_id = o.object_id
INNER JOIN sys.dm_db_partition_stats AS ps ON i.object_id = ps.object_id AND i.index_id =
ps.index_id
WHERE o.type_desc = 'USER_TABLE' ORDER BY o.name
```

More details on index types can be found at AI Skills Challenge: Indexes. Additional details on index architecture can be found in the SQL Server and Azure SQL index architecture and design guide.

Statistical Objects

Statistics are the lifeblood for the Query Optimizer in SQL Server. These objects are associated with columns and indexes. When an index is added to a table, a statistics object will be created. If there are any columns on the table used in aggregated reference or not included in an index, a column statistic object will be created. More details on statistics can be found at AI Skills Challenge: Statistics.

Fragmentation

Indexes will be the object type that deals with fragmentation. As you may use the alphabet or numbers to order a list, fragmentation in a table is when the physical order of that list no longer matches the logical order. Additional details on fragmentation can be found at Optimize index maintenance to improve query performance and reduce resource consumption.

Maintenance

The maintenance for indexes and statistics is intentionally split because it is recommended to perform them separately. From a pure performance perspective, when the database is relatively small (~under 50GB), both object types are not likely to take long; but it is purely based on SQL Server's resources. This type of maintenance is I/O intensive and can cascade to be memory and CPU intensive as the data footprint grows.

> **Important:** As the database grows, updating, adjusting, and monitoring this process are vital to getting the best performance out of SQL Server.

Indexes

Index maintenance covers fragmentation. Two types of maintenance tasks can be done with indexes: rebuild and reorganization. Each one has pros and cons:

Rebuild

Pros:

- Heavy resource usage for I/O on more extensive tables/indexes
- Potential to reclaim space in the data file and physical storage
- Updates index statistics object in the same transaction/processing

Cons:

- Resource intensive (I/O)
- The transaction cannot be killed without rollback occurring (that is, if the transaction runs for 2 hours, killing requires 2+ hours to rollback)

Reorg

Pros:

- Low resource usage
- The transaction can be killed without rollback
- It can pick up where it left off (to a degree), allowing for short burst during small maintenance windows
- Table locking is only on the current data page

Cons:

- Will not update statistics
- Based on the maintenance window, sizable indexes may take time to clear fragmentation

Statistics

The statistics objects exist for the columns and indexes on a table. These play a massive role with SQL Server's Query Optimizer. The statistics are how SQL Server knows how much data exist in a table. As the table grows, those statistics can become stale or out-of-date. SQL Server will update those statistics as they get marked out-of-date, but the method and schedule it does is not always optimal.

An example of how statistics work in SQL Server about data in a database can be found at Explaining SQL Server Statistics with Playing Cards.

Application Impact

When maintenance is performed on indexes and statistics, it is an I/O intensive process. For fragmentation to be cleaned up, the data has to be both read and written. If statistics have to be updated, the data has to be read; based on the sample rate, this can cause a higher workload based on data size.

When this maintenance is scheduled and implemented, it is recommended to monitor the process and periodically review the timing and workload it is causing on the SQL Server environment. There can be times when large tables need to be taken out of the regular schedule and have a dedicated schedule during a longer maintenance window or downtime for the application.

Index and Statistics Automation

Ola Hallengren's IndexOptimize (stored procedure)

This script is a standard tool used by many in the SQL Server community. You can download the script and find full details around this tool *here*. This procedure combines the ability to handle both indexes and statistics within one script, or you can create separate jobs when scheduling requires.

> The scripts provided below are simply samples and can be used for small-size databases. As the environment and data grow, the use of these scripts and configurations should be evaluated and tested.

The following T-SQL script can be used as a base template to manage both index reorg and statistics update in a single job (small environments):

```
EXECUTE \[dbo\].\[IndexOptimize\] @Databases = 'SecretServer', @FragmentationLow = 'INDEX_
REORGANIZE',
@FragmentationMedium = 'INDEX_REORGANIZE', @FragmentationHigh = 'INDEX_REORGANIZE',
@UpdateStatistics = 'ALL', @OnlyModifiedStatistics = 'Y',
@StatisticsSample = 80, @MSShippedObjects = 'N',
@TimeLimit = 28800, -- Time limit for work is 8 hours @LogToTable = 'Y'
```

Considerations on this command:

- This command's sampling rate is set to 80%; it is essential to monitor if this sampling rate is sufficient for the application's processing and workload.
- The TimeLimit set to 8 hours means when that limit is reached, no further commands on index reorg or statistic update will be issued; any current command executing will still have to complete.
- An additional parameter not specified, accepting the default value, is StatisticsModificationLevel. Please see the documentation link above for more details on this, if it needs to be used.

Cloud Providers

Azure SQL DB

Index and Statics maintenance is the responsibility of the customer.

AWS RDS - SQL Server

Index and Statics maintenance is the responsibility of the customer.

GCP Cloud SQL

Index and Statics maintenance is the responsibility of the customer.

Pruning Secret Server Log Data

> This section does not apply to cloud subscriptions.

Secret Server has processes that run as background processes, such as Discovery or Remote Password Changing, that frequently log the occurring activity. The majority of Secret Server features have a setting to control the data retention called *Days to Keep Operational Logs*. The default for this configuration is 30 days.

As well, the data retention feature was added to configure the Database Size Management. The management feature gives you a central location to control the data's max record age for particular Audit and Log/History tables. A number of the tables are included in this section as well.

The data is being stored in log tables within the database. These tables can commonly be the cause for the size of the database growing (logical space). Suppose your environment utilizes a large number of features in Secret Server heavily. In that case, you can benefit from having an external process such as a SQL Server Agent Job running to prune this data more frequently.

The following sections provide the query that can be used as a starting point for pruning each table as needed. It is recommended to adjust these based on each feature's usage and ***test*** before deploying to production instances.

Table pruning varies whether it is based on a DATETIME or record count. Adjust the **@stopDate** or **@batchSize** as environmental needs require.

Initial Purge Processing

Before implementing the following example queries on a scheduled basis, you may find that an initial purge of log data is required in the tables mentioned below. To trim the tables to their initial desired size, large amounts of data may require deletion. Doing this in SQL Server can be done utilizing a batch method to query a certain amount, delete and then get the next amount until it does not find any more to delete.

To delete in batches is done using *TOP (<number>)* for the DELETE statement. The below can be used as a template to wrap around the DELETE statement of the above queries:

```
DECLARE @BatchSize INT = 4999 WHILE 1 = 1
BEGIN
DELETE TOP (@BatchSize)
/\* place log script here, after the DELETE \*/
-- Availability Group configuration in use (uncomment next line)
--WAITFOR TIME @waitTime
IF @@ROWCOUNT \< @BatchSize BREAK END
```

An example for the **tbSystemLog** the query would look like this:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @MaxLogLength INT = 500 -- record count to keep DECLARE @BatchSize INT = 4999
WHILE 1 = 1 BEGIN
DELETE TOP (@BatchSize) FROM tbSystemLog
WHERE tbSystemLog.SystemLogId NOT IN ( SELECT TOP(@MaxLogLength) SystemLogId FROM tbSystemLog
ORDER BY tbSystemLog.LogDate DESC
,tbSystemLog.SystemLogId DESC
)
IF @@ROWCOUNT \< @BatchSize BREAK END
```

Example Pruning Code

tbStatusMessage Log Table

The bulk of logging for the activity occurring in Secret Server is being logged within this table.

Thread name examples: SecretItemHashUpdater, ActiveDirectoryMonitor, LegacyAgentMonitor, NodeClusteringMonitor, ConnectWiseMonitor, SSHProxyServer, ExpiredSecretMonitor, RPCHeartBeatMonitor, DiscoveryMonitor, ComputerScanMonitor, SecretComputerMatcherMonitor

Pruning code example:

```
USE \[SecretServer\]
SET NOCOUNT ON;
DECLARE @daysToKeep INT = 30 --days to keep of log
DECLARE @threadName varchar(250) = '' -- provide thread name to clean DECLARE @stopDate
DATETIME = DATEADD(DAY, -@daysToKeep, GETDATE()) DELETE
FROM tbStatusMessage WHERE
ThreadName = @threadName AND CreatedOn \< @stopDate
```

One consideration is utilizing the above as a template and control each *ThreadName* as your environment in different Agent jobs, that is, DiscoveryMonitor may contain more logs than RPCHeartBeatMonitor due to feature usage.

Do not remove the filter for *ThreadName* and do it purely on *CreatedOn*. There will be a varying amount of logs in Secret Server for each log that may affect the ability to troubleshoot.

tbComputerScanLastStatus Log Table

Pruning code example:

```
USE \[SecretServer\]; SET NOCOUNT ON;
DECLARE @daysToKeep INT = 30 --days to keep of log
DECLARE @stopDate DATETIME = DATEADD(DAY, -@daysToKeep, GETDATE()) DELETE
FROM tbComputerScanLastStatus WHERE LastScanDate \< @stopDate
AND NOT EXISTS (
SELECT NULL AS \[empty\]
FROM tbComputer AS c
WHERE c.ComputerId = tbComputerScanLastStatus.ComputerId
)
```

tbComputerScanLog Log Table

Pruning code example:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @MaxLogLength INT = 1000 -- record count to keep
/\* IF EXIST - SQL Server 2016+ only \*/ DROP TABLE IF EXISTS \#TempComputerScanLog
;WITH CslRowNumbersByComputer AS (
SELECT ComputerScanLogId,ROW_NUMBER() OVER (PARTITION BY ComputerId ORDER BY ScanDate DESC
) AS RowNumber
FROM tbComputerScanLog
)
SELECT ComputerScanLogId INTO \#TempComputerScanLog FROM CslRowNumbersByComputer
WHERE RowNumber \<= @MaxLogLength
```

```
DELETE
FROM tbComputerScanLog
WHERE ComputerScanLogId NOT IN (SELECT 1 FROM \#TempComputerScanLog) GO
```

tbEventPipelineActivity Log Table

Pruning code example:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @daysToKeep INT = 15 --days to keep of log
DELETE epa
FROM tbEventPipelineActivity AS epa
JOIN tbEventPipelinePolicyRun pr ON epa.EventPipelinePolicyRunId =
pr.EventPipelinePolicyRunId WHERE pr.QueuedDateTime \< DATEADD(DAY,-@daysToKeep,GETDATE())
```

tvEventPipelinePolicyRun Log Table

Pruning code example:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @daysToKeep INT = 15 --days to keep of log DELETE
FROM tbEventPipelinePolicyRun
WHERE QueuedDateTime \< DATEADD(DAY, -@daysToKeep, GETDATE())
```

tbSecretViewTracker Log Table

Pruning code example:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @daysToKeep INT = 1 --days to keep of log
DELETE
FROM tbSecretViewTracker
WHERE RecordedOn \< DATEADD(DAY,-@daysToKeep,GETDATE()) GO
```

tbOAuthExpiration Log Table

Pruning code example:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @daysToKeep INT = 1 --days to keep of log
DELETE
FROM tbOAuthExpiration
WHERE ExpirationDate \<= DATEADD(DAY,-@daysToKeep,GETDATE())
```

tbSystemLog Log Table

This is the main log table for Secret Server. Normally, you would use this data for troubleshooting, but, if needed, you can prune it too. Pruning code example:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @MaxLogLength INT = 500 -- record count to keep
```

```
DELETE
FROM tbSystemLog
WHERE tbSystemLog.SystemLogId NOT IN ( SELECT TOP(@MaxLogLength) SystemLogId FROM tbSystemLog
ORDER BY tbSystemLog.LogDate DESC
,tbSystemLog.SystemLogId DESC
)
```

tbSecretLog Log Table

Pruning code example:

```
USE \[SecretServer\]; SET NOCOUNT ON;
DECLARE @MaxDelete INT = 500
DECLARE @MaxLogLength INT = 1000 --record count on non-success
DROP TABLE IF EXISTS \#TempSecretNonSuccessLog
;WITH SecretLogRowNumbers AS (
SELECT TOP(@MaxLogLength) SecretLogId FROM tbSecretLog sl WITH (NOLOCK)
JOIN tbSecret s WITH (NOLOCK) ON s.SecretId = sl.SecretId AND s.Active = 1
WHERE sl.Status \<\> 'Success') SELECT SecretLogId
INTO \#TempSecretNonSuccessLog FROM SecretLogRowNumbers
DROP TABLE IF EXISTS \#TempSecretSuccessLog
;WITH SecretLogSuccessRows AS (
SELECT SecretLogId,
ROW_NUMBER() OVER (PARTITION BY sl.SecretId ORDER BY sl.DateRecorded DESC) AS rowNum FROM
tbSecretLog sl WITH (NOLOCK)
JOIN tbSecret s WITH (NOLOCK) ON s.SecretId = sl.SecretId AND s.Active = 1 WHERE Status =
'Success')
SELECT SecretLogId, rowNum INTO \#TempSecretSuccessLog FROM SecretLogSuccessRows WHERE rowNum
= 1
DELETE TOP(@MaxDelete) FROM tbSecretLog
WHERE SecretLogId NOT IN (
SELECT SecretLogId FROM \#TempSecretNonSuccessLog UNION
SELECT SecretLogId FROM \#TempSecretSuccessLog
)
```

Initial Purge Processing

Before implementing the above queries on a scheduled basis, you may find that an initial purge of log data is required in the tables mentioned above. To trim the tables to their initial desired size, large amounts of data may require deletion. Doing this in SQL Server can be done utilizing a batch method to query a certain amount, delete and then get the next amount until it does not find any more to delete.

To delete in batches is done using *TOP (<number>)* for the DELETE statement. The below can be used as a template to wrap around the DELETE statement of the above queries.

```
DECLARE @BatchSize INT = 4999 WHILE 1 = 1
BEGIN
```

```
DELETE TOP (@BatchSize)
/\* place log script here, after the DELETE \*/
-- Availability Group configuration in use (uncomment next line)
--WAITFOR TIME @waitTime
IF @@ROWCOUNT \< @BatchSize BREAK END
```

An example for the **tbSystemLog** the query would look like this:

```
USE \[SecretServer\] SET NOCOUNT ON;
DECLARE @MaxLogLength INT = 500 -- record count to keep DECLARE @BatchSize INT = 4999
WHILE 1 = 1 BEGIN
DELETE TOP (@BatchSize) FROM tbSystemLog
WHERE tbSystemLog.SystemLogId NOT IN ( SELECT TOP(@MaxLogLength) SystemLogId FROM tbSystemLog
ORDER BY tbSystemLog.LogDate DESC
,tbSystemLog.SystemLogId DESC
)
IF @@ROWCOUNT \< @BatchSize BREAK END
```

Availability Group Considerations

This section discusses specific considerations when performing database maintenance with Availability Group (AG) databases in SQL Server.

Backups

AGs allow backups to be offloaded to secondary replicas based on how the Backup Preference is configured. See Availability Group Properties: New Availability Group (Backup Preferences Page) for details. Full and Differential backups will be the only ones that can be performed on the secondaries (*only ones that support copy-only*). The Log backups can only be taken from the primary replica. As the database grows, this can be a consideration to offload that activity.

When utilizing the *DatabaseBackup* script and frequent log backups are being done (e.g., every 5 minutes), the cleanup of those log backups may need to be done in a different job. When a larger number of backup files need to be cleaned up, based on the *CleanupTime* configured, you may observe excessive waiting periods. If this begins to affect log backups not being done every 5 minutes, it is recommended to move that cleanup to a different job.

Transaction Log

The log file in a database joined to an AG is managed by SQL Server differently than a standard database. In an AG configuration where synchronous replicas are in use, the log transaction is not marked inactive until that transaction has been written on all log files for the database replicas.

Large transactions can affect this timing/latency. Maintenance such as Index rebuilds can cause large amounts of small transactions to occur. In that processing on an AG, the transaction won't complete until it is replayed on the log for all secondary replicas, in synchronous mode.

A common practice is to adjust those secondary replicas' the availability mode to asynchronous commit during maintenance windows. See Change availability mode of a replica within an Always On availability group for details.

It can ensure the activity can run more efficiently on the primary replica and complete within limited maintenance windows. Once the redo log catches up on the secondaries, they can be set back to synchronous commit mode.

Shrinking Log Files

Scheduling or frequently shrinking the database files for a SQL Server database is not recommended. In situations where the above log management scripts were used for the initial pruning of a large amount of data, you can shrink the data file to reclaim storage space. There may be other occurrences that a shrink is warranted. If proper maintenance is in place for the regular database, shrinking database files can cause more performance issues as time goes on.

When you need to shrink **the data files**, be aware that it requires exclusive locks on the database tables and indexes. More care is needed when shrinking the data file to ensure no connections are present to the database to complete the operation without interruption. Doing this while monitoring the progress is recommended, especially if this has to be done during business hours or when the application cannot be brought down. The data file shrink is also an IO and CPU-intensive operation.

When you need to shrink **the log file**, it is less intrusive and will not cause locking, and generally is not a CPU-intensive operation. The log file shrink will only be able to reclaim the inactive portion of the log file. Steps such as taking a full backup and then a log backup, at times, can help get those active portions switched to inactive so you can shrink the log file.

Shrinking Availability Group Log Files

Database log file growth can happen on the primary replica and even secondaries. When it becomes excessive, it can be a cause for concern. If the log file on the primary is growing and taking action to shrink them are not working, check your secondaries' performance.

Secondary replicas in asynchronous-commit mode still need that transaction from the primary replayed to keep the data synced. When those secondary replicas get behind, it prevents the log from clearing on the primary, and continuous log growth will be observed. Troubleshooting will be required on those secondaries to determine why they are not keeping.

One area to check if you see continuous log growth on the primary is ensuring all the secondaries have data movement enabled. If SQL Server paused data movement, you could see log file growth on the primary. Once you turn data movement back on, it will only be a waiting game until those secondaries are caught up. Once that happens, perform a full backup on the primary, and then the log file can be shrunk.

You can view the logical structure of the log file using *DBCC LOGINFO*. This command outputs a record for each virtual log file that SQL Server has created. The status column of that output will show you 2 (active) or 0 (inactive). The active records could mean several things: backup has not happened yet, active transaction, or waiting on replication.

Enabling Webservices

This topic only applies to **Secret Server On-Premises**.

Enabling webservices makes the ASP.NET webservices built into Secret Server available. They are found under `/webservices/sswebservice.asmx` in your Secret Server directory. Webservices run on the same port as the Web application. You can view them with a browser to see the functionality that is offered.

Specific webservice functionality is documented in the Secret Server Webservice API guide.

To enable webservices:

1. Search for **Application**, and click **Edit** to enable.
2. Search for **WebServices**.
3. Select the related checkbox to enable one or both of the following:
   - **Allow HTTP GET**: Enables the HTTP Get verb for webservices. This allows REST-style calls to many webservice methods, but reduces security.
   - **Hide Secret Server version numbers**: This disables the VersionGet SOAP call. It also hides the Secret Server version numbers from the headers and footer.
4. When done, click **Save**.

Exporting and Importing Secret Server Settings

Overview

Secret Server can now export and import Secret Server settings as a JSON file. With this, you can more easily move settings from an existing Secret Server environment to another.

Prerequisites

Required General Delinea Permissions

There are Delinea permissions required to access and perform the process. These are:

To view the Export/Import page or menu link:

- Administer Export or View Export
- Administer Import

To view audits (at least one is required):

- Administer Users
- Own User
- View Users

Exporting to a JSON file:

- Administer Configuration
- Administer Export

Importing from a JSON file:

- Administer Configuration
- Advanced Import

Required Additional Delinea Permissions

Some of the settings require additional Delinea permissions to export or import:

Table: Required Additional Permissions

Setting	Delinea Permission
OpenID Log on	Administer Delinea One
SAML	Administer Configuration SAML
Security	Administer Configuration Security
Session Recording	Administer Configuration Session Recording
SSH Commands	Administer SSH Menus
Delinea One Log on	Administer Delinea One
Two Factor Log on	Administer Configuration Two Factor

Required Licenses

Additional licenses may be required to import or export some settings.

Advanced Auditing License

This license is required for these settings in the Application Settings category:

- SyslogCefLogSite
- SyslogCefPort
- SyslogCefProtocol
- SyslogCefServer
- SyslogCefTimeZone

Enterprise Edition

These settings are also available with the Professional Edition and Approval Workflow Add-on licenses.

The Enterprise Edition license is required for these settings in the Launcher Settings category:

- CheckInSecretOnLastLauncherClose
- CloseLauncherOnCheckInSecret

It is required for these settings in the Permission Options category:

- EnableApprovalFromEmail
- ForceSecretApproval

It is required for the TicketSystems category.

Pro Edition

The Pro Edition license is required for these setting categories:

- SAML
- Session Recording

Platinum Edition

The Platinum Edition license (or Pro Edition and Unix SUPM licenses) is required for the SSH Commands setting category.

Procedures

Exporting Settings

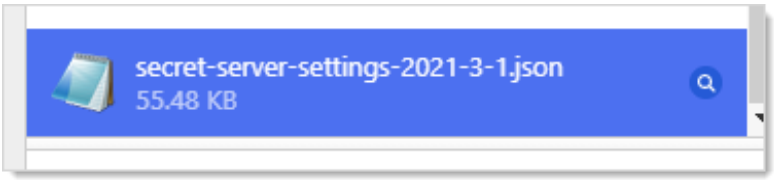
To export Secret Server settings:

1. Search for **Export/Import**, and select the Secret Server Settings tab.
2. Click the **Export** button at the top right. The Settings Export page appears.
3. Click to select the checkboxes for the settings categories you wish to include.

   Selecting the **Configuration** checkbox, selects or deselects all available categories.

   > See the Setting Category Reference section for details on the settings in each category.

4. Click the **Export** Settings button. A Confirm Export popup appears.
5. Select **Local Login**.
6. Type your password in the **Password** text box.
7. Click the **Export** button. The JSON file appears in your browser's downloads:



> This example is for the Vivaldi Chrome browser–yours will likely look different.

Importing Settings

To Import Secret Server settings:

1. Search for **Export/Import** and select the Secret Server Settings tab.
2. Click the **Import** button. The Settings Import page appears. Click the **Change** link, and navigate to and select the JSON file you want to import. The name of the file you chose appears above the Change link.

   Click to select the check boxes for the settings categories you wish to include. Clicking the **Configuration** check box selects all available categories.
3. Some settings may not allow you to select them, based on your permissions and licenses. Another possibility is the category was not included in the original export. Hover the mouse pointer over any of these settings to view a hint of what is likely causing it. See the Setting Category Reference section for details on the settings in each category.
4. Click the **Import Settings** button. A Confirm Import popup appears.
5. Click to choose **Local Login** or **QuantumLock**.
6. Type your password in the **Password** text box.
7. Click the **Import** button. An Import Summary popup appears.
8. Click the **Okay** button. The importation appears in the log that you saw earlier on the Export / Import page.

Setting Category Reference

This section details what setting are contained in the following settings categories:

Some settings are unavailable in certain environments or if requiring a license or permission.

Application Settings

These settings correspond to the Application Settings section on the Configuration General page.

This setting is unavailable in an on-premise environment:

- DisplayDowntimeMessageToAdminsOnly

These settings are unavailable in a cloud environment:

- AllowSoftwareUpdateChecks
- CustomURL
- EnableKeepAliveThread
- TmsRootUrl
- WriteSyslogToEventLog

This setting is unavailable in an IBM environment:

- AllowSendTelemetry

Advanced Settings

These settings correspond to the Advanced Settings section on the Configuration Advanced page.

Launcher Settings (Runtime)

These settings correspond to the Launcher Settings (Runtime) section on the Configuration General page.

Launcher Deployment Type setting can be one of the following:

- 0: Click Once
- 1: Protocol Handler

This setting is unavailable in a cloud environment:

- LauncherDeploymentType

Email

These settings correspond to the Email tab on the Configuration Email page.

These settings are unavailable in a cloud environment:

- SmtpDomain
- SmtpPassword
- SmtpPort
- SmtpServer
- SmtpUseCredentials
- SmtpUseImplicitSSL
- SmtpUserName
- SmtpUseSSL

Folder Settings

These settings correspond to the Folders tab on the Configuration Folders page.

Licenses

These settings correspond to the licenses listed on the Licenses page.

Local User Passwords

These settings correspond to the Local User Passwords tab on the Configuration Local User Passwords page.

Login

These settings correspond to the Login tab on the Configuration Login page.

These settings unavailable in a cloud environment:

- CacheAdCredentials
- TwoFactor.Radius.ClientPortRange

Delinea Permission Options

These settings correspond to the Permission Options section on the Configuration General page.

The Default Secret Permissions setting can be one of the following:

- 0: Secrets inherit secret permissions from folder
- 1: New Secrets copy secret permissions from folder
- 2: Only creator has secret permissions to new Secrets

Protocol Handler Settings (Install-Time)

These settings correspond to the Launcher Settings (Runtime) section on the Configuration General page.

SAML

These settings correspond to the SAML tab on the Configuration SAML page. To insert a new identity provider, in the same instance the export file came from, the IdentityProviderId setting must be set to 0. Otherwise, it will treat it as an update (see External Instance Id). The identity provider name cannot match another already in the database.

Security

These settings correspond to the Security tab on the Configuration Security page.

These settings are unavailable in a cloud environment:

- DatabaseIntegrityMonitoringSymmetricKey
- EnableDatabaseIntegrityMonitoring
- EnableHSTS
- FipsEnabled
- ForceHttps
- HSTSMaxAge

Session Recording

These settings correspond to the Session Recording tab on the Configuration Session Record page. The launcher must be enabled, and a valid license for Session Monitoring is required to export and import this feature.

These settings are unavailable in a cloud environment:

- ArchiveLocationBySite
- ArchivePath
- DaysUntilArchive
- EnableArchive
- EnableHardwareAcceleration
- StoreInDatabase
- VideoCodecId

To update SSHProxyRecordVideo or SSHProxyRecordKeyStrokes, SSH Proxy must be enabled.

To update RDPProxyRecordVideo or RDPProxyRecordKeyStrokes, RDP Proxy must be enabled.

SSH Commands

These settings correspond to the SSH command restrictions, the SSH commands, allowed command menus, and blocked command lists.

Ticket System

These settings correspond to the Ticket System tab on the Configuration Ticket System page. To insert a new ticket system in the same instance the export file came from, TicketSystemId must be set to 0. Otherwise, it will treat it as an update (see External Instance Id). The ticket system name cannot match another already in the database.

User Experience

These settings correspond to the User Experience section on the Configuration General page.

- Application Language
- Default Date Formats can be found in the tbDateOptions table.
- Default Time Formats can be found in the tbTimeOptions table.
- Default New User Roles can be found in the tbRoles table
- Server Time Zones can be found in the server registry: `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Time Zones`

User Interface

These settings correspond to the User Interface section on the Configuration General page.

These settings are unavailable in an IBM environment:

- AllowUserToSelectTheme
- CustomLogoCollapsed
- CustomLogoFullSize

JSON Export File

In addition to the setting categories, here are a few components of the JSON export file that you should be aware of.

External Instance ID

```
"externalInstanceId": "95931fb9-02b0-47a5-a59d-69d6543a192d",
```

The external instance ID is an identifier for the Secret Server instance the settings were exported from. If you change this ID, Secret Server will assume the export came from another database and will insert new records for the ticket system (TicketSystemId) or SAML (Identity Providers—IdentityProviderId) categories. To add a new record in the same instance, set the ID to 0 and it will be treated as a new item.

Configuration Version

```
"configurationVersion": "1.0.0",
```

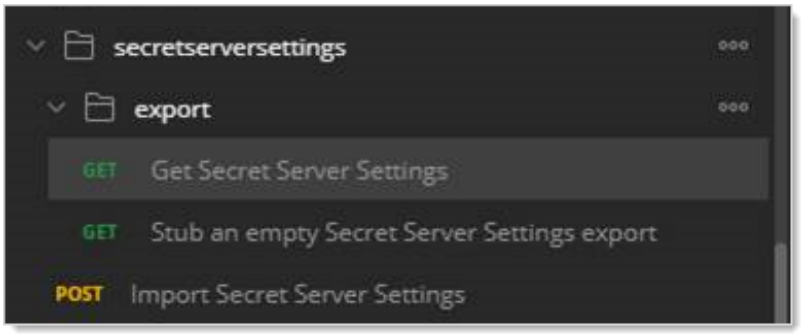
This is the configuration version the settings were exported from. In there future when other settings are added, it will help Secret Server determine which settings are available and which are not in the database.

JSON Import File

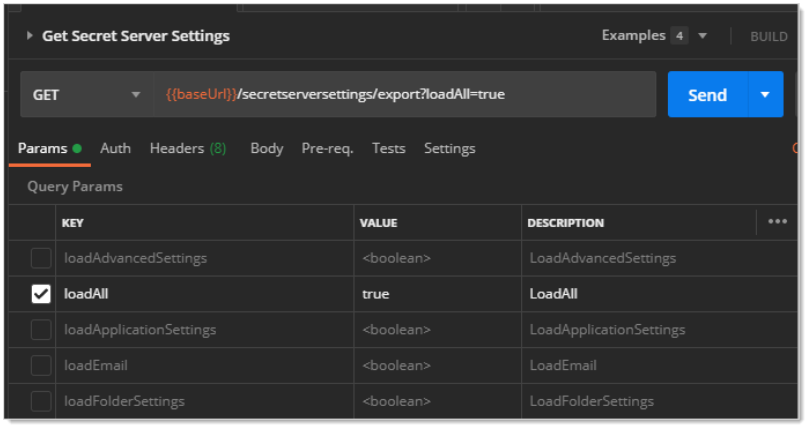
In the UI, the exported JSON file can be easily modified and used as the import JSON file. For the API, the exported JSON must be added to the data object. Then manually update the desired filter category load to true to import.

API Calls Filter

Secret Server has settings import/export endpoints for the API to manipulate. Opening Postman and going to **secretserversettings > export > GET Secret Server Settings**, you would see:



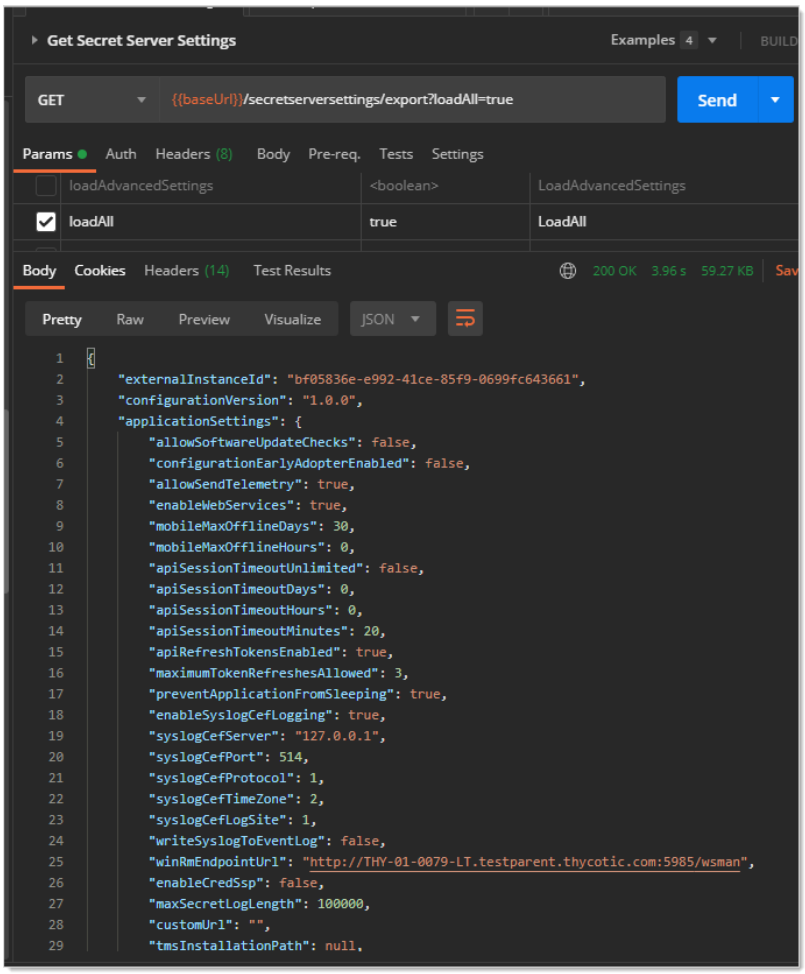
Looking at the query parameters for that endpoint, we see:



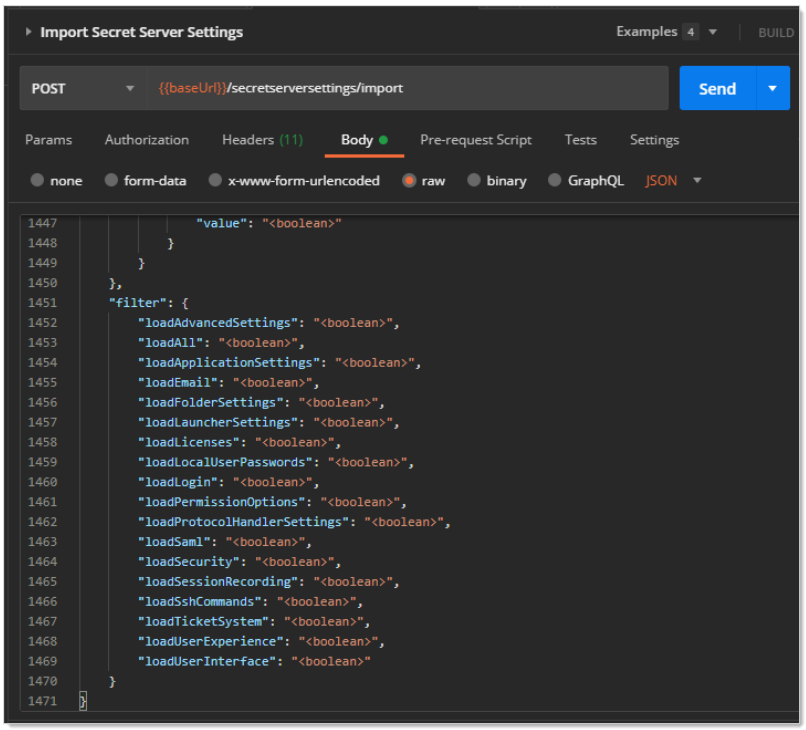
The keys are equivalent to those on the user interface or those in the JSON file.

The `loadAll` key tells Secret Server to update all the available settings. These include application settings, launcher settings, protocol handler settings, permission options, user experience settings, and user interface settings.

If you click the **Body** tab below, you can see what JSON code represents the key you chose for the export:



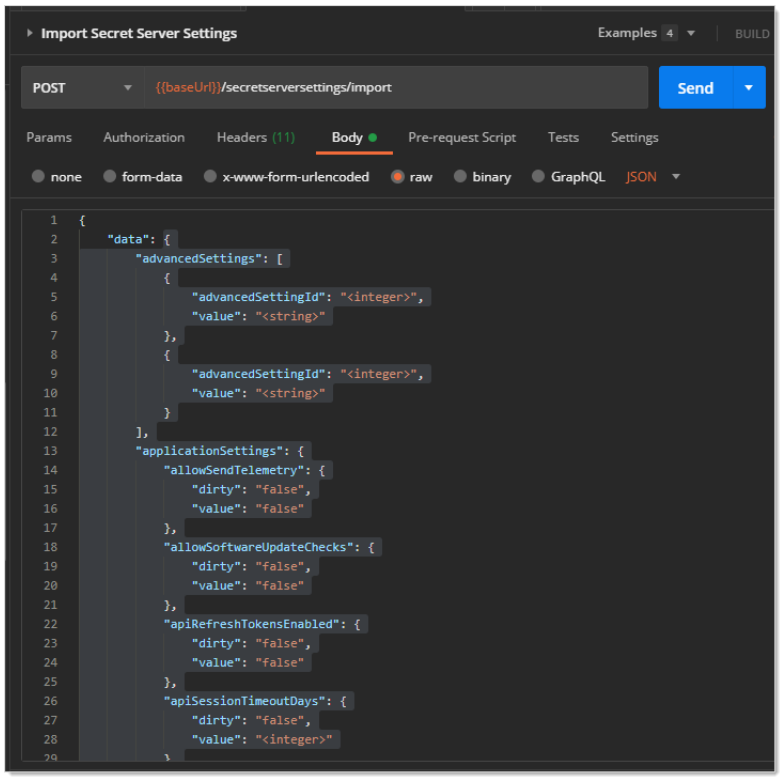
When using the POST Import Secret Server Settings command, you will see a filter object at the bottom of the code stipulating what to update:



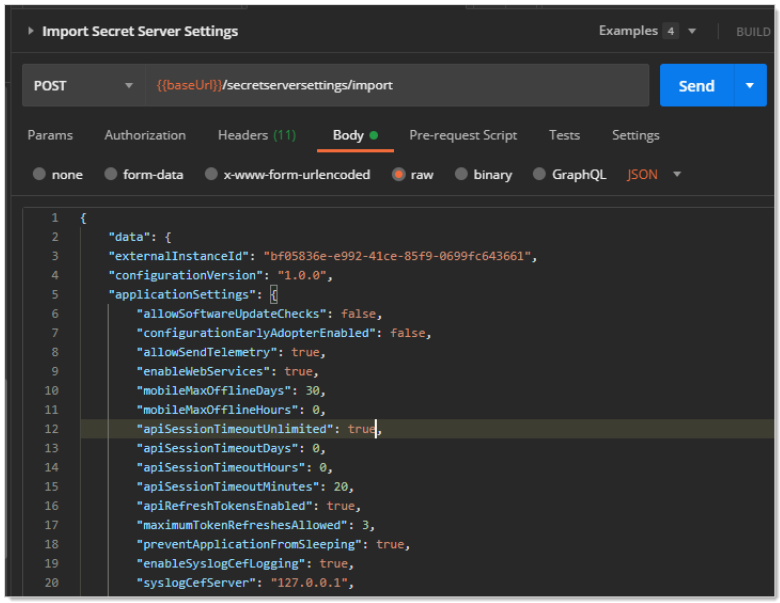
For example, if you set `loadApplicationSettings` to `true`, only the application settings are updated, assuming the objects stipulated were sent with the request. Similarly, included objects that are disallowed by the filter are ignored.

To make a GET call to update a single setting:

1. Import the category it belongs to. For example, if you want to update `apiSessionTimeoutUnlimited` to `true`, you would copy the entire `applicationSettings` result (the category and all of its settings).
2. For the POST Import Secret Server Settings call, remove the settings in the data section, leaving the filter section as is:



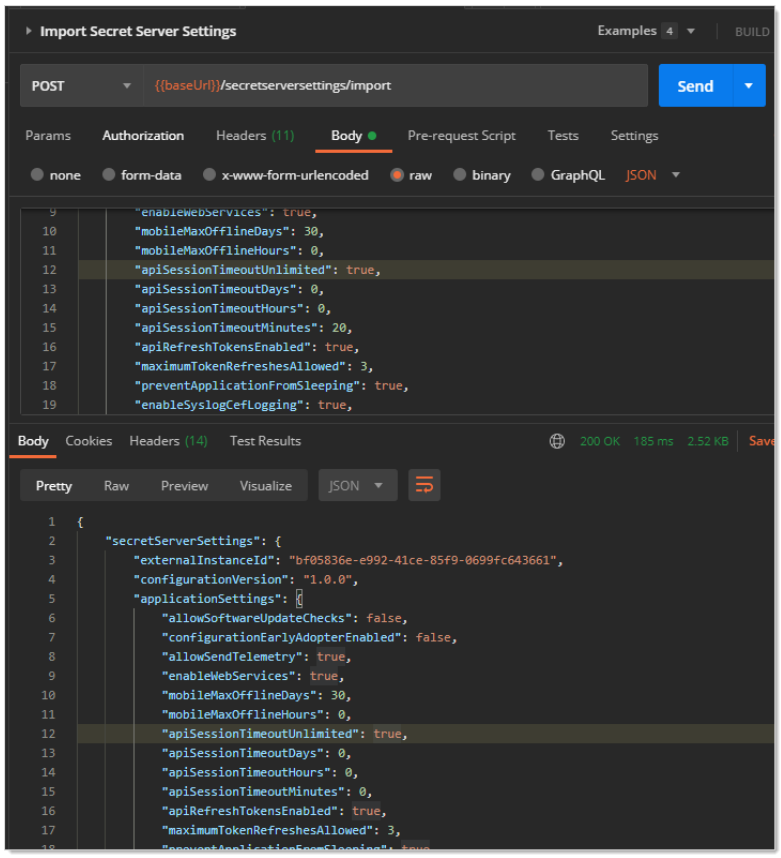
3. Paste the settings you copied earlier in its place.
4. Change the `apiSessionTimeoutUnlimited` setting to `true`:



5. Scroll down to the filter section and remove the filters you do not want to update. Alternatively, you can replace all the <bobolink> settings with `false` for the filters you do not want.
6. If you want to set a nullable field back to null, set the dirty flag and the value to null. For example:

```
"siteId": {
  "dirty": "true",  "value": null}
```

7. Click the **Send** button. If all goes well, Postman will return the updated category object:



> In this example, we copied the whole data object, but you do not have to. For a quick update, you can Import with just the settings you want to update. Anything not sent is ignored. This is the reason a nullable setting has to be explicitly set to null, along with setting the dirty flag–everything set to null is ignored, the same as if you did not send the setting at all.

8. If something went wrong, you will see an error section at the bottom of the results:

Audits

An audit is recorded for each setting category that was exported or imported by user. The individual setting audits can be viewed on the Configuration Audit page.

If there are errors, a system log entry will also be saved with details:

- Email
- Login
- Security
- Ticket System
- SAML - Completed with errors

Events

When Secret Server settings are exported or imported, an SECRETSERVERSETTINGS event is logged.

Logs

When Secret Server settings are exported or imported or validation errors occur, a new log entry will appear in the `SS.log` file.

`<Username>` and `<USERID>` are replaced with your values. The items in the parentheses are the errant category settings.

System Logs or CEF Example

```
<USERNAME> (<USERID>) - Secret Server Settings Import - Failed to import SAML for the
following reason(s): TicketSystem=Only one ticket system can be default.
(IsDefault);SAML=Identity Provider Id was not found in the database. Check that it was not
modified after export. (IdentityProviderId)
```

SS.log Examples

- `ERROR Delinea.Logging.ILogWriter - <USERNAME> (<USERID>) - Secret Server Settings Import - Failed to import SAML for the following reason(s): TicketSystem=Only one ticket system can be default. (IsDefault);SAML=Identity Provider Id was not found in the database. Check that it was not modified after export. (IdentityProviderId)`Secret Server.
- `ERROR Thycotic.Logging.ILogWriter - <USERNAME> (<USERID>) - Secret Server Settings Import - Failed to import some settings due to the following reason(s): Security=Access Denied;Login=Insufficient permissions to edit Radius settings. (Radius),Insufficient permissions to edit Delinea One or OpenId settings. (OpenIdConnect),Insufficient permissions to edit Duo settings. (Duo);TicketSystem=Only one ticket system can be default. (IsDefault);SAML=Access Denied`

Errors and Resolutions

Sample Error	Resolution
SAML=Access Denied	Need Administer Configuration SAML permission to update SAML settings.
SAML=Identity Provider Id was not found in the database. Check that it was not modified after export. (IdentityProviderId)	For SAML, the IdentityProviderId provided in the import file was not found in the database. If intending to add a new one, set this to 0.
TicketSystem=Only one ticket system can be default. (IsDefault)	For TicketSystem, IsDefault is set to true when there is already one set to true in the database. If intending to set it to true, set the other one to false.
Insufficient Delinea permissions to edit Radius settings. (Radius) Insufficient Delinea permissions to edit Duo settings. (Duo)	Need Delinea Administer Configuration Two Factor permission to update Radius or Duo settings.
Insufficient Delinea permissions to edit Delinea One or OpenId settings. (OpenIdConnect)	Need Delinea Administer OpenID Connect permission to update Open ID Connect settings.

Integrations

This list is current as of June 6, 2024. For a comprehensive list of Secret Server integrations see Delinea Integrations Documentation section.

Delinea Integrations

Integrations created by Delinea are code or applications that are not sold by Delinea for monetary compensation. They are provided free of charge for the use of Delinea customers and in some cases are available to the public.

Integrations are supported to the extent of the third-party product procedures documented for those integrations. Contact the third-party for customized setup of the integrated product.

Below is a list of Delinea integrations:

- AWS Discovery Integration with Secret Server
- Authy
- Automation Anywhere
- Atlassian
- Blue Prism
- BMC
- ConnectWise

- DUO Security
- Google Authenticator Integration with Secret Server
- Google Cloud Platform Discovery Integration with Secret Server
- Hardware Security Modules (HSM)
- IBM
- Radius
- JDBC Proxy Driver
- Microsoft
- OneLogin
- Okta
- Palo Alto Networks
- Rapid7
- Red Hat (IBM)
- SAP Hana
- SCIM Connector
- ServiceNow
- Slack
- Splunk
- Terraform
- UiPath Orchestrator

Third-Party Integrations

This category of integration encompasses any code or script which integrates with Delinea usually by API that is written by a third-party vendor. Delinea does not guarantee that third-party code is written correctly or that it respects Delinea product limitations.

For instance, the third-party code may fail to respect Token expiry or issue calls too quickly without waiting for responses and time-outs. Third-party integrations are supported by verifying that the Delinea application is functioning correctly. Delinea does not support, code or maintain third-party code or scripts.

For commercially sold third-party products which have vendor support, Delinea may elect to attend calls. The third-party product must be able to provide a knowledgeable resource and share specifics about how they integrate with the Delinea application. The goal of such calls would be to advise the third-party vendor about what they need to change to better integrate with Delinea products.

Assistance with configuration or troubleshooting these tools with third-party systems is not within the scope of what the Delinea Support organization can provide at this time. Delinea does not guarantee that every configuration of third-party systems will work with 3rd-Party integrations. Assistance with the use of these tools, configuration, or troubleshooting for customization of Delinea products can be worked on as part of a paid agreement with the Professional Services team.

Below is a list of third-party integrations:

- Argo
- Authomize
- BeyondTrust
- BMC
- Devolutions
- Entrust
- Fortanix
- IBM
- Imprivata
- Keyfactor
- LogicMonitor
- Monokee
- mRemoteNG
- Omada
- PagerDuty
- Qualys
- Royal TS
- Secure ID
- SailPoint
- Saviynt
- SurePassID
- Tenable
- Teradata
- Thales
- Trusona
- Twosense
- UIPath
- WitFoo

Maintenance Mode

Secret Server's maintenance mode is a crucial feature that allows administrators to temporarily prevent users from making changes to roles, secrets, or secret-related data such as dependencies, templates, and password requirements. This mode is particularly useful during critical operations like migrating the Secret Server application to a new server, performing upgrades, or rotating encryption keys to ensure data integrity and prevent corruption. While in maintenance mode, users can still view secrets in a read-only state, but cannot modify them or change their checkout status. Maintenance mode remains active until it is manually disabled, providing a controlled environment for administrators to perform necessary maintenance tasks without risking unauthorized changes or data loss.

- Enabling Maintenance Mode
- Maintenance Mode FAQ

Enabling Maintenance Mode

Turning on maintenance mode allows you to temporarily prevent users from changing roles, secrets, or secret-related data such as dependencies, templates, and password requirements. For example, you would want to enable Maintenance Mode while migrating the Secret Server application to a new server with a different domain.

To turn on Maintenance Mode:

1. Search for **Server Nodes**.
2. In the related node click the edit icon.
3. Check the box next to the Maintenance Mode.
4. Click **Save**.

> When Secret Server is in Maintenance Mode, a notification bar is displayed to alert users.

To return Secret Server from Maintenance Mode to normal operation, click the edit icon again and uncheck the box next to Maintenance Mode. When done, click **Save**.

> When Secret Server is in its normal running mode, the Maintenance Mode notification bar is no longer displayed to users.

Maintenance Mode FAQ

What is Maintenance Mode?

Maintenance mode prevents users from changing secrets or secret-related data such as dependencies, secret templates, and password requirements.

Why do we need Maintenance Mode?

When secret key rotation takes place, or the HSM configuration is changed, Secret Server needs to ensure that no data corruption occurs. To mitigate this, these operations turn on maintenance mode, which puts Secret Server into read-only mode. We also recommend manually enabling maintenance mode before performing upgrades.

Can I still access my Secrets when Maintenance Mode is turned on?

Yes. Secrets will be read-only, but you can still view them, including secrets that are double-locked or protected by "require approval for access." You are unable to change the checkout status of a secret during maintenance mode. This means if the secret is currently checked-in, you will be unable to check it out. If the secret is currently checked out, it cannot be checked in until the system leaves maintenance mode.

How long does Maintenance Mode last?

Maintenance mode lasts until it is manually disabled.

How do you enable and disable Maintenance Mode?

To enable and disable Maintenance Mode, see "Enabling Maintenance Mode" on the previous page.

Object Metadata

Overview

Object metadata allows you to store extended information on several Secret Server objects including users, groups, folders or secrets via the user interface or REST API. You can store most data types, including strings, Boolean values, numbers and users. You can combine this metadata into sections containing named fields of your defined types.

Unlike pre-existing object fields, this metadata is flexible and dynamic. No coding, structural changes, or database schema changes are required. The only constraint is a role permission that controls who can add metadata fields or sections, which is granular down to the sections level on a given entity. For example, users that can view a user might be allowed to edit the values in the "public" metadata section and users that can edit a user might be allowed to edit all the sections for that user.

Features

Secret Server object metadata features:

- You can store user-defined metadata sections and field values on users, groups, folders, or secrets.
- Sections and fields are defined once and can be used across any applicable object. This allows for a common description across all objects. For example, all the objects could have metadata fields for business owner, source system, and corporate department name.
- Metadata fields are grouped or organized into sections.
- When viewing metadata, only populated fields appear. Field names with blank values are never present.
- You can define who can edit which sections via a role permission and through setting the View or Edit permissions for the object.

- Each object maintains an audit history for all metadata fields, including previous values and who defined them.
- Audit history is viewable as a basic line chart for metadata fields stored as numbers. This provides a historical value table, as opposed to an audit log.

Example Use Cases

There are many ways to use Secret Server object metadata, such as:

- Defining common attributes from a corporate directory that are not available for a standard user, such as manager, hire date, or department.
- Allowing defined users to add data to an object without allowing that user to edit the object itself. For example, the user can not edit a certain secret but can add notations on the secret that are useful to others accessing the object.
- Storing external system link identifiers for integrations. For example, the employee ID from the HR system could be stored in the metadata for users. Integration jobs could then query this ID from the metadata and use it for synchronization.
- Adding a **department owner** field on a folder to store which department owns it. For instance, the folder contains secrets for marketing as defined by the metadata field.
- Avoiding users putting numerous items into the notes field on a secret, resulting in a disorganized mess. With metadata, those items could be stored in properly named fields. This organizes the notes and allows them to be easily searched without having to parse a block of text.

Adding Object Metadata

This instruction is on a user object. The process for folders, groups, and secrets is very similar.

1. Search for**Users**to get to the User Management page, listing several items/users.
2. Select a user you want to edit. The user's page appears.
3. Select the **Metadata** tab.
4. Click the **Add Metadata** button. The Add Metadata popup appears.
5. Click the **Section Name** dropdown list and select **Add New Section**. Additional controls appear.
6. Type the section name in the **New Section Name** text box.
7. (Optional) Type a description of the field in the **Section Description** text box.
8. Click the **Metadata Field** dropdown list and select **Add New Field**, more controls appear: **Metadata field name** and **Field type**.
9. Fill in the **Metadata field name** text box.
10. Click the **Field Type** dropdown list and select the desired data type. For our example we chose *Boolean*.
11. (Optional) Select the **Value** check box if you want the field to be pre-populated to true. This only applies to the Boolean data type.

> Boolean fields always appear later because they always have a value. Empty value fields do not appear.

12. Click the **Save** button. The new section and metadata field appears.

    The section appears in the top-left, with the field right under it. A true or false value is visible denoting if the user has this test-field.
13. Click the **Add Metadata** button again to add another field to the section. The Add Metadata popup returns.
14. This time, click the **Section Name** dropdown list and select the section that you just created.
15. Click the **Metadata Field** dropdown list box and select **Add New Field**.
16. Type a name for the new field in the **Metadata Field Name** text box.
17. Click the **Field Type** dropdown list to select *Date / Time*. Date and time text boxes appear. Add a date and time, do not leave them empty.
18. Click the **Save** button. The new field appears on the Metadata tab.
19. Add additional fields as required or desired. For our example, this makes the section, the test-field with its Boolean value, and the date / time field available for use across all Secret Server users.

Deleting Object Metadata

1. Search for**Users**to get to the User Management page, listing several items / users.
2. Select a user you want to edit. The user's page appears.
3. Select the **Metadata** tab.
4. Select a section you want to modify fields for and then click **Delete** for the field you no longer need. A prompt appears double checking you want to proceed as deleting a field will also delete its history and cannot be undone.

> Deleting all fields of a section will automatically delete the metadata section as whole. No warning prompt will be issued for this action, so double check before deleting all fields of a section.

Best Practices

How your organization uses object metadata requires some forethought, including:

- Will you allow anyone to add metadata or only a specific set of individuals? This is controlled by applying the above mentioned role.
- How do you want to standardize the naming of sections and fields? One user might call the same field *business owner* and another might call it *subject expert* if you do not establish the field nomenclature up front.
- Do you want to create a "public" field section that is available to all users to edit, even those with read only permission on the object?

Ticket System Integration

Introduction

Secret Server can allow users to enter a ticket number when viewing a secret. This number can be validated through a regular expression, and can also be marked as required, if needed. Secret Server can integrate with third party ticket systems. See below for more information.

Configurable Settings

Search for **Ticket system**, the Ticket systems page opens. Here you can view the list of all the existing Ticket systems. Click on a Ticket system from the list to edit it.

The ticket number appears in the audit log and can be queried in reports. Click **View Audit** to navigate to the system log. If the **View Ticket URL** has been set, the log shows the ticket number as a hyperlink linking to the external ticket system.

Ticket System Settings Section

You can add multiple ticket systems from the Ticket systems section. To add a new system, click **Create Ticket System** at the top right. The New ticket system window will open. Enter the following settings for your Ticket system settings section:

- **Name**: Enter the related ticket system name.
- **Description**: Enter your ticket system description.
- **Enabled**: Check to enable the ticket system.
- **Default**: Check to make this ticket system the default. If set as default, then this system will be selected by default when a user makes a request. Only one ticket system can be set as default. When saving as default, the previous that was the default will be deselected.
- **Ticket number label**: Enter the desired ticket number label, the text that displays next to the Ticket Number box on the Comment or Request Access page.
- **Ticket number reason options**: This option allows fine-grained control of what the user must enter when Require Comment is enabled and ticket system integration is turned on.
  - **Only Require Reason**: Ticket number is optional, reason is required.
  - **Require Both Ticket Number and Reason**: Ticket number and reason are required.
  - **Ticket Number or Reason Required**: Either ticket number or reason must be entered.
  - **Only Require Ticket Number**: Ticket number is required, reason is optional.
- **Ticket system publicly available**: This configuration is enabled by default, and if it is enabled, the ticketing system integration will attempt to run from the web server rather than the distributed engine. This setting is crucial for environments using Secret Server Cloud, as it may lead to failures if the integration is expected to run from DE. If you use Secret Server Cloud it is recommended to disable this field and select a **Site** from the dropdown that will appear below when the Ticket system publicly available field is disabled.

Ticket System Integration Section

Enter the following settings for your Ticket system integration section (also see Third Party Integrations for related details):

- **Type**: Select the related ticket system from the dropdown:
  - **Ticket number validation**: Secret Server can require users to enter a ticket number when viewing a secret. Admins can track access to secrets based on an external ticket system. After the ticket system is enabled in Secret Server, a user can enter a ticket number on the Comment screen or the Request Access screen. The secret needs to have Require Comment or Requires Approval for Access enabled to allow the user to enter a ticket number. When a ticket number is required, this secret setting is displayed as "Require Comment/Ticket Number" on the Security tab.
  - **BMC Remedy Incident Management**: See BMC Remedy Integration for more details.
  - **BMC Remedy Change Management**: See BMC Remedy Integration for more details.
  - **Custom Ticketing System (PowerShell)**: See Atlassian JIRA Integration (PowerShell), ManageEngine ServiceDesk Plus Integration (PowerShell), and PowerShell Ticketing Integration for more details.
  - **ServiceNow Change Management**: See ServiceNow Integration for more details.
  - **ServiceNow Incident Management**: See ServiceNow Integration for more details.
- **View Ticket URL Template:** The format of the URL to be used for viewing the ticket. This is placed in the audit log so you can easily view the corresponding ticket from Secret Server. The Ticket URL Format field can be edited on the "Ticketing System Integration" tab of the configuration page. In this field, the $TICKETID parameter will be replaced by the ticket number that is entered by the user. For example, if you specify the template as `http://myticketingsystem/ticket.aspx?ticketid=$TICKETID`, and a user enters 5125-242 as the ticket number, a link will appear in the audit log to `http://myticketingsystem/ticket.aspx?ticketid=5125-242`.
- **Ticket Number Format Pattern (Regex):** A regular expression to use for validating the ticket number entered. This can help prevent typos in the number. Considerations:
  - If you are using ticketing system integration, you can set a ticket pattern on the Ticket System Integration tab of the Configuration page.
  - If you do not want to restrict what ticket numbers a user can enter, you can leave the Ticket Number Validation Pattern (Regex) text box empty.
  - If you do want to restrict it, you can enter a regular expression in the text box. The ticket number entered must match the regular expression.
  - If you are supported and need assistance setting up a validation pattern, feel free to email support@delinea.com.
  - Here is an example for a ticket pattern that must be a valid number: `^[0-9]+$`
- **Ticket Number Validation Error Message:** The error message to display to the user when their entered ticket number fails the validation pattern regex.

Third-Party Integrations

Secret Server can integrate into third-party ticket systems as well. Those supported are listed below. You can add multiple ticket systems to Secret Server by clicking New Ticket System. You can make a specific ticket system the default system used by Secret Server by clicking the System link and then clicking the Set as Default button.

The third-party integrations:

- "Atlassian JIRA Integration (PowerShell)" below
- "BMC Remedy Integration" on page 243
- "ManageEngine ServiceDesk Plus Integration (PowerShell)" on page 246
- "PowerShell Ticketing Integration" on page 248
- "ServiceNow Integration" on page 248

Atlassian JIRA Integration (PowerShell)

Secret Server can integrate with Atlassian JIRA via PowerShell. This integration includes validating ticket numbers and their status, and adding comments.

For more information about integrating ticket systems with PowerShell, see "PowerShell Ticketing Integration" on page 248.

Requirements

- PowerShell, see "Creating and Using PowerShell Scripts" on page 1496.
- "Configuring CredSSP for WinRM with PowerShell" on page 1502.

> Atlassian has deprecated TLS 1.0 and 1.1, and will support only TLS 1.2 and 1.3 going forward. See Deprecating TLSv1 and TLSv1.1 for Atlassian Cloud Products.

Ticket Number Validation Pattern (Regex)

Before making a call to the ticket validation script, you can have Secret Server validate that the number matches a pattern. For example, you will probably have multiple JIRA projects and will want your users to specify these correctly. One regex would be to simply allow any project name followed by a dash and numbers:

```
^\w{3}-\d+$
```

Or perhaps you want to specifically match projects that you know are real followed by a dash and numbers:

```
^((PRO1)|(PRO2))-\d+$
```

For more information, see **Setting a Ticket Pattern Regex** on the "Ticket System Integration" on page 238 page.

Validating Ticket Status

> The system credentials are specific to your ticketing system. You can use any secret using the username and password extended mapping as your system credential. You can add other arguments in the secret's fields and reference them in your script.

You need to create a PowerShell script to retrieve and validate tickets. This integration assumes that the user will pass in the full ticket name, including the project name. For example: `(PROJ-123)`. This could easily be extended so that multiple JIRA instances could be made for each project. In that case, you could have the user provide only the ticket number and pass in an argument to the script that specifies the project. This implementation also assumes that any ticket not in "Closed" status is invalid.

```
$ticket = $args[0]
$user = $args[1]
$password = $args[2]
$url = $args[3]
$closedStatus = "Closed"
$fields = "status"
$p = $password | ConvertTo-SecureString -AsPlainText -Force
$credentials = New-Object System.Management.Automation.PsCredential($user,$p)
$getStatusMethod = "$url/rest/api/latest/issue/$ticket"
function ConvertTo-UnsecureString([System.Security.SecureString][parameter
(mandatory=$true)]$SecurePassword)
{
    $unmanagedString = [System.IntPtr]::Zero;
    try
    {
        $unmanagedString =
[Runtime.InteropServices.Marshal]::SecureStringToGlobalAllocUnicode($SecurePassword)
        return [Runtime.InteropServices.Marshal]::PtrToStringUni($unmanagedString)
    }
    finally
    {
        [Runtime.InteropServices.Marshal]::ZeroFreeGlobalAllocUnicode($unmanagedString)
    }
}
function ConvertTo-Base64($string)
{
   $bytes  = [System.Text.Encoding]::UTF8.GetBytes($string);
   $encoded = [System.Convert]::ToBase64String($bytes);
   return $encoded;
}
function ConvertFrom-Base64($string)
{
   $bytes  = [System.Convert]::FromBase64String($string);
   $decoded = [System.Text.Encoding]::UTF8.GetString($bytes);
   return $decoded;
}
function Get-HttpBasicHeader($Credentials, $Headers = @{})
{
 $b64 = ConvertTo-Base64 "$($Credentials.UserName):$(ConvertTo-UnsecureString
$Credentials.Password)"
 $Headers["Authorization"] = "Basic $b64"
 return $Headers
}
try
{
    $headers = Get-HttpBasicHeader $credentials
    $response = Invoke-RestMethod -Method Get -uri $getStatusMethod -Headers $headers -
ContentType 'application/json'
```

```
    if($response.fields.status.name -eq $closedStatus)
    {
        throw "JIRA ticket ($ticket) is closed."
    }
}
catch
{
    $exception = $_.Exception
    if ($exception.Response.StatusCode.value__ -eq 404)
    {
        throw "JIRA ticket ($ticket) does not exist."
    }
}
```

Adding Comments to Tickets

To add comments to tickets, you will need to create the script below.

```
$ticket = $args[0]
$comment = $args[1]
$user = $args[2]
$password = $args[3]
$url = $args[4]
$p = $password | ConvertTo-SecureString -AsPlainText -Force
$credentials = New-Object System.Management.Automation.PsCredential($user,$p)
function ConvertTo-UnsecureString([System.Security.SecureString][parameter
(mandatory=$true)]$SecurePassword)
{
    $unmanagedString = [System.IntPtr]::Zero;
    try
    {
        $unmanagedString =
[Runtime.InteropServices.Marshal]::SecureStringToGlobalAllocUnicode($SecurePassword)
        return [Runtime.InteropServices.Marshal]::PtrToStringUni($unmanagedString)
    }
    finally
    {
        [Runtime.InteropServices.Marshal]::ZeroFreeGlobalAllocUnicode($unmanagedString)
    }
}
function ConvertTo-Base64($string)
{
   $bytes  = [System.Text.Encoding]::UTF8.GetBytes($string);
   $encoded = [System.Convert]::ToBase64String($bytes);
   return $encoded;
}
function ConvertFrom-Base64($string)
{
   $bytes  = [System.Convert]::FromBase64String($string);
   $decoded = [System.Text.Encoding]::UTF8.GetString($bytes);
   return $decoded;
```

```
}
function Get-HttpBasicHeader($Credentials, $Headers = @{})
{
 $b64 = ConvertTo-Base64 "$($Credentials.UserName):$(ConvertTo-UnsecureString
$Credentials.Password)"
 $Headers["Authorization"] = "Basic $b64"
 return $Headers
}
try
{
    $updateObject = @{'body'=$comment}
    $body = $updateObject | ConvertTo-Json
    $addComment = "$url/rest/api/latest/issue/$ticket/comment"
    $headers = Get-HttpBasicHeader $credentials
    $response = Invoke-RestMethod -uri $addComment -Headers $headers -Method Post -
ContentType "application/json" -Body $body
    if ($response.body -ne $comment)
    {
        throw "There was an issue adding a comment to the ticket ($ticket)."
    }
}
catch
{
    $exception = $_.Exception
    if ($exception.Response.StatusCode.value__ -eq 404)
    {
        throw "The ticket ($ticket) does not exist.";
    }
    if ($exception.Response.StatusCode.value__ -eq 400)
    {
        throw "There was an issue adding a comment to the ticket ($ticket)."
    }
    throw "There was an unhandled issue with adding a comment: " + $exception.ToString()
}
```

BMC Remedy Integration

Overview

Secret Server can integrate with BMC Remedy's Incident and Change Management. This integration includes validating ticket numbers, their status, and adding work detail items to the request.

The integration with BMC Remedy leverages the out-of-the-box, SOAP-based Web services that are installed with the ITSM product installation. These services must be installed on your mid-tier BMC Remedy server to allow for this integration if they are not already installed and configured.

Requirements

- BMC Remedy SOAP Web Services enabled.
- A username and password that has access to execute the Web services. This can be set up in the developer studio by accessing the application in the navigator and viewing Permissions for the `CHG_ChangeInterface_WS`

or `HPD_IncidentInterface_WS`. This user should also have access to query requests and add work items to requests for the appropriate module.

- Secret Server environment needs to be able to connect to the BMC Remedy Web services via port 80 or 443. SSL is highly recommended because the SOAP messages contain a username and password.

Configurable Settings

Validating Ticket Status

When a BMC Remedy request number is entered into Secret Server, the status of that request is retrieved to ensure that it is an open state. For example, if an incident number is entered that is in the "Closed" state, the user is informed that the ticket is closed.

Incident Management: Service Incident request cannot be closed or canceled. Change Management: Change management requests cannot be complete, closed, or canceled.

View Ticket URL Template

The format of the URL to be used for viewing the ticket. This is placed in the audit log so you can easily view the corresponding ticket from Secret Server. Depending on your version of BMC Remedy, the URL to link directly to a request may be slightly different.

Incident management:

```
https://<midtier_server>//arsys/forms/<server
name>/SHR%3ALandingConsole/Default+AdmSearchTicketWithQual&F304255610='Incident
Number'%3D%22$TICKETID%22
```

Change management:

```
https://<midtier_server>//arsys/forms/<server
name>/SHR%3ALandingConsole/Default+AdmSearchTicketWithQual&F304255610='Change
Number'%3D%22$TICKETID%22
```

Ticket Number Format Pattern (Regex)

Before even making a call to the BMC Remedy Web service, you can have Secret Server validate that the number matches a pattern. For example, your incident numbers might all be prefixed with "INC" and you want to ensure users enter the prefix. Some sample expressions to validate the ticket number are listed below:

Incident management: `^INC_CAL_[\d]{7}$`

Change management: `^CRQ_CAL_[\d]{7}$`

Ticket Number Validation Error Message

The error message to display to the user when their entered ticket number fails the validation pattern regex.

Service Endpoint URL

This is the URL for the SOAP-based Web services. Below are some samples for what is expected. You can find the actual endpoint using BMC Remedy Developer Studio and accessing the correct application from the AR System Navigator and viewing the Web services section of the application.

Incident management: `HPD_IncidentInterface_WS`

Change management: `CHG_ChangeInterface_WS`

System Credentials

Select or create a secret that contains the username and password for a user that has access to execute the SOAP Web services. The username and password are added to the authentication header for the SOAP request.

> The system credentials are specific to your ticketing system. You can use any secret using the username and password extended mapping as your system credential. You can add other arguments in the secret's fields and reference them in your script.

Authentication

If your installation of BMC Remedy uses an authentication server, enter it in this text-entry field. Most installations allow this text-entry field to be blank.

Add Comments to Ticket

Check this box if you want the comment that a user enters to be added to the request in BMC Remedy. This adds information such as the secret for which access is requested, who requested access, and the requester's comments.

Comment Work Type

When a comment is added to a request as a work item, the Work Item type is required. "General Information" is selected by default, but all default Work Type options are supported.

Testing Your Integration Setup

After configuring the ticket system (see configurable settings below), use the **Test Validation** button to verify that Secret Server can successfully access BMC Remedy. This button opens a dialog in which you can enter a ticket number from BMC Remedy. This validation process returns success or an error code. BMC Remedy may not return much detail in the error message so you need to look at the BMC Remedy API log to see a detailed error message, see the next section.

BMC Remedy Error Messages

When Secret Server calls the BMC Remedy SOAP-based web services, there are times that BMC will only return a 500 error without any details of the exception. You can see the details of this exception from the BMC Remedy server logs as described below:

1. Log on BMC Remedy as a user with access to the administrative console.
2. Navigate to **AR System Administration** from the main menu.
3. Navigate to **System > General > Service Information**.
4. Click the **Log Files** tab.
5. Click to enable the **API Log** check box.
6. Click the **Apply** button.

7. Once enabled, you can click **View** from this window to see the log or navigate to the mid-tier server's file system at the location specified. Details of the SOAP web service exception are written to the log file including a stack trace.

ManageEngine ServiceDesk Plus Integration (PowerShell)

Secret Server can integrate with ManageEngine ServiceDesk Plus via PowerShell. This integration includes validating ticket numbers and their status, and adding comments (referred to as notes in ServiceDesk Plus).

For more information about integrating ticket systems with PowerShell, see "PowerShell Ticketing Integration" on page 248.

Requirements

- PowerShell, see "Creating and Using PowerShell Scripts" on page 1496.
- Access to the REST API for your ManageEngine ServiceDesk Plus instance.
- "Configuring CredSSP for WinRM with PowerShell" on page 1502.

Ticket Number Validation Pattern (Regex)

Before making a call to the ticket validation script, you can have Secret Server validate that the number matches a pattern. For more information, see **Setting a Ticket Pattern Regex** on the "Ticket System Integration" on page 238 page.

Validating Ticket Status

> The system credentials are specific to your ticketing system. You can use any secret using the username and password extended mapping as your system credential. You can add other arguments in the secret's fields and reference them in your script.

You need to create a PowerShell script to retrieve and validate tickets. This integration assumes that the administrator will set the technician key for accessing ServiceDesk Plus in the script. This could easily be extended to pass in the key as an argument so that it can be managed from the ticket system interface.

```
$ticket = $args[0]
$user = $args[1]
$password = $args[2]
$url = $args[3]
$validStatus = "Open"
$fields = "status"
$technicianKey = "<YOUR API GUID>"
$p = $password | ConvertTo-SecureString -AsPlainText -Force
$credentials = New-Object System.Management.Automation.PsCredential($user,$p)
$getStatusMethod = "$url/sdpapi/request/$ticket"
try
{
    $postParams = @{OPERATION_NAME='GET_REQUEST';TECHNICIAN_KEY=$technicianKey}
```

```
    [xml]$response = Invoke-WebRequest -Uri $getStatusMethod -Method POST -Body
$postParams -Credential $credentials
    if ($response.API.response.operation.result.status -ne "Success")
    {
     throw "Response not successful." + $response.API.response.operation.result.message
    }
    $statusNode = $response.API.response.operation.Details.ChildNodes | Where-Object {
($_.name -eq "status") }
    if($statusNode.value -ne $validStatus)
    {
        throw "Manage Engine Service Desk Plus ticket ($ticket) is not in Open status."
    }
}
catch
{
    if ($response.operation.result.message -eq "Invalid requestID in given URL")
    {
        throw "Manage Engine Service Desk Plus ticket ($ticket) does not exist."
    }
    throw "Manage Engine Service Desk Plus encounderted an error: " +
$response.operation.result.message
}
```

Adding Comments (Notes) to Tickets

To add comments (notes) to tickets you will need to create the script below. Other considerations are to pass in whether or not the note should be public.

```
$ticket = $args[0]
$comment = $args[1]
$user = $args[2]
$password = $args[3]
$url = $args[4]
$technicianKey = "<YOUR API GUID>"
$isPublic = 'true'
$p = $password | ConvertTo-SecureString -AsPlainText -Force
$credentials = New-Object System.Management.Automation.PsCredential($user,$p)
# Clean comment input for use in XML
$comment = $comment.replace('&', '&amp;').replace("'", ''').replace('"', '"').replace('<',
'<').replace('>', '>')
$inputData = @"
<Operation>
    <Details>
        <Notes>
            <Note>
                <isPublic>$isPublic</isPublic>
                <notesText>$comment</notesText>
            </Note>
        </Notes>
    </Details>
```

```
</Operation>
"@
$URI = "$url/sdpapi/request/$ticket/notes"
$postParams = @{OPERATION_NAME='ADD_NOTE';TECHNICIAN_KEY=$technicianKey;INPUT_
DATA=$inputData}
$response = Invoke-WebRequest -Uri $URI -Method POST -Body $postParams
[xml]$responseContent = $response.Content
if ($responseContent.API.response.operation.result.status -ne "Success")
{
    $message = $responseContent.API.response.operation.result.message;
    throw "Unable to add comment to ticket ($ticket). Message: " + $message
}
```

ServiceNow Integration

For information on system requirements, setup and validation see Integrating ServiceNow ITSM with Secret Server for details.

PowerShell Ticketing Integration

Secret Server can integrate with your ticketing system via PowerShell. This integration includes validating ticket numbers, their status, and adding comments. In our example we are connecting to a ServiceNow instance.

See "Creating and Using PowerShell Scripts" on page 1496.

Configurable Settings

View Ticket URL Template

You can configure the view ticket URL if you have a web based ticketing system to allow easy access to link to your ticketing system from Secret Server.

Ticket Number Validation Pattern (Regex)

Before making a call to the PowerShell script you can have Secret Server validate the number matches a pattern. For example, your incident numbers might all be prefixed with "INC" and you want to ensure they enter this prefix. See "Ticket System Integration" on page 238).

Ticket Number Validation Error Message

The error message to display to the user when their entered ticket number fails the validation pattern Regex.

The PowerShell RunAs Credentials

In Secret Sever a domain credential is required to execute the PowerShell script. This is a required field.

System Credentials

The system credentials are specific to your ticketing system. You can use any secret using the username and password extended mapping as your system credential. You can add other arguments in the secret's fields and reference them in your script.

Validating Ticket Status

Overview

To validate tickets you will need to create a PowerShell script to retrieve and validate the ticket. The integration will use arguments to pass custom values to your script. By default we will map certain fields to the first set of arguments. The ticket number will be collected by user input and assigned to the first parameter. When you have your ticketing system credentials mapped to a secret and assigned to the "System Credentials" field in the ticketing system setup, Secret Server inserts UserName and Password as the second and third parameters.

Therefore, for the sample script below, the Ticket Status Script Arguments text box should be only contain`$url` (which is also retrieved from the System Credentials secret), as `$ticket`, `$user` and `$password` are supplied automatically by the system.

Sample Script

```
$ticket = $args[0]
$user = $args[1]
$password = $args[2]
$url = $args[3]
$validStatus = "2"
$fields = "state"
$p = $password | ConvertTo-SecureString -AsPlainText -Force
$credentials = New-Object System.Management.Automation.PsCredential($user,$p)
$getStatusMethod = "$url/api/now/table/incident?sysparm_limit=10&sysparm_
query=number=$ticket&sysparm_display_value=&sysparm_fields=$fields"
$response = Invoke-RestMethod $getStatusMethod -Method Get -ContentType
'application/json' -Credential $credentials
if($response.result.state -ne $validStatus)
{
  throw "Invalid State"
}
```

Adding Comments to Tickets

To add a comment to tickets, create another script to do so. Example:

```
$ticket = $args[0]
$comment = $args[1]
$user = $args[2]
$password = $args[3]
$url = $args[4]
$p = $password | ConvertTo-SecureString -AsPlainText -Force
```

```
$credentials = New-Object System.Management.Automation.PsCredential($user,$p)
$restEndpoint = "$url/api/now/table/incident?sysparm_limit=10&sysparm_
query=number=$ticket&sysparm_display_value=&sysparm_fields=sys_id"
$response = Invoke-RestMethod $restEndpoint -Method Get -ContentType 'application/json' -
Credential $credentials
$id = $response.result.sys_id
$updateObject = @{'work_notes'=$comment}
$body = $updateObject | ConvertTo-Json
$addComment = "$url/api/now/table/incident/$id"
$response = Invoke-RestMethod $addComment -Method Put -ContentType 'application/json' -
Credential $credentials -Body $body
```

Adding Comments to a General Audit Log

In addition to adding comments to specific tickets, you may want general audit entries made in your ticket system. The arguments are passed in the following order.

```
$comment = $args[1]
$user = $args[2]
$password = $args[3]
## custom script here
```

Using $TEMPLATEARGS

`$TEMPLATEARGS` is used to pass dynamic arguments from the secret template to the ticketing system during integration. It is used to facilitate the transfer of specific field values required for ticket validation.

When setting up the template-specific arguments in the Secret Server UI, you should list the slug names without the $ symbol. For example, if you have a field with the slug `machine`, you would enter `machine` in the Ticket System Parameters field.

When referencing these arguments in the PowerShell script, you use them as variables, which requires the $ symbol. For example, `$templateArgs` in the script is used to capture the value passed from the Secret Server.

Example:

```
Ticket System Parameters: computername secretname
Ticket Integration Arguments: TEMPLATEARGS USERNAME SECRETSERVERDISPLAYNAME
```

Setting Up Ticket System Parameters

Define the parameters on the secret template that need to be passed to the ticket system.

Ensure slug names match exactly between the template and the ticket integration. Slug names are case-sensitive.

Example Configuration:

- Template:
  - Field Name: Machine
  - Slug: machine
- Ticket System Parameters: machine secretname

Example PowerShell Script:

```
# --- CONFIGURATION ---
$BasePath = "C:\temp\ServiceNow"
$LogDir = Join-Path $BasePath "Logs"
$SSPayloadPath = Join-Path $BasePath "SS_TicketValidation_Input.json"
$timestamp = Get-Date -Format "yyyyMMdd-HHmmss"
$LogFile = Join-Path $LogDir "TicketValidation_$timestamp.log"

$ValidationUrl = "https://yourinstance.service-now.com/api/validatechange"

# --- FIELD MAPPINGS ---
$ValidationFields = @{
"System Value" = "changeContainsCI"
"Change Status" = "isChangeinImplement"
"User" = "isMember"
"Secret Value" = "matchRequestedCredentials"
"Change Time Window" = "withinImplementationWindow"
}

# --- ARGUMENTS ---
if ($args.Count -lt 6) {
throw "Ticket Validation Failed: Missing arguments. Expected 6 total."
}

$ticket = $args[0].Trim()
$SNUser = $args[1].Trim()
$SNPass = $args[2].Trim()
$templateArgs = $args[3].Trim() # This is where TEMPLATEARGS is used
$username = $args[4].Trim()
$requestedBy = $args[5].Trim()

# --- LOGGING FUNCTION ---
function Write-Log {
param ([string]$Message, [string]$Level = "INFO")
$ts = Get-Date -Format "yyyy-MM-dd HH:mm:ss"
$entry = "[$ts][$Level] $Message"
Add-Content -Path $LogFile -Value $entry
}

# --- BUILD PAYLOAD ---
$payload = @{
change_number = $ticket
cmdb_ci = $templateArgs # Using TEMPLATEARGS to pass the computer name or other values
credentials_requested = $username
userid = $requestedBy
```

```
}

$payloadJson = $payload | ConvertTo-Json -Depth 3

# --- SEND POST TO SERVICENOW ---
try {
$response = Invoke-RestMethod -Uri $ValidationUrl -Method Post -Body $payloadJson
Write-Log "Received SN response: $(ConvertTo-Json $response -Depth 5)" "DEBUG"
} catch {
Write-Log "SN request failed - $_" "ERROR"
throw "Ticket Validation Failed: Unable to contact ServiceNow."
}

# --- VALIDATION LOGIC ---
$failures = @()

foreach ($label in $ValidationFields.Keys) {
$field = $ValidationFields[$label]
$value = $response.result.$field

if (-not $value) {
$reason = $FailureReasons[$label]
$failures += "$label - $reason"
Write-Log "Validation failed: $label => $reason" "ERROR"
} else {
Write-Log "Validation passed: $label ($field)" "DEBUG"
}
}

if ($failures.Count -gt 0) {
$errorMessage = "Ticket Validation Failed: $($failures -join '; ')"
Write-Log $errorMessage "ERROR"
throw $errorMessage
}

Write-Log "Ticket Validation Passed"
```

`$templateArgs` variable is used to capture the value passed from the secret template using `$TEMPLATEARGS`. It is intended to pass values like the computer name or other relevant fields from the secret template to the ticket system.

Approval vs. Comment Issue

Known Issue: When using approval workflows, `$TEMPLATEARGS` may not process correctly, resulting in the output of `$TEMPLATEARGS` instead of the expected values.

Workaround: Ensure comments are turned on for the arguments to output correctly.

Troubleshooting and Notices

The Troubleshooting section is designed to assist users in diagnosing and resolving common issues they may encounter. It includes a variety of subcategories, such as Enabling debug in system logs, Identifying release version numbers, addressing HTTP errors, and resolving SSH issues. Additionally, there are topics dedicated to IIS-specific troubleshooting, notices regarding system updates or changes, and other general troubleshooting topics.

> This section is a work in progress and supplements knowledge articles provided by Support. It does **not** contain a complete set of Secret Server troubleshooting and workaround articles.

IIS

> This topic only applies to **Secret Server On-Premises**.

This section is dedicated to troubleshooting issues specific to IIS, Microsoft's web server platform. These resources are designed to help users optimize the performance and functionality of their IIS setups.

Application Pool Load User Profile Setting Must Be Enabled

> This topic only applies to **Secret Server On-Premises**.

Secret Server requires the application pool to have the "load user profile" setting enabled. Secret Server will report a critical alert to notify admins if this setting is not enabled.

> The site will load to give access to secrets but many internal operations will not function correctly so we recommend fixing the issue as soon as possible.

> This applies to version 10.2 and later.

Steps to enable the "load user profile" setting:

1. On each Web server that is running Secret Sever, open IIS Manager.
2. Under the **Application Pool** node on the left, select **Secret Server**.
3. On the right-hand panel, select **Advanced Settings** to get to the full properties.
4. Scroll to the **Load User Profile** setting in the **Process Model** section.
5. Set **Load User Profile** to **True**.
6. Click the **OK** button.
7. Preform an `iisreset` on the server:
    a. Open a Windows command prompt as an administrator.

b. Type `iisreset`.

c. Press the **<Enter>** key.

Changing IIS to Not Stop Worker Process in IIS 7.0 and Later

This topic only applies to **Secret Server On-Premises**.

Overview

When using IIS version 7.0 and above, by default, the worker process terminates after a period of inactivity. If Secret Server is in its own application pool, the application pool will stop after a period of no requests. To make sure that the application pool associated with Secret Server does not stop when idle:

- Set the idle time-out to 0 minutes.
- Set the regular time interval to 0.
- Ensure there are no specific times scheduled for recycling.

Additionally, by default, IIS launches a worker process when the first request for the Web application is received. So if the Secret Server application takes a long time to start, we recommend launching the worker process as soon as IIS is started by setting the start mode to AlwaysRunning to launch the worker process for the Secret Server application pool as soon as IIS is started.

Procedure

To change IIS advanced settings:

1. Open **Internet Information Server (IIS) Manager**: On the taskbar, click **Server Manager**, click **Tools**, and then click **Internet Information Services (IIS) Manager**.
2. In the **Connections** pane, expand the server name.
3. Click **Application Pools**.
4. Locate the application pool Secret Server is running as. To determine this:
   a. Expand **Sites** at the left, then find the website Secret Server is running on.
   b. Click on the Secret Server website or virtual directory (if it is running on one).
   c. Click **Basic Settings** on the right panel. This indicates Secret Server's application pool.
5. Right-click the application pool, and select **Advanced Settings**. The Advanced Settings panel appears.
6. Go to the **(General)** section.
7. Set **Start Mode** to **AlwaysRunning**.
8. Set **Maximum Worker Processes** to **1**.
9. Go to the **Process Model** section.
10. Set **Idle Time-out (minutes)** to **0**.
11. Go to the **Recycling** section.

12. Set the **Regular Time Interval (minutes)** to **0**.
13. Select **Specific Times**.
14. **Either** click the **>** expander arrow to see if there is time specified below. **Or** click the **...** to see if there are any values in the **TimeSpan Collection Editor** dialog box. If so, clear it out.
15. Click the **OK** button. The dialog closes.
16. Click the **OK** button.

Notices

The Security and Technical Notices section serves as a central hub for important updates and alerts regarding system security and technical changes. This area provides critical information about security vulnerabilities, patches, and best practices to safeguard systems from potential threats. Additionally, it includes technical notices that inform users about upcoming changes, software updates, and system enhancements.

Notice: jQuery CVE-2019-11358

Relevance

This Delinea**technical issue** knowledge base article is relevant to:

- Product(s): Secret Server using jQuery 3.2.1
- Version(s): 10.7
- Edition(s): All

Technical Issue

Secret Server 10.7 uses jQuery 3.2.1, which is listed as vulnerable to the jQuery CVE-2019-11358 security issue on the Common Vulnerabilities and Exposures (CVE) list.

Resolution

Delinea removed the jQuery vulnerability from Secret Server's copy of jQuery v3.2.1 by applying a patch (see Related Articles and Resources).

To verify the fix:

1. Navigate to `https://<your_secret_server_URL>/assets/libs/jquery-3.2.1.js`
2. Open the file in a text editor.
3. Search for the string `proto` in the code: ...

```
ERROR: Invalid Code Highlighting Language
```

4. If the string appears, the patch has been applied.

Related Articles and Resources

- NIST website for CVE-2019-11358
- GitHub commits on the fix

> The commit shows two files, the top file is the security fix, and the bottom file is a unit test for the fix. Secret Server does not ship with any jQuery unit tests as found in that second file.

- Common Vulnerabilities and Exposures (CVE) list

Notice: jQuery CVE-2020-11022

Relevance

This Delinea **technical issue** knowledge base article is relevant to:

- Product(s): Secret Server using jQuery 3.2.1
- Version(s): 10.8.000004
- Edition(s): All

Technical Issue

Secret Server 10.8.000004 uses jQuery 3.2.1, which is listed as vulnerable to the jQuery CVE-2020-11022 security issue on the Common Vulnerabilities and Exposures (CVE) list.

Resolution

Delinea removed the jQuery vulnerability from Secret Server's copy of jQuery v3.2.1 by applying a patch (see Related Articles and Resources).

To verify the fix:

1. Navigate to `https://<your_secret_server_URL>/assets/libs/jquery-3.2.1.js`
2. Open the file in a text editor.
3. Search for the string `htmlPrefilter` in the code (line 5919):

```
jQuery.extend( {
htmlPrefilter: function(html) {return html;}
```

4. If the string appears, the patch has been applied.

Security Advisory 2019

Detection

During a security review of Secret Server on June 4, 2019, an internal security team found the security issue described below. The issue was also detected later by an internal team in Password Reset Server.

The Security Issue

An attacker with administrator permissions could modify the input field data in one specific location to execute a SQL injection attack against Secret Server or Password Reset Server. This means that the attacker could append, modify or delete data in the Secret Server or Password Reset Server SQL databases, and upgrade their access to code execution on the SQL server.

Common Vulnerability Scoring System Version 3.0

The CVSS score for this issue is 9.1. The CVSS vector string is CVSS:3.0/AV:N/AC:L/PR:H/UI:N/S:C/C:H/I:H/A:H

Products Affected

- Secret Server On-Premises version 10.6.000026 and earlier.
- Secret Server Cloud, which was updated June 15, 2019 to permanently remove this issue for all customers.
- Password Reset Server earlier than version 5.1.000005.

Recommended Actions

- All Secret Server On-Premises customers should upgrade to version 10.6.000027 or later.
- All Password Reset Server customers should upgrade to version 5.1.000005 or later.
- Secret Server Cloud users do not need to take any action.

HTTP Errors

This subsection focuses on diagnosing and resolving specific HTTP-related issues. Within this section, you will find folders dedicated to troubleshooting particular HTTP error codes, such as the "HTTP 404.2 Error" related to ISAPI and CGI restrictions and the "HTTP 404.17 Error" associated with the .NET Framework.

HTTP Error 404.17 - Not Found After Upgrading .NET Framework Version

Error

After upgrading Secret Server and changing the CLR version, when attempting to load Secret Server, you receive the following error in Internet Explorer:

```
HTTP Error 404.17 - Not Found The requested content appears to be script and will not be
served by the static file handler
```

Resolution

This error can be caused by ASP.NET 4.5 not being correctly registered on the server. To correct this:

Windows Server 2012 or 2012 R2

Use the Server Manager to install ASP.NET 4.5.

1. Open the Server Manager.
2. Select **Manage > Add Roles and Features**. The Add Roles and Features wizard appears.
3. Click the **Next** button. The Select Installation Type page appears.
4. Click to select the **Role-based or feature-based installation for your server** selection button.
5. Click the **Next** button twice. The Select Server Roles page appears.
6. Click to select the **Web Server (IIS)** check box in the **Roles** list.
7. Click the **Next** button until you arrive at **Role Services** under **Web Server (IIS)**.
8. Drill down to **Web Server > Application Development** in the **Role Services** list.
9. Click to select the **ASP.NET 4.5** check box.
10. Click the Next button until you arrive at the final page.
11. Click the **Install** button.
12. Once installed, follow the resolution instructions in HTTP Error 404.2 - ISAPI and CGI Restrictions to ensure ASP.NET 4.0 is allowed to execute in IIS.

HTTP 404.2 Error ISAPI/CGI Restrictions Stopping .NET Framework 4.5.1

Error

An HTTP 404.2 error code is received when ISAPI/CGI Restrictions are preventing the.NET Framework 4.5.1 from running.

Resolution

1. Open Internet Information Services.
2. Select the Server in the left tree view.
3. In the **IIS** section, open ISAPI and CGI Restrictions.
4. For all items beginning with **ASP.NET v4.0**, right-click the item and select **Allow**.

Other Troubleshooting

This section encompasses a wide range of issues that don't fall under more specific categories. This section includes troubleshooting guides for various platforms and services, such as Google Authenticator setup, invalid Oracle data source length errors, and SAML configuration upgrade errors. It also covers issues like Linux

connection errors, invalid domain errors, Quartz trigger job troubleshooting, VMware-related issues, and Windows local account access errors. Each folder offers targeted solutions to help users resolve uncommon or specialized technical problems efficiently.

Invalid Oracle Data Source Length

Error

Error Text

Oracle error: Invalid length for connection option 'Data Source', maximum length is 128.

Scenario

You run an SQL script that attempts to connect to an Oracle DB using the `System.Data.OracleClient.OracleConnectionStringBuilder.set_DataSource(String value)` call. The script runs from the local site as a database account, and an error occurs.

The error stack trace from the logs looks similar to this:

```
 2020-05-20 11:24:16,149 [CID:] [C:] [TID:PriorityScheduler Thread @ Normal] ERROR <Secret
Server URL />.PasswordChangers.DependencyChangers.Sql.SqlScriptRunner - Invalid length for
connection option 'Data Source', maximum length is 128.
System.ArgumentException: Invalid length for connection option 'Data Source', maximum
length is 128.
  at System.Data.OracleClient.OracleConnectionStringBuilder.set_DataSource(String value)
  at System.Data.OracleClient.OracleConnectionStringBuilder.set_Item(String keyword,
Object value)
  at System.Data.Common.DbConnectionStringBuilder.set_ConnectionString(String value)
  at <Secret Server URL
/>.PasswordChangers.DependencyChangers.Sql.SqlScriptRunner.BuildConnection
(DbProviderFactory dbProviderFactory, String connectionString, IDictionary2
additionalConnectionItems)
  at <Secret Server URL
/>.PasswordChangers.DependencyChangers.Sql.SqlScriptRunner.ExecuteScript(String
providerName, String connectionString, IDictionary2 additionalConnectionItems, String
commandText, IEnumerable`1 parameters)
```

Resolution

This error is an Oracle issue. Oracle has built-in string length restrictions on data source strings. One possible workaround is to use IP addresses for the Oracle server instead of FQDNs. Failing that, search the Internet for `"Invalid length for connection option 'Data Source', maximum length is 128"` to discover the latest information and workarounds.

TOTP MFA for Secret Server Accounts

Google Authenticator generates tokens based on time synchronization. If Secret Server's clock is inaccurate or unsynchronized with Google Authenticator devices, user token validation may fail during enrollment or login.

Solution A (Preferred)

Ensure that the clock on Secret Server is accurate and synchronized with the device running Google Authenticator. Configure the web servers to synchronize their clocks with a reliable domain controller clock or an NTP server.

Solution B

By default, the token time leniency value is set to zero, meaning the token supplied must be completely accurate. Follow these steps to configure Secret Server to accept tokens that are slightly behind or ahead:

1. Open the `web-appSettings.config` file and add the following key between the `appSettings` tags:
   ```
   <add key="TOTPLeniency" value="0 or greater value here" />
   ```
2. Change the leniency value. We recommend setting this value to no higher than 2.
3. Recycle your IIS application pool. You must recycle your IIS application pool for the setting to take effect.

Heartbeat and RPC Errors for Linux Secrets

When using Secret Server for SSH password rotation, you may encounter errors when changing a secret. This article helps the reader troubleshoot the configuration of Remote Password Changing (RPC) in Secret Server to avoid errors.

See "SSH Issues" on page 274 for other SSH issues.

Step 1: Verifying Ports and Connectivity

To determine if the heartbeat issue is outside of Secret Server:

1. Open the secret which is failing Remote Password Changing in Secret Server.
2. Scroll down to the **Advanced Information** section. You may have to click the **Advanced** link.
3. Note the **Site** parameter.
4. Search for **Distributed Engine**.
5. Under the Sites and engines tab, select the related site from the list. The Site View page appears.
6. Note the **Processing Location** parameter for the site.
7. If the processing location is **Local** and website processing is enabled, do your testing on the Secret Server application server. If it is **Distributed Engine**, do your testing on the distributed engine machine.
8. In PowerShell run one of the following command for the machine you are trying to connect to from the secret:
   ```
   Test-NetConnection -ComputerName <computer_name> -Port 22
   ```
   If you chose a custom port, note it—that port will need to be changed on the RPC too.
9. If the test was successful, proceed to the next step. If it was not successful, contact your networking team to open the port and test the connectivity. They can refer to "Ports and IP Addresses Used by Secret Server" on page 765.

Step 2: Testing Heartbeat and RPC in Secret Server

Procedure:

1. Return to the secret on Secret Server.
2. Under the **Remote Password Changing** tab, check the **Associated Secret** section to see if there is an associated account set on the secret for use with RPC.
3. Under the **Overview** tab for the secret, note the **Secret Template** type.
4. Determine the password type for the template:
   a. Search for **Secret templates**.
   b. Click to select the desired template from the list.
   c. Click the **Edit** button. The Secret Template Designer page appears.
   d. Click the **Configure Password Changing** button at the bottom of the page. The Secret Template Edit Password Changing page appears.
   e. Note the password types used, the applicable secret field, and the equivalent script variable. These indicate reserved variables that reference fields in the secret, in this case, `$USERNAME`, `$MACHINE` and `$PASSWORD`. You will need to test your script using known-good values for these.
5. Search for **Remote password changing**. The Remote Password Changing Configuration page appears.
6. Click **Options** and select **Configure Password Changers** from the dropdown. The Password changes configuration page appears.
7. Click the name link for the same password changer. The password changer page for that changer appears.

   The **Verify Password Changed Commands** section defines the secret fields and commands to use to confirm that a password has rotated (changed) successfully on the target machine. The **Password Change Commands** section defines the secret fields and commands to use to change the password on the target machine.
8. Click the **Edit** button at the bottom of the page. The Edit Password Changer page appears.
9. If a port for the RPC is listed in the **Custom Port** text box, it must match the port that Secret Server connects to when running the commands seen on the previous page.
10. Click the **Cancel** button to return to the previous page.
11. The **Verify Password Changed Commands Test Action** button tests the defined password-changed verification listed under it. When clicked, it uses the "Authenticate As" parameters to connect to the accounts and run the commands to test for a heartbeat and check that the account and password is valid.

    This authenticates with a non-privileged associated secret and then uses that account to connect to the Linux machine. This is needed because root accounts are often unable to directly authenticate. Thus, several commands are run to test if the active account can be set to root. If that fails, heartbeat fails.
12. In the example command set for the section, when the heartbeat runs, the associated account ($[1]$USERNAME) authenticates, logs into the remote SSH device, and runs:

a. `su $USERNAME` (The username from the secret)

b. `$CURRENTPASSWORD` (The password which the password should have been changed to)

c. `whoami` (Returns the name of the active user, which indicates the su command and the provided parameters worked). This test checks that the returned username is the same as the username field in the secret. If it is not, the heartbeat fails.

d. `CHECKFOR $USERNAME` (Checks if the 'whoami' returns the username field from the secret. If it does not, an error is thrown and the heartbeat fails)

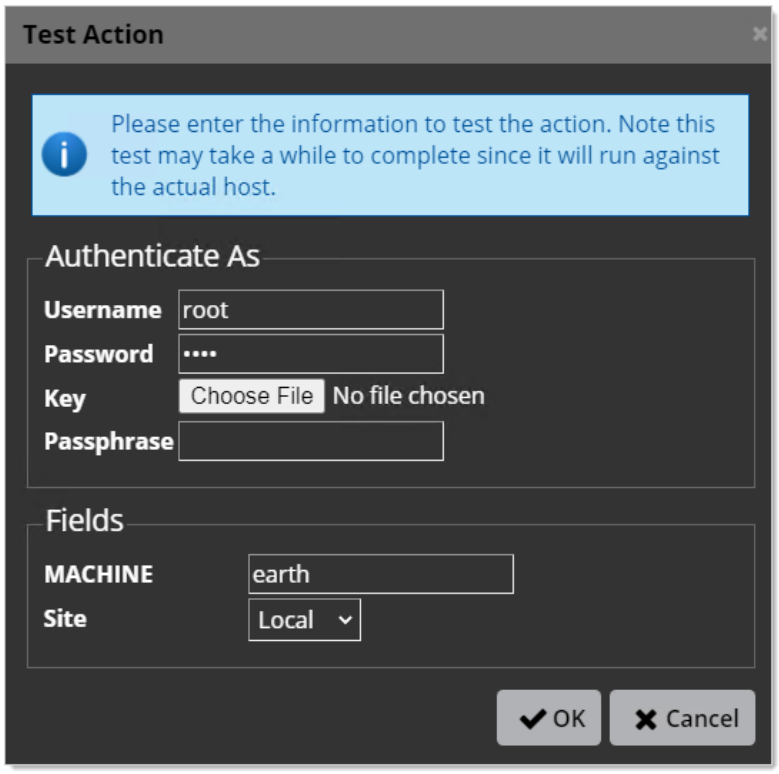
> Some of the command sets run by the "Verify Passwords Changed Test Action" button are empty. In that case, the test authenticates with the provided username and password, and if that is successful, so is the heartbeat. That is, the heartbeat uses the secret's own account (`$USERNAME`) and value to connect, rather than those of an associated secret.

> If the RPC is set up to use an associated secret but the secret does not have one, the secret fails to rotate and throws an error.

> For more on how Secret Server interprets what values to supply your custom script from the secrets involved, see "Editing Custom Commands" on page 1045 and "RPC Overview" on page 900.

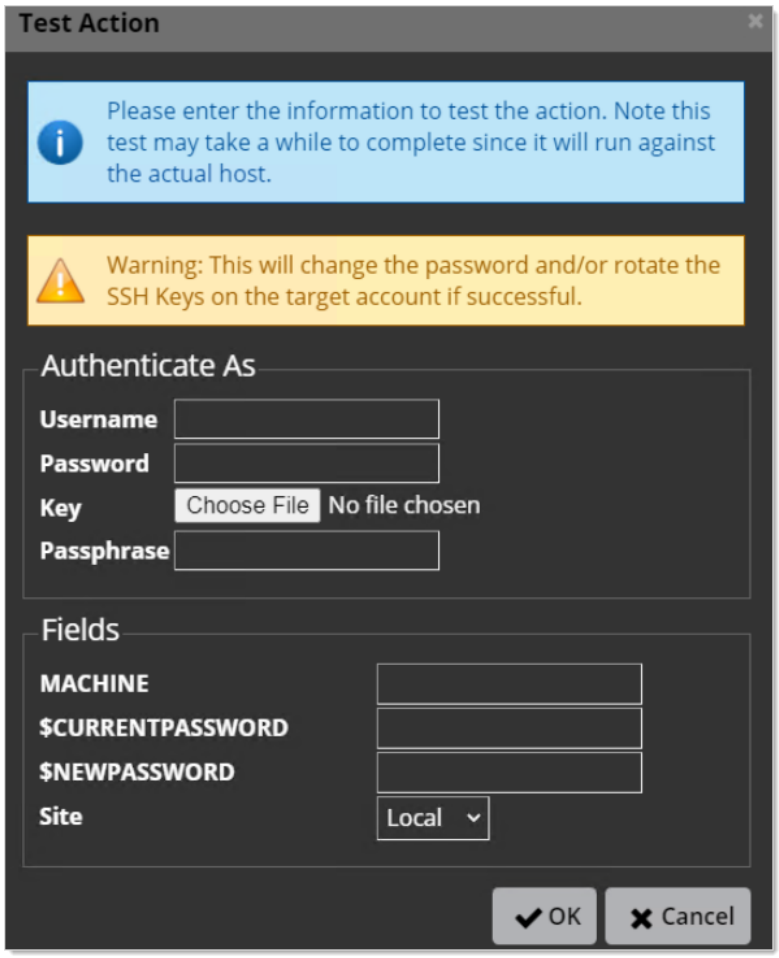
> The heartbeat above is designed to authenticate with a non-privileged associated secret and use that account to connect to the Unix machine because root accounts are often unable to authenticate directly. Then, several commands are run to check if root can be successfully switched to. If this fails, the heartbeat fails.

13. When you click the Verify Password Changed Commands **Test Action** button, the commands cannot read the fields from a secret or associated secret because when setting up the password changer no specific secret is calling it. Instead, for the test only, you manually provide the input parameters from the secret and associated secrets involved with the RPC. For example, the `$USERNAME` field refers to the user on the secret that you are trying to change. Whereas `[1][1]USERNAME` refers to the first associated secret linked to that secret.
14. When you click the button a popup appears for you to do just that:



15. Type or select your parameters.
16. Click the **OK** button. The password-changed command set is tested with a simulated heartbeat, using what you entered. If any errors occur, record them for troubleshooting later. The console outputs something similar to this:

    You then return to the previous page.
17. The **Password Change Commands** section defines the secret fields and commands to use to rotate (change) a password on the target machine. We now run a similar test on it.
18. Click the Password Change Commands **Test Action** button. Another Test Action popup page appears:



> Clicking the OK button in the following instructions **really changes the password or rotates the SSH keys on the target account** (the `$NEWPASSWORD` parameter gets changed), so record what you change it to, and update the secret with the new password (assuming the RPC is successful).

19. Similar to the last test, manually provide the input parameters. See Step 2: Testing Heartbeat and RPC in Secret Server for a description of how to fill in the parameters.
20. Click the **OK** button. The test connects with the "Authenticate As" accounts and runs the commands to change the password. A password rotation occurs, and more console output appears. Record any errors and output.
21. If the rotation did not occur, check the information that was presented to the changer from your secret. It is possible that the secret's data is involved in the issue.

Step 3: Troubleshooting Heartbeat or RPC Outside of Secret Server

This section troubleshoots the commands used by Secret Server to heartbeat and RPC outside of Secret Server. The intent is to confirm a successful authentication and password change on the endpoint when the same commands are issued outside of Secret Server. If they do not, the commands must be revised to work within Secret Server.

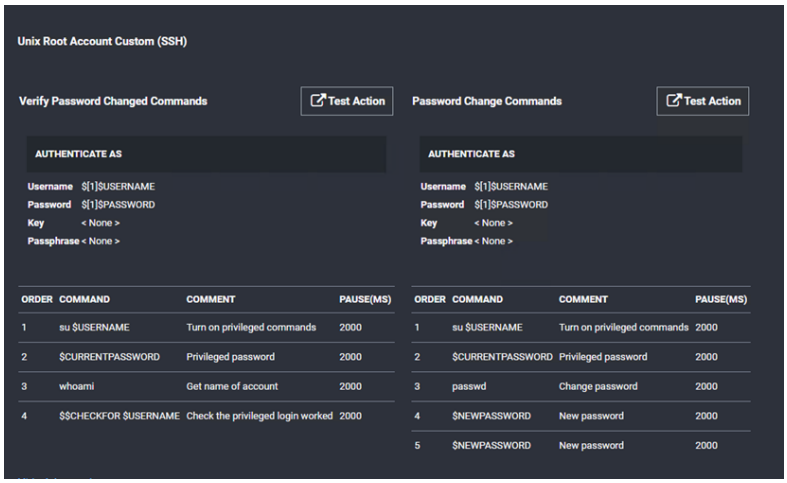
1. Use the procedure from Step 1 to determine which machine (Secret Server application or DE) to perform this step on.
2. If you did not already, Download PuTTY on the application or any of the DE servers.
3. Open a browser tab on the secret which is failing to Heartbeat or RPC.
4. Do the same for each associated secret of that secret.

> Instead of the following three steps, you can instead go to …\SecretServer\CustomCommandsEdit.aspx.

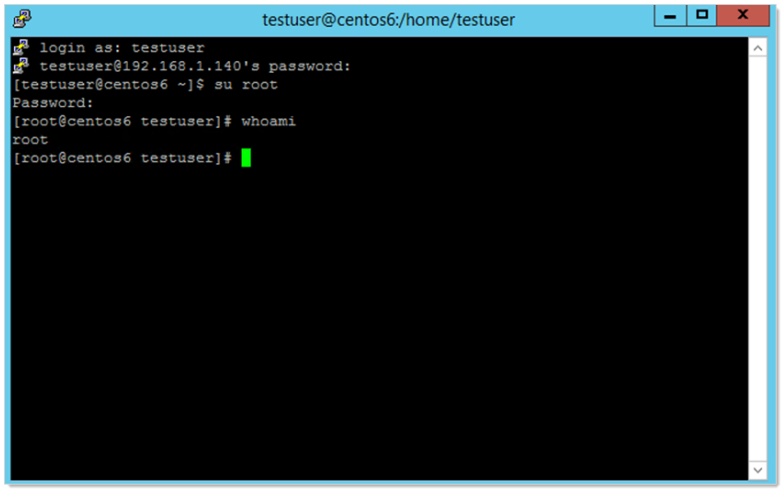
5. Search for **Remote Password Changing**. The Remote Password Changing Configuration page appears (not shown).
6. Click **Options** and select **Configure Password Changers** from the dropdown. The Password changes configuration page appears.
7. Click the name link for the subject password changer. The password changer configuration page for that changer appears.
8. Determine if you are troubleshooting heartbeat or RPC: The **Verify Password Change Commands** section applies to heartbeat, and the **Password Change Commands** section applies to RPC. Which you use (or both) depends on what failed in Step
9. Return the Secret Server or DE server you are testing.
10. Launch PuTTY.
11. Type the host name or IP address of the subject Linux machine (generally, the Machine field in the secret).
12. Log on with the username and password for the main or associated secret.

> If you are successful with connecting with PuTTY but not Secret Server, launch PuTTY in debug mode and collect a log file. Determine what cipher was used to connect. If you have a machine that works with Secret Server, compare the ciphers. Also check if the endpoint handles interactive logins differently. Secret Server's logins for RPC are non-interactive. See "SSH Issues" on page 274 for more information about troubleshooting connection issues in Putty.

13. Use the commands listed in the "Authenticate As" section you are troubleshooting directly in PuTTY to determine if they work outside of Secret Server. For example, given these heartbeat (Verify Password Changed) commands:



Your console would look like this:



In this example, we assumed the secret contained a value of "root" for the Username field, and the associated account in the first position was "testuser." This example was successful because the `$$CHECKFOR $USERNAME` found "root" on the previous line.

If the `su root` command were to fail above and reports the message "Username is not in the sudo users file. This incident will be reported." then the `$$CHECKFOR` would fail and the heartbeat would fail to verify. This type of issue needs to be remediated on the endpoint.

14. If the issue is clearly an endpoint issue, remediate it and repeat the commands in PuTTY.
15. Once the commands work properly in PuTTY, if the RPC or heartbeat command set needs adjustment to match the working PuTTY equivalent, return to Secret Server and make the changes to the command set (see the next step).

> Before you change the RPC commands, ensure that the device that you are working on belongs to the secret template you are using. Secret templates dynamically update all the secrets based on them, so **all secrets with this template are affected by your changes**. We strongly recommend that if this device is unique or you are storing an independent root account in the associated secret template, you should:

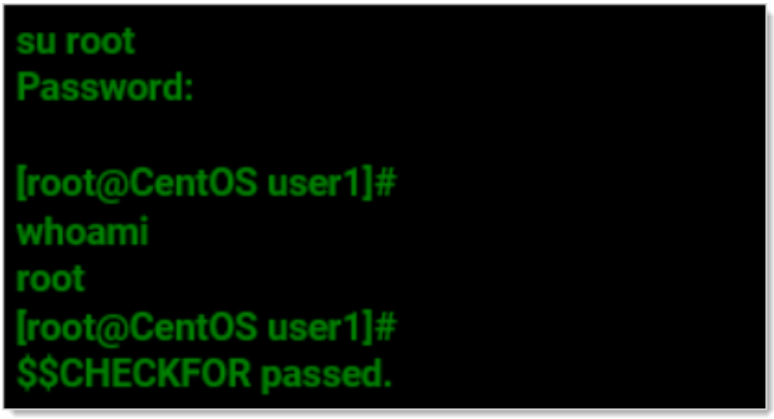
a. Copy the template you are using, giving the copy a descriptive name.

b. Create a new password changer based on the current one that you are using.

c. Assign it the secret template you just created.

This ensures that you do not change how ALL devices related to a secret template when you only intend to change a single devices. Accounts that are the same type on the same device should share the same template.

16. Click the **Edit Commands** button at the bottom of the subject password changer page. The commands for RPC and heartbeat appear.
17. Scroll down to the command list in the **Password Change Commands** section.
18. Click the blue edit icon to the right of any commands you want to change. The command becomes editable.
19. Edit the command to make it match your known-good revision.
20. Click the blue save icon next to the amended command.
21. Click the **Back** button to return to the password changer page.
22. One of the Test Action popups appears.
23. Type the known-good values from the secret in the text boxes.
24. Click the **OK** button to test heartbeat or RPC. The result should look something like this:



Invalid Domain Errors

This topic discusses resolving the "The specified domain is not a valid domain" error.

> Verify that the fully qualified domain name is correctly entered and that the DNS server is correctly configured, including SRV records for your domain controller.

Troubleshooting Procedure

1. Verify that you are entering the fully qualified domain name in the domain field and that the domain username and password fields are correct.
2. Ensure that the ports used for LDAP (389) or LDAPS (389 and 636) are open. For more information about the ports used by Secret Server, see "Ports and IP Addresses Used by Secret Server" on page 765.
3. Ensure that your server is connecting to the correct DNS server:
   a. Open the command console as an administrator (**Start > Run > cmd**).
   b. Type `ipconfig /all`.
   c. Press **<Enter>**.
   d. Find your primary Ethernet adapter and look in the **DNS Servers** section. Verify that the DNS server is correct.
4. If the DNS server is incorrect, then follow these steps to configure the DNS server:
   a. Open up your control panel (**Start > Control Panel**).
   b. Click on **Network and Sharing Center**.
   c. Click **Manage Network Connections** on the left.
   d. Right click on your primary network adapter and select **Properties**.
   e. Click **Internet Protocol Version 4 (TCP/IPv4)**.
   f. Click **Properties**.
   g. Click to select the **Use the following DNS server addresses selection** button.
   h. Type your primary DNS server in the first row.
   i. If you have a secondary DNS server, put it in the second row.

   > Both DNS servers must contain the SRV record for your domain controller.

5. Check that your server is retrieving domain controller DC records correctly:
   a. Open up your control panel (**Start > Control Panel**).
   b. Type `nslookup`.
   c. Press **<Enter>**.
   d. Type `set q=srv`
   e. Press **<Enter>**.
   f. Type `_ldap._tcp.dc._msdcs.<Fully_Qualified_Active_Directory_Domain_Name>`.
   g. Press **<Enter>**.
   h. If you get a result that looks like:

   ```
   _ldap._tcp.dc._msdcs.<Fully_Qualified_Active_Directory_Domain_Name> SRV service
   location: priority = 0 weight = 100 port = 389 svr hostname = *Domain_Controller_Host_
   ```

`Name*`

Then you are retrieving the DNS record correctly. Otherwise, your DNS records are not correctly configured.

Configuring the DNS Record on Your Server

1. If you are **not** using a Windows DNS server, contact your vendor to ask how to add SRV records. You will need to add a SRV record pointing `_ldap._tcp.dc._msdcs.<Fully_Qualified_Active_Directory_Domain_Name>` to your primary DNS server.
2. Connect to your Windows DNS server.
3. Open the DNS control panel (**Start >Administrative Tools > DNS**).
4. Expand the node corresponding to your server.
5. Expand the **Forward Lookup Zones** node.
6. Expand the node corresponding to your domain.
7. Delete the **_msdcs** node if it exists.
8. Right click on the domain node and select **New Domain...**
9. Type `_msdcs` as the name.
10. Right click on the new **_msdcs** node, and select **New Domain...**
11. Type `dc` as the name.
12. Right click on the new **dc** node and select **Other New Records...**
13. Select **Service Location (SRV)** as the record type.
14. Click the **Create Record** button.
15. Select **_ldap** as the service.
16. Select **_tcp** as the protocol.
17. Type `389` as the port.
18. Type the fully qualified host name of your DC or the IP address in the **Host offering this service:** text box.
19. Click the **OK** button.
20. Click the **Done** button.
21. Open up the services console (**Start > Run > services.msc**)
22. Right click on the **DNS Server** service and select **Restart**. Your domain DNS record should now be set up.

Resolving Other DNS Issues

Secret Server requires that the DNS is correctly configured to add a domain. For additional tips on tracking down DNS Issues, see this Troubleshooting Active Directory Installation Wizard Problems.

Also ensure the domain controller is using the appropriate DNS. The `ipconfig /registerdns` command (as per the link above) is frequently helpful for entering the correct DNS entries in for a given domain.

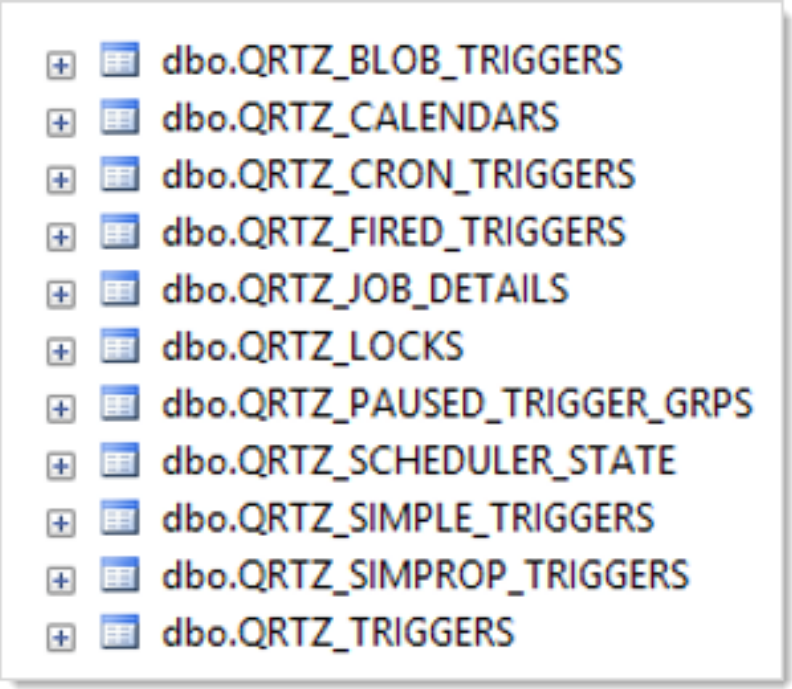
Quartz Trigger Jobs

> This topic only applies to **Secret Server On-Premises**.

In Secret Server 10.7 and newer, all background operations have moved to Quartz. All scheduled background operations have become jobs registered in tables inside the Secret Server database.

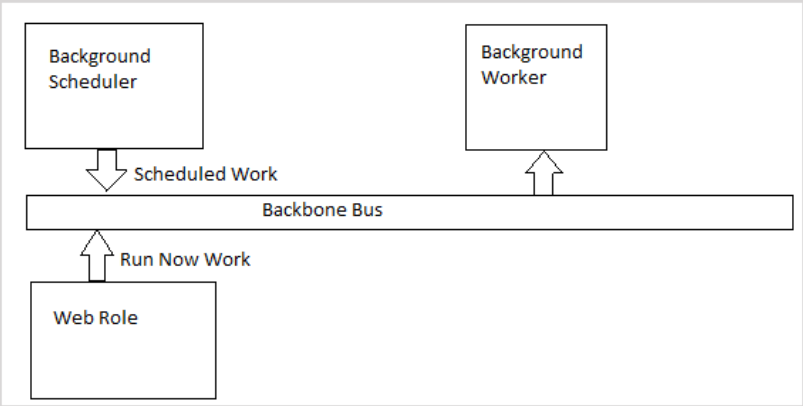
Quartz-Related Tables

All Quartz-related table names start with "QRTZ_ "



Trigger Job Components

Each background job runs as a consumer, similar to how a distributed engine (DE) works, in the background worker. Each job has a corresponding trigger job registered in Quartz. Quartz executes the trigger job at the configured time and interval. The trigger job puts a message on the backbone bus, which is picked up and executed by the background worker:



Simple Trigger Job

There are two kinds of registered trigger jobs, *simple triggers* and *cron triggers*. A simple trigger fires on an interval. For example, on premises the heartbeat job runs every 30 seconds:

```
select * from QRTZ_SIMPLE_TRIGGERS where trigger_name like '%heartbeat%'
```

SCHED_NAME	TRIGGER_NAME	TRIGGER_GROUP	REPEAT_COUNT	REPEAT_INTERVAL	TIMES_TRIGGERED
1 BackgroundScheduler	ProcessHeartbeatTriggerJob-trigger	group1	-1	30000	3
2 BackgroundScheduler	ProcessLocalHeartbeatTriggerJob-trigger	group1	-1	30000	3

In this case, you can ignore the TRIGGER_GROUP and REPEAT_COUNT columns. The latter column limits the number repetitions, which we do not do. The REPEAT_INTERVAL is in milliseconds, so 30000 is 30 seconds. TIMES_TRIGGERED is a counter of trigger firings. There are two trigger jobs for heartbeat. The local job handles secrets that do not run through a distributed engine while the other heartbeat handles secrets that do run through a distributed engine.

Cron Trigger Job

Cron jobs run at a specific time using a variation of the well-known cron syntax. For example:

```
select * from QRTZ_CRON_TRIGGERS where trigger_name like '%license%'
```

SCHED_NAME	TRIGGER_NAME	TRIGGER_GROUP	CRON_EXPRESSION	TIME_ZONE_ID
BackgroundScheduler	ExpiringLicenseTaskTriggerJob-trigger	group1	0 0 12 * * ?	UTC

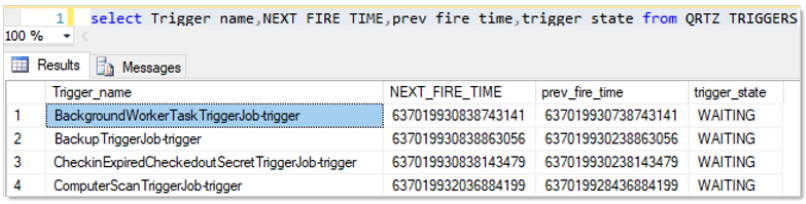
In this example, the trigger ExpiringLicenseTaskTriggerJob runs every day at 12:00 PM UTC.

The Quartz jobs are run within the background scheduler role, which runs on every node that has the background-worker-enabled bit set to true. Quartz coordinates trigger-job execution through the database to ensure that the same trigger-job is run just once, even if the Quartz scheduler is running on multiple nodes simultaneously.

Procedures

Viewing Trigger Job State (QRTZ_TRIGGERS Table)

The current state of each trigger-job can be seen in the QRTZ_TRIGGERS table:



```
1  select Trigger name,NEXT FIRE TIME,prev fire time,trigger state from QRTZ TRIGGERS
```

100 %

Results | Messages

	Trigger_name	NEXT_FIRE_TIME	prev_fire_time	trigger_state
1	BackgroundWorkerTaskTriggerJob-trigger	637019930838743141	637019930738743141	WAITING
2	BackupTriggerJob-trigger	637019930838863056	637019930238863056	WAITING
3	CheckinExpiredCheckedoutSecretTriggerJob-trigger	637019930838143479	637019930238143479	WAITING
4	ComputerScanTriggerJob-trigger	637019932036884199	637019928436884199	WAITING

Viewing Trigger Firing Times

In the previous figure, the NEXT_FIRE_TIME and PREV_FIRE_TIME columns are not human readable. To convert them to something you can read, run the following SQL query:

```
SELECT TOP 1000
    [TRIGGER_NAME]
    ,[TRIGGER_STATE]
    ,[TRIGGER_TYPE]
    ,NEXT_FIRE_IN = DATEDIFF(second, GETUTCDATE(), CAST(NEXT_FIRE_TIME/864000000000.0 -
 693595.0 AS DATETIME))
    ,UTCNOW  = GETUTCDATE()
    ,NEXT_FIRE_TIME2 = CAST(NEXT_FIRE_TIME/864000000000.0 - 693595.0 AS DATETIME)
    ,[PREV_FIRE_TIME2] = CAST(PREV_FIRE_TIME/864000000000.0 - 693595.0 AS DATETIME)
    ,[START_TIME2] = CAST(START_TIME/864000000000.0 - 693595.0 AS DATETIME)
    ,[END_TIME2] = CAST(END_TIME/864000000000.0 - 693595.0 AS DATETIME)
    ,[PRIORITY]
FROM [dbo].[QRTZ_TRIGGERS]
```

This query shows the NEXT_FIRE_TIME in seconds and the other fields as DateTimes, along with the current UTC date to make it easier to compare to the current time.

The TRIGGER_STATE is normally WAITING. If the trigger job is currently running, the state will be ACQUIRED. If there was an error running the trigger job, the state will be ERROR. Once a trigger job enters an ERROR state it will not run again. To address this, Secret Server automatically looks for any trigger jobs in the ERROR state every 10 minutes and changes their state to WAITING. If the NEXT_FIRE_TIME is a large negative number, it indicates that the scheduler role is not running–take a look at the Secret Server-BSSR.log file to see its status.

Adjusting Trigger Job Frequency

Secret Server populates the Quartz schedules when it starts up and creates them if they do not exist. Secret Server does not update pre-existing schedules, so it is possible to change the frequency of a job in the table and have the system run with that frequency from that point on.

> Do not change the job frequency unless it is absolutely necessary.

Delinea controls those schedules and in future releases may not recognize changes you have made to those schedules. Furthermore, we do not test with a variety of schedules and have no plans to do so. Therefore, adjusting the schedules is a risky undertaking that may cause issues within Secret Server. If you must change the tables, you must bounce IIS on all the nodes where the scheduler runs, after you change the table values.

To trigger an infrequent task just once, without altering its schedule, follow these steps:

1. Update the NEXT_RUN_TIME value in the QRTZ_TRIGGERS table to match the NEXT_RUN_TIME value from a trigger that fires frequently, such as one of the heartbeat triggers.
2. Recycle the scheduler role by running Recycle Background Processes on the Diagnostics page,
3. Reset the background worker (inside the application pool) in one of the following ways:
   - Click Recycle Background Processes on the Diagnostics page. This shuts down and restarts the scheduler.
   - Recycle the application pool. This restarts Secret Server in its entirety.
   - Reset IIS. From Secret Server's perspective this is nearly the same as the second option.

> The PDF version of this online document is automatically generated and thus may have minor formatting anomalies.

> This document is not updated with every release–many releases do not affect the guide's contents and thus do not warrant a document update.

SAML Configuration Errors After Upgrading

> This topic is for upgrades of Secret Server from a version earlier than 10.2.

Initial Troubleshooting

Changes to the `saml.config` were introduced in Secret Server 10.2. Secret Server should automatically convert the existing `saml.config` to the latest format. If it does not:

1. Ensure that the application pool has write access to the `saml.config` file.
2. Restart the application pool in IIS and try to log in again.
3. If Secret Server is running in a clustered environment:
   a. Copy the `saml.config` from the Web node that was upgraded to the remaining web nodes.
   b. Restart their application pools in IIS.

If that does not resolve the issue or Secret Server is not running in a clustered environment, there may be some other issue that prevented the `saml.config` from converting successfully during the upgrade. Please contact "Technical Support" on page 72 for assistance.

> See the "Configuring SAML Single Sign-on" on page 431 article for more information on configuring your saml.config in 10.2

Additional Troubleshooting

If the `saml.config` is not loading properly, there are a few possibilities:

- The `saml.config` file is invalid. Ensure that it contains valid XML. Element and attribute names are case sensitive. Ensure that the elements and attributes names and value are valid for SAML configuration.

  > See the `saml.config.template` file in Secret Server's root folder for guidance on which elements and attributes can be used.

- Secret Server is running in a clustered environment and some nodes are not yet configured. Copy the `saml.config` from the functioning Web node to all of the remaining Web nodes and restart their Application Pools in IIS.

Restart the Application Pool in IIS any time changes are applied to the `saml.config` file. If issues remain after following these steps, please contact "Technical Support" on page 72 for assistance.

SSH Issues

When troubleshooting performance or connectivity issues with SSH with or without proxy it is useful to enable SSH debug logging on your remote host. There are several things that could go wrong during the connection process and the SSH debug log tells you how far the connection gets before failing. To enable debug logging on a host the SSH service should be started with the debug flag.

> A UNIX administrator should be tasked with these operations because if the box is a remote host with no local access then an incorrect action could leave you locked out of the machine if SSH is the only remote connection possible.

Local Servers with Direct Access

The following example works best with a local connection. You can start the SSH service in verbose debug mode where the debug output is sent to a file on the local system and the service terminates after the remote connection ends with the following:

```
/usr/sbin/sshd -ddd 2> sshd-debug.log
```

Remote Servers

Another way to configure SSH to log debugging information is to have syslog set up. You will need to add a syslog entry for the SSH service in `/etc/syslog.conf`:

```
*.* /var/log/sshd/sshd.log
```

And then configure the SSH service to have a log level of DEBUG3, which can be modified in `/etc/ssh/sshd_conf`:

```
LogLevel DEBUG3
```

Then restart the SSH service:

```
service sshd restart
```

> On some systems, the log may already be configured to output to `/var/log/auth.log`.

Logging from the Client Perspective

You can also do logging from the perspective of the client connection to the remote host. This sort of logging helps you to understand what a normal successful connection should look like. To obtain logging from the client connection, you can run SSH in verbose mode.

```
ssh -vvv user@host
```

The debug information will be sent to the console. Or if you are using PuTTY, then you can right click the PuTTY window title after connecting to the remote host and selecting "Event Log".

Understanding SSH Logging

Example

The following is an example of standard debug output from PuTTY looks like the following:

1. The client begins by looking up the hostname and see if the host is valid:

   ```
   2016-01-07 12:23:57 Looking up host "192.168.1.60"
   ```

2. The client proceeds to make a TCP connection to the host:

   ```
   2016-01-07 12:23:57 Connecting to 192.168.1.60 port 22
   ```

3. The client sends a message to the server saying what version of SSH we are using. In this example we are using SSH 2 over PuTTY v0.65:

   ```
   2016-01-07 12:23:57 We claim version: SSH-2.0-PuTTY_Release_0.65
   ```

4. The server sends back a message saying what version of SSH they are using. In this example we are connecting to an Ubuntu Server running an SSH 2 over OpenSSH v6.6.1p1:

   ```
   2016-01-07 12:23:57 Server version: SSH-2.0-OpenSSH_6.6.1p1 Ubuntu-2ubuntu2
   2016-01-07 12:23:57 We believe remote version has SSH-2 channel request bug
   ```

5. The client confirms the type of connection that can be used with the server. In this example the communications will be done using SSH 2:

   ```
   2016-01-07 12:23:57 Using SSH protocol version 2
   ```

6. The client begins the key exchange process and agrees on using Diffie-Hellman Group Exchange 256:

   ```
   2016-01-07 12:23:57 Doing Diffie-Hellman group exchange
   2016-01-07 12:23:57 Doing Diffie-Hellman key exchange with hash SHA-256
   ```

7. The server replies with their host key fingerprint information to identify its identity and aide in the prevention of Man in the Middle attacks. In this example the server is presenting an RSA 2048-bit key:

   ```
   2016-01-07 12:23:57 Host key fingerprint is:
   2016-01-07 12:26:53 ssh-rsa 2048 e0:d4:94:36:e9:20:fd:e3:58:ad:8d:4c:4a:1f:27:e8
   ```

8. The client initializes the transport layer encryption using AES-256 with SDCTR enabled and uses SHA-256 for message authentication:

   ```
   2016-01-07 12:26:53 Initialized AES-256 SDCTR client->server encryption
   2016-01-07 12:26:53 Initialized HMAC-SHA-256 client->server MAC algorithm
   ```

9. The server initializes the transport layer encryption using AES-256 with SDCTR enabled and uses SHA-256 for message authentication:

   ```
   2016-01-07 12:26:53 Initialized AES-256 SDCTR server->client encryption
   2016-01-07 12:26:53 Initialized HMAC-SHA-256 server->client MAC algorithm
   ```

10. The client sends a password.

    ```
    2016-01-07 12:27:12 Sent password
    ```

11. The server validates the password and granted access to the user:

    ```
    2016-01-07 12:27:12 Access granted
    ```

12. The session opens a shell for user interaction:

    ```
    2016-01-07 12:27:12 Opening session as main channel
    2016-01-07 12:27:12 Opened main channel
    2016-01-07 12:27:12 Allocated pty (ospeed 38400bps, ispeed 38400bps)
    2016-01-07 12:27:12 Started a shell/command
    ```

Confirming Proper Operation

Things to look for in an SSH log:

- Verifies the host IP address that you are connecting to.
- Verifies the port is correct for the address that you are connecting to.
- Verifies that you are not using an outdated SSH client.
- Verifies the SSH protocol you are using.
- Verifies what group exchange algorithm is being used.
- Verifies the server identity using the presented fingerprint. If the fingerprint is not expected then there may be malicious server between you and the remote host you want to connect to. Alert the administrator to verify if the host key has changed or if there is another issue.
- Verifies the transport layer and HMAC ciphers being used.
- Verifies that the password or key being sent is accepted by the server.
- If a connection does not open, it notes what the last successful step was and then what the next failed step is to find what the issue is.
- If using Secret Server proxy, it is useful to collect the client-to-proxy SSH log and then the proxy-to-remote-host log from the remote server.

VMware Issues

Secret Server supports operating systems in a VMware virtual machine environment in an identical manner as it runs on any other major x86-based systems without initially requiring reproduction of issues on native hardware. Should Delinea Support suspect that the virtualization layer is the root cause of an incident, you must contact VMware support provider to resolve the VMware issue. While Delinea products are expected to function properly in a VMware virtual environment, there may be performance implications that can invalidate Secret Server sizing and recommendations.

Migrating between CPU families or versions will require re-activation.

Windows Local-Account Access-Denied Error Workaround PowerShell Scripts

Overview

Beginning with Windows 10 version 1607 (Creator's Update) and Windows Server 2016, the default GPO security descriptor denies users remote access to Security Account Manager (SAM) with non-domain credentials. This prevents remote heartbeat and password changes made by otherwise-authenticated local user accounts. Affected Windows local account secrets return "Access Denied" on a heartbeat or remote password change.

This document provides a script and instructions to address these "access denied" errors. The script modifies the default local group policy remote SAM access security descriptor to allow all local users on a specified machine remote SAM access after authentication. This script requires elevated PowerShell permissions.

Adding an account to the local computer's Administrators group does not solve the problem.

With default local policy, the Administrators group on the local machine is part of the "Network Access: Restrict clients allowed to make remote calls to SAM" security policy setting, so these procedures will allow non-administrators to heartbeat successfully. On domain controllers, "Everyone" is already a part of this setting.

Additional Requirements

For heartbeat to work correctly, make sure that the local or authenticated users are:

- *Not* in the "Deny access to this computer from the network" security policy
- *In* the "Access this computer from the network" security policy

Additionally, user access control settings can prevent password changing. There are two settings involved: For Built-In Administrator accounts, "User Account Control: Use Admin Approval Mode for the built-in Administrator account." would need to be disabled. For another other user added to the Administrator group, "User Account Control: Run all administrators in Admin Approval Mode" would need to be disabled.

These settings may be contrary to certain CIS Benchmarks.

Remediation Options

Option 1: Creating a custom group and adding users to it (this is what the script does for users on the endpoint) then adding that group to the security setting to allow the user to heartbeat successfully. New local users need to be added to the custom group if they are created in the future.

Option 2: Adding a user individually to the security setting to allow the user to heartbeat successfully.

Option 3: Modifying the Default GPO: Adding "allow authenticated or local users" to the security setting. This allows all local users or all users who are authenticated to the machine to bypass this setting. This does requires the PowerShell Script below. The drawback is that this allows all users to remotely access SAM, so long as they are authenticated.

Option 4: Create a heartbeat workaround for GPO "Network Access: Restrict Clients Allowed to Make Remote Calls to SAM." This is addressed in the last section. This is for situations where the GPO needs to be completely bypassed.

Option 3: Modifying the Default GPO

PowerShell Script Description

This script adds a local non-privileged user group to the machine (a custom group name can be specified with the `-GroupName` parameter), adds all local users to the group, and then adds this group to the "Network Access: Restrict clients allowed to make remote calls to SAM" local group policy. This allows all local users within the group remote access to SAM after authentication, which is required for Secret Server heartbeat and password changing.

Download

Extract the .ps1 script found here: https://updates.thycotic.net/secretserver/support/PowerShell_Win10-HB-RPC-Fix/Win10-HbFix.zip. Run in an elevated PowerShell ISE session.

Script Argument Help

Command Prompt Help

For full help text, run:

```
> Get-Help C:\Script\Win10-HbFix.ps1 -Examples
```

Parameters

-ComputerNames (string[])

Specifies the computers on which the script runs (comma separated). If unspecified, the default is the local computer.

-Username (string)

Specifies a username of an account that has administrative permissions on the computer to add a local user group and modify the local group policy. You will be prompted for a password. Examples: `Administrator` or `TestDomain\AdminUser`.

-GroupName (string)

Specifies a name for the SAM access local user group. If unspecified, the default group name is "Secret Server Remote SAM Access"

-ForceGPUpdate

Specifies whether a group policy update should be forced for immediate effect following the script. (Otherwise Group Policy changes may take up to 120 minutes to take effect by default).

Examples

`> C:\Script\Win10-HbFix.ps1` This example gives remote SAM access to all local users on the current machine. The current PowerShell credentials would be used for authentication.

`> C:\Script\Win10-HbFix.ps1 -LogDir "D:\Win10-HbFix\log"` This example changes the default output log path to `D:\Win10-HbFix\log` (default is `[user temp directory]\log`).

`> C:\Script\Win10-HbFix.ps1 -ComputerNames "WINSERVER","TestDomain\SOMEMACHINE" -Username "TestDomain\Administrator"` This example gives remote SAM access to all local users on the WINSERVER and TestDomain\SOMEMACHINE remote computers. The domain user "TestDomain\Administrator" credentials will be used. You would be prompted for a password.

```
> C:\Script\Win10-HbFix.ps1 -ComputerNames "D:\Win10MachineList.txt" -Username "TestDomain\Administrator"
```

This example gives remote SAM access to all local users on the remote computers listed in D:\Win10MachineList.txt (one machine per line). The domain user "TestDomain\Administrator" credentials will be used. You would be prompted for a password.

```
> C:\Script\Win10-HbFix.ps1 -ComputerNames "WINSERVER" -GroupName "Secret Server Group"
```

This example gives remote SAM access to all local users on the WINSERVER remote computer. The local group created will be named "Secret Server Group". Current PowerShell credentials would be used for authentication.

`> C:\Script\Win10-HbFix.ps1 -ComputerNames "WINSERVER" -ForceGPUpdate -Verbose` This example gives remote SAM access to all local users on the WINSERVER remote computer, with verbose output. The current PowerShell credentials will be used for authentication. Group policy update will be forced on WINSERVER for immediate effect.

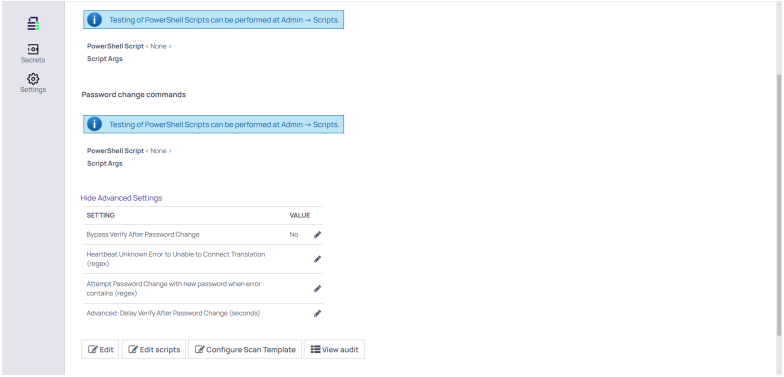
Related Articles and Resources

Network access: Restrict clients allowed to make remote calls to SAM

Option 4: Creating a Heartbeat GPO Workaround

1. Download, unzip, and run this script HBWorkAroundScripts.zip.
2. Search for **Scripts: PowerShell, SQL, SSH**.
3. Add the HBWorkAroundScript and the HBWorkAroundPasswordChange scripts.
4. Test the first script. Add the appropriate `args[]` as needed. Add arguments 0-4 with no quotes or commas. Spaces are the argument separator and are required.
5. You should get a return of "True," such as this:

6. Search for **Remote Password Changing.**
7. Click the **Options** dropdown and select **Configure Password Changers**.
8. Click the **Create Password Changer**.
9. Click the **Base Password Changer** dropdown list to select **PowerShell Script** as your password changer.
10. Type a name in the **Name** text box.
11. Click the **Save** button. The password change command page appears.



12. Click **Edit Scripts** at the bottom of the page to select the script you ran earlier.
13. Add the appropriate tokens in the **Script Args** text box.

> See "Dependency Token List" on page 1512 for a complete list.

12. Click the **Save** button.
13. Search for **Secret Templates**.
14. Select **Windows Account**.
15. Click the **Edit** button.
16. Click the **Copy Secret Template** button.
17. Click the **Configure Password Changing** button.
18. Click the **Edit** button.
19. Click the **Password Type to Use** dropdown list to select the password change you created earlier.
20. Create your windows secret using the custom template.

> Modifying the secret template with a custom password changer will make the secret template incompatible with discovery.

21. Once it is created, add your privileged and associated secret to the RPC tab as seen below. In that example we use the same one for the privileged and associated secret.
22. Run a heartbeat to confirm it works as desired.

Enabling Debug Mode in System Logs

This topic discusses enabling debug mode for application system logs for troubleshooting.

> Note that these settings are valid for Secret Server versions prior to 11.1.6. See Setting the Logging Levels section for more details.

Overview

You can expand Secret Server's logging capabilities to locate additional information regarding an error or to help with troubleshooting an issue.

To enable debug mode for distributed engine log files, see "Enabling Debug Mode in Distributed Engine Log Files" on page 385

Procedure

To enable debug logging mode:

1. Log in as an administrator on the application server.
2. Locate the *web-log4net.config* file. This file can be found in the web application's root directory. If you cannot locate your web application directory, see How to: Find the Web Application Root. Secret Server is typically located in the **C:\inetpub\wwwroot* directory, however, this is configurable so the location may be different in your environment.
3. Open the file in a text editor.
4. Run a find command (Control+ F).
5. Type in *log4net* and press **Enter** to locate that section, which is usually at the top.
6. Locate the commented out *<level value="DEBUG" />*
7. Uncomment the line by removing the *<!-- and -->*.
8. Locate the *<level value="INFO" />* line in the same section.
9. Comment out the entire line by adding a *<!-- and -->* around it.
10. Restart IIS to apply the log configuration change.

    This restarts all websites hosted under IIS

11. After DEBUG mode is enabled in the system log, you can reproduce the issue, investigate the error, or send the updated logs in with your support case.

Finding the Version Number of Your Secret Server Release

There are several ways to find the version number of your Secret Server release, which are detailed below.

> The procedures in this section apply to the Professional and Platinum editions of the Secret Server on-premises application.

Through Secret Server

You can find the version number of your Secret Server release from any Secret Server page. Just click your user icon in the top right corner, and a box opens displaying information including the full version number.

Through Windows File Explorer

1. Log into the web server where the Secret Server application is installed.
2. Open Windows File Explorer.
3. Navigate to `C:/inetpub/wwwroot/SecretServer/bin`
4. Right-click the `Thycotic.ihawu.Business.dll` file and select **Properties**.
5. In the Properties dialog, click the **Details** tab, which displays information including your product version.

Through SQL

1. Log into your Secret Server database server.
2. Open and log into your Microsoft SQL Server Management Studio application.
3. Click **Connect**.
4. At the top level of the **Object Explorer** pane, click the **+** symbol next to servername\instance.
5. Click the **+** symbol next to **Databases**.
6. Right-click your Secret Server database and select **New Query** from the dialog.
7. In the SQL Query pane that opens, paste the following query:

```
SELECT * from tbVersion
ORDER BY CAST(REPLACE(VersionNumber, '.', '') AS INT) DESC;
```

8. Click **Execute**.
9. On the **Results** tab below the SQL Query pane, confirm that your query executed successfully and find the version number of your current Secret Server release in the top row.

Through the API

You can also use the REST API to check the version of Secret Server using the endpoint `GET /v1/version`.

Through PowerShell

1. Open a PowerShell prompt on the machine(s) running secret-server.
2. Run the following command, changing the drive and/or path as required: `(Get-Item C:\inetpub\wwwroot\SecretServer\bin\Thycotic.ihawu.Business.dll).VersionInfo.FileVersion`

Unlimited Vault Access

Overview

> The legacy names of *Unlimited Vault Access* are *Unlimited Admin* and *Unlimited Administration Mode*.

Unlimited vault access (UVA) is a feature designed to allow an administrator access to all secrets and folders in their Secret Server instance without explicit permission. This can be used in the instance a company has an emergency where access to a secret is needed when no users who have permission are available. Alternately, it can be used when company policies require administrators to have access to all information in the system.

A user with unlimited vault access in Secret Server has extensive capabilities, including access to all secrets and folders even without explicit permission. Here are some of the key capabilities and associated risks:

Capabilities and Risks

UVA is a double-edged sword and must be carefully managed:

Capabilities

Users with UVA have:

- Complete Control: Access to all administrative features without restriction.
- Access to All Secrets: Access to all secrets and folders.
- Audit and Reporting: UVA users can generate and view over 90 out-of-the-box reports to monitor privileged access and ensure proper password hygiene.
- Break-the-Glass Capability: This feature is part of the disaster recovery capabilities, allowing emergency access to secrets in critical situations.
- Secret Checkout Override: UVA users can access secrets even when they are checked out by another user, ensuring accountability and traceability of secret usage.
- Bypass SAML: Users with the UVA role will effectively inherit the bypass SAML role permission and be able to bypass the SAML login process.

Risks and Mitigation

Risks

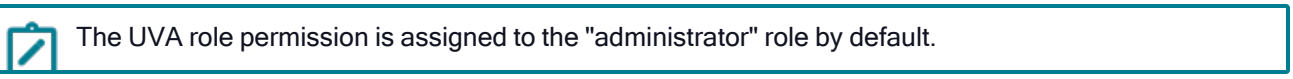
UVA exposes Secret Server to:

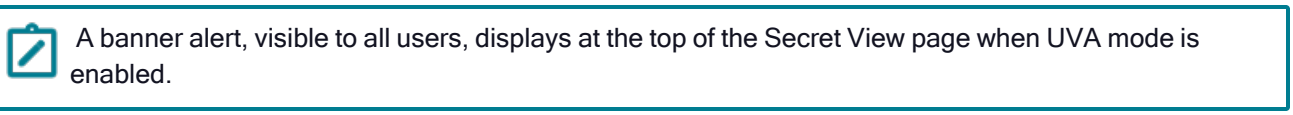
- Potential for Abuse: With the ability to access all secrets, there is a risk that a user with UVA could misuse their privileges, intentionally or accidentally.
- Security Gaps: Without proper monitoring and auditing, the extensive access granted to UVA user could be exploited by bad actors if the administrator's credentials are compromised.
- Insider Threats: A UVA user could potentially become an insider threat if they decide to act maliciously or if their account is taken over by an external attacker.

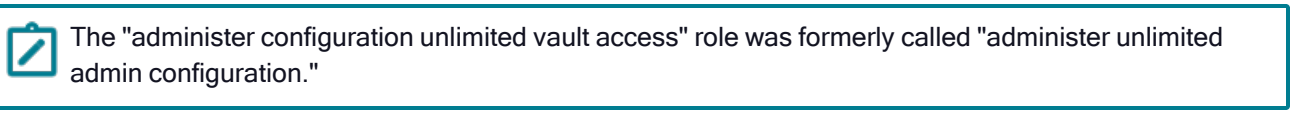
Mitigation

To mitigate these risks, it is crucial to have robust monitoring, auditing, and alerting mechanisms in place. Secret Server provides features such as automatic email alerts for UVA access, detailed audit trails, and the ability to require dual control for certain actions to enhance security.

A user with the UVA role permission can view and edit all secrets in the system, regardless of Delinea permissions–if and only if UVA is enabled in the configuration settings–**but** the UVA role does **not** have permission to enable UVA. To enable it, the "administer configuration unlimited vault access" role permission is required. This provides dual control, ensuring no single user can enable UVA mode. Of course, you can bypass this safeguard by simply assigning both roles to the same user.

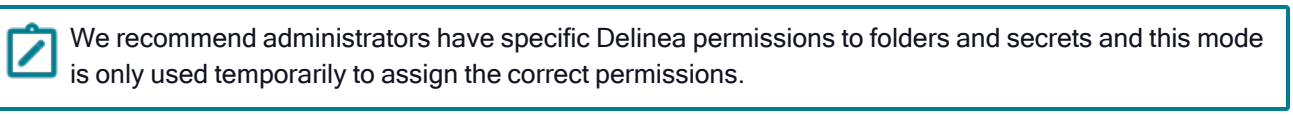


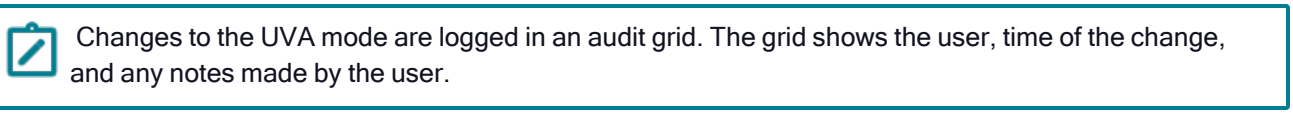




Enabling UVA Mode

1. Ensure you have the "administer configuration unlimited vault access" role permission.
2. Search for **Unlimited Vault Access**and proceed to the Unlimited Vault Access page.
3. Click the **Edit** button.
4. Check to select **Enable unlimited vault access**.
5. If prompted, add the details in the **Enter any additional notes or explanations for the configuration switch** field.
6. Click **Save**.





Alerts, Audits, Events, and Logs

The Alerts, Audits, Events, and Logs section provides comprehensive guidance on monitoring and managing system activity. This section is divided into four key areas: Audits, which covers audit data retention, generating audit reports, and managing PII exports; Events, which focuses on event pipelines and subscriptions for system notifications; and Logs, detailing logging procedures such as syslog configuration, SQL Server transaction logs, and setting logging levels. This section ensures users can effectively track and respond to system events, audits, and alerts to maintain security, compliance, and performance oversight.

Comparison of Secret Server Alerts, Events, Audits, and Logs

Alerts

- **Definition**: Notifications sent to users or administrators when specific actions are performed or events occur within Secret Server.
- **Customization**: Can be customized through Event Subscriptions to notify users about specific actions such as Secret Edit/Add/View, Role and Group Assignment changes, Secret expiration, Configuration changes, and Heartbeat failures.
- **Delivery**: Typically sent via email and can be configured to have high priority.
- **Purpose**: Provide real-time notifications to administrators and users about critical actions or changes, enabling them to respond promptly.

Events

- **Definition**: Specific actions or occurrences within Secret Server that are recorded for auditing and logging purposes.
- **Logging**: Events are logged and can be sent to external systems using protocols like Syslog and CEF (Common Event Format) for added security and compliance.
- **Types of Events**: Can include system events, errors, warnings, user activities, and other operational data.
- **Purpose**: Provide a detailed audit trail of activities within Secret Server, which is crucial for compliance, security monitoring, and troubleshooting.

Audits

- **Definition**: Detailed records of actions taken on secrets, including who performed the action and when it occurred.
- **Access**: The audit log for a secret can be accessed by clicking the View Audit button on the Secret View page or navigating from the User Audit report.
- **Details**: Shows the date, username, action, and any other details about the event. Includes actions like adding, updating, removing secret dependencies, editing permissions, forced expiration, and more.

- **Purpose**: Provide accountability and detailed records of changes or views on secrets, which is essential for security and compliance.

Logs

- **Definition**: Records of system events and actions that occur while Secret Server is executing.
- **Types**: Includes system logs, which can be enabled to communicate different events occurring during execution, and can be helpful in troubleshooting unexpected behavior.
- **Parameters**: System log parameters include maximum log length, notifications to administrators when the log is shrunk, and the ability to clear the log.
- **Purpose**: Provide a comprehensive record of system events for troubleshooting, monitoring, and ensuring the system is functioning as expected.

Key Differences

- **Real-Time Notification vs. Detailed Records**: Alerts provide real-time notifications, while events, audits, and logs provide detailed records of actions and system events.
- **Customization**: Alerts can be customized through Event Subscriptions, while audits and logs are automatically recorded based on system activities.
- **Purpose**: Alerts are for immediate action, events and audits are for compliance and monitoring, and logs are for troubleshooting and system monitoring.

Auditing Overview

Secret Server provides comprehensive auditing features to help organizations meet regulatory requirements and ensure security compliance. Here is an overview of the auditing capabilities in Secret Server:

Local Auditing

Secret Server locally audits all actions taken within the system.

- Auditable events include secret access, configuration changes, and user activities.
- Various user permissions are tailored for specific kinds of audits, such as viewing secret audits, user audits, and configuration audits.
- Local audit records can be accessed through the Reports tab and specific audit buttons on configuration pages.

Enhanced Auditing, Reporting, and Compliance

- Audit Reports: Generate reports to see all actions taken by a user or on a secret within a specified date range.
- Dual Control: Requires two people to access sensitive reports or recordings, enhancing security by implementing the "four eyes principle."
- Event Subscriptions: Customizable alerts that notify users or administrators when specified actions occur, such as secret edits or heartbeat failures.
- Scheduled Reports: Set up reports to be generated and sent via email on a regular schedule.

- Custom Reports: Create custom reports with database queries, including charts and rollup graphs for visualization.
- FIPS Compliance: Enable FIPS 140-2 compliant algorithms to meet U.S. Federal standards for cryptography.
- Privileged Behavior Analytics: Detect anomalies in privileged account behavior to preemptively address potential cyber threats.

Exporting and Importing Settings

- Secret Server allows exporting and importing settings, with audits recorded for each setting category that is exported or imported.
- Errors and resolutions are logged, and detailed logs are available for troubleshooting.

Alerts, Auditing, Events, and Logs

- Secret Server records specific events and can send alerts when they happen.
- Logs are maintained for various activities, providing a detailed trail of actions for auditing and compliance purposes.

Accessing Audit Records

- Local Reports: Access out-of-the-box and custom reports.
- Windows Event Log: Configure Secret Server to send audit logs to the Windows Event Log for local auditing and troubleshooting.
- Configuration Audit: View individual setting audits on the Configuration Audit page.

User Permissions for Auditing

- View Secret Audit: Allows viewing of secret audit logs.
- View User Audit Report: Allows viewing of user audit reports.
- Add Secret Custom Audit: Allows making custom audit entries via the web services API.
- User Audit Expire Secrets: Allows viewing and forcing expiration of secrets accessed by a user.

Audit Data Retention

In This Section

- Overview
- Data Retention Policies
- Permissions
- Procedures
  - Viewing the Status and History of Audit-Data Retention Policies

- Editing Audit Data Policies
- Running an Old Audit-Data Purge Right Now

Overview

Secret Server can automatically delete older audit and audit-like information (both are called "audit data" here). By default, Secret Server does not delete any audit data.

> Do not configure automatic record deletion for compliance or other important data.

> If you are installing Secret Server 11.7.000031 and newer, data retention is on by default.

If enabled, old data deletion occurs automatically at 0600 UTC every day. Data deletion can be run immediately by clicking the "Run Now" button. The maximum record age for each audit-data retention policy is configurable to any value greater than or equal to 30 days.

Data Retention Policies

The audit data retention offers two data retention policies:

- Personally Identifiable Information (PII): Tables containing identifiable user or organization data.
- Database Size Management: Tables that are prone to grow large, which may affect Secret Server performance.

Each policy has a title and description, which are displayed to users, as well as a defined set of Secret Server audit tables it manages. There is some overlap between the two policies' table sets as some tables fall under both PII and size management.

Personally Identifiable Information (PII)

Personally identifiable information is information such as email addresses or names that can be used to identify an individual. Some audit records contain one or more of these data types. Companies may choose to delete these records for compliance or security reasons.

The following list details which records are deleted under the PII data retention setting:

- Event Subscription Audit
- Dual Control Audit
- Group Audit
- Secret Audit
- Folder Audit
- Secret Policy Audit
- Workflow Template Audit
- Event Audit
- User audit
- Admin Log

- Access Request History
- Access Response History
- Secret access request history

Database Size Management

Certain tables in the database will grow very large over time in active enterprise organizations, which can in turn impact performance. Organizations may choose to delete these records to preserve server storage space or to prevent data-bloat and reduced performance that could accompany the growth of these tables.

The following list details which records are deleted under the database size management data retention setting:

- Group Audit
- SDK Client Audit
- Secret Audit
- Event Audit
- User audit
- Secret Log
- Secret Item Transition History
- Secret History
- User Secret Event
- Disaster Recovery Configuration Audit
- Disaster Recovery Data Replica Audit

When an audit-data retention policy runs, all records in each table for that policy that are older than the set maximum record age in days are deleted from the database. This also includes all dependent records in other tables that would otherwise prevent deletion.

Secret Session Management Only

In certain organizations, tables related to Secret Sessions may grow much faster than others. These organizations may choose to delete these records after they reach a certain age but retain other types of data, including audits, that would normally be truncated as part of database size management.

The following list details which records are deleted under the secret session manangement only data retention setting.

- Secret session history

Permissions

Access to the audit-data detention management pages in Secret Server is limited to users with the roles "View Data Retention" and "Administer Data Retention." As the names imply, only the latter role can manage audit data retention, such as editing and running now.

The "Unlimited Admin" role does not include audit data retention management at this time.

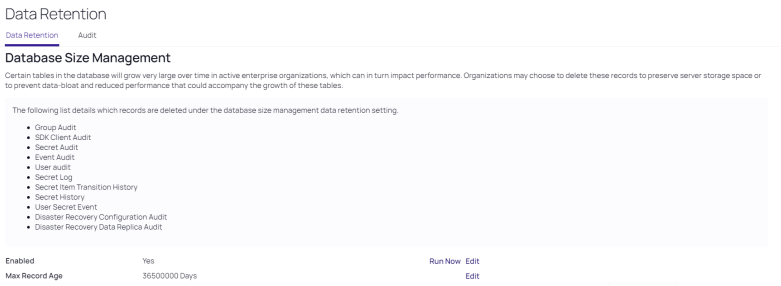
By default, these two audit-data retention roles are not assigned to users. An admin must first assign the roles to users requiring access.

Procedures

Viewing the Status and History of Audit-Data Retention Policies

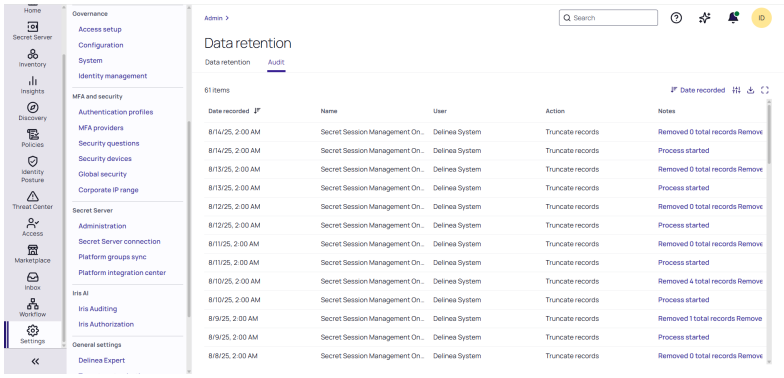
1. In the search bar, search for the **Data Retention** page:

   The Personally Identifiable Information (PII) policy is displayed on the Data Retention tab. If you scroll down, you will see the Database Size policy:



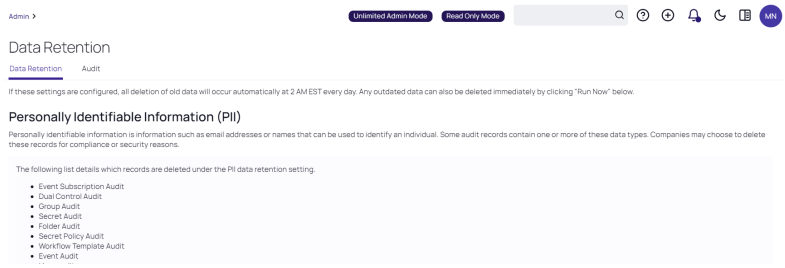
2. Notice that each policy lists:
   - The enabled status (editable)
   - The maximum age audits are allowed to remain (editable)
   - The last time the policy ran
   - The last time the policy finished running
   - All the audit data tables that the policy covers
3. To view a list of previous "runs," click the **Audit** tab. You can also hover the mouse pointer over individual

records to view details:



Editing Audit Data Policies

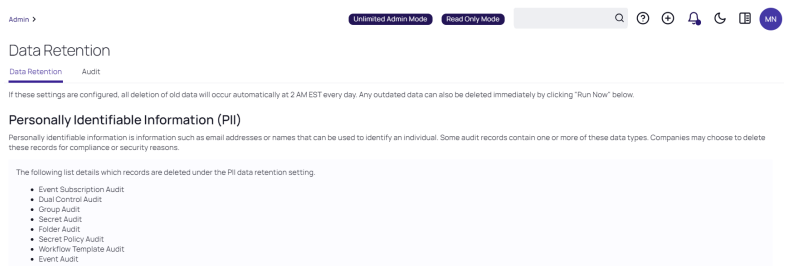
1. In the search bar, search for the **Data Retention** page:



2. Click the **Edit** link on the **Enabled** row on the policy that you wish to edit. A popup appears (not shown).
3. Click to select the **Enabled** check box.
4. Click the **Save** button. The policy becomes enabled.
5. Click the **Edit** link on the **Max Record Age** row on the policy that you wish to edit. A popup appears (not shown).
6. Type the number of days you want to retain the data (at least 30) in the **Max Record Age** text box.
7. Click the **Save** button. The maximum record age changes.

Running an Old Audit-Data Purge Right Now

1. In the search bar, search for the **Data Retention** page:



2. Click the **Run Now** link on the **Enabled** row on the policy that you wish to edit. A popup appears (not shown).
3. Click the **Run Now** button. The popup disappears and the policy is running now.

> If a policy is currently running and you click the Run Now button. It will not work, and a popup will tell you so. There is a built-in five-minute wait after a policy finishes before you can run it again.

4. The **Last Start Time** row changes to the current time, and a progress indicator appears.
5. When the run is complete, the **Last Complete Time** row changes to the current time.

Audit Reports

In addition to the user audit and individual secret audit, the reporting feature provides a series of activity, user, and secret reports. See "Built-in Reports" on page 882 for the most up-to-date list of reports included.

> Users can also create their own, custom reports. See "Creating and Editing Reports" on page 887.

Preventing PII Export in Audit Reports

Overview

You can enable the marking or obfuscation (hiding) of Personally Identifiable Information (PII) in audit exports. This allows for data exportation for review by third parties without including any PII. Marking PII prepares exports for external, separate cleanup, and obfuscation automatically hides or removes it during exportation.

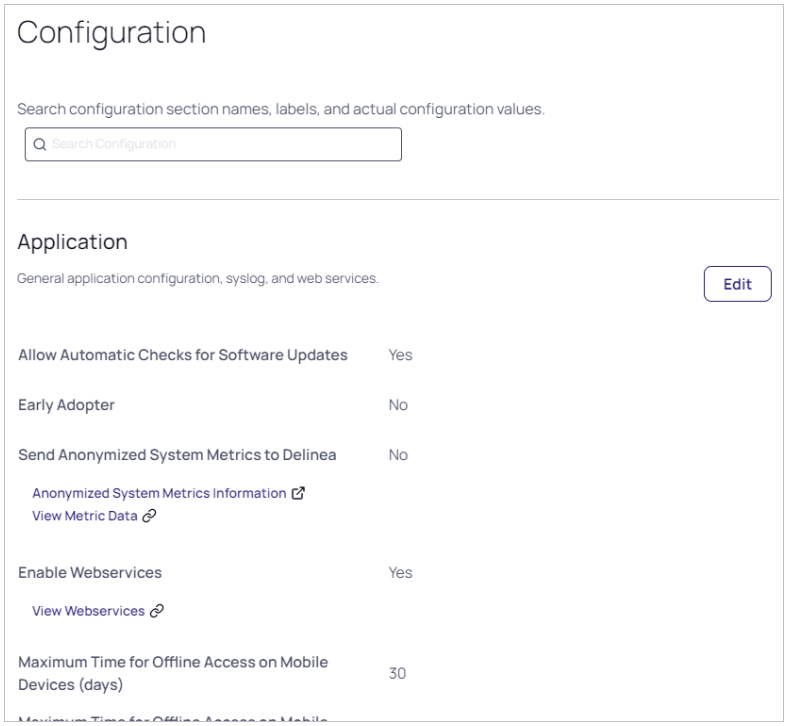
PII includes many internal stored attributes, such as IP addresses, usernames, and email addresses. Metadata fields can be flagged on creation as potentially containing PII, which aids applying the same filtering to user-configured metadata fields. PII can potentially appear in:

- System logs
- Thread logs (RPC, heartbeat, discovery, and others)
- Event logs
- Log4net files

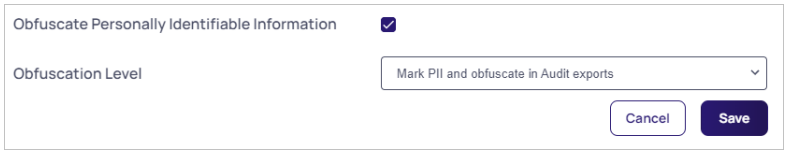
> This feature currently only applies to audit tables available in the interface.

Procedure

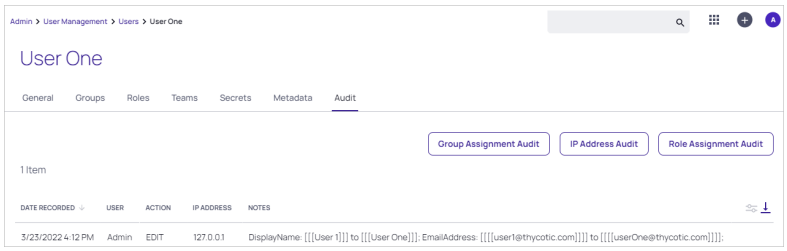
1. In the Admin Side Panel, search for and click **Application**. The Application Configuration page appears.



2. Click the **Edit** button.
3. Scroll down and click to select the **Obfuscate Personally Identifiable Information** check box. An Obfuscation Level dropdown list appears:



4. Click the Obfuscation Level dropdown list to select one of the following:
   - **Mark PII and Obfuscate in Audit Exports**: Permanently hide or remove all PII in the exported audit report. The following PII data is hashed (replaced with unique, scrambled text that provides no PII): user ID or name, IP address, and folder path. Any other PII data is replaced with `[PII REMOVED]`. The hash value allows audit viewers to see that multiple entries belong to a single user without having any specifics on who that user is.
   - **Mark PII**: Delimit all PII in easy-to-search-for markers. This allows other applications to process the PII after the export.
5. Marked PII is surrounded with three square brackets on each side, as seen below:



Obfuscated exports appear as seen in MS Excel below. Note the removed data `[PII REMOVED]` and the unique hash values for the user and display names:

Date Recorded	User	Action	IP Address	Notes
2022-03-23T20:12:10.483Z	1788267786	EDIT	1638446219	DisplayName: 665120776 to 1077913347; EmailAddress: [PII REMOVED] to [PII REMOVED];

Secret Audit Log

The audit log for a secret can be accessed by clicking the **Audit** button on the **Secret View** page or navigating from the User Audit report. The log shows the date, the username, the action, and any other details about the event. Secret auditing provides a detailed view of each change or view on a secret.

> Audit logs are visible to anyone with the "list" permission. Thus, anybody with that Delinea permission can view permission changes, users whose permissions were changed, secret dependency information, and the machine.

> Audit records are created whenever a user accesses a secret. Audits of the same action will only occur once every five minutes no matter how many times an action is carried out within the time period. Users with Delinea permissions to edit the secret can also choose to include Heartbeat and Remote Password Changing events within the audit.

Secret audits are taken for the following user actions:

- Adding, updating and removing secret dependencies
- Check out
- Editing permissions
- Forced expiration
- Hide launcher password changes
- Set for check-in
- Update
- View

For certain audit items, action notes are added providing additional details. For example, if permissions are edited, an audit record is generated detailing which users or groups gained or lost permissions. Detailed audit records add accountability to sensitive secrets where auditors or administrators need to know exactly what was modified.

The **Password Change Log** dropdown allows you to include password change log events.

Viewing a User Audit Report

To view a user audit report:

1. From the **Reports** page, click the **User Audit** tab.
2. From the dialog on the tab, select a user and a date range to view.
3. Click **Search History** to view the user's audit trail.

The audit search displays results for all the secrets the selected user has viewed or edited during the selected time period. The administrator has the option of expiring all the viewed secrets, to notify users to change sensitive information, or to force password changing (if the RPC is configured).

To get a full view of the actions taken on a secret, select that secret from the results list. The secret audit displays the specific user actions for a secret.

Events

The Events section is designed to help users manage and respond to system activities by providing tools and processes for monitoring important events. It includes guidance on Event Pipelines, which track the flow of system events, and Event Subscriptions, which allow users to subscribe to specific event types for timely notifications. The Notification Inbox feature is also covered, offering a centralized location for reviewing system alerts. This section ensures users can stay informed and take appropriate actions based on the events occurring within their systems.

Event Pipelines

Overview

Event pipelines (EPs) are a named group of triggers, filters, and tasks to manage events and responses to them. Event pipelines themselves can be grouped into EP policies. The Secret Server EP system is essentially a flexible instruction set builder and manager for controlling events and responses.

Event Pipeline Components

Definitions

Event Pipeline

An EP is a single named group of triggers, filters, and tasks. The same EP can be in multiple EP policies. Changing an EP affects all EP policies that EP is a part of. EPs do nothing if not assigned to an EP policy. There are two types of event pipelines–secret and user. To run an EP, include it in an active EP policy of that same type (secret or user) with set EP policy targets, such as user groups or folders.

Event Pipeline Policy

An *EPpolicy* is a named group of EPs that are run at the same time (in sequential order). Similar to EPs, there are two types of EP policies: *secret* or *user*. Secret EP policies target secret policies or folders and can only contain secret EPs. User EP policies target users in Groups and can only contain user EPs. EP policies must have an assigned EP policy target to work. Similarly, an EP policy with no assigned EPs does nothing.

Event Pipeline Filter

EP *Filters* are parameters that limit when an EP task runs. All Filters have settings and can be added to an EP multiple times. The filters are:

Secret Policy Filters

The current secret policy filters:

- Custom Variable
- Day of Week
- Event Time
- Event User: Group
- Event User: Has Two Factor
- Event User: Role
- Event User: Role Permission
- Event User: Team
- Event User: User Domain
- Event User: User Last Login
- Event User: User Setting
- IP Address
- Group
- Policy on a Secret
- Role
- Role Permission
- Secret Access Role Permission
- Secret Field
- Secret has Field
- Secret has RPC enabled
- Secret Name
- Secret Setting
- Secret Template
- Site
- Target User: Two Factor Type
- Two Factor Type

User Policy Filters

The current user policy filters:

- Custom Variable
- Day of Week
- Event Time
- Event User: Group
- Event User: Has Two Factor
- Event User: Role
- Event User: Role Permission
- Event User: Team
- Event User: User Domain
- Event User: User Last Login
- Event User: User Setting
- IP Address
- Multi-Group
- Target User: Group
- Target User: Has Two Factor
- Target User: Multi-Group
- Target User: Role
- Target User: Role Permission
- Target User: Team
- Target User: Two Factor Type
- Target User: User Domain
- Target User: User Setting
- Two Factor Type

Some filters prompt you for additional information when you select them.

Event Pipeline Policy Target

EP policy *targets* are Secret Server folders, secret policies, or user groups that are the *subject* an EP policy is applied to. For secret EP types, the secrets inside the folders or secrets under the secret policies trigger the EPs in an EP policy. As targets, folders are not recursive–only the secrets directly in the folder can trigger an EP. For user EP types, only users in the selected groups can trigger an EP.

EP policy targets are *not* the receivers of task action. Those receivers are usually components of Secret Server. The term *target* is instead used for the *subject* of an EP policy–the policy targets the secret in the policy or folder to trigger the EPs to process.

Event users are different than target users: The event user triggers the event. The target user is the recipient of the event.

Event Pipeline Task

Important: Tasks are powerful and can potentially do a lot of damage, so we highly recommend testing EPs in a safe environment before using them on production secrets.

EP *tasks* are actions that are triggered in an EP, assuming any filtering conditions are met. Tasks can edit secrets, move secrets, change Delinea permissions, send notifications, and more.

Tasks run in order of their appearance on the Task tab of the Event Pipeline details page. To change the task running order, hover the mouse pointer over the one you want to move, and use the anchor on the left of its card to drag the task to the order you want it to run. If a task fails, the follow-on tasks will not run.

EP targets are *not* the receivers of task action. Those receivers are usually components of Secret Server. The term *target* is instead used for the *subject* of an EP policy—the policy targets the secret in the policy or folder to trigger the EPs to process.

To reference the additional secrets in the script's Args field for the update secret with a script task or run script, use `$[ADD:1]` before the token. For example: `$[ADD:1]$USERNAME` to reference additional secret one and `$[ADD:2]$USERNAME` to reference additional secret two.)

Secret Tasks

The secret tasks are:

- Add Custom Audit
- Add Share
- Assign Secret Policy
- Assigning Site to Secret
- Change Secrets to not require a comment when viewed
- Change Secrets to not require Check Out
- Change Secrets to require Check Out
- Change Secrets to require Comment on View
- Change to Inherit Permissions
- Delete
- Disable Auto Change
- Disable Heartbeat
- Edit Share
- Enable Heartbeat

- Expire Secrets
- Fail with a message
- Hide Launcher Password
- Move to Folder
- Post Slack Message (WebHook)
- Retry with new random password
- Run Heartbeat
- Run Script
- Schedule Pipeline
- Secret: Add Custom Audit
- Secret: Add Share
- Secret: Assign Secret Policy
- Secret: Assigning Site to Secret
- Secret: Change Password Remotely
- Secret: Change Secrets to not require a comment when viewed
- Secret: Change Secrets to not require Check Out
- Secret: Change Secrets to require Check Out
- Secret: Change Secrets to require Comment on View
- Secret: Change to Inherit Permissions
- Secret: Delete
- Secret: Disable Auto Change on Secret
- Secret: Disable Heartbeat
- Secret: Edit Share
- Secret: Enable Auto Change on Secret
- Secret: Enable Heartbeat
- Secret: Expire Secrets
- Secret: Fail with a message
- Secret: Move to Folder
- Secret: Retry with new random password
- Secret: Run Heartbeat
- Secret: Send Email to Owners
- Secret: Set Privileged Account
- Secret: Stop RPC

- Secret: Undelete
- Secret: Update Secret by field
- Secret: Update Secret Name
- Secret: Update Secret with a script
- Secret: Viewing Password Does Not Require Edit
- Secret: Viewing Password Requires Edit
- Send Email to Event User
- Send Email to Group
- Send Email to List
- Send Email to Owners
- Set Custom Variable
- Set Privileged Account
- Stop RPC
- Undelete
- Unhide Launcher Password
- Update Secret by field
- Update Secret Name
- Update Secret with a script
- Update Secrets to automatically change the password

User Tasks

The user tasks are:

- Post Slack Message (WebHook)
- Run Script
- Schedule Pipeline
- Send Email to Event User
- Send Email to Group
- Send Email to List
- Set Custom Variable
- Target User: Add User to Group
- Target User: Add User to Team
- Target User: Disable Duo Two Factor
- Target User: Disable Email Two Factor
- Target User: Disable FIDO2 Two Factor

- Target User: Disable RADIUS Two Factor
- Target User: Disable TOTP Auth Two Factor
- Target User: Disable Users
- Target User: Enable Duo Two Factor
- Target User: Enable Email Two Factor
- Target User: Enable FIDO2 Two Factor
- Target User: Enable RADIUS Two Factor
- Target User: Enable TOTP Auth Two Factor
- Target User: Enable Users
- Target User: Force Logout
- Target User: Lock User
- Target User: Remove User from Group
- Target User: Remove User from Team
- Target User: Reset FIDO2 Two Factor
- Target User: Reset TOTP Auth Two Factor
- Target User: Send Email to Target User
- Target User: Unlock User

Event User

An event user is the user making the action. For example: Admin updated user Jane's email. Admin is the event user.

Event Variable

An event variable is a place holder for a piece of information that will manifest when the event occurs, for example the user initiating the event ($ByUser) or whether or not the applicable secret is active ($secret.active).

Target User

A target user is the affected user. Example: Admin updated user Jane's email. Jane is the target user.

Triggers

EP *triggers* are events in Secret Server that cause the EP to begin processing. All triggers have no settings and can only be added to an EP once.

Pipelines are triggered following an action in most cases–pre-checkout being the exception. Therefore, you cannot interrupt an action during an event.

The triggers are:

Secret Triggers

- Access Approved
- Access Denied
- Cache View
- Check In
- Check Out
- Copy
- Create
- Custom Audit
- Custom Password Requirement Added To Field
- Custom Password Requirement Removed From Field
- Delete
- Dependency Added
- Dependency Deleted
- Dependency Failure
- Edit
- Expired Today
- Expires in 1 Day
- Expires in 15 Days
- Expires in 3 Days
- Expires in 30 Days
- Expires in 45 Days
- Expires in 60 Days
- Expires in 7 Days
- Export
- File Save
- Heartbeat Failure
- Heartbeat Success
- Hook Create
- Hook Delete
- Hook Edit
- Hook Failure
- Hook Success

- Launch
- Password Change
- Password Change Failed
- Password Change Maximum Attempts Reached
- Password Displayed
- Pre-Check In

> When using the Pre-Check In trigger, we recommend applying a group filter too. That trigger is a blocking call prior to secret check in that runs a script or causes the check in to fail with a warning. A problem arises when Secret Server does the same check-in process for the system "user" in the background at the end of the checkout interval. When the Pre-Check In trigger causes the check in to fail with a warning, the Secret Server background process continues to attempt check in forever, causing Secret Server to disable the pipeline. Applying a group filter ensures the trigger does not apply to the system user.

- Pre-Check Out
- Secret Policy Change
- Session Recording View
- Undelete
- View
- Viewed Secret Edit
- Web Password Fill

User Triggers

- Added to Group
- Challenge Applied
- Challenge Cleared
- Disable
- Enable
- Lockout
- Login
- Login Failure
- Logout
- Owners Modified
- Remove Personally Identifiable Information
- Removed From Group
- Two Factor Changed

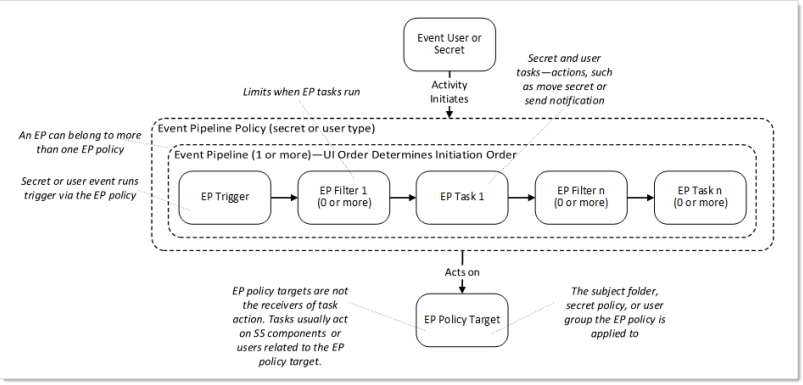
- Two Factor Reset Failure
- Two Factor Reset Success
- User: Create
- User: Edit
- User: Password Change

Component Relationships

The following diagram shows how the components in the Definitions section relate.

> Please refer to the Definition section when viewing this diagram.

Figure: Component Relationships



Event Variables

Event variables are used in EP filters or tasks. They are:

Secret Field Tokens

These can be any secret field name in the tbSecretField table that is not a Password (IsPassword=0) or File (IsFile=0) type. For example, for an Active Directory Account (SecretTypeID=6001), these tokens are available: $Username, $Domain, or $Notes.

Event Setting Tokens

Table: Event Setting Tokens with Filter Values

- $metadata.secret.section.fieldname
- $metadata.folder.section.fieldname
- $metadata.user.section.fieldname
- $metadata.secretfolderuser.section.fieldname

Token Name	Purpose	Values
$ByUser	Username that initiated the event	Text
$ByUserDisplayName	Display name of user that initiated event	Text
$ContainerName	Folder name for the event	Text
$EventAction	Action that occurred on the event entity type. See list of triggers.	Text
$EventDetails	Event notes. For heartbeats and RPC, this contains the status and any error message.	Text
$EventUserKnownAs	Username for user that caused the event. If a domain account exists, then this appears as domain\username.	Text
$ItemId	Secret ID for the event	Text
$ItemNameForDisplay	Event secret name	Text

Secret Setting Tokens

Table: Secret Setting Tokens with Filter Values

Token Name	Purpose	Values
$Secret.Active	Active	Boolean
$Secret.AutoChangeOnExpiration	Auto change on expiration	Boolean
$Secret.ChangePasswordNow	Change password now	Boolean
$Secret.CheckOutChangePassword	Checkout change password	Boolean
$Secret.CheckOutEnabled	Checkout enabled	Boolean
$Secret.EnableInheritPermissions	Enable inherit permissions	Boolean

Token Name	Purpose	Values
$Secret.EnableInheritSecretPolicy	Enable inherit secret policy	Boolean
$Secret.Expired	Expired	Boolean
$Secret.HideLauncherPassword	Hide launcher password	Boolean
$Secret.IsDoubleLock	Double lock	Boolean
$Secret.IsSessionRecordingEnabled	Session recording enabled	Boolean
$Secret.IsSSHProxyEnabled	SSH proxy enabled	Boolean
$Secret.LastHeartBeatStatus	Status of last heartbeat	AccessDenied; AccountLockedOut; ArgumentError; Disabled; DnsMismatch; Failed; IncompatibleHost; Pending; Processing; Success; UnableToConnect; UnableToValidateServerPublicKey; UnknownError
$Secret.PasswordChangeFailed	Password change failed	Boolean
$Secret.PasswordChangeOutOfSync	Password change out of sync	Boolean
$Secret.PasswordChangeStatus	Password change status	None; Pending; Processing
$Secret.PasswordComplianceCode	Password compliance code	Pending; Pass; Fail

Token Name	Purpose	Values
$Secret.RequireApprovalForAccess	Require approval for access	Boolean
$Secret.RequireApprovalForAccessForEditors	Require approval for access for editors	Boolean
$Secret.RequireApprovalForAccessForOwnersAndApprovers	Require approval for access for owners and approvers	Boolean
$Secret.RequireViewComment	Require view comment	Boolean
$Secret.RestrictSshCommands	Restrict SSH commands	Boolean
$Secret.RPCAttemptCount	RPC attempt count	Boolean
$Secret.SecretId	Secret ID	Text
$Secret.SecretPolicyId	Secret policy ID	Text
$Secret.SecretTemplateName	Secret template name	Text

Additional Tokens

Secret

- $SecretName
- $SecretId

Folder

- $FolderId
- $FolderName
- $FolderPath

Event User

- $EventUserDomain
- $EventUserKnownAs
- $EventUserName
- $EventUserLastLogin
- $EventUserId

Metadata

- $metadata.folder.section.fieldname (secret event pipelines)
- $metadata.secret.section.fieldname (secret event pipelines)
- $metadata.secretfolderuser.section.fieldname (secret event pipelines)
- $metadata.user.section.fieldname (secret and user event pipelines)
- $metadata.user.section.fieldname (user event pipelines)

Target User

- $TargetUser.DisplayName
- $TargetUser.IsApplicationAccount
- $TargetUser.IsSystemUser
- $TargetUser.UserEmail
- $TargetUser.UserEnabled
- $TargetUser.UserName
- $TargetUserDomain
- $TargetUserId
- $TargetUserKnownAs
- $TargetUserLastLogin
- $TargetUserName

Custom Task Variables

These are variables created with the EP task. There are two types, global and item, both of which are referenced in the same way.

You must set a custom variable before using it. Thus, you cannot set a variable and use it in the same pipeline. One way around this is to create two pipelines in a policy–the first pipeline sets the variable and the second one uses it. Another way is to first set the variable in Secret Server.

Global Variable

- $GlobalVariable.CustomVariableName
- This custom task variable is global, so there should only be one per variable name.

Item Variable

- $ItemVariable.CustomVariableName
- This variable is per SecretId (secret pipeline) or UserId (user pipeline).

> The first time an EP task is invoked, an item variable is not translated, but subsequent invocations have the variable. Global variables are immediately available.

Permissions

There are three permissions:

- **Administer Pipelines:** Allows the user to create, edit, and remove EPs and EP policies.
- **Assign Pipelines:** Allows the user to assign an EP policy to secret policies, or folders.
- **View Pipelines:** Allows the user to view EP policies and policy activities.

Procedures

Event Pipelines

Activating or Deactivating Event Pipelines

To control if an EP is available to all EP policies, you can toggle the EP's active status:

1. Go to the **Event Pipelines** page.
2. Click the **Pipelines** tab.
3. Locate the card for the EP you want to activate or deactivate.
4. Click the **Active/Inactive** toggle button. A confirmation popup appears.
5. Click the **OK** button. The EP's status is changed for all EP policies it belongs to.

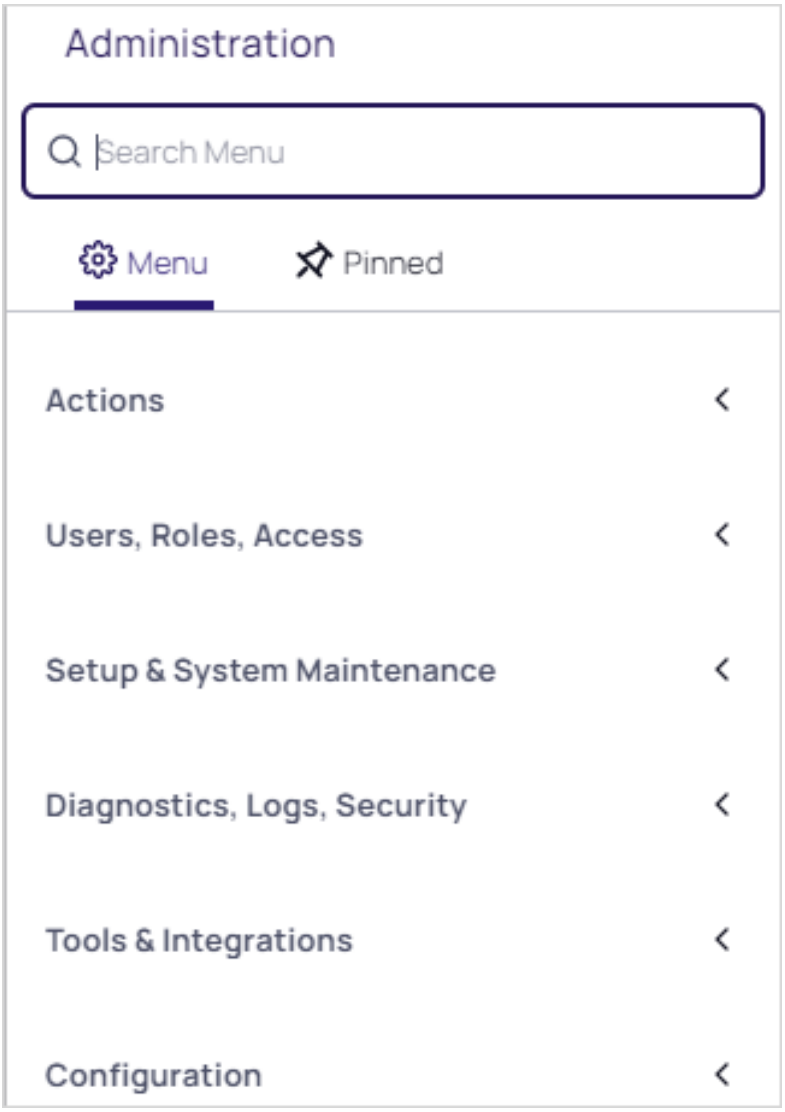
Creating New Event Pipelines

> You can create EPs from the Event Pipelines list (shown below) or an EP policy's details view. With the former method, you will have to add the EP to an EP policy separately. With the latter method, the EP is automatically added to the EP policy you are viewing. You can later manually add additional EPs to the policy as desired.

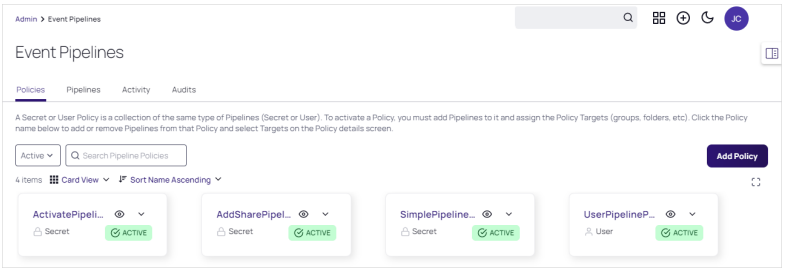
To create a new EP:

Step One: Create the EP

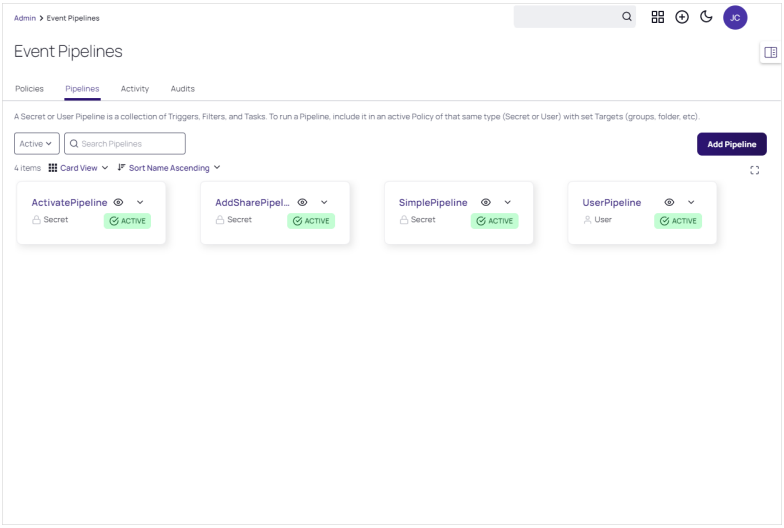
1. Navigate to **Administration**. The Admin Side Panel appears:



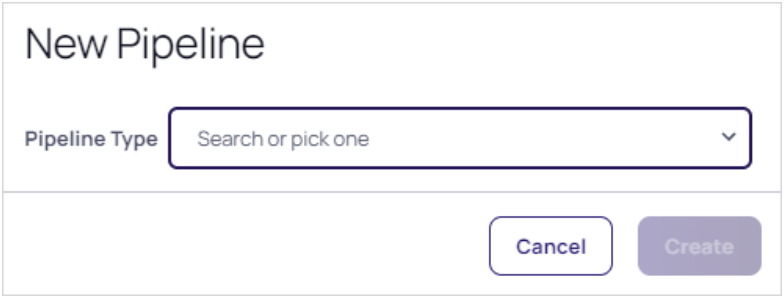
2. Click **Actions** and select **Event Pipeline Policy** in the list. The Event Pipelines: Policies tab of the Event Pipelines page appears:



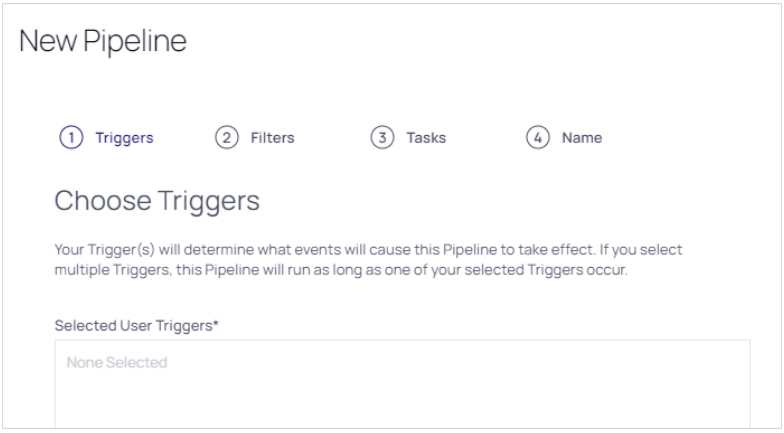
3. Click the **Pipelines** tab:



4. Click the **Add Pipeline** button. The New Pipeline popup appears:



5. Click the **Pipeline Type** dropdown list to select the EP type: **Secret** or **User**. For this instruction, we chose User.
6. Click the **Create** button. The New Pipeline wizard appears on the Choose Triggers page:

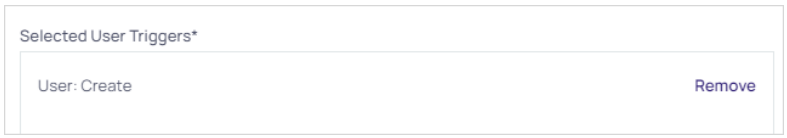


Step Two: Add Triggers

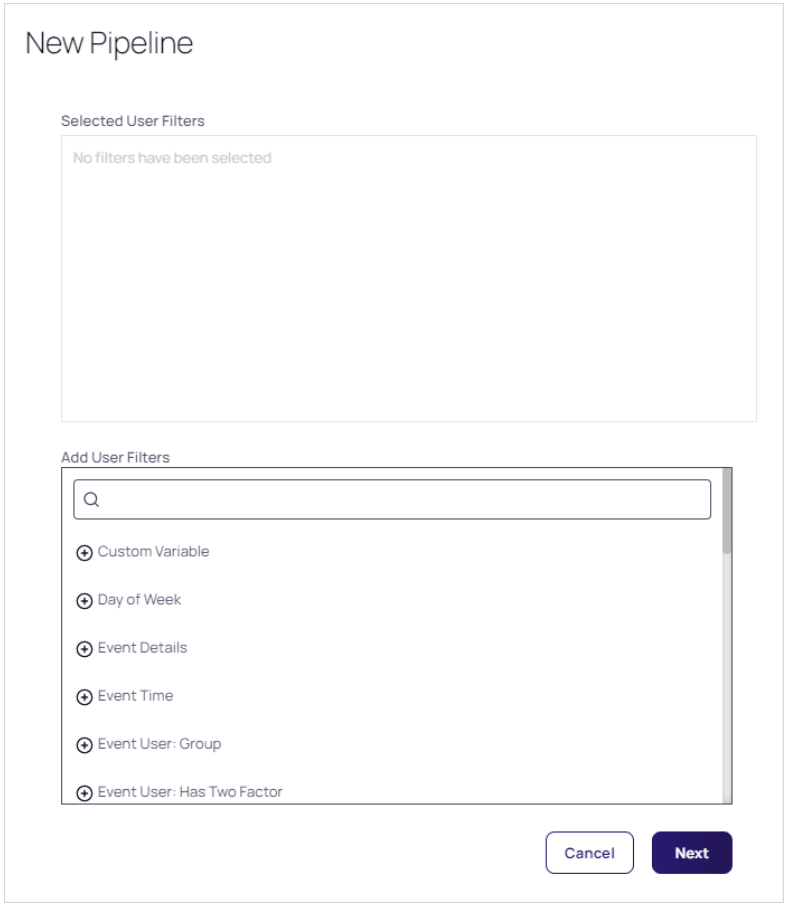
> When using the pre-check-in trigger, we recommend applying a group filter too. That trigger is a blocking call prior to secret check in that runs a script or causes the check in to fail with a warning. A problem arises when Secret Server does the same check-in process for the system "user" in the background at the end of the checkout interval. When the Pre-Check In trigger causes the check in to fail with a warning, the Secret Server background process continues to attempt check in forever, causing Secret Server to disable the pipeline. Applying a group filter ensures the trigger does not apply to the system user.

1. In the **Add Triggers** section, click the **+** button next to the triggers you desire. You can also search for a trigger by typing in the search text box. The selected triggers appear in the Selected Triggers list. Consider the following when selecting triggers:
   - Currently triggers are centralized around events that are linked to a secret.
   - You can add multiple triggers.
   - You can limit when the EP runs by adding filters.
   - Multiple triggers are logically ORed (not XORed) together. Each trigger is considered individually, and only one needs to apply for the EP to run—if concurrent triggers do not apply, it does not matter. If multiple triggers do apply, the EP will only run once per EP policy.

   The added trigger appears in the Selected User Triggers box:



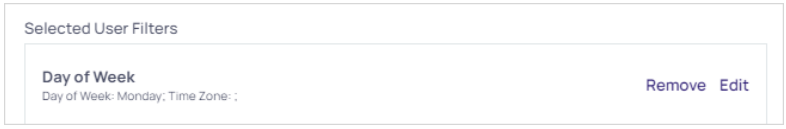
2. Click the **Next** button. The Choose Filters page of the wizard appears:



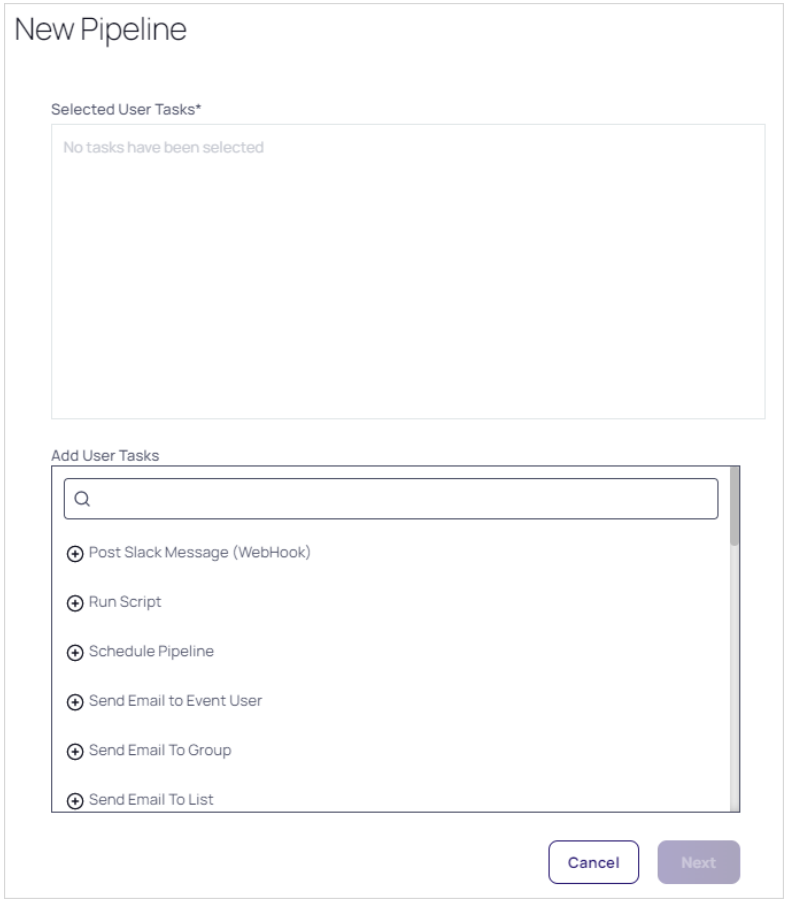
Step Three: Add Filters

1. Use the exact same method to add filters to the EP. All filters present a popup page for you to provide additional information when you click on them. Consider the following when selecting filters:
   - Whereas triggers focused on secrets, filters can also access secret and user information.
   - Because the same filter can differ by its settings, you can add the same filter multiple times to an EP.
   - Filters are logically ANDed together–all filters apply at once and all matter.
   - Metadata (MetaData) filters are available for secrets, folders, or user (secret/folder/user hierarchy). Metadata filters can filter for group names.

   The selected filters appear in the Selected User Filters section:

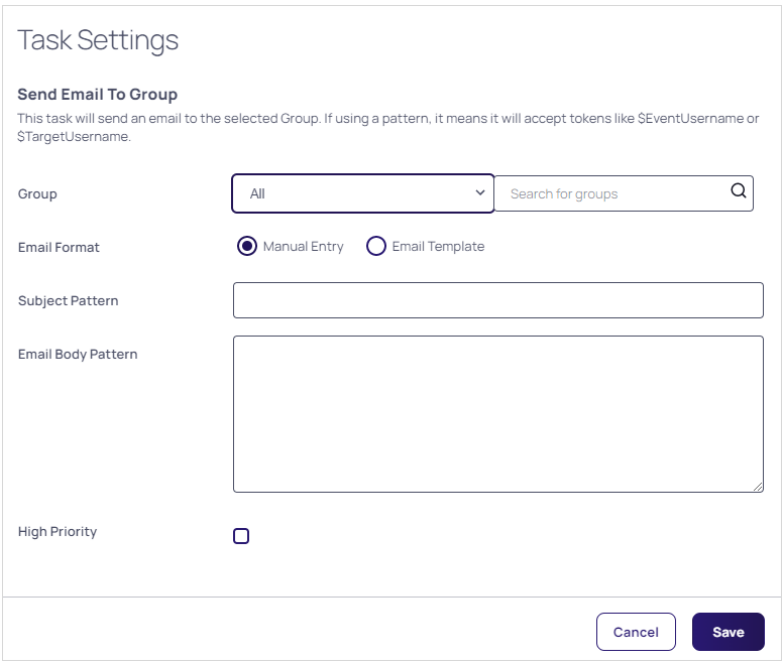


2. Click the **Next** button. The Choose Tasks page of the wizard appears:



Step Four: Choose Tasks

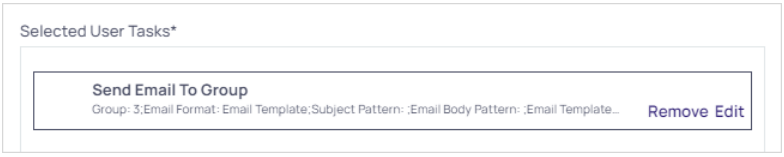
1. Use the exact same method to add tasks to the EP. Many tasks present a popup page for you to provide additional information when you click on them. For example, we chose Send Email to Group:



In this instance, you would choose the groups and the email format, either manual or using an email template, which is the same as an inbox template (see "Using Inbox Templates" on page 342).

> The email templates for EPs can use the EP tokens in addition to the standard inbox template tokens in the message subject and body. Messages are sent directly to the user's inbox based on the email addresses generated by the send email task, not subscribers from any inbox rule.

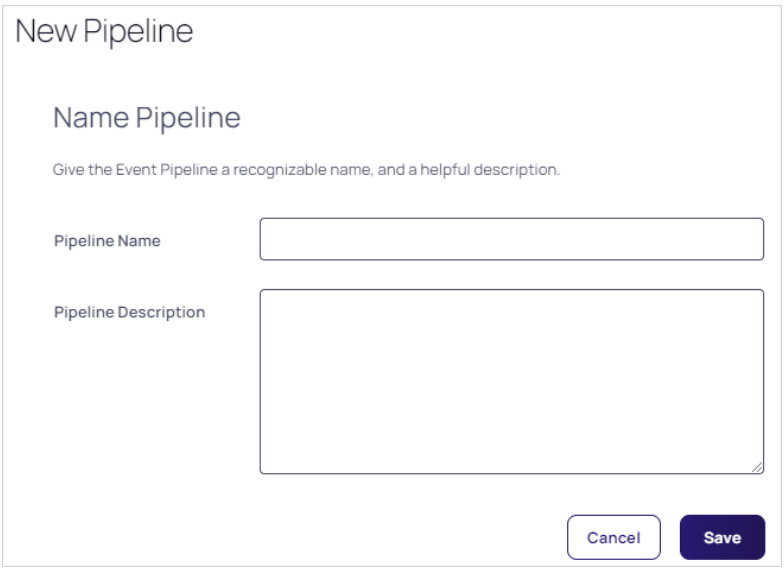
2. The selected user tasks appear :



3. Set the task order if you selected more than one. Tasks run in order of their appearance in the **Task** tab of the **Event Pipeline** page. To change the task running order, hover the mouse pointer over the one you want to move, and use the anchor on the left of its card to drag the task to the order you wish it to run. If a task fails, then the following tasks will not run.

> Tasks are very powerful and thus can be dangerous. You can alter Secret Server in dramatic, sometimes irreversible ways. We strongly recommend testing EPs in a safe sandbox environment before applying them to production Secret Server servers.

4. Click the **Next** button. The Name Pipeline page of the wizard appears:



5. Type the EP's name in the **Pipeline Name** text box.
6. Type a description of the EP in the **Pipeline Description** text box.
7. Click the **Save** button.

Editing Existing Event Pipelines

To create an EP:

1. Go to the **Event Pipeline** page.
2. If necessary, click the **Pipelines** tab. The Event Pipeline Pipelines page appears.
3. Click the title of the card representing the EP you want to edit. The EP wizard appears.
4. See Creating New Event Pipelines for instructions on using the wizard.

Viewing Event Pipelines

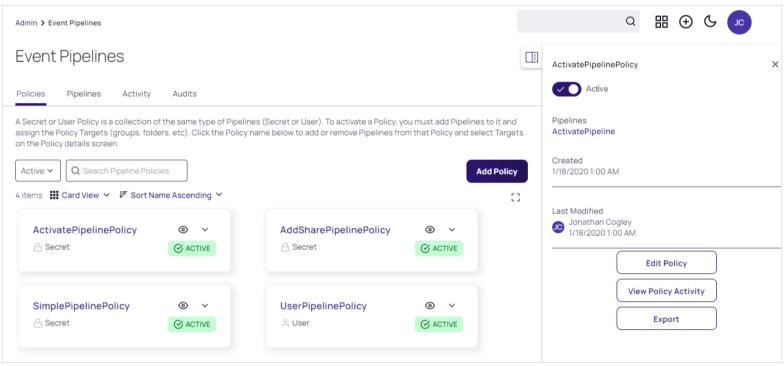
Because EPs are not directly tied to a single EP policy, they can be viewed through an EP policy or directly from the EP list. The EP list is a tab on the main Event Pipeline Policy page directly after navigating from the Admin page. After selecting an EP policy, its associated EPs are displayed in cards.

Event Pipeline Policies

Activating or Deactivating Event Pipeline Policies

To control if an EP policy is available, you can toggle its active status:

1. Go to the **Event Pipelines** page.
2. If necessary, click the **Policies** tab.
3. Locate the card for the EP policy you want to activate or deactivate.
4. Click the eye icon to open the preview panel:



5. Click the **Active/Inactive** toggle button. A confirmation popup appears.
6. Click the **OK** button. The EP policy's status is changed.

> The EPs belonging to the EP policy remain available to other EP policies.

Adding an Existing Event Pipeline

> Adding an existing pipeline enables that pipeline to be used in other policies. Only pipelines of the same type (secret or user) can be added.

> This does not create a copy of the existing pipeline, it creates a link. Thus, any changes to the pipeline will affect the other policies that use it.

1. Go to the **Event Pipelines** page.
2. If necessary, click the **Policies** tab.
3. Select the EP policy you want to add a pipeline to.
4. Click the **Add Pipeline** button.
5. Click the **Add Existing Pipeline** dropdown list and select the pipeline (only pipelines of the same type will show).
6. Click the **Create** button.

Assigning Folders and Secret Policies to Event Policy Targets

Folders

1. Go to the **Event Pipeline** page.
2. If necessary, click the **Policies** tab. The Event Pipeline Policies page appears.
3. Click the title of the EP policy on its card on the **Event Pipeline Policies** page. The page for that EP policy appears.
4. Click the **No Folder Selected** link in the **Targets** section. A destination page appears.

5. Click to select the check boxes for the desired target folders in the tree. Click the tiny arrow next to the check box to expand the tree. Remember, selecting a folder does *not* automatically select its subfolders.
6. Click the **Save** button.

Secret Policies

1. Click **Admin > Secret Policies**. The Secret Policy page appears.
2. Click the desired secret policy's name in the list. The Secret Policy page for that policy appears.
3. Click the **Edit** button. The list becomes editable.
4. Click the **Event Pipeline Policy** dropdown list in the **Security Setting** section and select **Enforced**.
5. Click the **Save** button. All secrets under that secret policy are now affected by the EP policy.

Creating, Importing, and Duplicating Event Pipeline Policies

1. Click **Admin > See All**.
2. Click the **Action** button and select **Event Pipeline Policy**.
3. If you plan to duplicate an existing EP policy, click the card for that policy in the **Event Pipeline Policies** list.
4. Click the **Add Policy** button, and you will be presented with the following options:
   - **Create New Policy:** Click the selection button, and type a name in the **Policy Name** text box, and optionally type a description in the **Policy Description** text box.
   - **Import Policy:** Import an exported EP policy in JSON format. This can be a policy exported from a separate Secret Server instance. Click the selection button, and paste the JSON payload in the **Add Policy** text box, click the **Create** button.
   - **Duplicate Selected Policy:** Copy an existing EP policy. Click the selection button, and then click the **Create** button. The new EP appears in the Event Pipeline Policies list.

Monitoring Event Pipeline Policies

There are two ways to monitor your EP policy:

- **Audit:** Shows changes to EP policies, targets, and EPs. Click the **Audits** tab on the **Event Pipeline Policies** page.
- **Activity:** Shows the actions each EP policy or single EP took each time it is triggered. This includes failures, skips, and successes. Click the card for the desired EP policy, and then click the **View Policy Activity** button on the right. Alternatively, you can click the title on the card. When the page for the EP policy appears, click the **Activity** tab.

Ordering Event Pipelines in Event Pipeline Policies

Event Pipelines run in order they appear in the EP policy. Since EPs can be in multiple EP policies, the order is unique to each policy. To change the EP order in the EP policy:

1. Go to the **Event Pipeline Policies** page.
2. Click the name on the card for the EP policy you want to edit. The policy's page appears on the Details tab.
3. Hover the mouse pointer over the EP you want to reorder. An anchor appears on the left of the card.
4. Drag that anchor to the desired position.

> If an error occurs in a policy's EP, then the following EP still runs.

Removing Event Pipelines from Event Pipeline Policies

To remove an EP from an EP:

1. Go to the **Event Pipeline Policies** page.
2. Click the name on the card for the EP policy you want to edit. The policy's page appears on the Details tab.
3. Click on an EP in the details of an EP policy. A panel appears on the right of the page.
4. Click the **Remove Pipeline** button.

> The button removes the EP from the EP policy, but it does not remove it from Secret Server. Other EP policies using the EP still have access to it.

Advanced Settings and Troubleshooting

Configuring Advanced Settings

There are a few new advanced settings you can use with EP polices:

- **Event Pipeline Activity Log entries removed after (days)**: The EP activity log entries stay in the log for this many days. Default value: 90.
- **Event Pipelines: Allow Confidential Secret Fields to be used in Scripts**: Allows confidential secret fields to be used in EP script, such as $password. Default value: False.
- **Event Pipelines Infinite Loop Time (Minutes)**: If an EP executes the number of times specified in the infinite loop threshold during the Infinite Loop Time period, it is marked as an infinite loop. Default Value: 5 (on premises), 20 (cloud).
- **Event Pipelines Infinite Loop Threshold:** Number of times that an EP can execute within the infinite loop time on an individual item before it is considered to be an infinite loop. Default Value: 5.
- **Event Pipelines Log Skipped Policies**: If true, the pipeline activity log will log filtered policies runs. Default value: False.
- **Event Pipelines Maximum Script Run Time (Minutes)**: Scripts ran by EP tasks are stopped after this many minutes. Default Value: 5 minutes.
- **Heartbeat: Include UnableToConnect as Heartbeat Failure Event**: Adds the ability to trigger EPs on heartbeat UnableToConnect status. When toggled to true, this setting allows the user to include UnableToConnect as part of the heartbeat failure EPs. It defaults to false.

Infinite Loops

It is possible for EPs to trigger each other over and over in an endless loop. For example:

1. Editing a secret triggers one EP to run a heartbeat on the secret.
2. The heartbeat triggers another EP to edit the secret.
3. Editing the secret triggers the original EP to run another heartbeat, restarting the cycle, creating an infinite feedback loop.

Fortunately, Secret Server detects these loops and automatically deactivates the involved EPs. So, if you have EPs that seem to be deactivating themselves, look for circular logic paths involving the EPs.

> By default, pipelines are configured to consider any event that executes five tasks within five minutes from the same trigger as an infinite loop. For example, "secret edit" is selected as a pipeline trigger, and "remote password change" is selected as the task. After the first edit is made on a secret, an RPC is triggered. Every time the RPC completes, a new edit is triggered, which, in turn, triggers another RPC. If this happens five times within five minutes, then an infinite loop is declared. If the RPC is slow, taking more than five minutes for five password changes to occur, then an infinite loop is **not** declared. In this case, use the "configuration advanced" page to change "event pipelines infinite loop time (minutes)" to a longer time.

Event Subscription Overview

Event Subscriptions in Secret Server are a powerful feature designed to keep administrators and users informed about critical activities and changes within the system. These subscriptions trigger notifications for defined events, ensuring that relevant stakeholders are promptly alerted to important occurrences.

Customizable Alerts

Event subscriptions can be set up to alert users or administrators when specific actions are performed or events occur.

Notifications can be sent to the inbox and further communicated externally via email or Slack.

Event Types

- Unlimited access mode toggle
- Secret Edit/Add/View
- Role and Group Assignment changes
- Secret expiration
- Configuration changes
- Heartbeat failure when a password is invalid.

Notification Management

- Notifications are an alert of specific events and not intended for archived reporting.
- Users can manage how long notifications last in the inbox before expiration.
- High-priority emails can be sent for critical events.

User and Group Subscriptions

- Event subscriptions can be assigned to specific users or groups within Secret Server.
- This ensures that only the relevant individuals receive notifications about events that concern them.

Example Use Cases

- Security Alerts: Notify administrators immediately when there is a configuration change or a heartbeat failure, ensuring quick response to potential security issues.
- Compliance Monitoring: Keep track of role and group assignment changes to maintain compliance with internal policies and external regulations.
- Operational Efficiency: Alert IT teams about secret expirations or edits to ensure smooth and secure operations.

Creating Event Subscriptions

Event subscriptions trigger notifications of defined events within the system. These notifications are sent to the inbox, which may send them externally via email or Slack, depending on your configuration.

These notifications are an alert of specific events and not intended to be used for archived reporting.

To add an event subscription:

Task 1: Creating an Event Subscription

1. Navigate to the **Event Subscriptions**.
2. Click the **Create Event Subscription** button. The Create Event Subscription page appears.
3. In the **Name** text box, enter a name for this new event subscription.
4. Click to select the **Send Email** check box if you want to send an email via an inbox notification.
5. Click to select the **Send Slack** check box if you want to send an Slack message via an inbox notification.

Task 2: Adding Events

Create the events that trigger notifications:

1. Click the **Events** dropdown list to select an event object to trigger a notification.
2. Click the second **Events** dropdown list to select the event for the chosen object. For some events, one or more follow-on dropdown lists may appear. For example, if you chose Secret and then Create, another dropdown list would appear for you to select whether you want all secrets, those in the selected folder or those in the selected

folder and its subfolders. Similarly, if you chose those in a folder, a link appears for you to chose the folder.

3. Click the **Add Event** button to add the event. An event table appears below.
4. Add more events as desired.
5. Click the **Create Event Subscription** button. The event subscription's page appears.
6. If you want to change the status from active to inactive or adjust the number of days before an event notification expires, click the **Edit** link next to **Event Subscriptions** and make changes.

Task 3: Adding Subscribers

Subscribers are users that are explicitly defined or are a subscribed group member. They receive a notification in their inbox when this event subscription is triggered.

> Communication to external emails or other channels is defined by inbox notification rules.

1. Scroll down the **Subscribers** section and click **Edit**.
2. Click the **Add** button. The Users & Groups popup page appears.
3. Type the name of the user or group you want to add in the **Search** text box.
4. Click to select the check box next to the user or group that remains.
5. Repeat the process for additional users or groups.
6. Click the **Add** button. The new subscriber appears in a table in the section.

Task 4: Associating Rules

Inbox rules filter a specified event subscription (or other alerts)—in this case, the one you just created. When you create an event subscription, an inbox rule based on the event subscription system rule is automatically created. It can be updated or reviewed to change the actions, email template, or other communication preferences.

The event subscription subscribers defines who *potentially* receives the event alert. The associated inbox rules filters which events are shared with those subscribers via Slack or email messages. Inbox rules search for specified text strings in specified locations in the incoming notification.

> Notifications can be triggered by defined conditions and not a specific event subscription. Those rules may not appear in this list.

1. Scroll down to the **Associated Rules** section. Note that a link to your new event subscription inbox rule already appears at the bottom.
2. If you want to edit the rule, click the link for the inbox rule. See "Using Inbox Rules" on page 330.

Disabling an Event Subscription

To disable an event subscription:

1. Navigate to **Event Subscriptions** and click the subscription name link.
2. Click to uncheck the **Active** checkbox on the following page.

Editing an Event Subscription

To edit an event subscription:

1. Navigate to **Event Subscriptions**, click the subscription name, and then **Edit**.
2. To remove a subscribed user, group, or event, click the button next to the entry in the appropriate list.
3. To add entries to either list, see "Creating Event Subscriptions" on page 321.
4. Click **Save** to save all changes.

Event List

The following events are available:

Table: Folder Events

Event	Scope
Create	All, In this Folder
Delete	All, For this Folder, In this Folder
Edit Permissions	All, For this Folder, In this Folder
Secret Policy Change	All, For this Folder, In this Folder

Table: Secret Events

Event	Scope

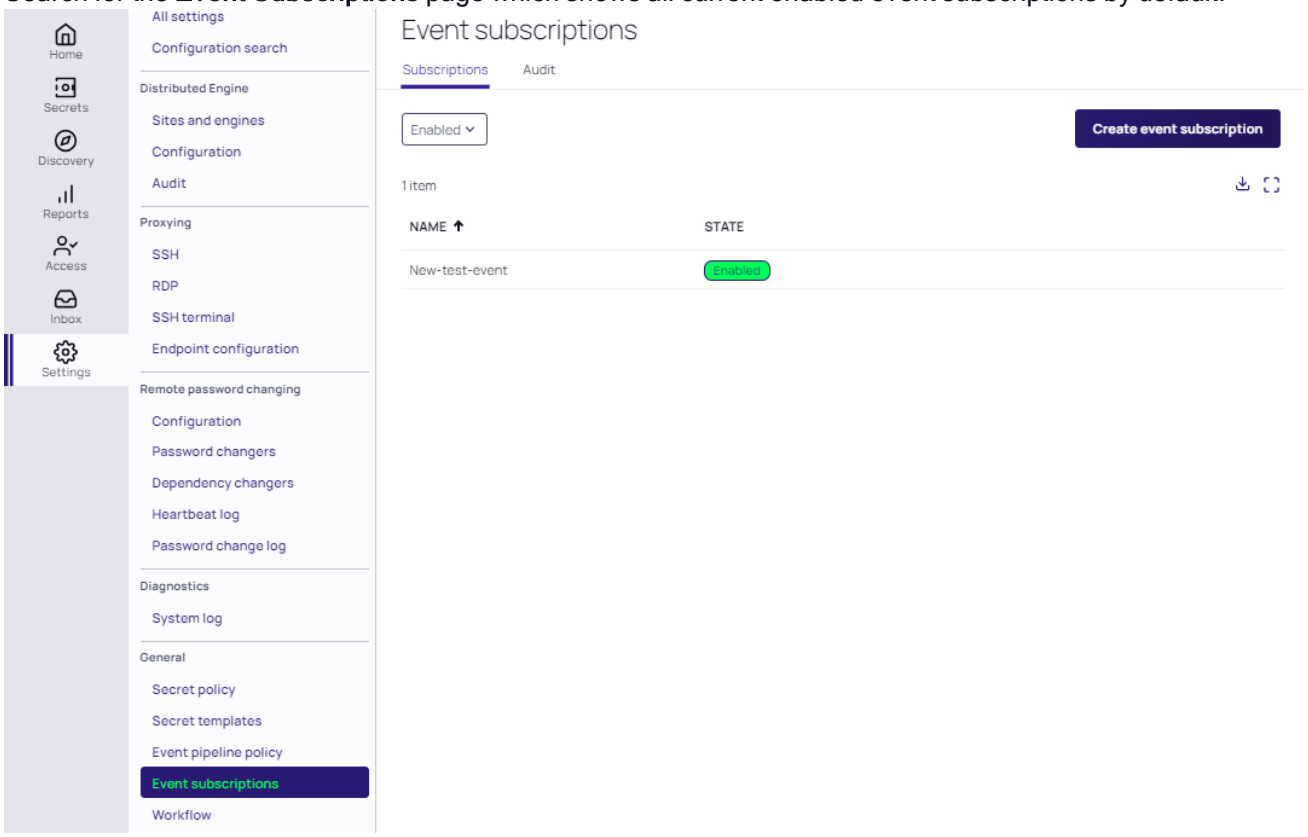
Site	Engine Added, Domain Assigned to Site, Create, Disable, Edit, Enable, Engine Downloaded, Engine Offline, Engine Online, Domain Removed from Site, Engine Removed
Site Connector	Create, Credential View, Disable, Edit, Enable
Unlimited Vault Access	Disable, Enable
User Audit	Expire Now

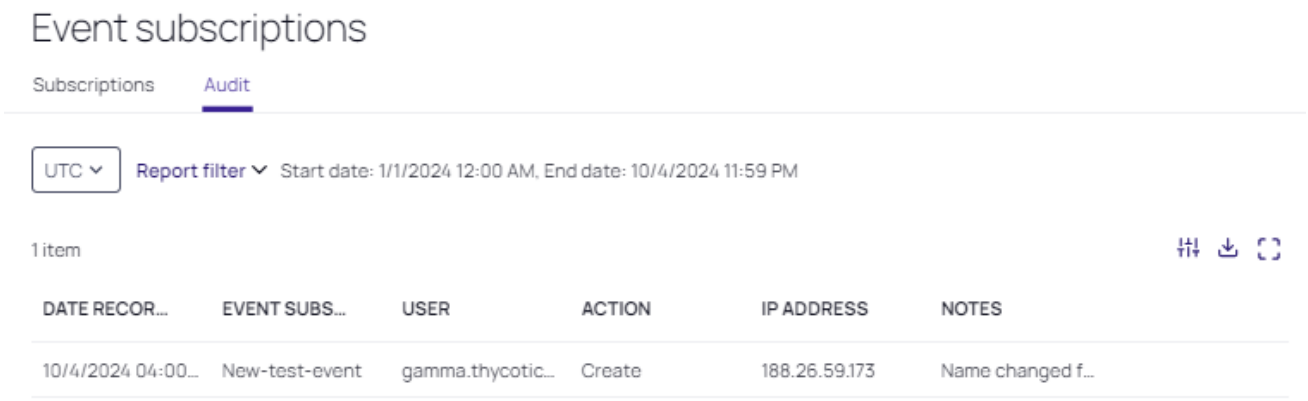
Viewing Event Subscription Logs

To view the events that have been triggered in a subscription perform the following:

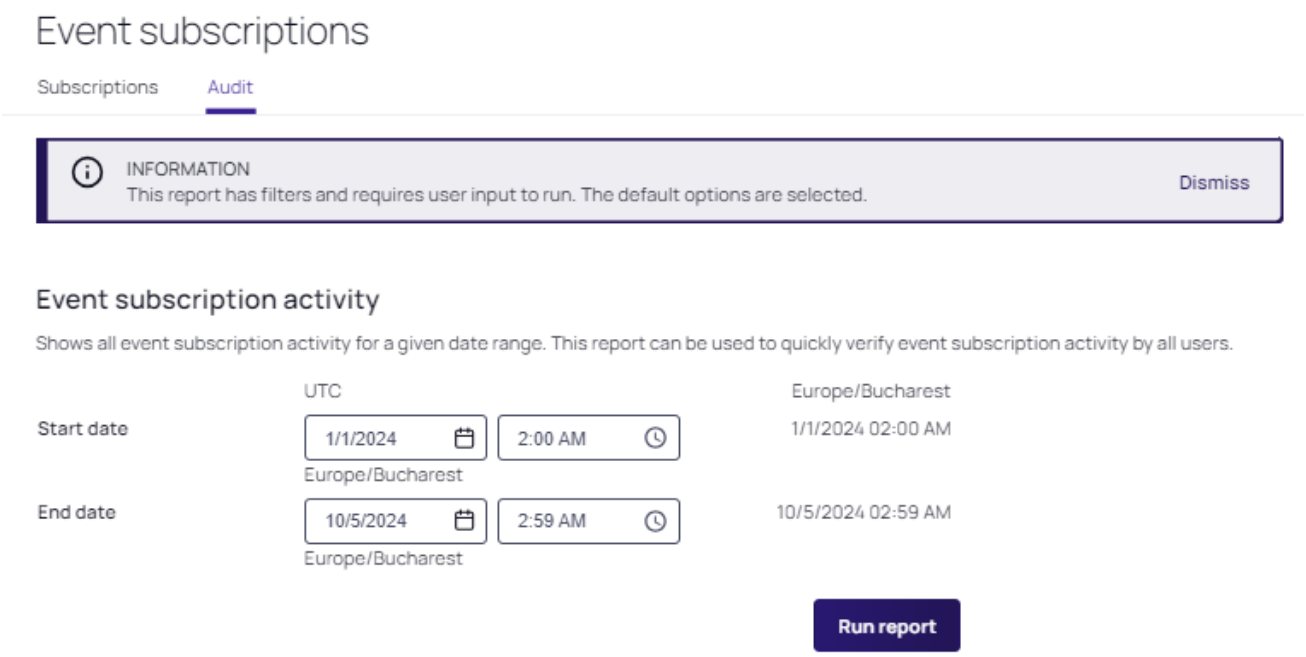
1. Search for the **Event Subscriptions** page which shows all current enabled event subscriptions by default.



2. Navigate to the **Audit** tab. A report is generated automatically for the event subscriptions you have enabled. The most recent events to have been triggered are typically at the top of the list.
3. To select a specific time frame, click the **Report filter** drop-down:



4. The Event subscription activity date range selectors for your current location appear here. Select the start and end dates, along with their respective times. Click **Run report** to return the corresponding log entries:



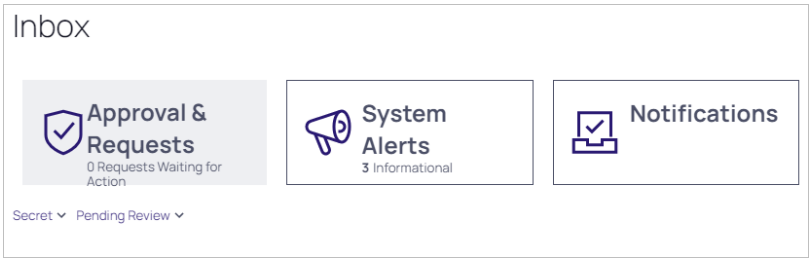
It may take a few seconds for the events to make it into the log.

Notification Inbox Overview

The notification Inbox, or simply inbox, is a centralized interface for managing notifications such as event subscription alerts, access requests and approvals, and other configuration alerts. Here are the key features and functions:

- Notifications: The Inbox displays various notifications, including event subscription alerts, access requests, and system alerts. You can configure notifications to be forwarded via email or Slack based on customizable criteria.
- Access: You can access the Inbox by clicking the Inbox button on the main menu.
- Customization: The format of email messages can be customized. Notifications can be configured to disappear from the notification center after being viewed, while system alerts and access requests remain active until resolved.
- Inbox Templates: Templates are used to format notifications. These templates can be customized and include variables that are replaced by Secret Server when sending messages. Templates can be used for both email and Slack notifications.
- Inbox Rules: Rules can be set up to trigger notifications and send them to specified users or groups via email or Slack. Rules can be created from scratch or based on existing notifications.
- Marking Alerts as Viewed: Alerts can be marked as read, which removes them from the main view but allows them to be seen again if needed.

The Inbox was also called the *Alert Notification Center* in earlier Secret Server versions.



Event subscriptions disappear from the notification center after you view them. System alerts and access requests stay active until resolved.

Marking Alerts as Viewed

1. Access the alert notification center by clicking the **Inbox** button on the main menu. The Inbox appears.
2. Click the **System Alerts** button. The System Alerts page appears.
3. Click the **Mark as Read** button for the each alert you no longer wish to view. The alert disappears, but you can still see it if you click the **Include Read** toggle button.

Using Inbox Rules

Overview

An inbox rule (notification rule) triggers on notifications and sends either an email or a Slack message to a specified group of users. First, we discuss an inbox rule's components. Second, we show how to create an inbox rule from scratch and based on an existing notification.

There are some emails types that Secret Server sends that do not go through the inbox. For example, the test email button on the email configuration page sends a plain-text email directly. There are also some diagnostic emails that are directly sent. For example, discovery can directly send a detailed log which is essentially a text dump. Inbox rules are primarily for non-admin end-user communications and event subscriptions.

You can still send legacy emails (earlier email notifications that did not go through the inbox) if desired. Search for **Enable Legacy Email** to set this up.

Inbox Rule Components

Inbox rules have the following components:

Message (Notification) Types

This is the notification message (alert) types that the rule responds to. These include:

- Dependency Failure
- Event Subscription

- Inbox Test Message
- Password Reset
- Secret Access Approved
- Secret Access Cancel Request
- Secret Access Deny Request
- Secret Access Request
- Secret Changed
- Secret Heartbeat Failed
- Secret View
- Workflow Access Approval Request
- Workflow Access Request Expired
- Workflow Access Request Incomplete
- Workflow Access Request Next Step
- Workflow Access Step Approved

Rule Conditions

Rule conditions are filters that define who receives the email or Slack message when a notification arrives. Conditions are matched with text string matching: equals, not equals, or regex. If no condition exists, the rule triggers for every message of the defined types. Condition types include:

- **ActionType:** Specific entities via text matching of the action's value or display value. Actions types vary by inbox message type. For example, "EXPORTED."

  In the case of an event subscription notification, these are the same as the event subscription events. Other notification types have different action types.

- **Container:** Specific containers via text matching of the container name. Containers include folders (secret containers) and roles (quasi user containers).
- **Details:** Specific text string in the details section. The Details type serves as a summary of the message for display in the inbox. Sometimes it contains information that is from other condition types. For example: "App Settings Exported - SECRETSERVERSETTINGS - EXPORTED."
- **EntityType:** Specific entities via text matching of the entity name or value. Entities are what is having the action done to it, for example, "SECRETSERVERSETTINGS." These are the same as the event subscription entities.
- **EventDetails:** Specific text string in the Event Details section. For example: "Application Settings," "Launcher Settings," and "Protocol Handler Settings."
- **ItemName:** The source item. Specific items via text matching of the item's value or display value. The "item" varies by message. For an event subscription secret action it contains the secret name. For an event subscription folder action, it contains the folder name.

- **SubscriptionName:** The source event subscription. Specific subscriptions via text matching of the subscription's value or display value.
- **User:** The user that created the rule. Specific users via text matching of the username's value or display value.
- **Rule Subscribers:** What users receive the action result (an email or Slack message).
- **Rule Actions:** What actions the rule performs:
  - Send to an email address using a specific HTML template, which the user defines.
  - Send to Slack using a specific markdown template, which the user defines.

Predefined System Rules

Secret Server ships with several predefined system rules in inbox templates. These rules can only be disabled or enabled. However, you can copy a system template to your own custom template and edit that. This allows us to upgrade system rules without interfering with your customizations. The predefined system rules are:

- Dependency Failure
- Inbox Test Message
- Password Reset
- Secret Access Deny Request
- Secret Access Request
- Secret Changed
- Secret Heartbeat Failed
- Workflow Access Approval Request

Example Rule Diagram

This example diagram is specific to event subscription notifications. There are many other types that differ slightly, especially in content.

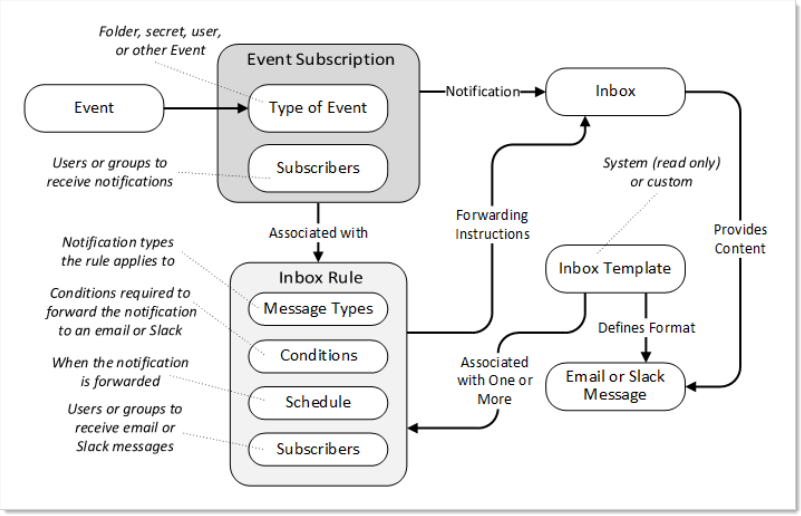
In the following diagram:

1. A secret triggers an event matching an event subscription.
2. Secret Server notifies the users and groups on the event subscription subscribers list. The notifications appear in their inboxes.
3. The inbox rule associated with the event subscription evaluates the conditions for forwarding the notification via email or Slack.
4. The inbox rule checks its schedule to determine when to forward the message.
5. The inbox rule checks its subscribers list to determine who to forward the message to.

> Remember, arriving notifications may have already been filtered by whose inbox gets the notification in the first place. Thus, the inbox rule could be set to sent to everybody but only those who receive the notification in their inbox will receive the email or Slack message.

6. The inbox rule references the message type's inbox template to format and populate the message's variables.
7. When the scheduled time arrives, which can be immediately, Secret Server sends the messages to the subscribers.

Figure: Event Subscription Using an Inbox Rule to Forward a Notification via the Inbox



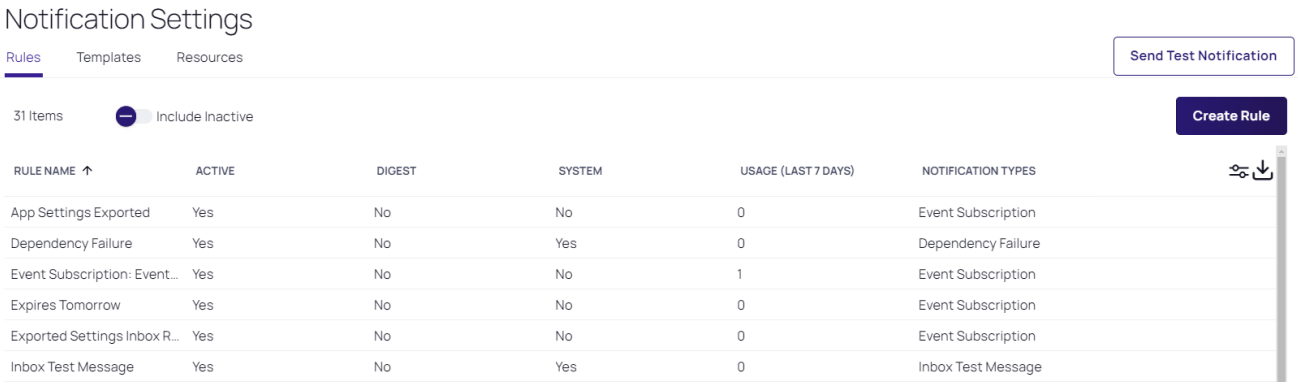
Procedures

Creating a Rule from Scratch

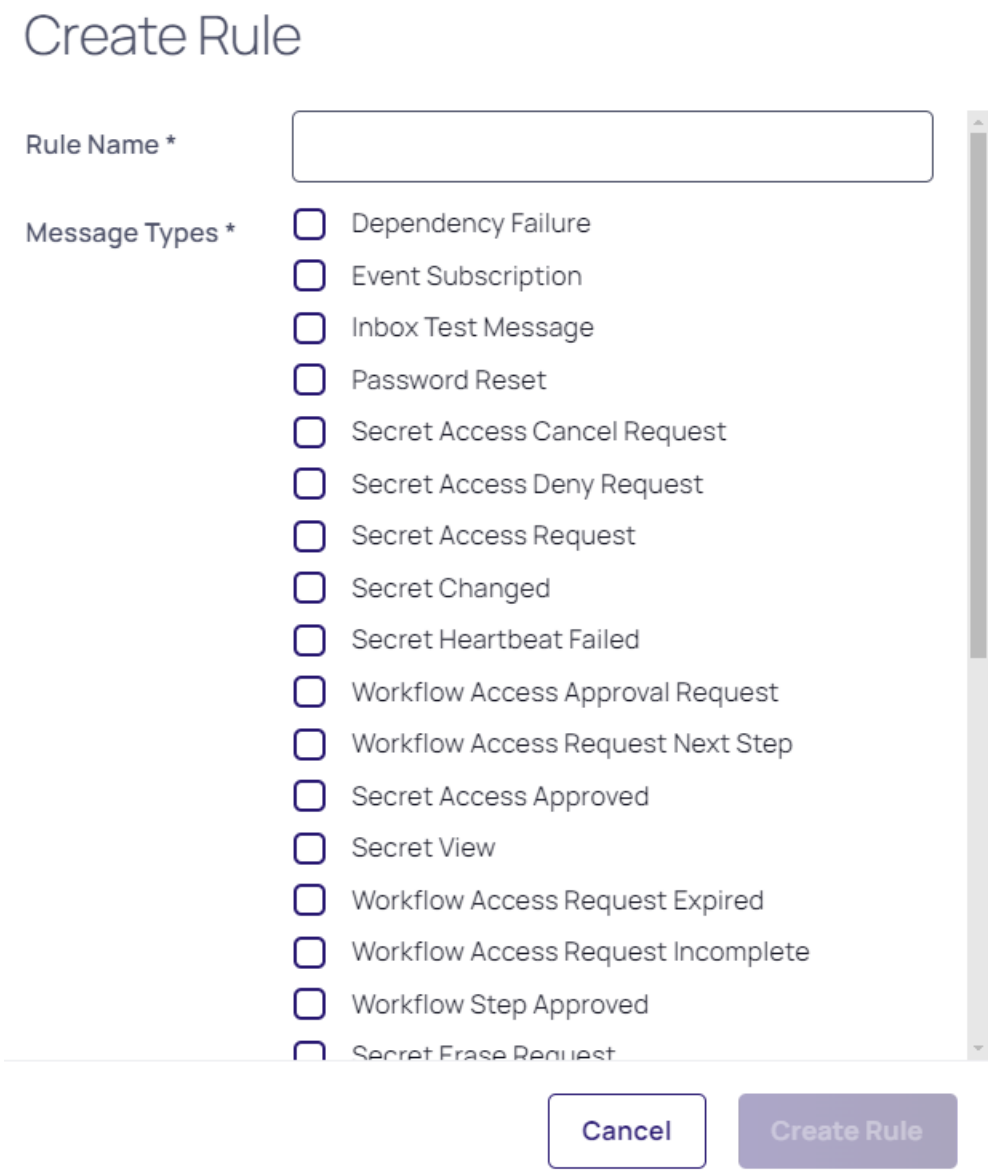
Let us say we want to be notified when anybody tries to edit secret permissions on the "No-Go Secrets" folder. This is an event, so the notification type will be an event subscription.

Task 1: Create the Inbox Rule

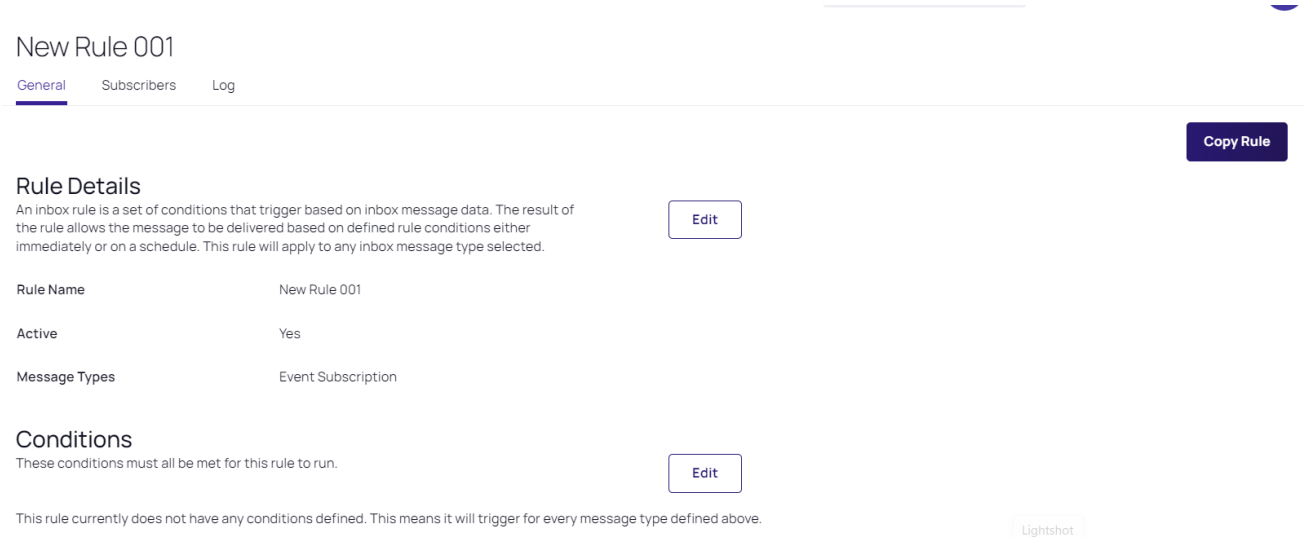
1. Navigate to **Notification Rules and Templates** The Notification Settings page appears:



2. Click the **Create Rule** button. The Create Rule popup appears:



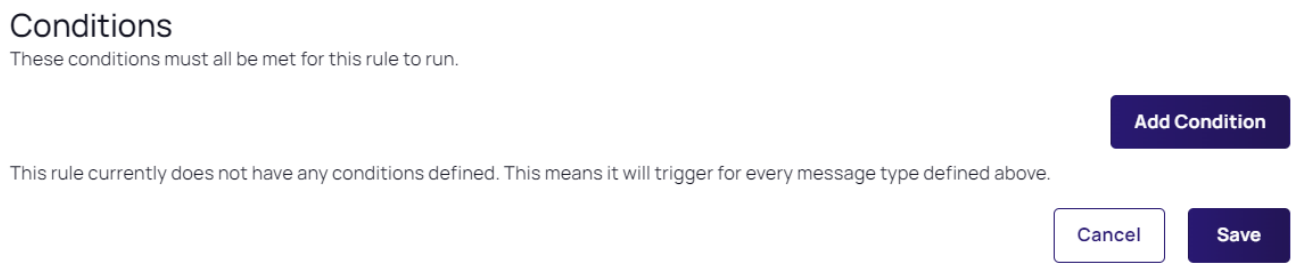
3. Type the new rule's name in the **Rule Name** text box.
4. Click to select the **Message Types** check box for the message types you wish to apply the new rule to. (**Event Subscription** for this case).
5. Ensure the **Active** check box is selected.
6. Select the desired radio button for **Action** (**Email** or **Slack**).
7. If necessary, scroll down to the bottom of the popup.
8. Click the **Template** dropdown list to select the desired inbox template to associate the rule with.
9. Click the **Create Rule** button. The configuration page for the new rule appears:



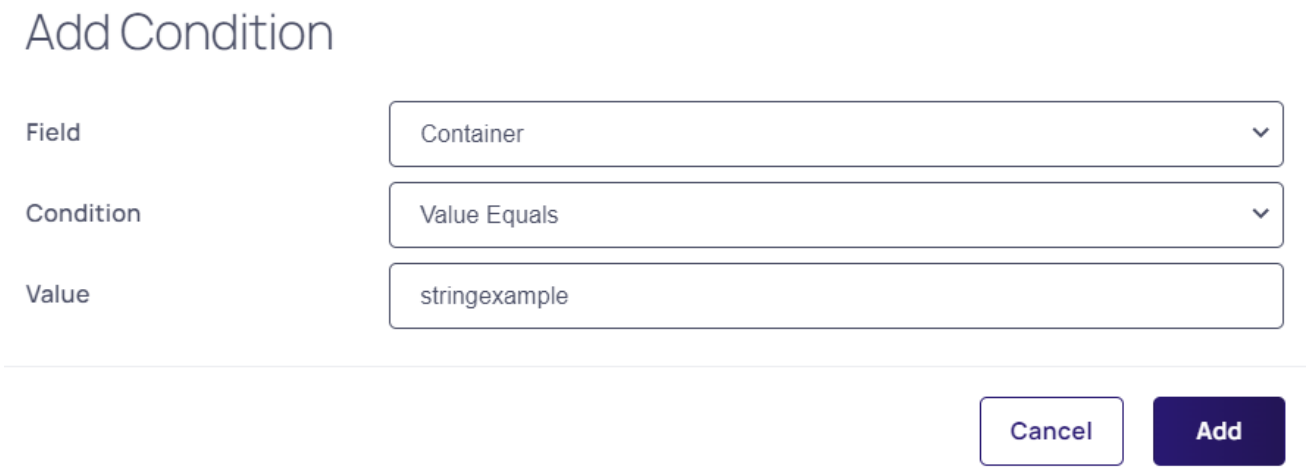
Task 2: Add Rule Conditions

1. Click the **Edit** button in the **Conditions** section.

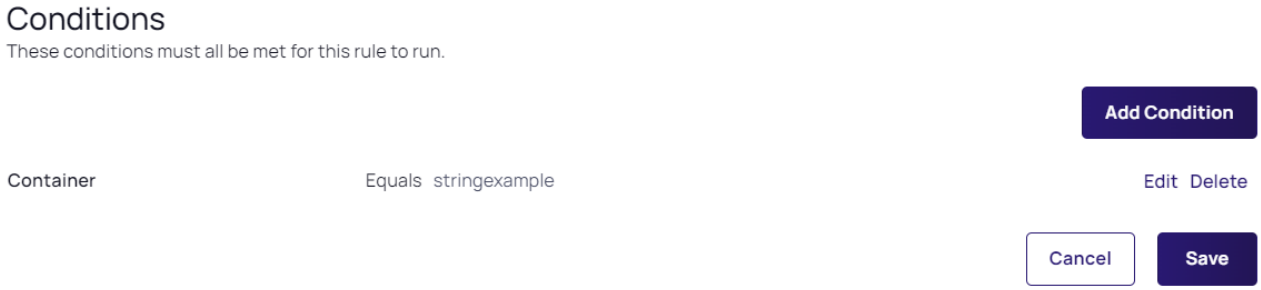
   If you do not add any conditions, the rule will apply to all messages of the types you chose. New buttons appear:



2. Click the **Add Condition** button. The Add Rule Condition popup appears.
3. Click the **Field** dropdown list to select the type of rule condition. For this instruction, we chose Container (a folder). A Condition dropdown list appears:
4. Click the **Condition** dropdown list to select how the value (added next) is compared to the message. Choose "Value RegEx" if you want to create a regular expression to further refine the condition. We chose Value Equals. The Value text box appears. Type the string you want to test for in the **Value** text box.

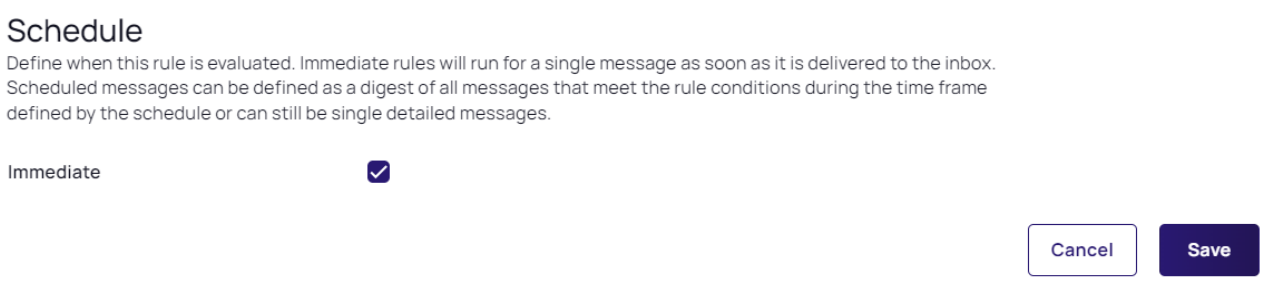


5. Click the **Add** button. The new condition appears:



It tells us the rule is triggered if there is an associated event.

6. Click the **Save** button.
7. Click the **Edit** button in the **Schedule** section. The section becomes editable:

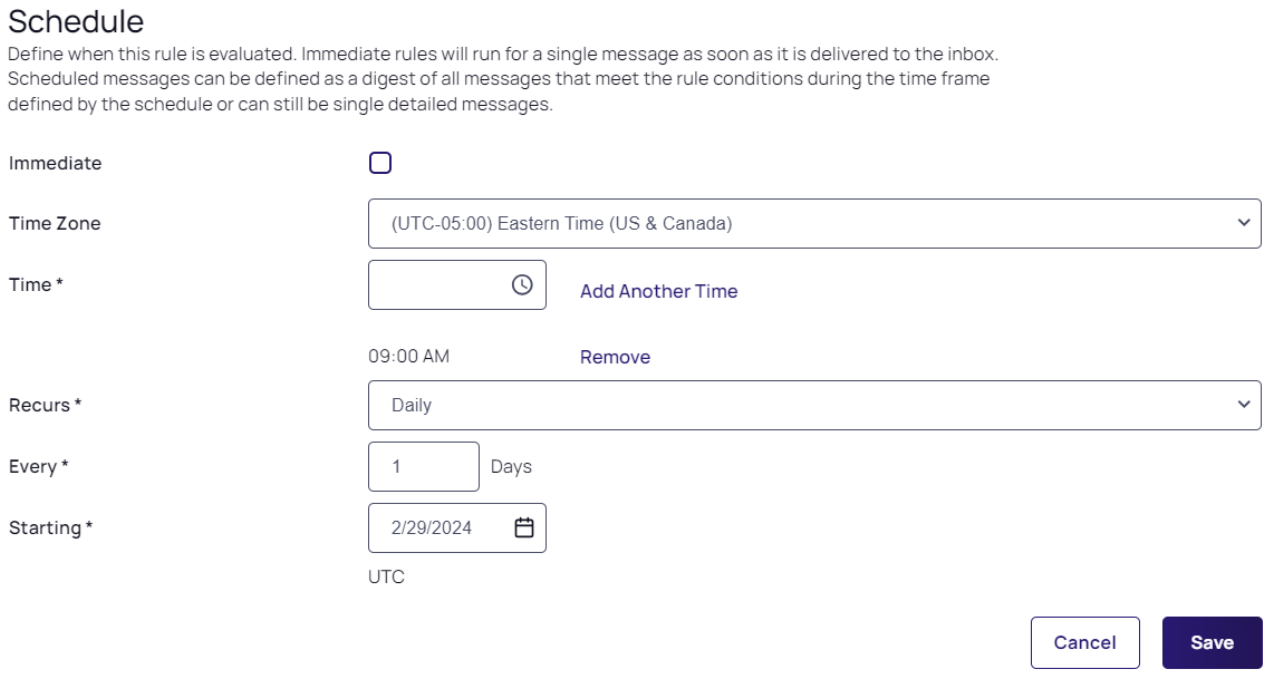


> Any schedule choice other than Immediate produces a digest (summary) of notifications. Users receiving a digest can click on individual entries to see the notification. The following instructions show how to set up a digest.

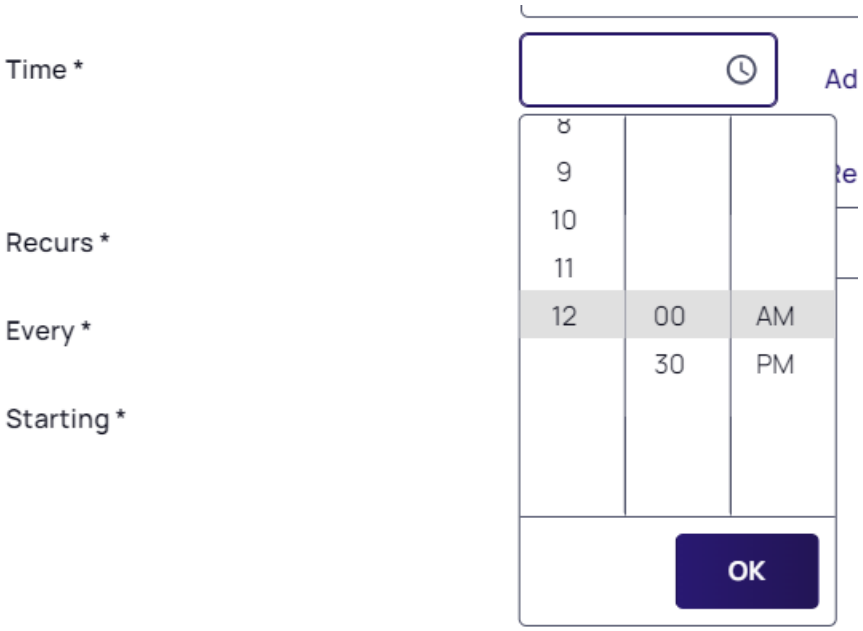
8. If you want to send one email per notification, ensure the Immediate check box is selected, and skip to Task 4.

Task 3: Set up an Email Digest

1. If you do not want the notifications sent immediately, click to deselect the Immediate check box. A time setting section appears:



2. Click the **Timezone** dropdown list to select a time zone for the scheduled notification.
3. Click the clock icon to select a time to add. A time setting table appears:

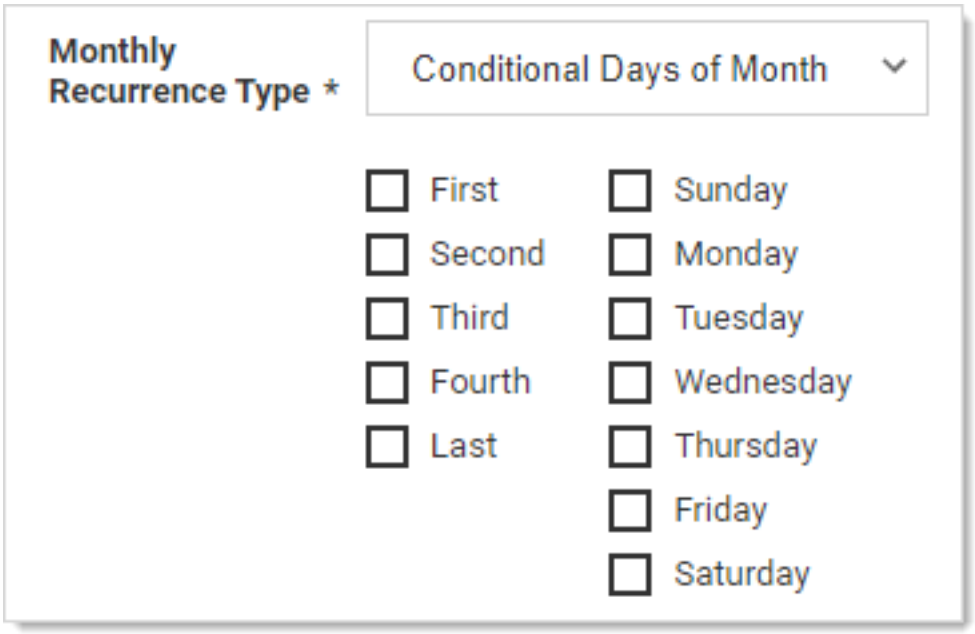


4. Hover the mouse over the one of the columns for a scrollbar appears. Click or drag to select the hour, half hour, or AM/PM.

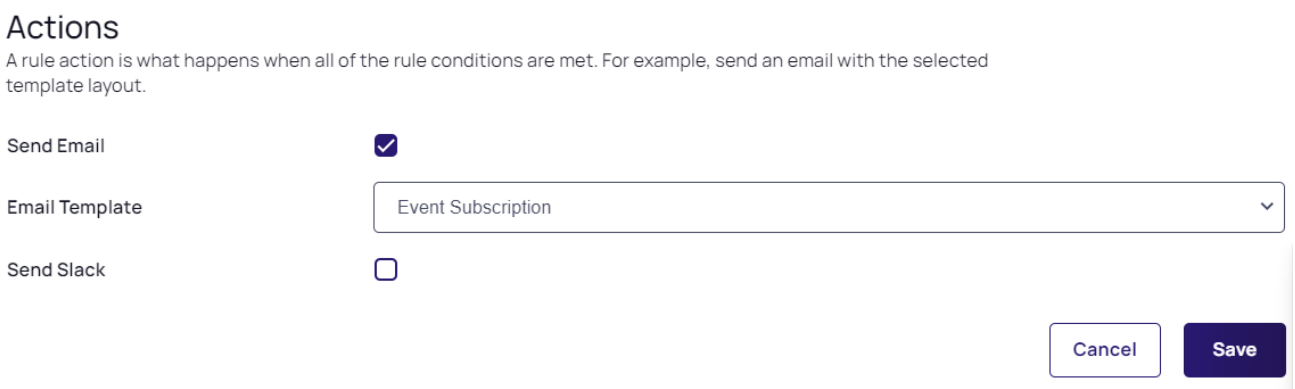
   You also can simply type the time prior to clicking the clock icon in the format hh:mm AM/PM. If you choose minutes other than 00 or 30, it will be converted to the nearest 00 or 30 when you input it.

5. Click the **OK** button. The time appears in the text box.
6. Click the **Add Another Time** link to commit the time.
7. Add more times as desired.
8. Click the **Recurs** dropdown list to choose the frequency. The Every section will change, depending on what you chose:
   - Daily: Type the number of days that pass between notifications in the **Days** text box.
   - Weekly: Type the number of weeks that pass between notifications in the **Weeks** text box. Click to select the days of the week check box to select which days to send the notifications.
   - Monthly: Click the **Monthly Recurrence Type** dropdown list to select either specific or conditional days of the month. The former provides a calendar to choose which days. The latter provides check boxes for selecting relative days where you choose the day of the week and the position in the month, for example,

Last and Friday.



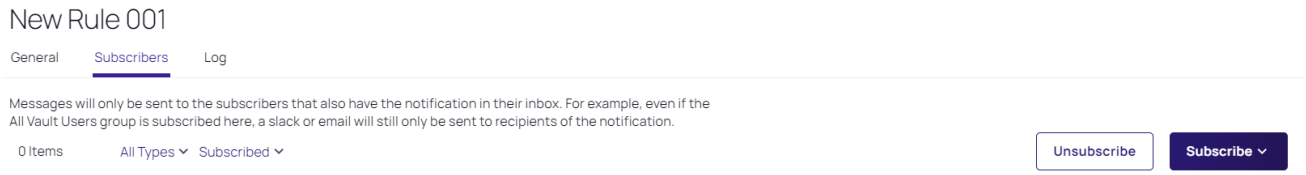
9. Click the **Starting** calendar icon to select the date when you want to start the notification schedule.
10. Click the **Save** button to commit your choices.
11. Scroll down to the **Actions** section.
12. Click the **Edit** link next to **Actions**. The section becomes editable:



13. Click to select either the **Send Email** or **Send Slack** check box (or both).
14. If you chose to send email, click the **Email Template** dropdown list to choose the email format (inbox template). There are several standard ones, and you can customize your own. For this instruction, we choose **Standard Email** if did not create a digest and **Standard Email Digest** if we did. See "Using Inbox Templates" on page 342 for details.
15. Click the **Save** button

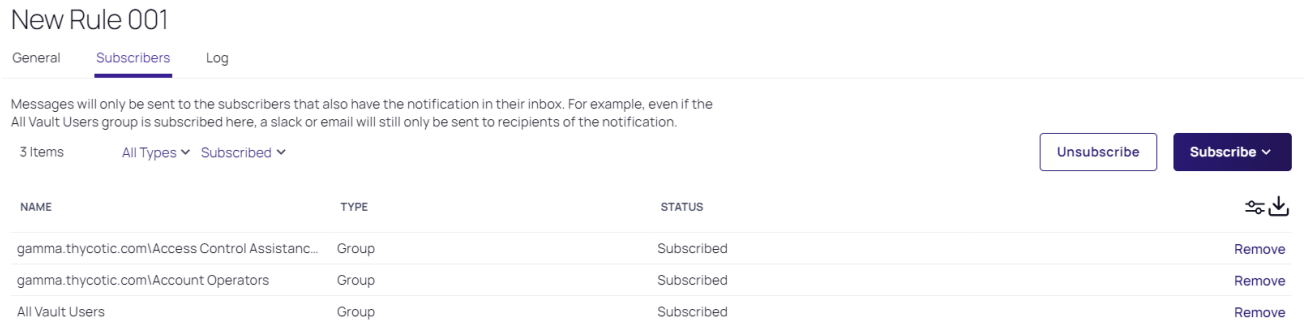
Task 4: Add Subscribers to the Email or Slack Message

1. Click the **Subscribers** tab:



2. Click the Subscribe button and select **Users**, **Groups**, or **External Emails**. Users provides a list of users for you to select from. Groups provides a list of groups for selection. External Emails provides a text box to enter a specific email to somebody without a Secret Server account. For this instruction, we added one of each:

> External emails get sent without regard to whether somebody has a notification in their inbox because external "users" do not have an inbox.



3. You can return to this page at a later date to edit this list. You can also unsubscribe users that are members of a subscribed group without actually removing them from the list for ease of subscribing them later.

Creating an Inbox Rule from a Notification

If a inbox notification is what you want to forward to an email or Slack message from here on out, we provide a shortcut feature that allows you to quickly build an inbox rule from the notification. To create the inbox rule:

1. Click a notification in the inbox. A details popup appears.
2. If you desire an inbox rule to react to that sort of message, click the **Quick Create Rule** button. A very similar, editable page appears.
3. Type the new rule's name in the **Rule Name** text box.

4. Click to select the check box for each rule component you want to include.
5. Click to select the **Action** selection button for the type of notification.
6. If necessary, scroll down to the bottom of the popup.
7. Click the **Template** dropdown list to select the desired inbox template to associate the rule with.
8. Click the **Add Rule** button. The configuration page for the new rule appears.
9. Edit the rule as desired. See Creating a Rule from Scratch.

Using Inbox Templates

Overview

> Inbox templates are also used by "Event Pipelines" on page 295. When used for event pipelines, the templates can use event pipeline tokens in addition to the standard inbox template tokens in the message subject and body. Event pipeline messages are sent directly to the user's inbox based on the email addresses generated by the send email event pipeline task, not subscribers from any inbox rule.

First, let us open a system inbox template to look at:

1. Go to the **Admin** page.
2. If necessary, click the view link to switch to **Alphabetized View**.
3. Click the **Notification Rules and Templates** link. The Notification Settings page appears:
4. Click the **Templates** tab:
5. Note that most, if not all, of the inbox templates are system templates. These are **read-only** templates that you can clone to create custom templates. That is, system templates are templates for your templates. Most of the templates are email templates, and one is a Slack template.
6. Click the Template Name for the Event Subscription template. The template's page appears:
7. Note that each template has:
   - A details section that contains the name, a system template flag, and a template type (email or Slack).
   - A body section that defines the subject, language used, and the canned text for the message. The message contains variables that are drawn from the alert or event. The body is read only in system templates and is editable in custom templates cloned (copied) from system templates.
   - Zero or more associated inbox rules. These are the inbox rule types that use this inbox template (message type). Rules define filters for the alerts or events (what characteristics trigger the rule) and who gets externally notified via email or Slack (the subscribed users or groups). The following table lists the system templates and their associated inbox rules that use them.
   - Zero or more resources. These are items, such as images, that go along with any email based on the template.

Table: System Inbox Rules by Inbox Template

System Inbox Template	Type	Associated Inbox Rules
Event Subscription	Email	App Settings Exported Event Subscription
Password Reset	Email	Password Reset
Secret Access Approved	Email	Secret Access Approved
Secret Access Request	Email	Secret Access Request
Standard Email	Email	Dependency Failure Inbox Test Message Secret Access Cancel Request Secret Access Deny Request Secret Changed Secret Heartbeat Failed
Standard Email Digest	Email	
Standard Slack	Slack	
Workflow Access Approval Request	Email	Workflow Access Approval Request

8. Note the Body section is HTML for emails and Slack template text. For the Event Subscription template it looks like this:

```
<!DOCTYPE html>
<html lang="en">
<head>
    <title>Message Type</title>
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8">
    <meta name="viewport" content="width=device-width, initial-scale=1, maximum-
scale=1" />
    <style>
        body, td {
            font-family: Roboto, Helvetica, Arial;
            font-size: 16px;
        }
        table {border-collapse:separate;}
        a, a:link, a:visited {text-decoration: none; color: #1071D4;}
        a:hover {text-decoration: underline;}
        h2,h2 a,h2 a:visited,h3,h3 a,h3 a:visited,h4,h5,h6,.t_cht {color:#000 !important;}
        .ExternalClass p, .ExternalClass span, .ExternalClass font, .ExternalClass td
{line-height: 100%;}
        .ExternalClass {width: 100%;}

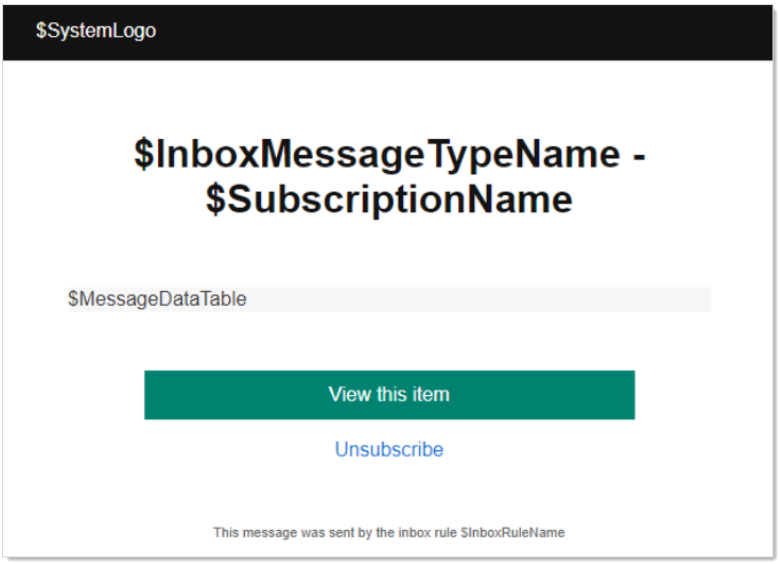
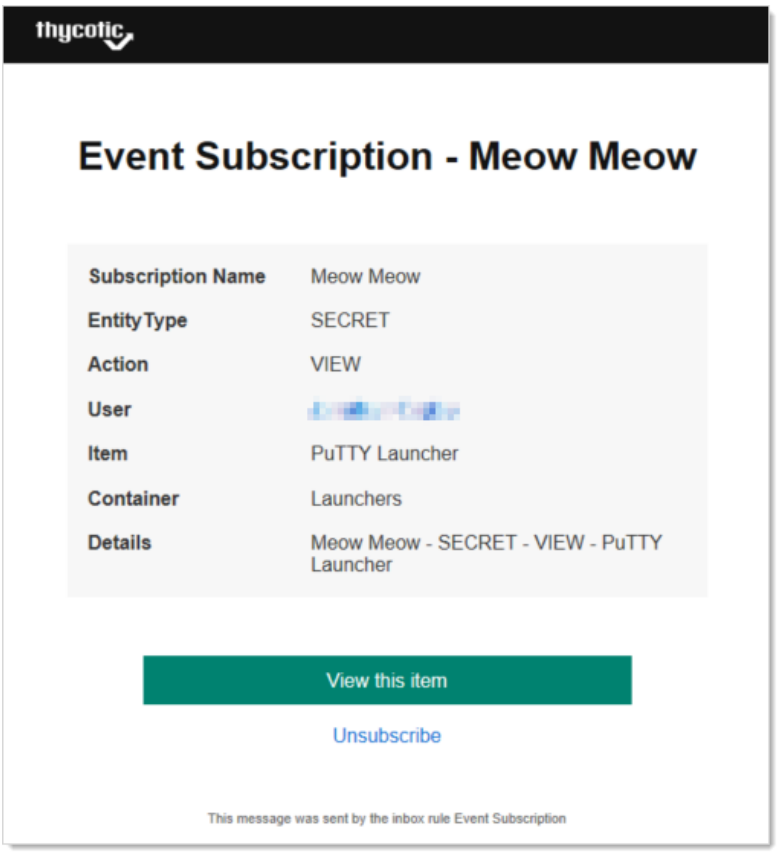
font-size: 16px; color: #323232; padding: 16px" align="center">
                        <p>
                            <a
href="$ApplicationUrl/app/#/inbox/view/notifications?messageId=$MessageId" style="text-
decoration: none; display: inline-block; background-color: #008270; width: 400px; height:
40px; line-height: 40px; color: #ffffff; text-align: center">
                                View this item
                            </a>
                        </p>
                        <p>
```

```
                                <a
href=
"$ApplicationUrl/app/#/inbox/view/notifications?messageId=$MessageId&unsubscribe=true">
                                    Unsubscribe
                                </a>
                            </p>
                        </td>
                        <td> </td>
                    </tr>
                    <tr>
                        <td> </td>
                        <td style="font-family: Roboto, Helvetica, Arial; font-weight: normal;
font-size: 11px; color: #646464" align="center">
                            This message was sent by the inbox rule $InboxRuleName
                        </td>
                        <td> </td>
                    </tr>
                </table>
            </td>
    </table>
    </td></tr></table>
</body>
</html>
```

9. Rendered, the body looks like this:



Note the variables starting with $ that are in the message. These are replaced by Secret Server when it sends the message. For example:



10. The variables here include:
    - `$InboxMessageTypeName` was replaced by the inbox template type.
    - `$InboxRuleName` was replaced by the inbox rule that sent the message. In this case, it is the same name as the inbox template type–Event Subscription.
    - `$MessageDataTable` was replaced by an entire table that summarized the message.
    - `$SubscriptionName` was replaced by the event subscription name.
    - `$SystemLogo` was replaced by the image resource containing the Delinea logo.

    For a complete list of variables for the template, go to the template editor (see below).
11. Nearly the entire template HTML is customizable once you make a customized clone of the system template. To clone the template click the **Copy Template** button at the top. The Copy Template popup appears.
12. Type the name of the new template in the **New Template Name** text box.
13. Click the **Copy Template** button. The template page reappears, but this time it is editable and named differently.
14. Click the **Edit** link next to **Template Body**. The section becomes editable.

15. You can directly edit the HTML, but if you intend to add variables for Secret Server to fill in, click the **Template Editor** link. The Inbox Template Editor popup appears.
16. In addition to directly editing the HTML, you can insert variables by clicking the **Search or pick one** dropdown list.
17. You have three categories of variables: message, global, and digest.
18. Click the desired variable. The dropdown changes to show your choice.
19. The variable appears immediately below the dropdown list, as well as a description of the variable.
20. Copy or type the variable in the desired location in the HTML.
21. Edit and insert more variables as desired.
22. Click the **Apply** button. The popup disappears.
23. Click the **Save** button.

Logging Overview

Secret Server provides robust logging capabilities to ensure comprehensive tracking and auditing of all activities within the system. Here is an overview of the logging features in Secret Server:

Key Logging Features

- Syslog and CEF Logging:
  - Syslog: A standard protocol used for sending and receiving log and event messages between network devices, servers, and applications.
  - CEF (Common Event Format): A standardized log format for capturing and transmitting security-related events across various systems and devices.
- Secret Server can send log messages to an external syslog server using protocols like UDP, TCP, and Secure TCP (TLS).
- Configuration options include setting the syslog server, port, protocol, time zone, and date-time format.
- Secure TCP is recommended for sensitive log data to ensure encrypted transmission.

Secret Server Log List

- Distributed Engine Log: Logs distributed engine activity.
- Protocol Handler Log: Logs protocol handler activity, including RDP and SSH sessions.
- SS log: The main system log that reports when roles start and stop and any activity occurring on the site.
- SS-BSSR log: Logs jobs triggered by the background scheduler.
- SS-BWSR log: Logs work triggered by the background scheduler and legacy monitors, including heartbeat, password changing, and discovery.
- SS-EWSR log: Logs responses from distributed engines.

- SS-MMSR log: Logs internal site connector activity when RabbitMQ is not used.
- SS-SRWSR log: Logs session recordings.

Secret Server Log List

Distributed engine logs and the web node logs will roll over and will not fill up your hard drive. Automatic log management rotates the logs at 34 log files at 10 mb before rolling off the oldest.

Below is a collection of log lists that can be used with Secret Server.

Secret Server Logs

This section only applies to **Secret Server On-Premises**.

SS log

The Secret Server system log is a top-level IIS log that reports when roles start and stop, along with any activity occurring on the site, as well as any legacy monitors.

Location: `C:\inetpub\wwwroot\SecretServer\log`

Please refer to "Setting the Logging Levels" on page 382 for more information. See "Enabling Debug Mode in System Logs " on page 280for more information.

SS-BSSR log

The **background scheduler server role log** is responsible for jobs that fire upon a trigger. Currently, we have some monitors that schedule work from the website but will transition to trigger jobs in the scheduler.

Location: `C:\inetpub\wwwroot\SecretServer\log`

SS-BWSR log

The **background worker server role log** is responsible for logging work triggered by the background scheduler and legacy monitors. Work includes heartbeats, password changing, discovery, event pipelines, and more.

Location: `C:\inetpub\wwwroot\SecretServer\log`

SS-EWSR log

The **engine worker server role log** is responsible for processing all responses from distributed engines, such as discovery and heartbeats.

Location: `C:\inetpub\wwwroot\SecretServer\log`

SS-MMSR log

The **MemoryMq server role log** records internal site connector activity when RabbitMQ is not installed or used.

Location: `C:\inetpub\wwwroot\SecretServer\log`

SS-SRWSR log

The **session recording worker server role log** is responsible for processing session recordings from Secret Server.

Location: `C:\inetpub\wwwroot\SecretServer\log`

Protocol Handler Log

SS-RDPWin log

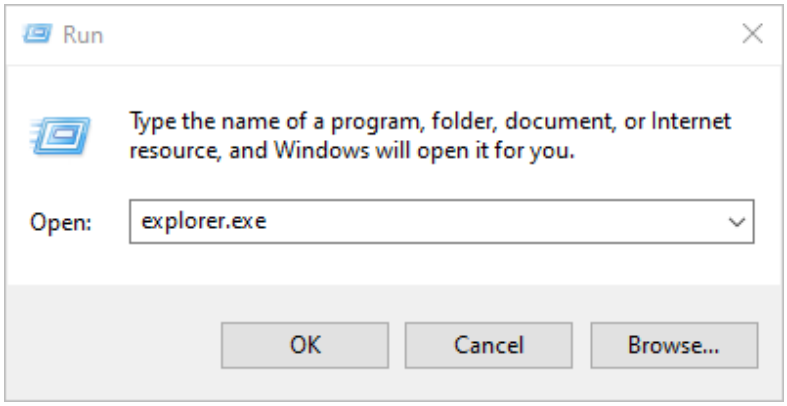
The **Protocol Handler log** records protocol handler activity among other features.

Location: stored per user on the workstation, search for: `%AppData%\Thycotic\log\SS-RDPWin.log`.

> Despite the name, the log covers more than just RDP.

To access the log:

1. Type `Run` in the Windows start menu search text box to launch the **Run Command** application. The Run popup appears:



2. Type `%AppData%\Thycotic\log` into the **Open** text box.
3. Click the **OK** button. The folder containing the file appears.

Enabling Debug Logging for the Protocol Handler Log

This section explains how to enable verbose debug logging for the Protocol Handler:

1. Navigate to `C:\Program Files\Thycotic Software Ltd\Secret Server Protocol Handler`.
2. Open the `log4net-rdp.config` configuration file in a text editor as an administrator:

```
<log4net>
    <root>
        <!--<level value="DEBUG" />-->
        <!--<level value="VERBOSE" />-->
        <!--<level value="OFF" />-->
        <level value="INFO" />
        <appender-ref ref="Thycotic.LogFileAppender" />
    </root>
```

```
    <appender
name="Thycotic.LogFileAppender" type="log4net.Appender.RollingFileAppender">
        <!--<file value="C:\LogFiles\Thycotic\SS-RDPWin.log" />-->
        <file value="${AppData}\Thycotic\log\SS-RDPWin.log" />
        <rollingStyle value="Size" />
        <maxSizeRollBackups value="34" />
        <maximumFileSize value="10MB" />
        <lockingModel type="log4net.Appender.FileAppender+MinimalLock" />
        <layout type="log4net.Layout.PatternLayout">
            <conversionPattern value="%utcdate [CID:%property{Correlation}] [C:%property
{Context}] [TID:%thread] %-5level %logger - %message%newline" />
        </layout>
    </appender>
</log4net>
```

3. Comment out `<!--<level value="INFO" />`.
4. Remove the comment out of `<level value="DEBUG" />`.
5. Recreate the original issue a couple of times with DEBUG enabled.
6. Navigate to `~\AppData\Roaming\Thycotic\log`" on the machine you are launching the Protocol Handler from.
7. Copy and save the `SS-RDPWin.log` log file.
8. Return `log4net-rdp.config` to its original state by removing the comment out of `<!--<level value="INFO" />` and commenting out `<level value="DEBUG" />`

Distributed Engine Log

SSDE log

The **Secret Server distributed engine log** is responsible for recording distributed engine activity.

Location: `C:\Program Files\Thycotic Software Ltd\Distributed Engine\log`.

Customers using Secret Server 11.1.6 and newer can adjust audit logging directly from the UI. Please refer to "Setting the Logging Levels" on page 382 for more information.

Customers using a Secret Server version prior to 11.1.6 need to use a manual method of adjusting the audit logs:

1. Log in as an administrator on the distributed engine server.
2. Locate the `Thycotic.DistributedEngine.Service.exe.config` file in the `C:\Program Files\Thycotic Software Ltd\Distributed Engine` directory.
3. Open the file in a text editor.

Enabling Debug Mode in Distributed Engine Log Files

Please see "Enabling Debug Mode in Distributed Engine Log Files" on page 385 for more details on how to proceed.

Enabling Discovery Logging

To enable discovery logging, change the `Thycotic.DistributedEngine.Service.exe.config` configuration file as follows:

```
<logger name="Thycotic.Discovery">
  <level value="VERBOSE" />
</logger>
```

RabbitMQ Log

Access the RabbitMQ logs at `C:\RabbitMq\log`.

Syslog Event List

Table: Syslog Event List

Type	Type ID	Action	Action ID	Description
AUTOEXPORT		DOWNLOADEXPORT	10164	Autoexported has been downloaded
AUTOEXPORT		EDIT	10161	Autoexport was edit
AUTOEXPORT		EXPORT	10162	Autoexport was exported
AUTOEXPORT		RUNEXPORT	10163	Run Autoexport
BACKUPCONFIGURATION	10023	EDIT	10143	The back configuration was edited
CHARACTERSET	10020	CREATE	10132	A character set was created

ENCRYPTION	10012	ROTATE SECRET KEYS SUCCESS	10071	Rotate secret keys succeeded
ENGINE	10014	ACTIVATE	10083	An engine was activated

Type	Type ID	Action	Action ID	Description
ENGINE	10014	CREATE	10082	An engine was created
ENGINE	10014	DEACTIVATE	10084	An engine was deactivated
ENGINE	10014	DELETE	10085	An engine was deleted
ENGINE	10014	OFFLINE	10151	An engine was taken offline
ENGINE	10014	ONLINE	10152	An engine was brought online
ENGINE		PROXYENDPOINTCHANGED	10180	Proxy endpoint was changed for node
EXPORTSECRETS	10003	EXPORTED	10016	Secrets have been exported from Secret Server
FOLDER	2	CREATE	7	A folder has been created
FOLDER	2	DELETE	8	A folder has been deleted

Type	Type ID	Action	Action ID	Description
FOLDER	2	EDITPERMISSIONS	14	A folder's permissions have been changed
FOLDER	2	SECRETPOLICYCHANGE	10053	A folder's secret policy was changed
GROUP	6	CREATE	10140	A group was created
GROUP	6	EDIT	10141	A group was edited
IMPORTSECRETS	10004	IMPORTED	10017	Secrets have been imported to Secret Server
IPADDRESSRANGE	7	CREATE	10109	An IP range was created
IPADDRESSRANGE	7	DELETE	10111	An IP range was deleted
IPADDRESSRANGE	7	GROUP ASSIGN	10114	A group was assigned to an IP range
IPADDRESSRANGE	7	GROUP UNASSIGN	10115	A group was removed from an IP range

Type	Type ID	Action	Action ID	Description
IPADDRESSRANGE	7	UPDATE	10110	An IP range was updated
IPADDRESSRANGE	7	USER ASSIGN	10112	A user was assigned to an IP range
IPADDRESSRANGE	7	USER UNASSIGN	10113	A user was removed from an IP range
LICENSES	10007	ADD	10119	A license was added
LICENSES	10007	DELETE	10120	A license was removed
NODE		PROXYENDPOINTCHANGED	10181	Proxy endpoint was changed for a Secret
PASSWORDCHANGER	10019	AUTHEDIT	10130	The password changer's authentication method was edited
PASSWORDCHANGER	10019	COMMANDCREATE	10128	A command in a password changer was created

Type	Type ID	Action	Action ID	Description
PASSWORDCHANGER	10019	COMMANDDELETE	10129	A command in a password changer was deleted
PASSWORDCHANGER	10019	COMMANDEDIT	10127	A command in a password changer was edited
PASSWORDCHANGER	10019	CREATE	10123	A password changer was created
PASSWORDCHANGER	10019	DISABLE	10126	A password changer was disabled
PASSWORDCHANGER	10019	EDIT	10124	A password changer was edited
PASSWORDCHANGER	10019	ENABLE	10125	A password changer was enabled
PASSWORDCHANGER	10019	SCANFIELDEDIT	10131	The fields the password changer uses from the secret was edited

Type	Type ID	Action	Action ID	Description
PASSWORDREQUIREMENT	10021	CREATE	10136	A password requirement was created
PASSWORDREQUIREMENT	10021	EDIT	10137	A password requirement was edited
RDPPROXY		DISABLED	10174	RDP Proxy was disabled
RDPPROXY		ENABLED	10173	RDP Proxy was enabled
ROLE	3	ASSIGNUSERORGROUP	10	A user or group was assigned to a role
ROLE	3	CREATE	9	A role was created
ROLE	3	DISABLEROLE	21	A role was disabled
ROLE	3	EDIT	10142	A role was edited
ROLE	3	ENABLEROLE	20	A role was enabled
ROLE	3	UNASSIGNUSERORGROUP	11	A user or group was unassigned from a role
ROLEPERMISSION	4	ADDEDTOROLE	12	A permission was added to a role

Type	Type ID	Action	Action ID	Description
ROLEPERMISSION	4	REMOVEDFROMROLE	13	A permission was removed from a role
SCRIPTPOWERSHELL	10008	CREATE	10027	A PowerShell script was created
SCRIPTPOWERSHELL	10008	DEACTIVATE	10028	A PowerShell script was deactivated
SCRIPTPOWERSHELL	10008	EDIT	10029	A PowerShell script was edited
SCRIPTPOWERSHELL	10008	REACTIVATE	10030	A PowerShell script was reactivated
SCRIPTPOWERSHELL	10008	VIEW	10031	A PowerShell script was viewed
SCRIPTSQL	10011	CREATE	10061	A SQL script was created
SCRIPTSQL	10011	DEACTIVATE	10062	A SQL script was deactivated
SCRIPTSQL	10011	EDIT	10063	A SQL script was edited

Type	Type ID	Action	Action ID	Description
SCRIPTSQL	10011	REACTIVATE	10064	A SQL script was reactivated
SCRIPTSQL	10011	VIEW	10065	A SQL script was viewed
SCRIPTSSH	10010	CREATE	10056	An ssh script was created
SCRIPTSSH	10010	DEACTIVATE	10057	An ssh script was deactivated
SCRIPTSSH	10010	EDIT	10058	An ssh script was edited
SCRIPTSSH	10010	REACTIVATE	10059	An ssh script was reactivated
SCRIPTSSH	10010	VIEW	10060	An ssh script was viewed
SECRET	10001	ACCESS_APPROVED	10044	A secret's access request was approved
SECRET	10001	ACCESS_DENIED	10045	A secret's access request was denied

Type	Type ID	Action	Action ID	Description
SECRET	10001	CACHEVIEW	10103	A secret has been viewed, but cached data was presented
SECRET	10001	CHECKIN	10025	A secret was checked in
SECRET	10001	CHECKOUT	10026	A secret was checked out
SECRET	10001	COPY	10020	A secret was copied
SECRET	10001	CREATE	10001	A secret has been created
SECRET	10001	CUSTOM_AUDIT	10038	A custom audit has been created
SECRET	10001	CUSTOM_PASSWORD_REQUIREMENT_ADDED	10046	A custom password requirement was added to a secret
SECRET	10001	CUSTOM_PASSWORD_REQUIREMENT_REMOVED	10047	A custom password requirement was removed from a secret

Type	Type ID	Action	Action ID	Description
SECRET	10001	DEACTIVATE	10002	A secret has been deactivated
SECRET	10001	DEPENDENCY_ADDED	10049	A dependency was added to a secret
SECRET	10001	DEPENDENCY_DELETED	10048	A dependency was removed from a secret
SECRET	10001	DEPENDENCYFAILURE	10008	A secret's dependency failed
SECRET	10001	EDIT	10005	A secret was edited
SECRET	10001	ERASE_COMPLETED	10166	A secret erased completed
SECRET	10001	ERASE_REQUESTED	10165	A secret erased request has been made
SECRET	10001	EXPIREDTODAY	10009	A secret is expiring today

USER	1	TWO FACTOR UPDATED	10101	A user's two factor settings were updated
USER	1	TWOFACTORRESET	10149	A user's two factor was reset
USER	1	TWOFACTORRESETFAILED	10150	A user's two factor authentication failed
USERAUDIT	10005	EXPIRENOW	10018	Secrets have been manually expired

System Log

The System Log is used to communicate the different events that are occurring while Secret Server is executing. It can be helpful in troubleshooting unexpected behavior. The system log can be enabled by clicking **Edit** and checking the **Enable System Log** check box on the **System Log** page.

See the "Syslog Event List" on page 351 for a list of system events.

System log parameters include:

- **Notify Administrators when System Log is Shrunk:** This setting is used to send an email to all system log administrators when the system log has been truncated. A system log administrator is any user in a role with the Administer System Log permission included.
- **Maximum Log Length:** This is the maximum number of rows to keep in the system log table in the SQL database. When it reaches that amount, it is reduced by 50%.
- **Allow viewing log files online:** If enabled, the server may parse its internal log file on demand to view online. Parsing the log file takes a very short time, typically less than 150 ms, but the log file cannot be rolled while the file is being read. (Adding new entries to the log file without rolling is unaffected.) If a log file roll is attempted during that time, then log entries may be dropped until the roll is successful.

To clear the system log of all its records, click **Clear log** under the Logs tab.

Secure Syslog and CEF Logging

Overview

Syslog and CEF are two widely used standards for logging and event management in the field of IT and network security.

Syslog is a standard protocol used for sending and receiving log and event messages between network devices, servers, and applications. It provides a structured and standardized way of capturing and forwarding system messages, allowing IT administrators to monitor and troubleshoot network and system issues more effectively. Syslog messages can contain various types of information, including system events, errors, and warnings, as well as user activity and other operational data.

CEF (Common Event Format) is a standardized log format for capturing and transmitting security-related events across various systems and devices. CEF provides a common language and format for security information and event management (SIEM) systems, allowing for more efficient and effective analysis of security events and threats.

See the "Syslog Event List" on page 351 for a complete list of events.

Secret Server and Syslog or CEF Logging

Secret Server can send a copy of important log messages to an external syslog server for added security using the following protocols:

Common Event Format (CEF) is an industry-standard format on top of syslog messages that ensures event interoperability between different platforms.

Table: Syslog Transportation Protocols

Protocol	Encrypted	Notes
UDP	No	Least reliable. User Datagram Protocol (UDP) traffic is fire-and-forget with no assurance messages are delivered and no error checking.
TCP	No	More reliable. Transmission Control Protocol (TCP) ensures messages arrive in order, missing messages are resent, and has built in error checking.
Secure TCP	Yes	Establishes a secure connection – Transport Layer Security (TLS) 1.1 or 1.2 only. Syslog Server's certificate is validated by Windows to ensure it is trusted and not revoked. Can be used with or without client certificates (configured in **Configuration > Security tab > TLS Auditing > Advanced**).

Due to the sensitive nature of Secret Server logs, we strongly recommend using Secure TCP.

Configuring a Secure TCP Syslog or CEF External Audit Server in Secret Server

Compatible Audit Servers

- syslog-ng
- Any Audit server that accepts TLS encrypted messages using the BSD syslog protocol

Special Characters in Syslogs

Secret Server uses UTF-8 encoding for syslog messages, which supports non-ASCII characters. Some syslog servers may only support ASCII. If you cannot change your server to UTF-8, your syslog messages may include error characters (often question marks) where non-ASCII characters appear.

Configuring an External Audit Server

1. Navigate to **Admin** > **Application**. The Application page appears.
2. Click the **Edit** button at the top right of the page.
3. Click to select the **Enable Syslog/CEF Log Output** check box. A syslog/CEF section expands below.

   Note: syslog/CEF may require an additional license key. To install licenses, search for **Install New License**. Once installed, the license requires activation. Contact your Delinea Sales Representative with any questions.
4. Type IP address or name for the IIS server hosting the syslog/CEF server in the **Syslog/CEF Server** text box.

   You can add multiple entries, separating each with a semicolon.

5. Type the port number where the logging information will be passed (6514 is the default port for secure TCP syslog) in the **Syslog/CEF Port** text box.

   Note: Secret Server requires outbound access to this server and port so communication can pass freely.
6. Click the **Syslog/CEF Protocol** dropdown list and select **Secure TCP**. Secure TCP means either TLS v1.2 or v1.1 because other versions of SSL, such as SSL v3 and TLS v1.0, have known weaknesses.
7. Click to select **Syslog/CEF Time Zone** list box to **UTC Time** or **Server Time**, depending on your preference.
8. Click the **Syslog/CEF DateTime Format** dropdown to format Syslog timestamps. The standard for Syslog is ISO timestamps; however, some still use the legacy format. Syslog is the default for upgrades to allow current configurations to retain their behavior, and ISO format is the default in new instances. Syslog format: Jun 23 2022 11:22:33. ISO 8601 format: 2022-06-23T11:22:33.000. You must enable the configuration preview to modify this setting.
9. Click the **Syslog/CEF Site** dropdown to select the related Site that Syslog/CEF will run on.
10. Click to select the **Write Syslogs As Windows Events** check box to write audits and event subscriptions to the Windows Event Log of the server.
11. Click the **Save** button.

Caching Syslog Audits and the Syslog Circuit Breaker

Enabling Secure Syslog Logging

Once secure syslog logging is enabled in Secret Server, ensure that the system is set to cache syslog failure notification messages in the Secret Server database if the connection to the external syslog server breaks.

Configuring Syslog Server for Non-Local Sites

If the syslog server uses a non-local site, implement a circuit breaker system to avoid overwhelming the distributed engine and message queues during likely failure scenarios.

Understanding Circuit Breaker States

- The circuit breaker enters the "open" state after ten failures within five minutes.
- In the "open" state, the system will not attempt to send syslog messages.
- Every five minutes, the circuit breaker shifts to the "half-open" state to attempt recovery by sending a limited number of syslog messages.
- Successful delivery of three syslog messages transitions the circuit breaker to the "closed" state, resuming normal syslog message processing.

Monitoring System Alerts

When the circuit breaker is in "open" or "half-open" mode, administrators will receive a notification banner. This banner provides a link to the system log for accessing diagnostic messages, including details on which engines had issues sending messages to the syslog server and other diagnostic information.

Configure Auditing for TLS Connections

To track problems with TLS connections (including whenever the connection fails), enable the TLS certificate chain policy and error auditing in Secret Server:

1. In the Secret Server settings, navigate to the **Configuration**.
2. In the **Security** section, click **TLS Auditing**
3. Click **Edit**.
4. Ensure the **Apply TLS Certificate Chain Policy and Error Auditing** check box is enabled. If not, you cannot use client certificates.

> If secure TCP is used for the syslog/CEF protocol and there are one or more client certificate thumbprints entered, Secret Server checks the local computer's Web hosting and personal certificate store and uses the first one it finds.

Adding Client Certificate Thumbprints

1. Navigate to **Admin** > **Configuration**.
2. Click the **Security** tab.
3. Click the **Edit** button at the bottom of the page.
4. Scroll to the **TLS Auditing** section.
5. Click the **Advances (not required)** link. A client certificate thumbprint section appears.
6. Copy and paste a list of SHA1 SSL certificate thumbprints into the **Client Certificate Thumbprints(s)** text box. Separate each thumbprint (40 characters each) with a semicolon. Up to ten are allowed.

> Secret Server's IIS application pool must be granted permission to use the client certificates, using the Windows HTTP Services Certificate Configuration Tool (WinHttpCertCfg.exe). See Compatibility Notes for Client Certificates.

Determining the Status of a Remote Audit Server

To view the logs for any TLS-Connection related errors, perform the following:

1. Open the **Microsoft SQL Server Management Studio**.
2. Navigate to your SecretServer database.
3. Set up a new query.
4. Type and enter `select from tbSecurityAuditLog` to view the events from the TLS audit.

> For more detailed troubleshooting reporting, reference the logs on the Secret Server Web server at `C:\inetpub\wwwroot\SecretServer\log`). View the `SS.log`, `SS-BSSR.log` (background scheduler), and `SS-BSWR.log` (background worker) for any errors.

Compatibility Notes for Client Certificates

IIS Application Pool Certificate Permissions

> Applicable only to Secret Server Cloud

Secret Server's IIS application pool must be granted permission to use the client certificates, using the Windows HTTP Services Certificate Configuration Tool (WinHttpCertCfg.exe).

For example: `winhttpcertcfg.exe -g -c LOCAL_MACHINE\MY -s "Certificate Subject" -a "HOSTNAME\IIS APPPOOL\SecretServer"`

You can download the tool at:

Windows HTTP Services Certificate Configuration Tool (WinHttpCertCfg.exe)

You can view the documentation at:

WinHttpCertCfg.exe, a Certificate Configuration Tool

Otherwise, if Secret Server is configured to use a client certificate, and IIS does not have permission, errors like this may appear in the logs:

TLS Error Detected (Authentication Error connecting to IP:PORT) - The credentials supplied to the package were not recognized.

If you are using a client certificate, and a syslog-ng logging server, the following message may occasionally appear in the main syslog-NG log file:

SSL error while reading stream; tls_error='SSL routines:ssl_get_prev_session:session id context uninitialized'

On the Secret Server side, this appears:

TLS Error Detected (Authentication Error connecting to IP:PORT) - Authentication failed because the remote party has closed the transport stream.

This is caused by Windows trying to cache secure connections when client certificates are used, but because syslog-ng has not configured the OpenSSL "session id context", OpenSSL displays this error when it tries to resume a previous session.

Secret Server automatically reconnects and resends any missed messages, so the errors should not have an impact. However, you can disable Window's secure connection caching by adding the ClientCacheTime setting set to 0 in the Registry and then rebooting. This did not cause any significant performance impact in internal testing.

> If changing back to a previous syslog IP address and port, you will receive a closed connection TLS error on the first attempted syslog connection after making the change. A subsequent call will succeed as the first failure will clear the cached connection on Windows. This is due to the issue with syslog-ng.

> If syslog-ng configures their OpenSSL session id context, this error message correction is no longer needed.

AlienVault

It is common for people to incorrectly use the client certificate thumbprints feature when setting up secure AlienVault for syslog. This can cause Secret Server to try to connect to LDAPS with the AlienVault certificate, which can break LDAPS. Users should not use the Secret Server client certificates thumbprint for specifying one certificate for syslog and another for LDAP. The certificate list is intended for each Secret Server or DE to have its own, unique certificate.

Giving Application Pools Event Log Access

This topic only applies to **Secret Server On-Premises**.

Overview

When the database becomes inaccessible, Secret Server will try to log errors to the Windows event log. By default, network service and standard service accounts will not have Windows permissions to the event log. Permissions must be added to specific event log registry keys.

Applying Windows Event Log Permissions

1. Determine the account that is running Secret Server:
   a. Log on Secret Server.
   b. Go to the **Diagnostics** page.
   c. Look for any of the **Thread Identity** labels. These contain the identity of Secret Server (often `NT AUTHORITY\NETWORK SERVICE` or `IIS APPPOOL\SecretServer` or the service account set up for IWA. See "Running the IIS Application Pool As a Service Account" on page 63.

      You can also determine the identity by logging in and navigating to http://yoursecretserverurl/Installer.aspx. The first step of this page will tells you the application pool identity.
2. Open the Windows registry editor on the machine running Secret Server (regedit at the command prompt or Window search text box).
3. On the left, navigate to **HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > EventLog**.
4. Right click the **EventLog** folder in your registry editor and select **Permissions**. A permissions dialog box appears.
5. Click the **Advanced** button.
6. On the **Permissions** tab, Click the **Add** button. A Permission Entry dialog appears.
7. Click the **Select a principal** link. The Select User, Computer… dialog box appears.
8. Find the account running Secret Server, such as Thycotic_Service (svc_thycotic@test.com).
9. Click the **OK** button. The dialog box closes.
10. In the **Basic Permissions** section of the **Permission Entry** dialog, click to select the **Read** check box.

11. Click the **Show advanced permissions** link. The pane switches.
12. Click to select the **Set Value** and **Create Subkey** check boxes in the **Advanced Permissions** section.
13. Click **OK** buttons on the remaining dialogs to apply the permissions. You are returned to the main registry editor window.
14. Navigate to **HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > EventLog > Security,** right-click and select "**Permissions...**"
15. Right click **Security** folder and select **Permissions**. A permissions dialog box appears.
16. Click the **Add** button.
17. Find the account running Secret Server.
18. Click the **OK** button.
19. Click to select the **Read** check box in the Allow column.
20. Click the **OK** button to apply the permission.
21. If you are running Windows Server 2019 or above, use the same procedure to add Read permission to **HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > EventLog > State**.

> You may need to run regedit as the system user when using more recent versions.

Required Registry Permissions

After setup, the following permissions appear in the registry:

HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > EventLog

Applies to key and subkeys

- Read permissions:
  - Query Value
  - Enumerate Subkeys
  - Notify
  - Read Control
- Set Value permission
- Create Subkey permission

HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > EventLog > Security

Applies to key and subkeys

Read permissions:

- Query Value
- Enumerate Subkeys
- Notify
- Read Control

HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > EventLog > State

Applies to key and subkeys. Only applies to Windows Server 2019.

Read permissions:

- Query Value
- Enumerate Subkeys
- Notify
- Read Control

Managing Full SQL Server Transaction Logs

This topic only applies to **Secret Server On-Premises**.

SQL Server maintains a history of all operations in a transaction log. If this transaction log becomes full, you may receive one or more of the following errors:

```
System.ArgumentException: Cannot add two background tasks with the same name.
```

```
Thycotic.Data.DataAccessorException: The transaction log for database '{database}' is full. To find out why space in the log cannot be reused, see the log_reuse_wait_desc column in sys.databases
```

By default, a transaction log can grow to an unrestricted size, but some may become full in the following circumstances:

- The drive where the transaction log file is kept is out of disk space.
- The transaction log file hits its growth limit.

Potential Solutions

- Back up the log.
- Free up disk space so that the log can grow automatically.
- Move the log file to a disk drive with sufficient space.
- Increase the size of the log file.
- Add a log file on a different disk.
- Complete or kill a long-running transaction.
- Switch to simple recovery mode and truncate the log.

For more detailed information on transaction logs in SQL, see Manage the size of the transaction log file.

Setting the Logging Levels

Overview

Secret Server Web nodes and distributed engines log levels are remotely configurable and collectable. This feature is especially useful for large systems with many nodes and engines.

Configuration for the web nodes is found on the Server Nodes configuration page, alongside role settings. Configuration for distributed engines is found in the Distributed Engine configuration page. Log levels include: All, Debug, Info, Warn, Error, Off, and Not Set (the default). Previously, manual configuration file changes were required. "Not Set" relies on the configuration files for the logging level, which was the previous default behavior.

The diagnostic feature for collecting logs is improved and now gathers logs from all nodes and engines.

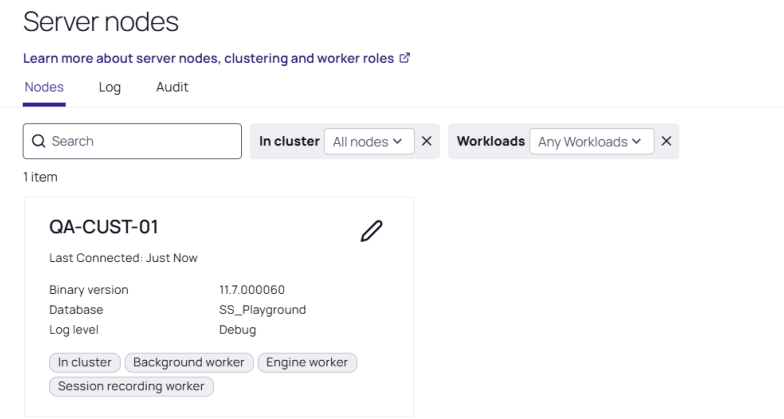
This feature is at **Admin > Server Nodes and Admin >**

Setting the Logging Level

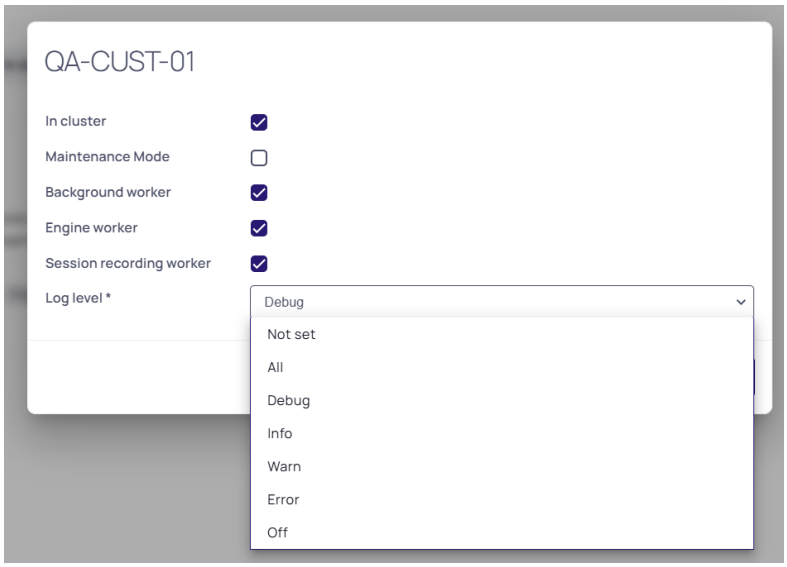
Secret Server Web Servers

For Web servers, you can set the log Level for web server nodes from the Server Nodes page:

1. Navigate to the **Server Nodes** page.



2. Click the edit icon next to the server you want to change. The settings become editable.
3. Click the **Log Level** dropdown list to select the desired level.

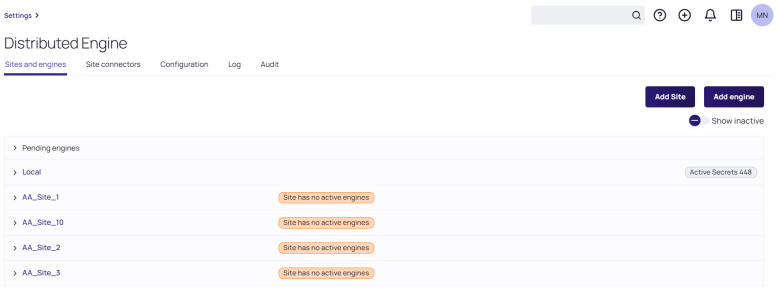


4. Click the save icon on the far right to save the change.

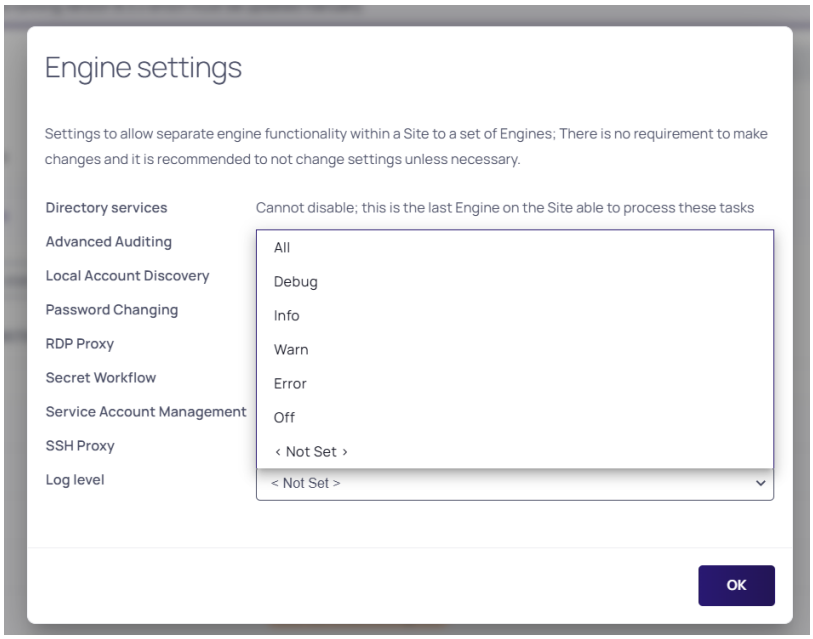
Distributed Engines

Similarly, for distribution engines:

1. Navigate to the **Distributed Engine**.



2. Hover the mouse pointer over the desired engine. Three dots appear on the far right.
3. Click the dots icon and select **Show Settings**. The Engine Settings popup page appears:
4. Click the **Log Level** dropdown list to select the desired level.
5. Click the **OK** button to save the change.



Setting the Logging Level when a Node is Down (No Access to UI)

To manually change the logging level when a web node is down and there is no access to the UI, you can follow these steps:

1. Locate the Configuration File:
   - Access the server where Secret Server is installed.
   - Navigate to the web application's root directory, typically found at *C:\inetpub\wwwroot\SecretServer*.
2. Edit the *web-log4net.config* file:
   - Open the *web-log4net.config* file in a text editor.
   - Use the find function (Ctrl + F) to locate the `<log4net>` section.
   - Modify the Logging Level:
     - Find the line with `<level value="INFO" />` or the current logging level.
     - Change the value to the desired logging level, such as `<level value="DEBUG" />`.
     - Ensure that the line is uncommented by removing any surrounding `<!-- and -->`.
3. After making the changes, restart the IIS service to apply the new logging configuration. This can be done by running `iisreset` in the command prompt.
4. Verify the Changes:
   - Check the logs to ensure that the new logging level is capturing the desired information.

   See Enabling Debug Mode in System Logs for more details.

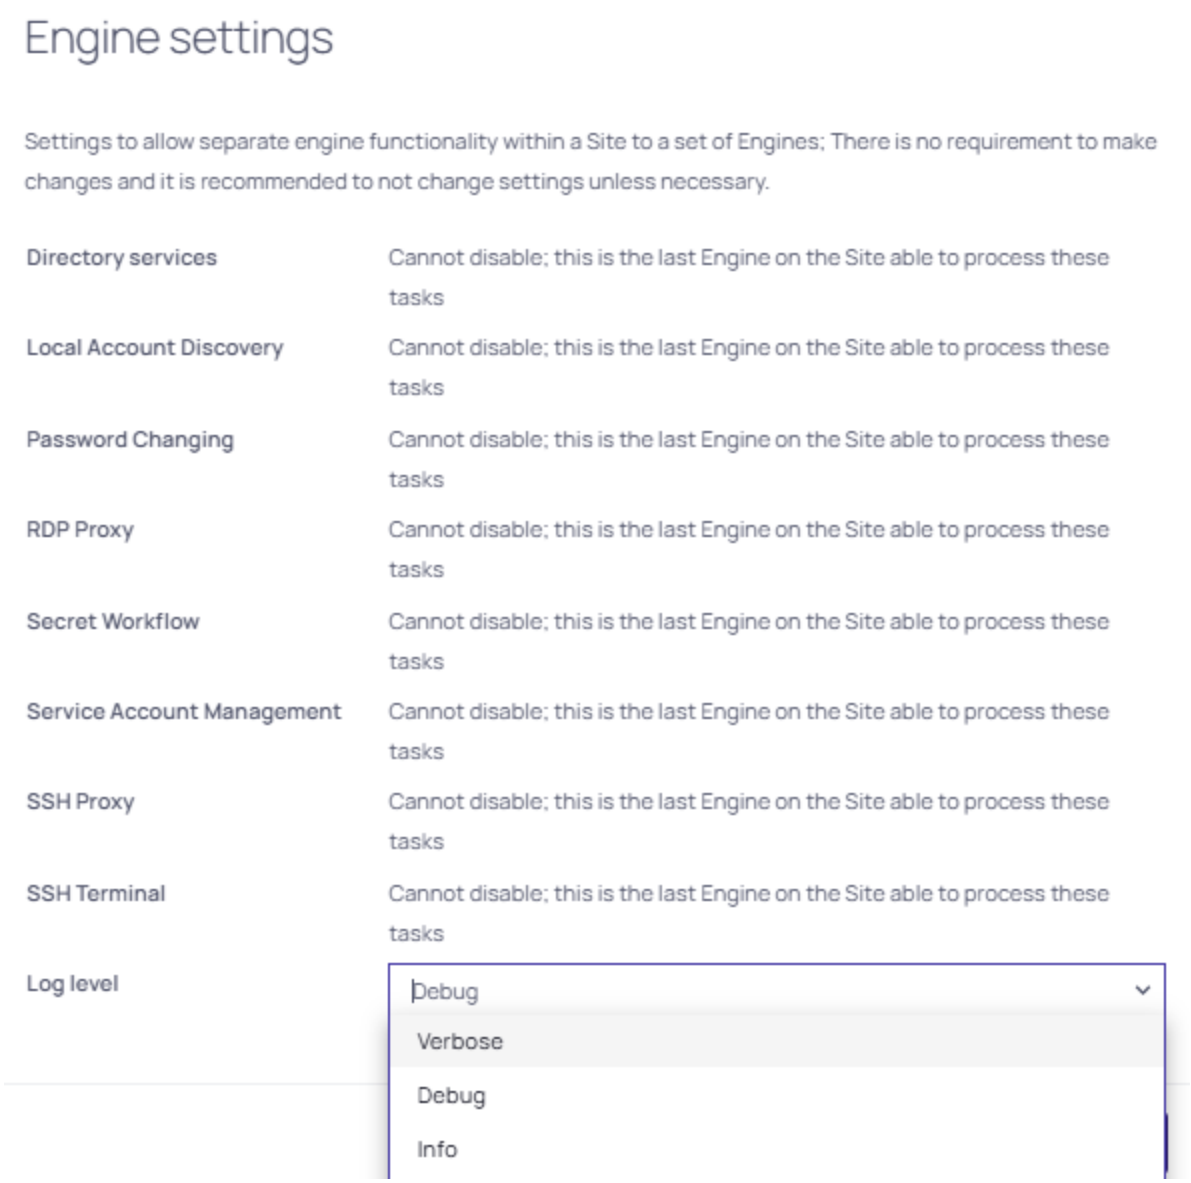
Enabling Debug Mode in Distributed Engine Log Files

You can expand Secret Server logging capability to locate additional information regarding an error or to help with troubleshooting an issue.

Enabling Verbose Debug Log Mode via the User Interface

Configure the log mode in Secret Server by doing the following:

1. Log into Secret Server.
2. Search for **Distributed Engine**. The Distributed Engine page loads.
3. Select a relevant **Site** from the list and expand it to see each Distributed Engine it has.
4. On the engine you want within that site listing, hover over its name, a 3-dot hidden menu appears on the far right. Click on it.
5. From the drop-down options, select **Show Settings**. The Engine Settings pop-up appears, example:



6. Toggle the **Log Level** setting so that it is now set to **Verbose**.
7. Click **OK** to save your changes.

Downloading Distributed Engine Logs (Cloud / On-Prem)

Downloading the Distributed Engine Log (Cloud)

1. Log into Secret Server.
2. Search for **Distributed Engine**. The Distributed Engine page loads.
3. Select a relevant **Site** from the list and expand it to see each Distributed Engine it has.

4. On the engine you want within that Site listing, hover over its name, a 3-dot hidden menu appears on the far right. Click on it.
5. From the drop-down options in the menu, select **Download Log**.
6. A download pop-up will automatically appear listing the file name, and location options for where you can save the file.

   Example file name: `engine-QA-CLOUD-DE01.gamma.thycotic.com`
7. Set the local folder location to: `C:\Program Files\Thycotic Software Ltd\Distributed Engine\log`
8. Click **Save** to download your log file.

Downloading the Distributed Engine Log (On-Premises)

1. Log into Secret Server.
2. Navigate to **Settings**.
3. Select **Diagnostics** and choose **Export Logs**.
4. Click **Collect** to trigger collection.
5. Once completed, select **Download**.
6. Choose the following local folder location: `C:\Program Files\Thycotic Software Ltd\Distributed Engine\log`, and save your log file.

Enabling Logging Manually on the DE Server

How to enable DEBUG logging mode manually:

1. Log in as an administrator on the Distributed Engine server.
2. Navigate to the `C:\Program Files\Thycotic Software Ltd\Distributed Engine` directory.
3. Locate the `Thycotic.DistributedEngine.Service.exe.config` file.
4. Open the file in a text editor.
5. Use **Find (Ctrl + F)** and search for `log4net`, which is usually at the top.
6. Locate all entries that contain `INFO`.
7. Replace each instance of `INFO` with `DEBUG`.
8. Restart the **Thycotic Distributed Engine** service to apply the log configuration change.

After DEBUG mode is enabled in the system log, you can reproduce an issue, investigate an error, or send the updated logs in with your support case.

Enabling Verbose Logging Mode Manually on the DE Server

On occasion, you may be instructed to enable the `VERBOSE` mode to capture extra details for troubleshooting. Do this by using the same procedure as shown in the previous section, but replace `INFO` or `DEBUG` with `VERBOSE` instead.

Enabling VERBOSE mode will create very detailed log information with large numbers of log files that can accumulate and quickly consume available resources on the machine. Therefore, you should only enable it during the troubleshooting process and immediately turn it off afterward in order to prevent performance issues.

Secret Server Authentication and Authorization

Secret Server provides integration options for Windows authentication and SAML to automatically authenticate users to the application when they browse to Secret Server on their workstations. Secret Server also allows you encrypt data at various locations.

IWA Overview

Integrated Windows Authentication (IWA) is a Microsoft protocol used for user authentication in web services and applications. It leverages the credentials of logged-in Windows users to authenticate them automatically without prompting for a username or password. This mechanism is particularly beneficial in corporate environments where users access multiple services frequently and streamlines the authentication process while enhancing security.

If you are using IWA to login, there is a new Chrome security requirement. You can make and apply a GPO Policy that'll apply the setting and allow websites you wish to have local network access.

Key Features of IWA Webservices

- Single Sign-On (SSO): IWA allows users to log in once with their Windows credentials and gain access to multiple applications without needing to re-enter their credentials. This feature significantly improves user experience and productivity.
- Security: By using Kerberos or NTLM (Windows challenge/response) protocols, IWA provides robust security. Kerberos is preferred due to its stronger encryption and mutual authentication capabilities, but NTLM is used for compatibility with older systems.
- Seamless Integration: IWA integrates seamlessly with Active Directory (AD), enabling organizations to manage user identities and AD permissions centrally. This integration ensures that security policies are consistently enforced across all applications.
- Reduced Administrative Overhead: With IWA, there is less need for maintaining separate authentication systems or databases for different applications. This consolidation reduces administrative overhead and potential points of failure.
- Support for Modern Web Applications: IWA is supported by various modern web servers and browsers, including Internet Information Services (IIS), Google Chrome, and Microsoft Edge. This broad compatibility ensures that it can be used in diverse IT environments.

Typical Use Cases

- Intranet Applications: IWA is ideal for intranet applications where all users are within the same Windows domain.
- Corporate Portals: It can be used to authenticate users accessing corporate portals that aggregate multiple services.
- Web Services: Developers can leverage IWA to secure web services that need to authenticate users against Active Directory.

Implementation Considerations

- Browser Configuration: For IWA to work, browsers must be configured to allow automatic logins. This typically involves setting trusted sites or intranet zones.
- Kerberos vs. NTLM: While Kerberos is more secure, NTLM may be necessary for compatibility reasons. The choice depends on the specific environment and security requirements.
- Network Topology: IWA works best in environments where users and services are within the same network or domain. Cross-domain or internet-based access might require additional configurations or different authentication mechanisms.

For details on how IWA works and best practices for its implementation, see Windows Authentication Overview.

Integrated IWA

Secret Server also provides a Integrated Windows Authentication (IWA) webservice that uses IWA instead of a username and password. This webservice can be used in an application or script to access Secret Server and retrieve secrets with storing the login credentials in the application or configuration file.

See "Configuring Integrated Windows Authentication" below for more advanced technical information on using this webservice.

Configuring Integrated Windows Authentication

This article applies to Secret Server On-Premises only.

Introduction

Integrated Windows Authentication (IWA) allows users to log into Secret Server automatically if they are logged into a workstation with their Active Directory credentials.

To ensure users can access the Health Status page see "Checking Secret Server Site Status" on page 764 without logging in, be sure to enable Form and Anonymous authentication in IIS.

"Secure LDAP" on page 533 only works with Integrated Windows Authentication in Server 2008 R2 and later.

Important: The SDK is designed to be used as it is shown below and is not designed to be run using IWA to retrieve tokens or Secret information. Given this, the SDK is not supported with IWA.

Setting Up Windows Authentication

Task 1: Configuring Secret Server

1. Log into Secret Server as a user with Active Directory administration privileges.
2. Navigate to and click **Administration > Directory Services** (In the General section). The Directory Services page appears, opened to the Domains tab.
3. Click the **Add Domain** button and select **Active Directory Domain** or **Azure Active Directory Domain**. An Active Directory popup appears.
4. If you chose Active Directory Domain:
   a. Type your FQDN in the **Fully Qualified Domain Name** text box.
   b. Type the name for people to read in the **Friendly Name** text box.
   c. Click to select the **Active** check box.
   d. If you wish to use secure LDAP, click to select the **Use LDAPS** check box.
   e. Click the **Create New Secret** link under **Synchronization Secret**. A popup appears.
   f. Click **Active Directory** Account in the Choose a Secret Template dropdown list. A Create New Secret popup appears.
   g. Fill in the popup with your desired parameters for your AD secret.
   h. Click the **Create Secret** button. The popup disappears and the secret name appears on the previous popup.
   i. Click the **Site** dropdown list to select your desired site.
   j. Click the **Multifactor Authentication** dropdown list to select your desired type of MFA, if any.
   k. Click the **Validate & Save** button to commit your choices. The popup disappears and your directory service appears in the table on the Directory Services page.
5. If you chose Azure Active Directory Domain:
   a. Type your name for people to read in the **Domain Name** text box.
   b. Click to select the **Active** check box.
   c. Type your tenant ID in the **Tenant ID** text box.
   d. Type your client ID in the **Client ID** text box.
   e. Type your client password in the **Client Secret** text box.
   f. Click the **Multifactor Authentication** dropdown list to select your desired type of MFA, if any.
   g. Click the **Validate & Save** button to commit your choices. The popup disappears and your directory service appears in the table on the Directory Services page.
6. Click the **Configuration** tab.
7. Click the **Edit** button in the **Directory Services** section. The section becomes editable.

8. If necessary, click to select the following check boxes:
   - **Enable Directory Services**
   - **Enable Integrated Windows Authentication**.
9. Click the **Save** button.
10. Click the **Edit** button in the **User Synchronization** section. The section becomes editable.
11. Ensure the **Enable User Synchronization** check box is selected.
12. Type the in the **Days**, **Hours**, and **Minutes** text boxes to choose a synchronization interval, which is how often Secret Server pulls in users from AD.
13. Select your desired option from the **User Account Options** dropdown list.
14. Select how to handle inactive users in the **Automatic User Management** dropdown list.
15. Type your desired number of days in the **Days to Keep Operational Log** text box.
16. Click the **Save** button. The Active Directory Configuration page returns to being read only.
17. Click the **Domains** tab.
18. Click the **Synchronize Now** button. This pulls all the users of the specified groups into Secret Server.

Task 2: Configuring IIS

1. Start the Internet Information Services (IIS) Manager.
2. Navigate to and select your Secret Server website in the **Connections** tree:
3. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
4. Enable the **Windows Authentication** parameter by right-clicking it and selecting **Enable**. For now, ignore the alert if it appears in the Alert section.

   If Windows Authentication is not visible, ensure that the Windows Authentication Role service is enabled in Windows. This is different than earlier versions.

5. Disable the **Anonymous Authentication**.
6. Disable the **Forms Authentication**. The alert in the Alert section should disappear.
7. When finished, the Authentication settings should only have Windows Authentication enabled.
8. Restart your IIS server with an `iisreset` command.
9. On the Secret Server folder, ensure users have read or higher permission, and ensure the security settings are set to be inherited by child objects. Because Secret Server impersonates those users, they require access to Secret Server files.
10. Log in to the Secret Server site from an authenticated workstation.

Task 3: Configuring Secret Server Launchers

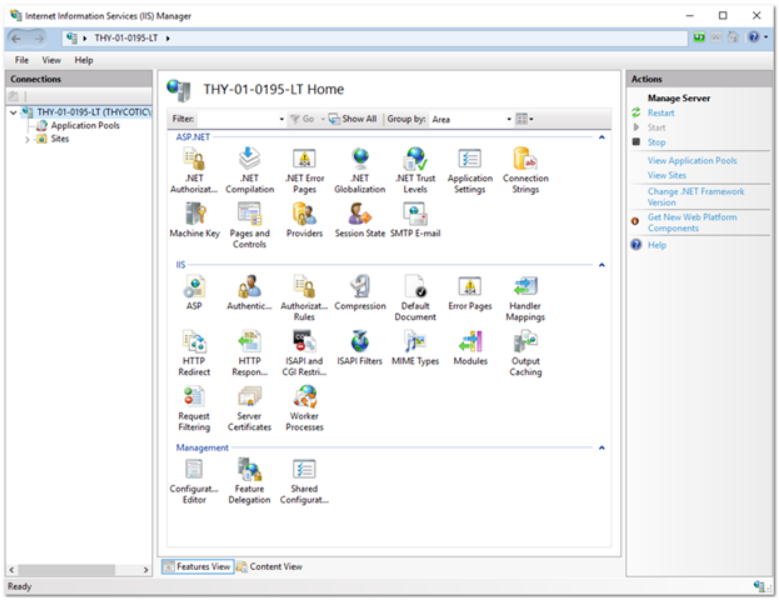
By default, a launcher will not work when using IWA, resulting in an HTTP 401: Unauthorized error. If this is an issue, ensure Secret Server is on Windows Server 2008 or later and complete the following steps:

1. Open IIS and browse to your Secret Server application.
2. Click the **>** to see the application's folders.
3. Click to select the **launchers** folder. The launchers Home panel appears.
4. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
5. Ensure the **Anonymous Authentication** is set to **Enabled**.
6. Ensure the **Windows Authentication** is set to **Disabled**.
7. Ensure all others are disabled. When you are finished, the settings should have Anonymous Authentication enabled.
8. Click the **webservices** folder.
9. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
10. Ensure the **Anonymous Authentication** is set to **Enabled**.
11. Ensure the **Windows Authentication** is set to **Disabled**.
12. Ensure all others are disabled. When you are finished, the settings should have Anonymous Authentication enabled
13. Click the **rdp** folder.
14. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
15. Ensure the **Anonymous Authentication** is set to **Enabled**.
16. Ensure the **Windows Authentication** is set to **Disabled**.
17. Ensure all others are disabled.

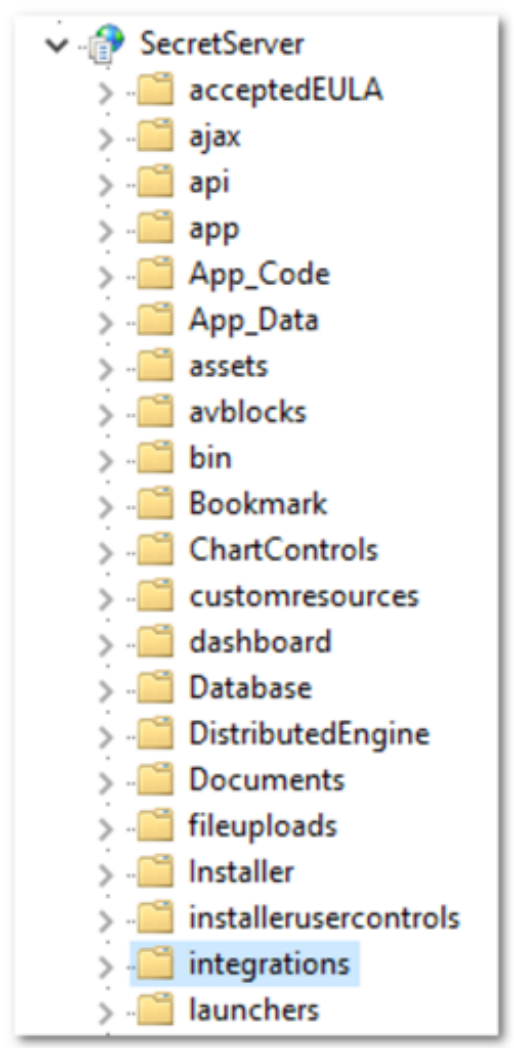
Task 4: Configuring Distributed Engines

Similarly, Secret Server with distributed engines will not work with IWA by default. If this is an issue, complete the following:

1. In Windows Explorer, navigate to the …`\SecretServer\` folder. This folder is mapped to your `SecretServer` folder in your webserver.
2. Create a subfolder named …`\SecretServer\integrations`.
3. Create a subfolder called …`\SecretServer\api` in the same location.
4. In your …`\SecretServer\api` folder, create a subfolder named …`\SecretServer\api\DistributedEngine`.
5. Start IIS Manager:



6. Navigate the **Connections** tree back to **integrations** folder in the **SecretServer** node:

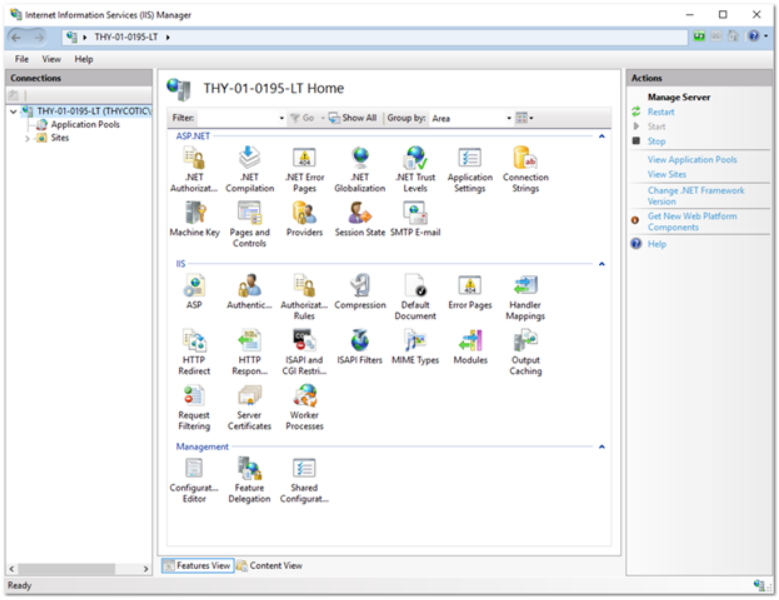


7. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
8. Ensure the **Anonymous Authentication** is set to **Enabled**.
9. Ensure the **Windows Authentication** is set to **Enabled**.
10. Ensure all others are disabled.
11. Navigate to the …`\SecretServer\api\DistributedEngine` folder.
12. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
13. Ensure the **Anonymous Authentication** is set to **Enabled**.
14. Ensure the **Windows Authentication** is set to **Disabled**.
15. Ensure all others are disabled.

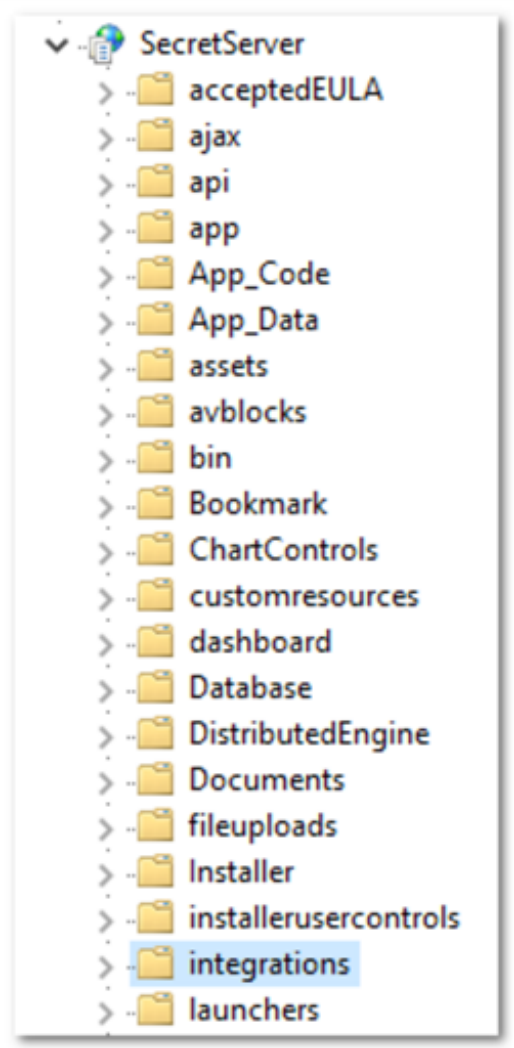
Task 5: Configuring Disaster Recovery

Similarly, Secret Server Disaster Recovery will not work with IWA by default. If this is an issue, complete the following:

1. In Windows Explorer, navigate to the …\SecretServer\ folder. This folder is mapped to your SecretServer folder in your webserver.
2. Create a subfolder named …\SecretServer\integrations.
3. Start IIS Manager:



4. Navigate the **Connections** tree back to **integrations** folder in the **SecretServer** node:



5. Double-click the **Authentication** icon in the **IIS** section to open the **Authentication** pane.
6. Ensure the **Anonymous Authentication** is set to **Enabled**.
7. Ensure all others are disabled.

Task 6: Configuring Client Certificates

If you are using client certificates, configure the following in IIS for launchers to work:

1. Click to select the **launchers** folder. The launchers Home panel appears.
2. Double-click the **SSL Settings** icon. The settings panel appears.
3. Click to set the **Client Certificates** selection button to **Accept**.
4. A dialogue box requiring a **yes** response pops up.
5. Click **Yes**.
6. Click to select the **Webservices** folder.

7. Once again, double-click the **SSL Settings** icon.
8. This time, set the **Client Certificates** selection button to **Ignore**.

If you are not automatically logged in to Secret Server after setting up IWA, IIS may not be handling the credentials correctly. To fix this, recreate the web site in IIS.

When testing IWA, keep in mind the requirements at Your Browser May Prompt You for a Password.

You may not be able to log in using IWA on the server running Secret Server for Server 2008 or later because of security settings.

Troubleshooting

AD User Prompted for Credentials Even Though IWA Is Active

A user is logged onto their machine with the same Active Directory credentials they can log into Secret Server with, but the browser still prompts them for their credentials to reach the site. Ensure your Secret Server site is included in a security zone that allows for automatic logon:

1. In your browser, go to Internet **Options > Security**.
2. Click the **Trusted Sites** security zone.
3. Click the **Custom Level** button. The Security Settings – Trusted Sites Zone dialog box appears.
4. Scroll down to **User Authentication**.
5. Click to select the **Automatic logon with current user name and password** selection button.
6. Click the **OK** button.

Logging in as a Local Account Is Not Available

In Secret Server 10.0 and later, Secret Server requires Integrated Mode in IIS. The Integrated Mode can only support either Window Authentication or Forms Authentication (used for local account authentication), not both. Because of this limitation, Forms Authentication must be disabled for the site when using Integrated Windows Authentication. Thus, logging in as Secret Server local account is not available when IWA is enabled.

Installing Windows Authentication in Windows Server 2012 Manager

1. In Server Manager, click the **Manage** menu and select **Add Roles and Features**. The Add Roles and Features wizard appears.
2. Click the **Next** button. The Select installation type window appears.
3. Select the installation type.
4. Click the **Next** button. The Server selection window appears.
5. Select the destination server.
6. Click the **Next** button. The Server roles window appears.
7. Click to expand **Web Server (IIS) > Web Server > Security**.
8. Click to select **Windows Authentication**.

9. Click the **Next** button. The Select features window appears.
10. Click the **Next** button. The Confirmation window appears.
11. Click the **Install** button. The Results window appears.
12. Click the **Close** button.

Using Webservices with IWA via Perl

Overview

You can enable webservices at **Admin > Configuration** on the **General** tab. Checking the **Enable Webservices** check box makes the ASP.NET SOAP and REST webservices built into Secret Server available for use. Additional steps are needed in IIS to ensure proper access.

> Integrated Windows Authentication (IWA) does **not** work on Secret Server Cloud.

> This procedure only works if Secret Server on-premises is installed on IIS 7 or greater.

Procedure

To enable IWA for webservices in IIS:

1. Open IIS Manager (`inetmgr`).
2. Expand the **Sites** node until you locate your Secret Server application or website
3. Expand the **Secret Server** node to locate the **winauthwebservices** folder.
4. Click on the **winauthwebservices** folder.
5. Click on **authentication** in the **Security** section.
6. Disable **Anonymous Authentication**.
7. Enable **Windows Authentication**.

   > If you are using IIS7 or greater and do not see this option, the option will need to be added through the server roles (webserver). IIS may give an alert about using both challenge and redirect-based authentication, which you can ignore.)

8. Open Windows Explorer.
9. Navigate to the **winauthwebservices** folder.
10. Give **read access** to the **winauthwebservices** folder to the domain users and groups that will be using IWA to access the webservices.

Example

Overview

The SOAP web service URL for IWA is `<Secret Server URL>/winauthwebservices/sswinauthwebservice.asmx`.

The method below uses the `SecretServerGetSecret.ps1` PowerShell script to make the SecretGet WebService call, exposing it through the `SecretServer.pm` Perl package. The `Sample.pl` file uses the `SecretServer.pm` package to retrieve specific fields from the result.

The flow is as follows:

1. Your Perl script (`sample.pl`) makes a request to the `SecretServer.pm` package.
2. The `SecretServer.pm`package passes the request on to the `SecretServerGetSecret.ps1` PowerShell script.
3. The `SecretServerGetSecret.ps1` PowerShell script calls the Secret Server web services and authenticates using the service account that `sample.pl` is running under.
4. The results are passed back to `SecretServer.pm` and then on to your Perl script (`Sample.pl`)
5. Create the following three files:

SecretServerGetSecret.ps1

```
# Sample Powershell Script
# demonstrating retrieval of a Secret from <Secret Server URL />
# via web service protected by Windows Authentication
# returned as Xml
$where = $args[0]
$secretId = $args[1]
$ws = New-WebServiceProxy -uri $where -UseDefaultCredential
$wsResult = $ws.GetSecret($secretId)
$res = convertto-xml $wsResult.Secret -As string -Depth 20
$res
```

SecretServer.pm

```
package SecretServer;
use strict;
sub usage {
    print "\nUsage: GetSecret [webservice url] [secretid]\n";
}
sub new {
    my($class, %args) = @_;
    my $self = bless({}, $class);
    return($self);
}
sub get_secret {
    my($self, $url, $secretid) = @_;
    my $result = powershell.exe .\\SecretServerGetSecret.ps1 $url $secretid;
```

```
    return($result);
}
sub get_field_from_result {
    my($self, $result, $field) = @_;
    $result =~/<Property Name="Value" Type="System.String">([^<>]+)<\/Property>
(?:\s*<Property Name="(?!FieldName)[^"]+"[^>]+>[^<]+<\/Property>\s*)*<Property
Name="FieldName"[^<>]+>$field<\/Property>/gsi;
    return("$1");
}
1;
# this is if you want to execute the Get Secret call manually from the command line
# if (@ARGV != 2)
# {
  # usage();  # Call subroutine usage()
  # exit();   # When usage() has completed execution,
            # # exit the program.
# }
# my $url = $ARGV[0];
# my $secretid = $ARGV[1];
# my $result = powershell.exe .\\SecretServerGetSecret.ps1 $url $secretid;
# print $result;
```

Sample.pl

```
use lib 'C:/<Path to the SecretServer.pm file>';
use SecretServer;
my $x = SecretServer->new();
# Change this value to match your URL
my $url = '<Secret Server URL> /winauthwebservices/sswinauthwebservice.asmx';
# Change this value to match your desired Secret Id
my $secretid = 17;
my $result = $x->get_secret($url, $secretid);
my $username = $x->get_field_from_result($result, 'UserName');
my $password = $x->get_field_from_result($result, 'Password');
print "$username : $password";
```

Using Webservices with IWA via PowerShell

Overview

You can enable webservices at **Admin > Configuration** on the **General** tab. Checking the **Enable Webservices** check box makes the ASP.NET SOAP and REST webservices built into Secret Server available for use. Additional steps are needed in IIS to ensure proper access.

> Integrated Windows Authentication (IWA) does **not** work on Secret Server Cloud.

> This procedure only works if Secret Server on-premises is installed on IIS 7 or greater.

Procedure

To enable IWA for webservices in IIS:

1. Open IIS Manager (`inetmgr`).
2. Expand the **Sites** node until you locate your Secret Server application or website
3. Expand the **Secret Server** node to locate the **winauthwebservices** folder.
4. Click on the **winauthwebservices** folder.
5. Click on **authentication** in the **Security** section.
6. Disable **Anonymous Authentication**.
7. Enable **Windows Authentication**.

   If you are using IIS7 or greater and do not see this option, the option will need to be added through the server roles (webserver). IIS may give an alert about using both challenge and redirect-based authentication, which you can ignore.)

8. Open Windows Explorer.
9. Navigate to the **winauthwebservices** folder.
10. Give **read access** to the **winauthwebservices** folder to the domain users and groups that will be using IWA to access the webservices.

Access Examples

SOAP

The SOAP web service URL for IWA is `<Secret Server URL>/winauthwebservices/sswinauthwebservice.asmx`.

Example script:

```
# Sample Powershell Script
# demonstrating retrieval of a Secret from <Secret Server URL />
# via web service protected by IWA
$where = 'http://mysecretserver/winauthwebservices/sswinauthwebservice.asmx';
$secretId = 1
$ws = New-WebServiceProxy -uri $where -UseDefaultCredential
$wsResult = $ws.GetSecret($secretId, $false, $null)
if ($wsResult.Errors.length -gt 0){
    $wsResult.Errors[0]
}
else
{
    $wsResult.Secret
}
```

REST

REST web service references the same winauthwebservices folder as SOAP when doing IWA, but in code the URL endpoint does not need to change.

Example script:

```
# Sample Powershell Script
# demonstrating authentication via web service protected by IWA
$api = 'http://mysecretserver/winauthwebservices/api/v1';
$endpoint = $api'/secrets/3844'
$secret = Invoke-RestMethod $endpoint -UseDefaultCredentials
```

OAuth

OAuth is an open-standard authorization framework that enables secure, delegated access to protected resources on the web. It allows a client application to access a user's resources on another service provider's website without sharing their login credentials. Instead, the client application requests an access token, which is granted by the service provider after the user authenticates and authorizes the request. The access token is then used to authenticate and authorize subsequent requests to the protected resources, allowing the client application to access the user's data without exposing their sensitive login information. OAuth provides a standardized, secure, and flexible way to manage access to APIs, enabling users to control how their data is shared and used by third-party applications.

OAuth in Secret Server provides a secure and efficient framework for token-based API authentication, enabling seamless integration with various applications and services. By leveraging OAuth, Secret Server allows for the delegation of access rights without sharing credentials, enhancing security and simplifying the management of OAuth permissions. This is particularly useful for enabling single sign-on (SSO) and integrating with identity providers like OpenID Connect, which is layered on top of OAuth 2.0. The implementation of OAuth in Secret Server supports multi-factor authentication (MFA) and conditional access policies, ensuring robust security measures are in place for accessing sensitive data and performing privileged operations.

Enabling Refresh Tokens for Web Services

Overview

Many modern secure applications use access tokens to ensure that users have access to the resources appropriate for them. Access tokens typically have a limited lifetime to ensure that information they contain or reference doesn't become stale, and to limit the time available for an attacker to use a stolen token.

When an access token expires or becomes invalid but the application still needs to access a protected resource, the application must use a new access token. To provide a new access token without requiring the user to grant permission a second time, OAuth 2.0 introduced an artifact called a *refresh token*.

Note the following:

- You cannot use a refresh token more than once.
- You cannot use a refresh token if your API Session Timeout is set to `unlimited`.

- In Secret Server, the refresh token "Time to live" equals the APISessionTimeout plus 15 minutes.
- Access tokens retrieved from REST can also be used for SOAP.

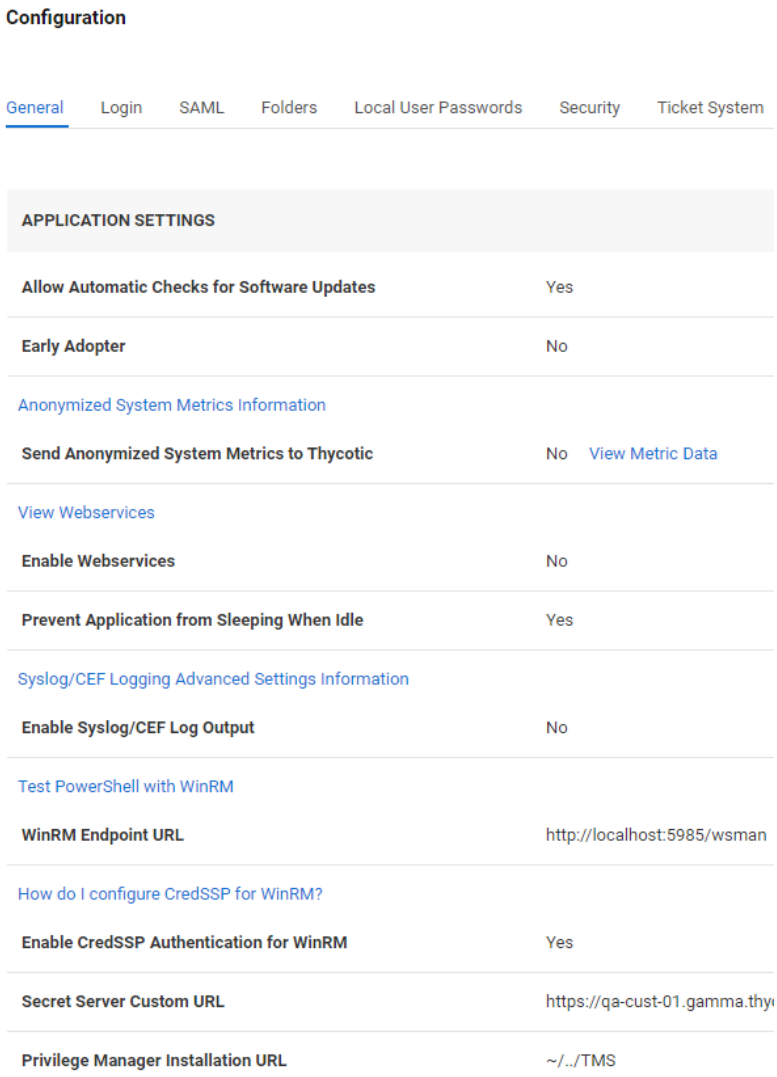
How to Enable Refresh Tokens in Secret Server

Procedure

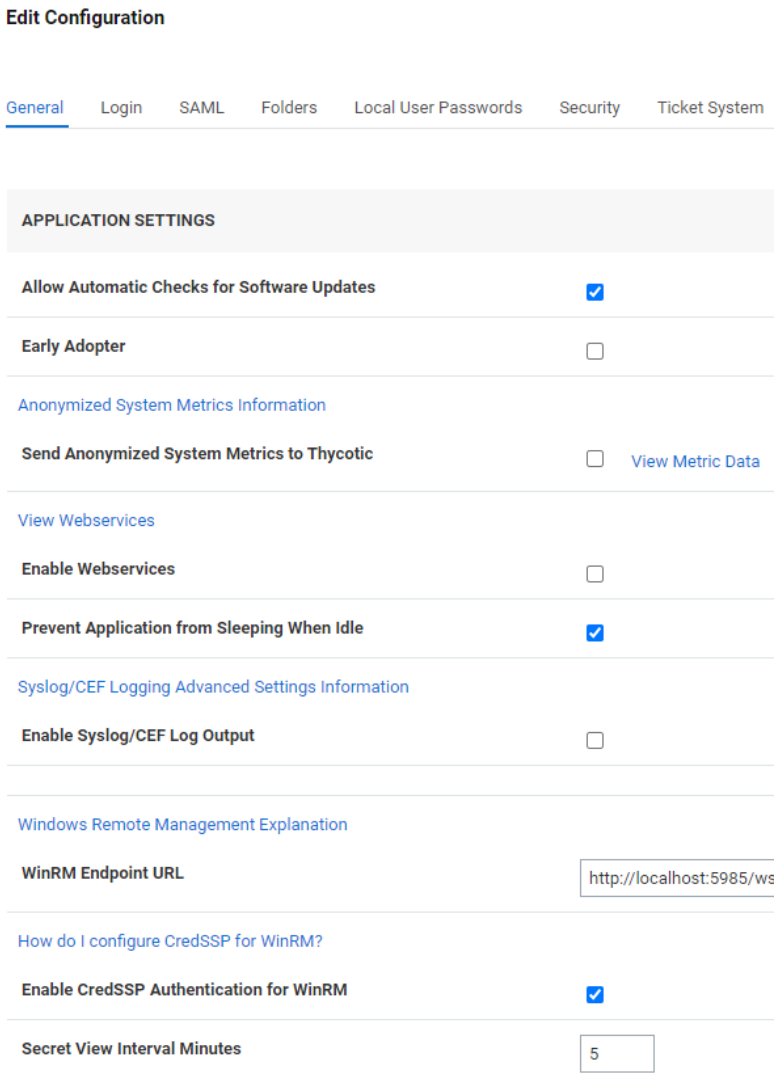
You will receive a refresh token only if the option is enabled in **Admin** > **Configuration** as described below.

1. Click **Admin** > **Configuration** > then click the **General** tab.

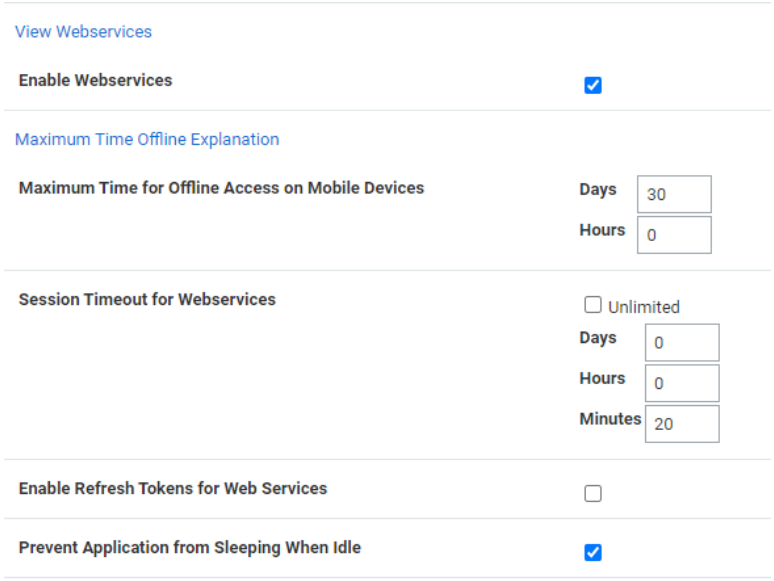
   The **Enable Web Services** field is visible but not editable.



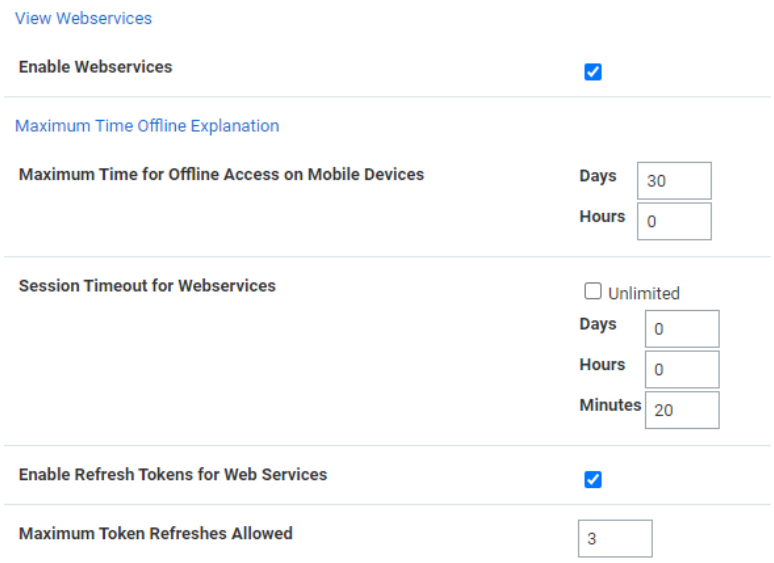
2. Scroll to the bottom of the window, click the **Edit** button, and scroll back up. The window title changes from **Configuration** to **Edit Configuration** and the **Enable Web Services** field is now editable.



3. Check the box next to **Enable Web Services**. The menu expands and the **Enable Refresh Tokens for Web Services** field is now visible.



4. Click to enable the check box next to **Enable Refresh Tokens for Web Services**. The menu expands and the **Maximum Token Refreshes Allowed** field is now visible.



5. Enter a numeral in the box next to **Maximum Token Refreshes Allowed**.
6. Scroll to the bottom of the page and click **Save**.
7. Authenticate with REST. You should receive both an access_token and a refresh_token.
8. Use the access token until it expires.
9. When the access token expires, POST to the same endpoint for authentication ("oauth2/token") with the body containing the following:

```
grant_type = "refresh_token"
Set refresh_token = <YOUR REFRESH TOKEN>
```

10. You should receive a refresh_token and a new access_token.

Example

```
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
$uri = "https:// < yoursecretserverinstance >"
$api = "$uri/api/v1"
function Authenticate {
    $args= @{
        username = "username"
        password = "password"
        grant_type = "password"
    }
    echo "----------------"
    echo "--Authenticate--"
    echo "----------------"
    $response = Invoke-RestMethod "$uri/oauth2/token" -Method Post -Body $args -
ContentType "application/json"
    $global:token = $response.access_token
    $global:refreshToken = $response.refresh_token
    $global:headers = New-Object "System.Collections.Generic.Dictionary[[String],
[String]]"
    $global:headers.Add("Authorization", "Bearer $token")
}
function Refresh {
    $args= @{
        grant_type = "refresh_token"
        refresh_token = $refreshToken
    }
    echo "---------------"
    echo "----Refresh----"
    echo "---------------"
    echo "--Sending Refresh Token"
    echo $refreshToken
    $response = Invoke-RestMethod "$uri/oauth2/token" -Method Post -Body $args -
ContentType "application/json"
    if($response.access_token){
        $global:token = $response.access_token
       $global:refreshToken = $response.refresh_token
        $global:headers = New-Object "System.Collections.Generic.Dictionary[[String],
[String]]"
        $global:headers.Add("Authorization", "Bearer $token")
    }
}
```

OpenID Connect

OpenID Connect (OIDC) in Secret Server is an identity protocol built on top of the OAuth 2.0 framework, designed to facilitate secure and streamlined authentication processes. By integrating with external OpenID Connect providers such as Azure AD, ADFS, Auth0, or Okta, Secret Server enables single sign-on (SSO) capabilities, allowing users to authenticate using their existing credentials from these providers. This integration not only enhances security by leveraging robust authentication mechanisms but also simplifies user management and access control. Administrators can configure Secret Server to delegate authentication to these external providers, ensuring a seamless and secure login experience for users across various applications and services.

OpenID Connect Integration

This applies to Secret Server Version 10.7 SP2+.

Introduction

OpenID Connect

OpenID Connect is an industry-standard single-sign-on (SSO) protocol. An identity provider implementing OpenID Connect can be used as an identity source for Secret Server, allowing users to log in with external credentials.

OpenID Connect Support in Secret Server

Secret Server

Secret Server implements OpenID Connect authorization code flow, allowing any standards-compliant provider to be used as an identity source. To use OpenID Connect, a Secret Server administrator must configure the login integration. Additionally, user accounts must be created in Secret Server that correspond to the external accounts.

Prerequisites

General

- Secret Server version 10.7 SP2+
- An OpenID-Connect-compatible identity provider, such as Delinea One, Azure AD, Auth0, or Okta.

Permissions

- To configure the login integration, a Secret Server user must have Administer OpenID Connect permissions. Secret Server
- To add user accounts that can be used with OpenID Connect, a Secret Server user must have administer user permissions.

Configuration

Task One: Acquire and Configure an OpenID Connect Provider

1. Follow your OpenID Connect provider's setup instructions for configuring a new identity client.
2. Gather the configuration data from the provider. To configure an OpenID Connect login provider, the provider must supply these:
   - **Provider URL**: An HTTPS URL, acting as an authentication endpoint. Secret Server expects the provider URL to be the "issuer" URL of the provider. For example, if the OpenID Connect configuration for the provider is accessible at

     `https://example.com/oidc/endpoint/default/`,

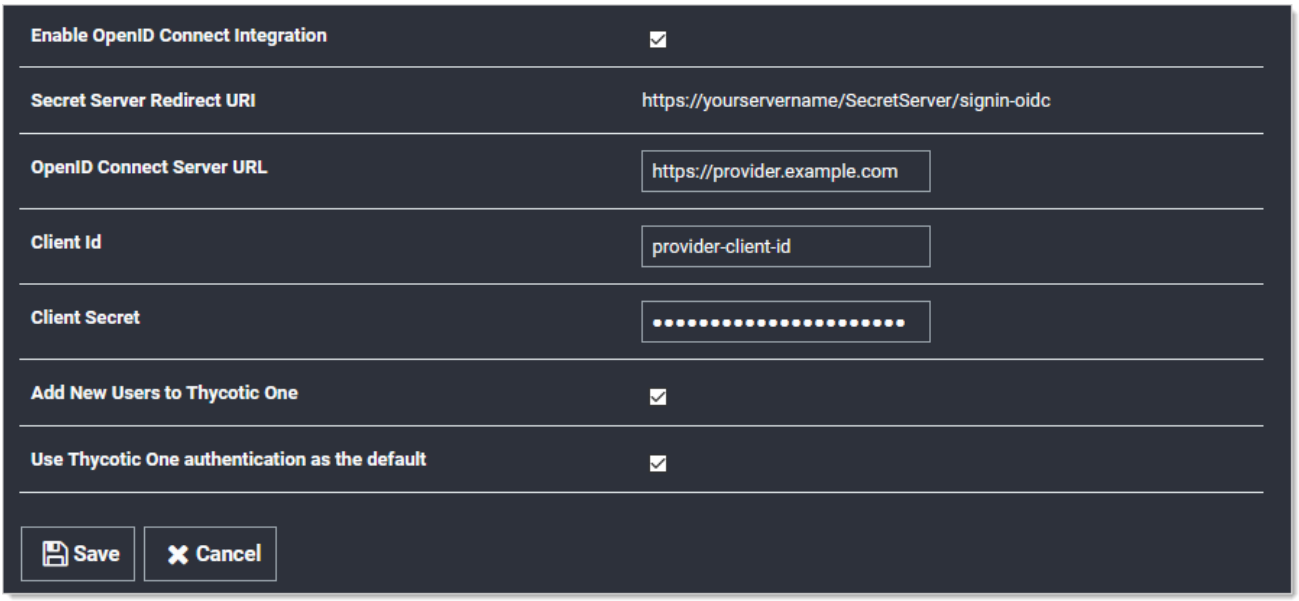
     then the URL used in the Secret Server configuration should be

     `https://example.com`.
   - **Client ID**: The ID portion of the credentials used to interact with the provider.
   - **Client Secret**: The password portion of the credentials used to interact with the provider.

   The process for determining this information varies by provider and you can usually find it by following the provider-specific documentation for configuring an OpenID Connect client.
3. Configure the provider with the Secret Server Redirect URI, as shown below, when configuring OpenID Connect integration in Secret Server. It is usually `https://YourWebServer/SecretServer/signin-oidc`. The Secret Server Redirect URI value must be added to the provider's configuration, so that the Secret Server instance can perform the authentication handshake. This process varies by provider, but it is usually known as a post-login redirect URI or callback URI.

Task Two: Configure Secret Server

1. Locate the Secret Server OpenID Connect configuration at **Admin > Configuration > Login**:



2. Click to select the **Enable OpenID Connect Integration** check box.
3. Fill in the other values using the what you gathered earlier.

> The two Thycotic One options are not relevant unless you use Thycotic One as your OpenID Connect provider. They have no effect for other providers.

4. Click the **Save** button.

Task Three: Matching External Accounts to Secret Server Users

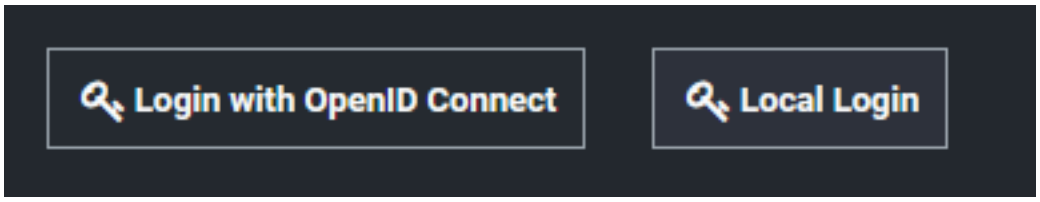
Ensure a matching user already exists in Secret Server, which is required when logging on an OpenID Connect account. OpenID provides for no user list synchronization or on-the-fly account creation. Users are matched according to the claims provided in their authentication ticket. Matching occurs using the following criteria:

- If the name identifier value matches an active user that has already logged in with OpenID Connect, then this user will be logged on.
- If not, then if the email or UPN values match an existing, unique, active Secret Server user, then this user will be logged on.

Otherwise, the login attempt will fail, and information about the failure will be added to the system log.

Task Four: Logging on with OpenID Connect

Finally, confirm the configuration by logging on with OpenID Connect. Once Open ID Connect has been configured, the Secret Server login page will have a new **Login with OpenID Connect** button:



Clicking this button initiates the OpenID Connect log on process with the external provider. Depending on provider settings, you may be asked to approve the login request or grant access to specific profile info. Once you have approved the request and logged in to the external provider, you will be redirected back to Secret Server and logged in as the corresponding local user.

Thycotic One and Secret Server

Overview

Thycotic One is a legacy single-sign-on provider for Delinea applications. With Thycotic One, one user account can be granted access to multiple Delinea products, such as Secret Server, Privilege Manager, DevOps Secrets Vault, and Account Lifecycle Manager. Thycotic One enables login integration using the OpenID Connect protocol, an industry standard single-sign-on method.

This article describes the Thycotic One configuration options available in Secret Server.

Cloud versus On-Premise

For Secret Server Cloud, Thycotic One is the default identity provider. When you set up the cloud instance, it will already be configured and ready to use Thycotic One. The initial admin user will log in with their Thycotic One account, and optionally, all newly created Secret Server accounts can be synchronized with Thycotic One, so they can log in that way as well.

For the on-premise version of Secret Server, Thycotic One integration is off by default, but it is supported. You can turn on Thycotic One integration and configure it. For example you might want to share an identity provider between your on-premise instance, and one or more other cloud products.

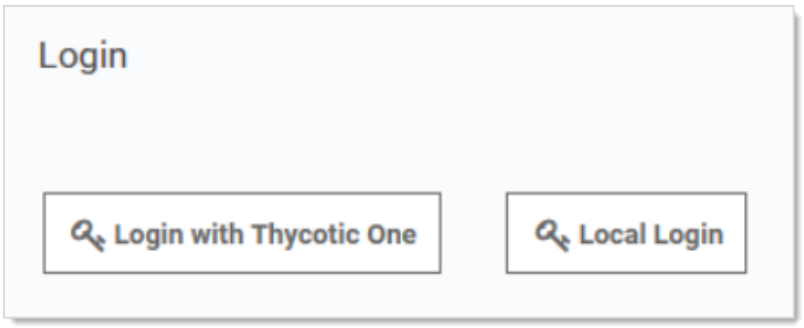
Procedures

Logging in with Thycotic One

When Thycotic One integration is turned on, all Secret Server users can log in either with their local passwords or with Thycotic One. All Secret Server permissions and configuration will apply to that user regardless of how they logged in.

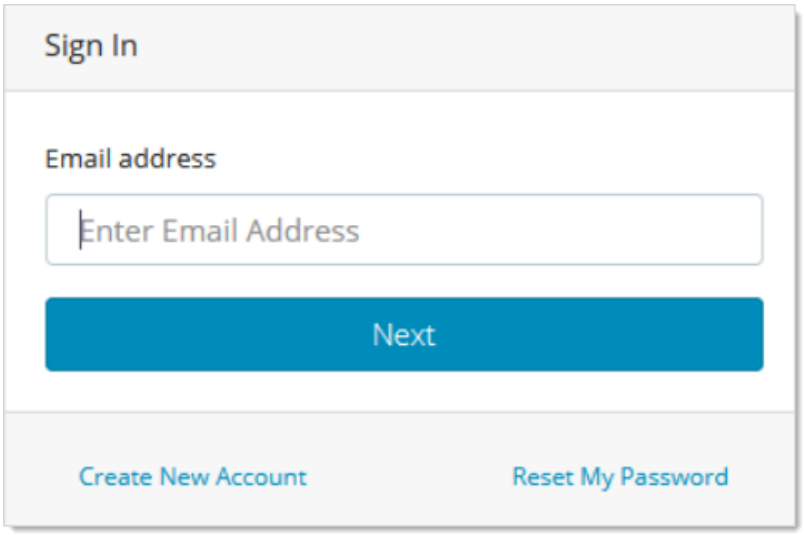
However, the local username and password and the Thycotic One username and password are not necessarily the same thing. In Thycotic One, you'll log in with your email address rather than your username, and the password you use may very well be different from the Secret Server password.

You'll see this on the login screen:



Clicking **Local Login** will bypass Thycotic One and allow the user to log in with their local Secret Server password. Clicking **Login with Thycotic One** will redirect the user to Thycotic One to authenticate. Once that is successfully done, the user will be redirected back to Secret Server.

After clicking **Login with Thycotic One**, users will type their email address and password:



And then be redirected back to their dashboard in Secret Server.

Configuring Thycotic One

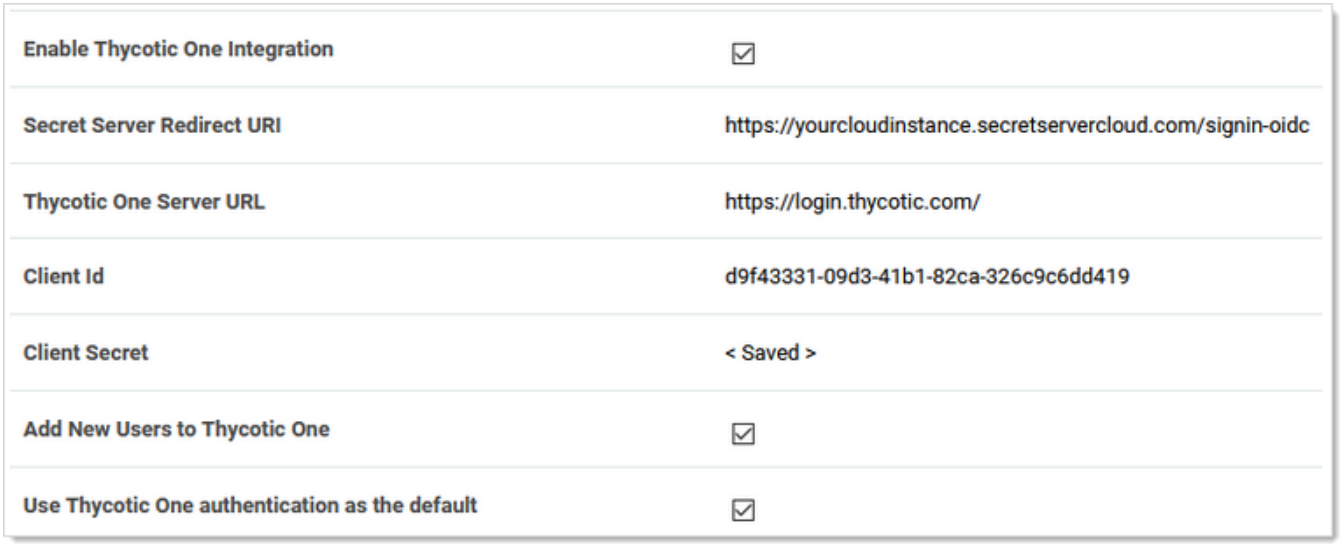
Thycotic One integration is configured on the **Admin** > **Configuration** page, under the **Login** tab. You can view the configuration there:

The **Sync Now** button provides a way for you to trigger a synchronization of your Secret Server accounts with Thycotic One. In most cases, you will not need to use this, as synchronization will happen on a schedule or whenever a relevant event happens, such as enabling a user or performing an Active Directory synchronization. Only active user accounts with email addresses will be synchronized.

Click **Edit** at the bottom of the page to change the configuration. The available options are slightly different between the cloud and on-premise versions of Secret Server.

Secret Server Cloud

When editing the options in Secret Server Cloud, you'll see something like this:



Here are the available options:

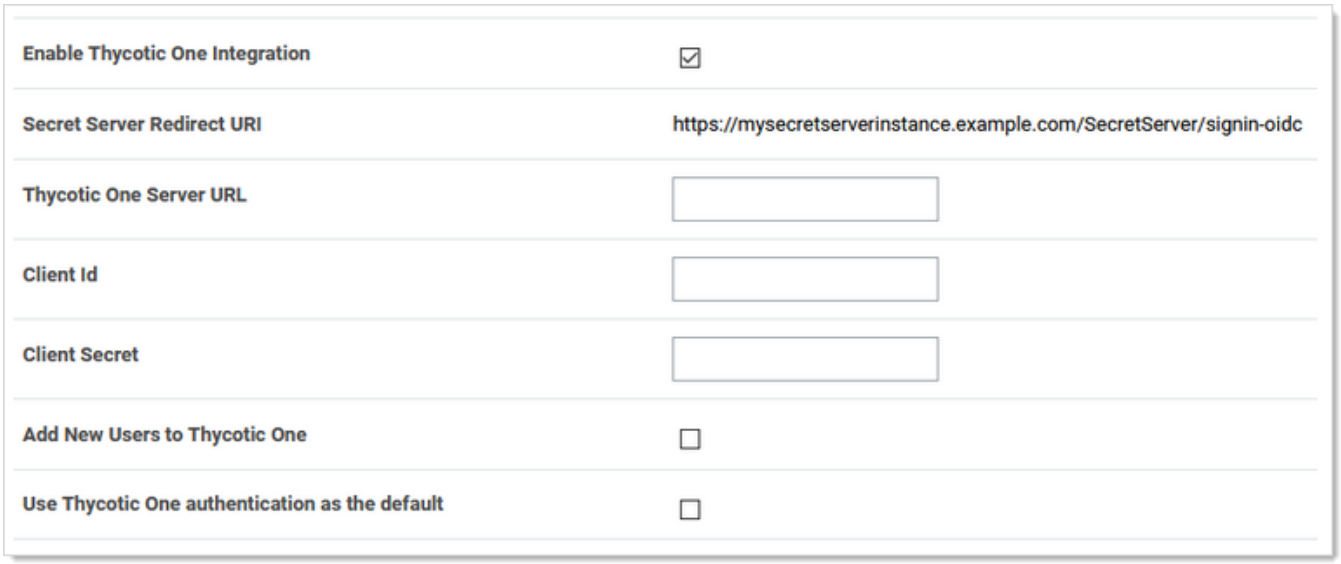
- **Enable Thycotic One Integration:** Turn on to enable Thycotic One functionality. Turn off to completely disable Thycotic One logins and synchronization. Make sure you have an admin account with a working local password.
- **Secret Server Redirect URI:** For informational purposes, this shows the page address to which you are redirected after you have logged in with Thycotic One.

- **Thycotic One Server URL:** The Thycotic One server you have connected to. There is one separate Thycotic One instance in each Secret Server Cloud region.
- **Client ID:** The client ID portion of the Thycotic One server credentials.
- **Client Secret:** Not shown, the client password portion of the credentials.
- **Add New Users to Thycotic One:** When checked, Secret Server accounts will be synchronized with Thycotic One. Adding a user will send them a welcome email, where they can set up their Thycotic One account password and log into Secret Server. When unchecked, users will not be synchronized and no email will be sent. New users will not be able to log in with Thycotic One, unless you click **Sync Now** on the **Admin** > **Configuration** > **Login** page, which will synchronize all active users.
- **Use Thycotic One authentication as the default:** When checked, Thycotic One authentication is used for the REST and SOAP APIs and mobile apps. Users who have logged in with Thycotic One use their Thycotic One account passwords for those activities, rather than their local Secret Server account passwords. When unchecked, they will use their local Secret Server account passwords for those activities.

In Cloud, the server URL, client ID, and client secret cannot be edited—they are set up for you when the instance is provisioned and cannot be changed.

Secret Server On-Premise

When editing the options in Secret Server on-premise, you'll see something like this:

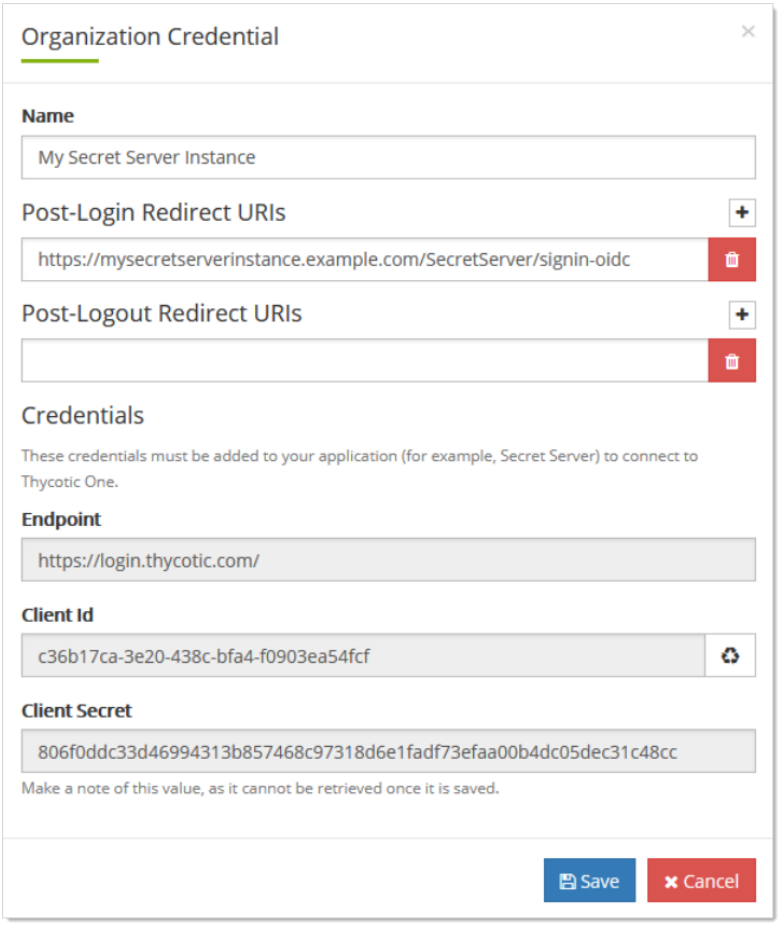


Unlike in Cloud, the server URL, client ID, and client secret can be edited in an on-premise instance. You can generate Thycotic One credentials using Delinea's cloud management portal, Cloud Manager. Otherwise, the configuration options behave the same as in Cloud.

Generating a Thycotic One Credential

To generate a credential for use in an on-premise Secret Server instance, follow the steps below:

1. From Cloud Manager, choose a Thycotic One region under Other Login Options.
2. Log into Thycotic One as a user that will be managing your organization's credentials. Create an account if you have not yet done so.
3. Go to Cloud Manager.
4. Click **Sign In**. You are redirected to our tech support portal login.
5. Click the button for the Thycotic One region you chose. Since you are already logged in to Thycotic One, this will redirect you back to Cloud Manager.
6. Next, choose a team: In the menu, go to **Manage** > **Teams**. You may already have one if you have an existing cloud product. If not, create one. Each team can handle multiple Thycotic One credentials.
7. Having selected your team, go to **Organizations**. Again, if you already have an organization, you can use it; if not, you can create one. An organization provides a way to manage the global login policies for all users.
8. Go to **Credentials**. Click **Add**. An Organization Credential dialog box appears:



9. The available fields are as follows:

- **Name:** A description of the application using this credential, for informational purposes.
- **Post-Login Redirect URIs:** A list of valid URIs that will be allowed to authenticate with this credential. The value of "Secret Server Redirect URI" from your on-premise instance should go here. If users access your instance with more than one URI, you may want to add all of them here by clicking the **+** button to create additional fields. Unless an application supplies a URI that is an exact match to one of these, Thycotic One will not complete the authentication.
- **Post-Logout Redirect URIs:** Secret Server does not support this feature, so this may be left blank.
- **Credentials:** The fields in this area contain the values you need to put into the Thycotic One configuration in SS. Copy and paste them into the corresponding fields.

10. Once you capture all the values, click **Save**, and then save the configuration in Secret Server as well. Your instance is now fully integrated with Thycotic One. If you selected the synchronization option, Secret Server will immediately sync your active users with Thycotic One, and they'll receive welcome emails describing how to continue the process.

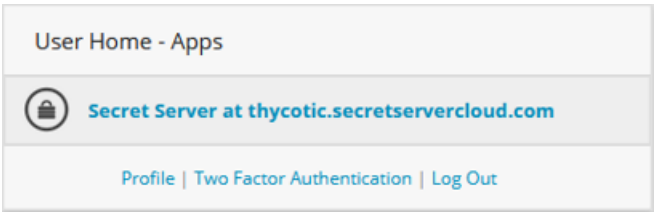
Enabling Two-Factor Authentication in Thycotic One

When two-factor authentication is enabled, Thycotic One presents a two-factor challenge to the user logging in. The Thycotic One two-factor authentication supplements and does not replace any other two-factor authentication methods used by a client application such as Secret Server. Thycotic One supports two-factor authentication using TOTP or SMS. You can have only one two-factor authentication method active at any time. We recommend using TOTP over SMS whenever possible for better security.

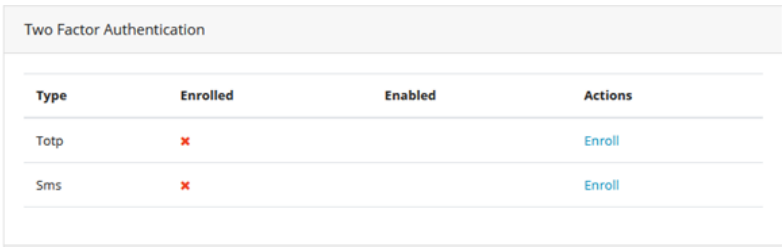
TOTP Two-Factor Authentication

To use TOTP two-factor authentication with Thycotic One, you must first have a mobile device with an installed TOTP application such as Google Authenticator, Authy, or Microsoft Authenticator. When you have the app installed, follow the steps below.

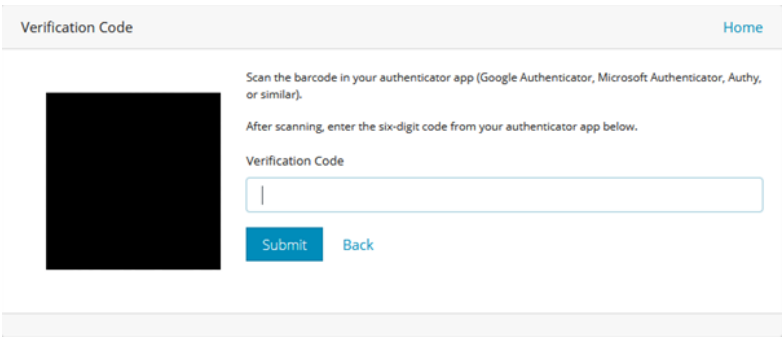
1. Log intoThycotic One and on the account homepage in the **User Home - Apps** dialog, click **Two-Factor Authentication**.



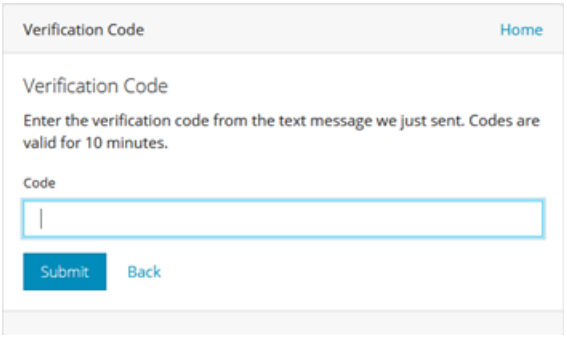
2. Choose **TOTP** and click **Enroll**.



Thycotic One displays a barcode (redacted in the example shown).



3. Using the TOTP app on your mobile device, scan the barcode. You will receive multiple six-digit codes.
4. In the Verification Code field, enter one of the six-digit codes (a new code is generated every 30 seconds).

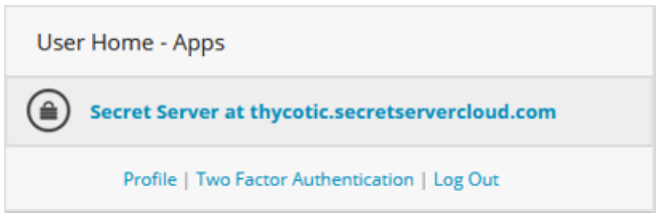


When you have correctly entered and submitted a six-digit code, the setup of TOTP two-factor authentication is complete. From this point forward, each time you attempt to log in you will receive a text message on your mobile device with a code that you must enter to complete the login process.

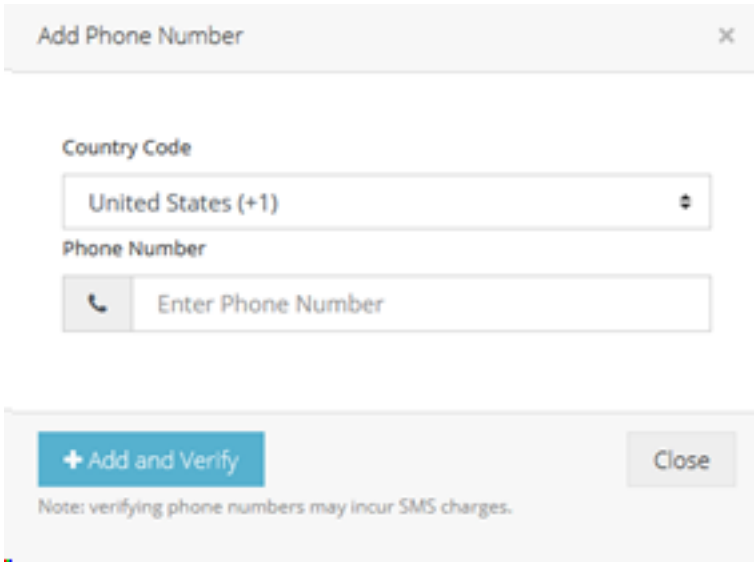
SMS Two-Factor Authentication

To use SMS two-factor authentication with Thycotic One, you must first provide and verify a mobile phone number.

1. To provide a mobile phone number, log into Thycotic One, and on the account homepage in the **User Home - Apps** dialog, click **Profile**.



2. Click **Add Phone** and enter the country code and phone number of a mobile phone that accepts text messages.



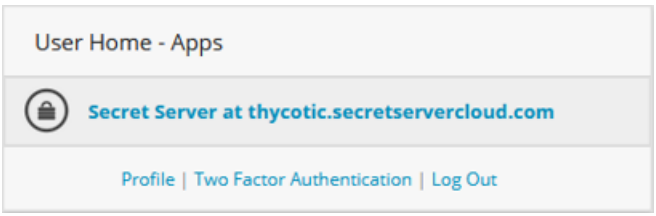
3. Click **+Add** and **Verify**.

   Delinea One sends a text message to the phone number, with a code.

4. Enter the code and click **Submit** in the Verification Code dialog.

   The phone number now appears as Verified on your profile page.

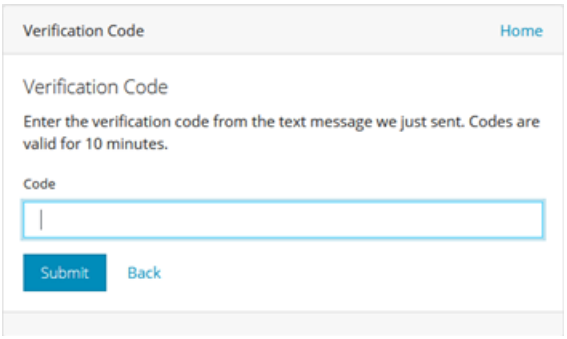
5. 1. On the Thycotic One account homepage in the **User Home - Apps** dialog, click **Two-Factor Authentication**.



6. Choose **SMS** and click **Enroll**.

   Delinea One sends a text message to your phone with a six-digit code.

7. Enter the six-digit code into the box provided.



When you have correctly entered and submitted the six-digit code, the setup of SMS two-factor authentication is complete. From this point forward, each time you attempt to log in you will receive a text message on your mobile device with a code that you must enter to complete the login process.

SAML

SAML (Security Assertion Markup Language) in Secret Server enables secure, single sign-on (SSO) authentication by allowing Secret Server to act as a SAML Service Provider (SP) that communicates with any configured SAML Identity Provider (IDP). This integration facilitates seamless user authentication across various applications and services, leveraging existing identity management systems such as Okta, OneLogin, Azure AD, and Microsoft ADFS.

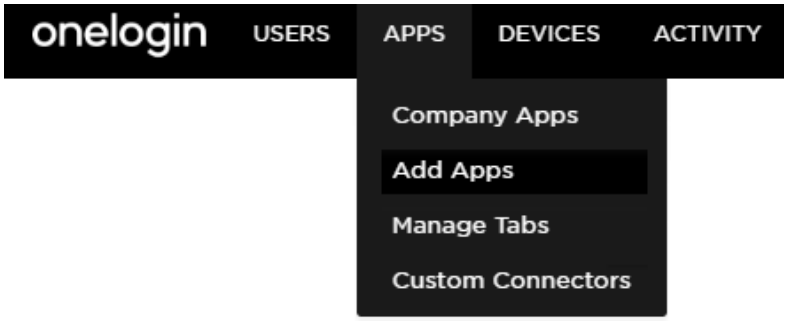
By using SAML, organizations can streamline the authentication process, enhance security through centralized identity management, and provide a consistent multi-factor authentication (MFA) strategy across their environment. Configuring SAML in Secret Server involves setting up the SAML Service Provider, importing the necessary certificates, and configuring the IDP to ensure secure and efficient authentication workflows.

Configuring SAML OneLogin

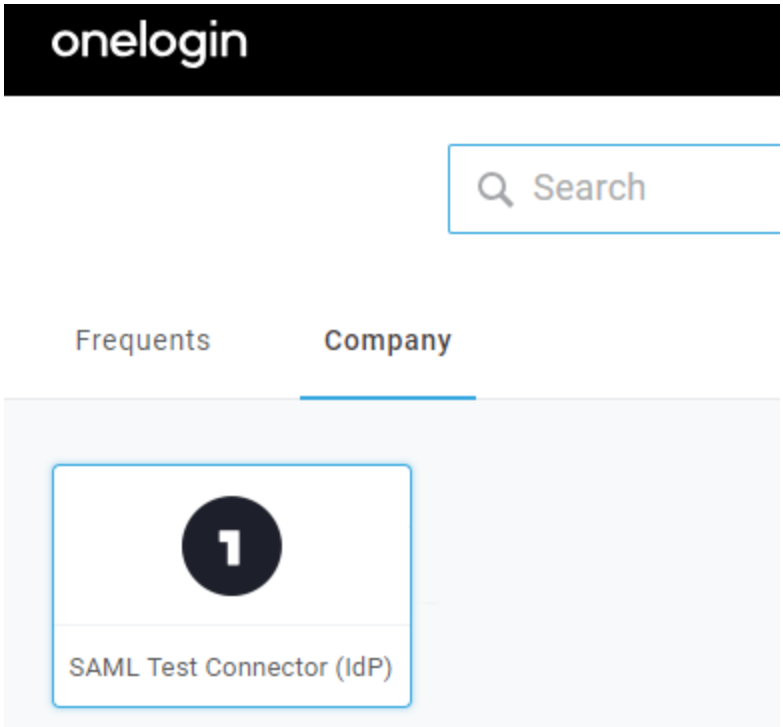
To access Secret Server using OneLogin for SAML, follow the steps below for OneLogin, then follow the steps for Secret Server.

Step One: OneLogin

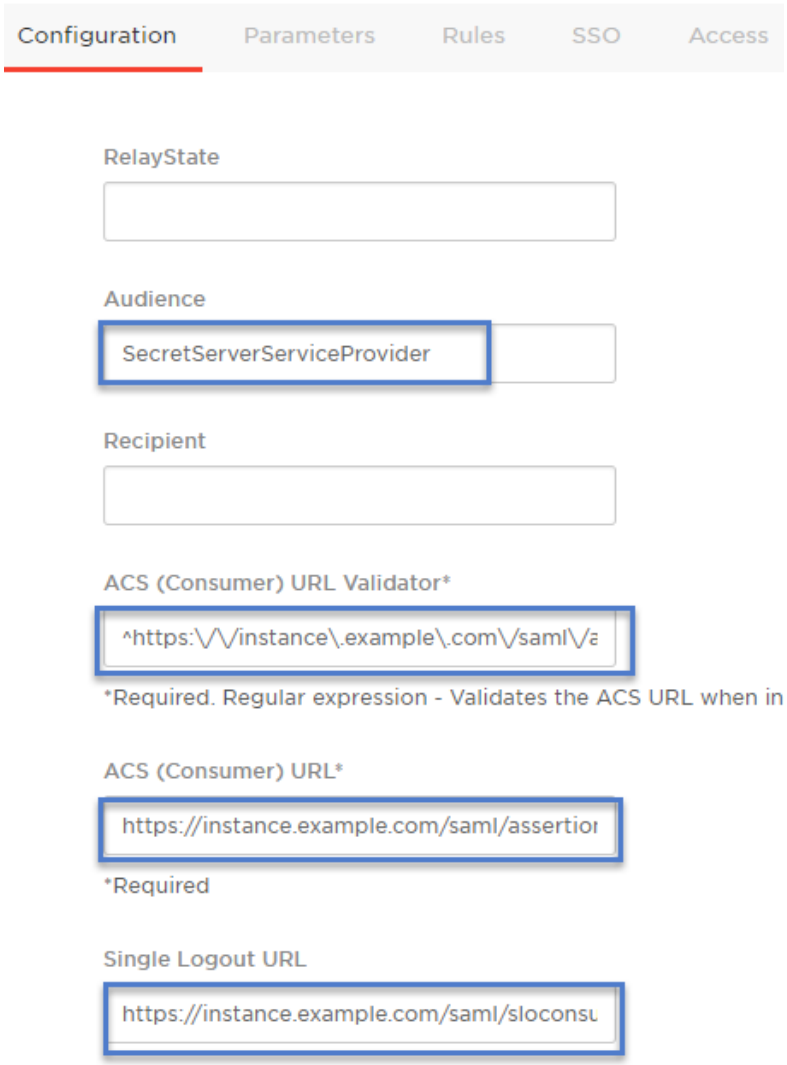
1. Navigate to your OneLogin instance and log in as an administrator.
2. Select **Administration > Apps > Add Apps**.



3. Search for **SAML Test Connector (IDP)** and select it, then click **Save**.



4. Click on the **Configuration** tab and fill out the details as described below:



- **RelayState** can be left blank.
- **Audience** is the name of the Service Provider configured in Secret Server (for instance "SecretServerServiceProvider").
- **Recipient** can be left blank.
- **ACS (Consumer) URL Validator** a required field that needs to be a valid RegEx of the ACS (Consumer) URL.

  Modify the text in the example below according to the URL string of your Secret Server instance:

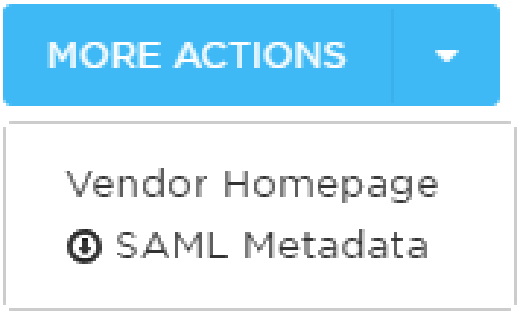
  `https:\/\/instance\.example\.com\/saml\/assertionconsumerservice\.aspx$`
- **ACS (Consumer) URL** like the step above, but no longer in RegEx format.

  Modify the text in the example below according to the URL of your Secret Server:

  `https://instance.example.com/saml/assertionconsumerservice.aspx`

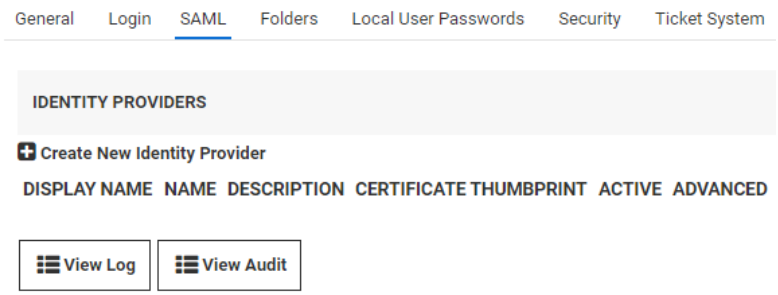
- **Single Logout URL** the Secret Server URL for SLO (Single Logout):
  `https://instance.example.com/saml/sloservice.aspx`

5. Click **Save** when done.
6. Click **More Actions** and **SAML Metadata** to download the metadata for OneLogin.

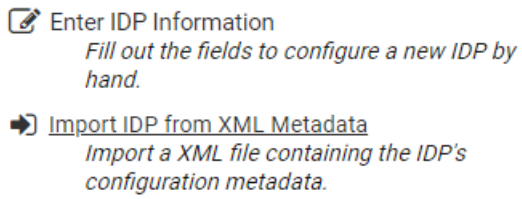


Step Two: Secret Server

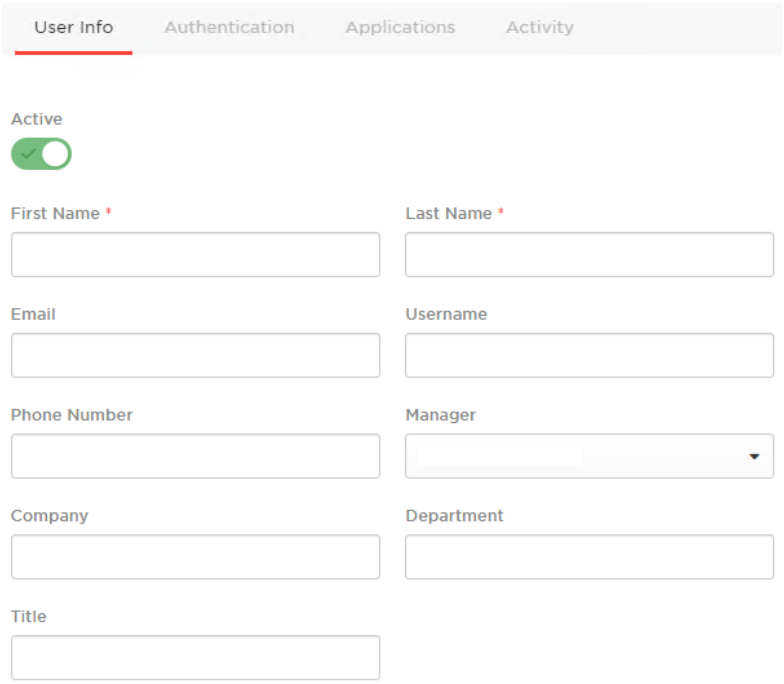
1. Log into your Secret Server instance, then go to **Admin** > **Configuration** > **SAML** tab and click **Create New Identity Provider**.



2. Click **Import IDP from XML Metadata** and select the OneLogin metadata you saved previously. If you don't see the file, you may need to change the metadata filetype to .xml



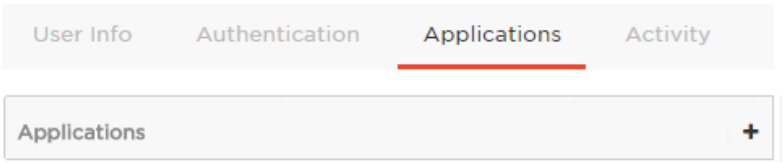
3. To add users to OneLogin, navigate to OneLogin and log in as an administrator once more, then click **Administration** > **Users** > **New User**.



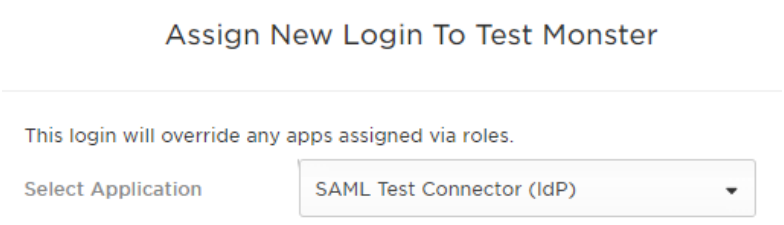
4. Fill out the required information and click **Save** when finished.

> If you are using a Secret Server local account or Secret Server Cloud, the username will be in email format and it must be identical on OneLogin and Secret Server. For an Active Directory account, it should be the samAccountName.

5. Click on the **Applications** tab, then click the plus sign (+).

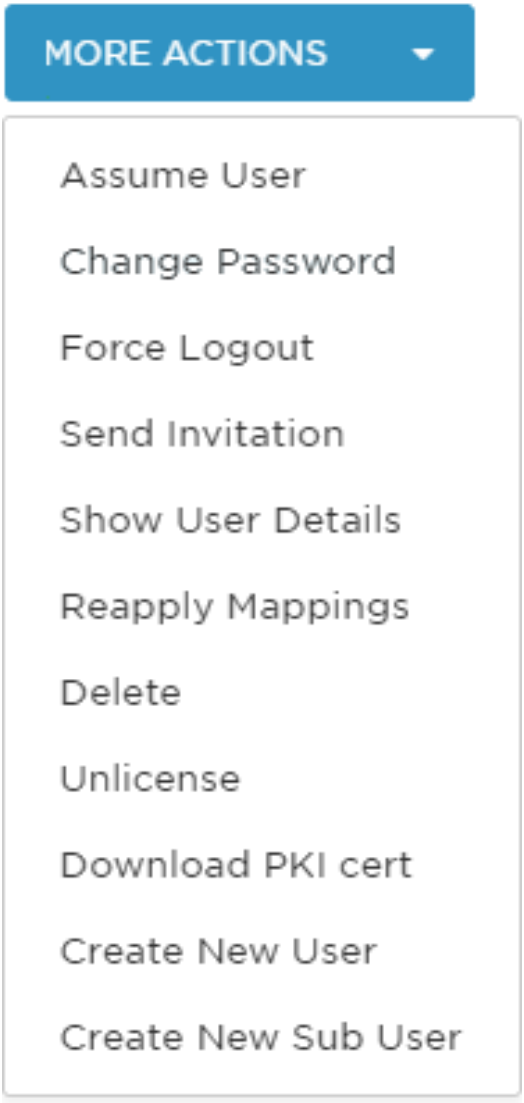


6. Select **SAML Test Connector (IDP)**, then click **Continue**.



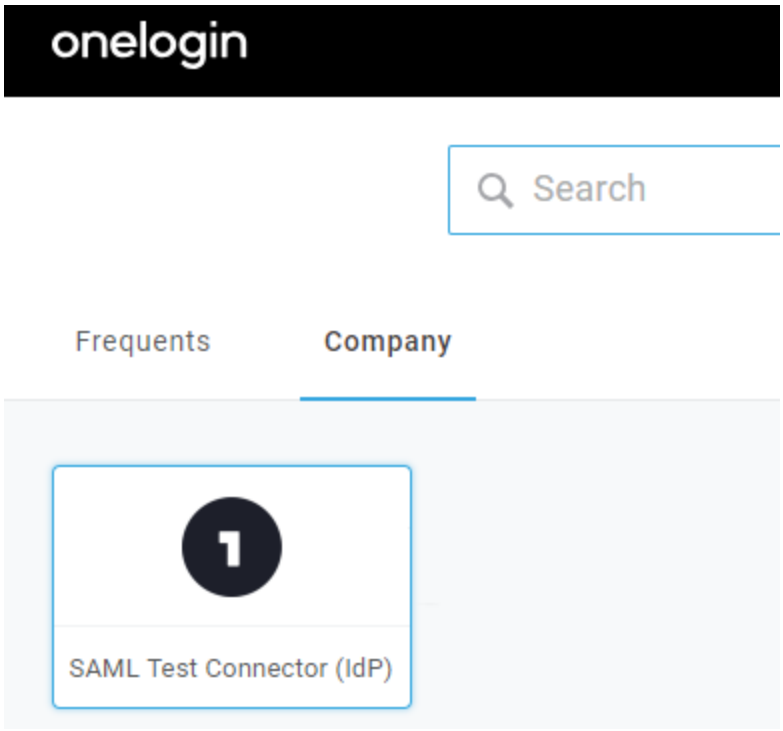
7. Enter the user's Secret Server username (email format) then click **Save**.

8. Mouse over **More Actions** and click **Change Password** to give the user a login password.



9. In another browser or in incognito mode, log into your OneLogin instance as the user you just created. If prompted to add OneLogin to your browser, click **Skip**.

10. You should see the **SAML Test Connector (IDP)**. Click on it to authenticate into Secret Server using the SAML workflow.

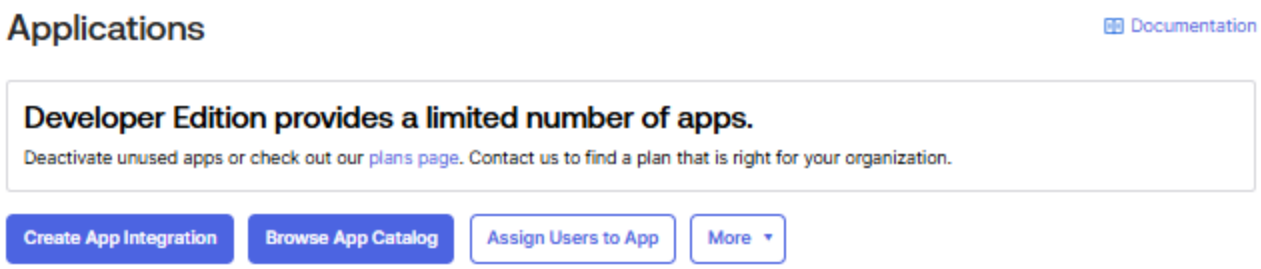


Configuring SAML Okta

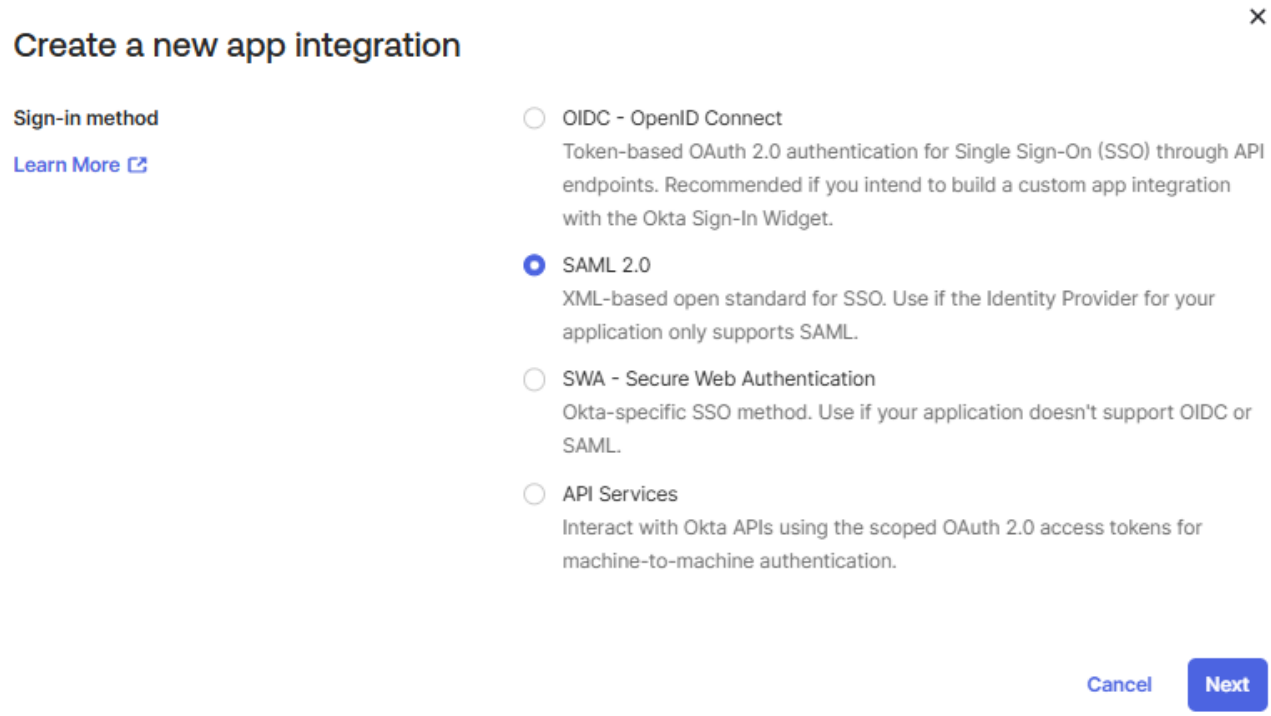
> Note that Okta does not support importing SAML settings directly from a Service Provider metadata file. You must manually enter the required URLs and settings as described above. Ensure you configure the Single sign-on URL, Audience URI (SP Entity ID), and Signature Certificate fields according to your Secret Server instance details.

Creating the Application Integration

1. Log into your Okta instance using an administrative account.
2. From the left-hand menu, click **Applications > Applications**.
3. Select **Create App Integration**:



4. In the **Create a new app integration** pop-up, select **SAML 2.0**, and click **Next**:



5. The **Create SAML Integration** page loads.
6. In the **General Settings** tab, type the preferred name (for example, SecretServer) in the **App name** field, and click **Next**.

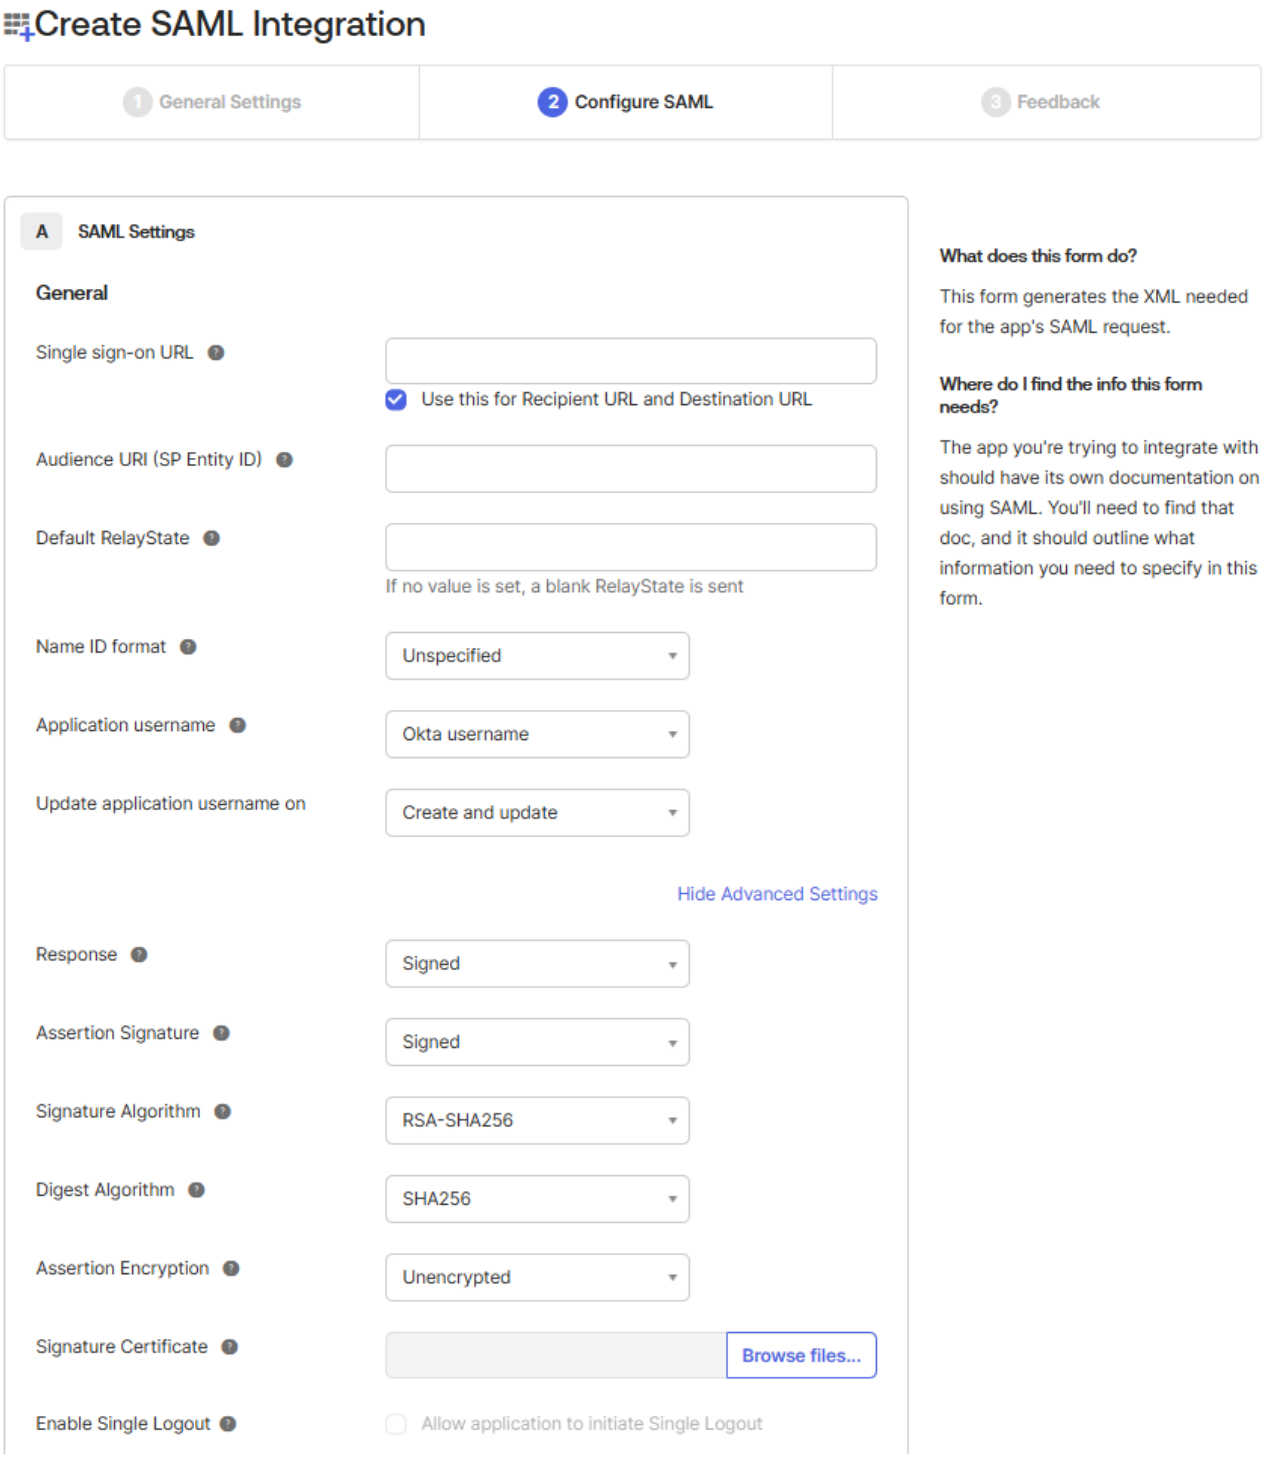
> The App name field is the only required input on this screen.

7. In the **Configure SAML** tab, in the **A SAML Settings** section, under **General** fill in the following mandatory fields:
   - **Single sign-on URL**: your [SecretServerInstanceName] URL.

     For example: https://[YourSecretServerInstance.com]/saml/assertionconsumerservice.aspx
   - Make sure the **Use this for Recipient URL and Destination URL** checkbox is selected.

- **Audience URI (SP Entity ID)**: SecretServerServiceProvider.
- **Default RelayState**: leave the field blank.
- **Name ID format**: select **Unspecified** from the dropdown list.
- **Application username**: select **Okta username** from the dropdown list.

8. Click **Show Advanced Settings** . A plethora of settings will load.
9. Look for the **Signature Certificate** option:



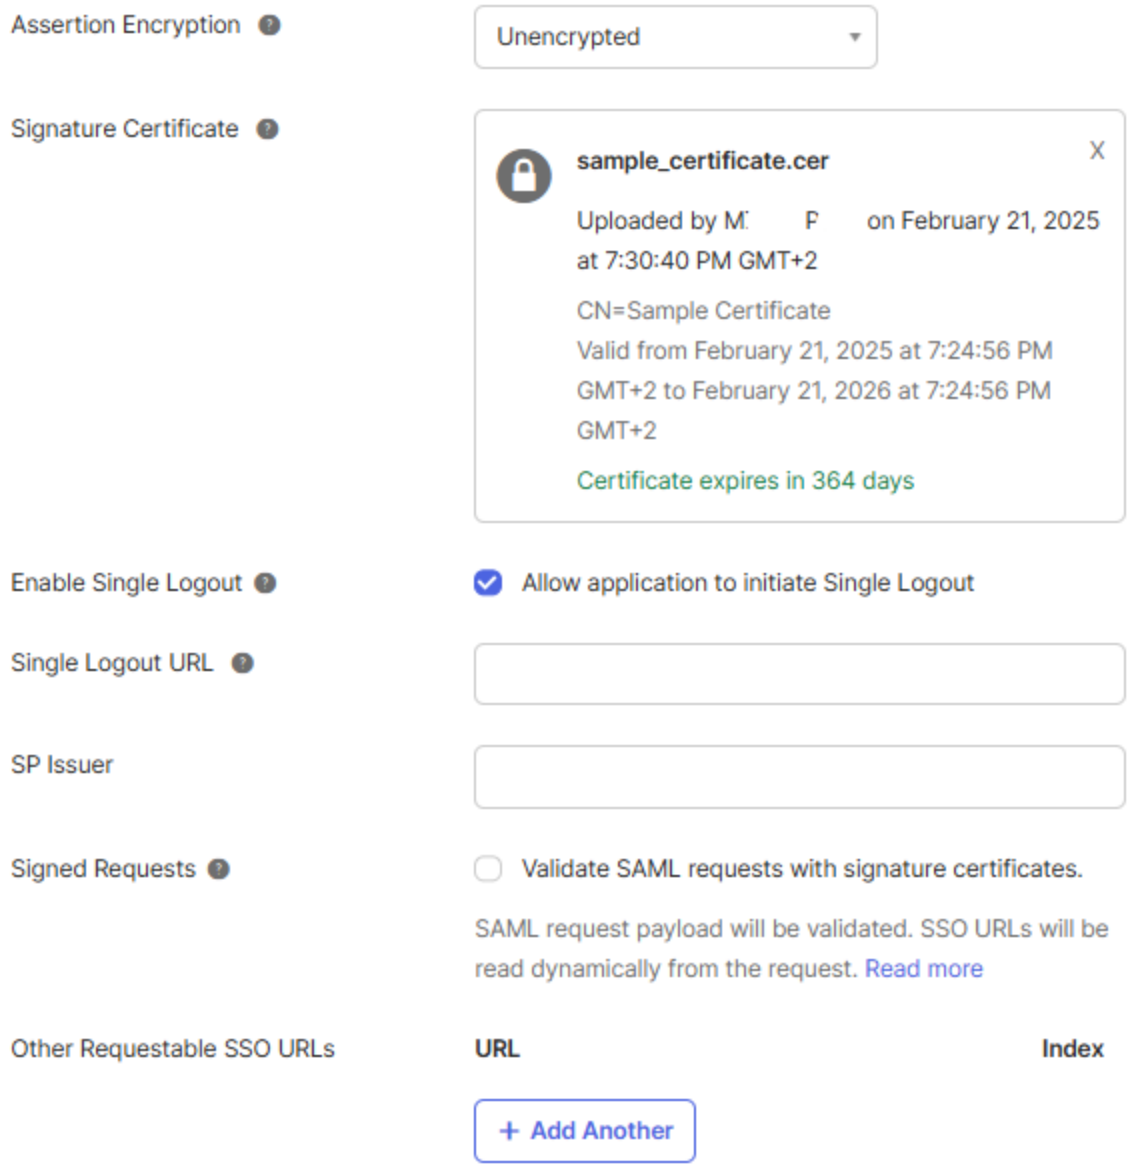
10. Click **Browse files...** to locate your public key `.cer` file.

    The public key (".cer") can be extracted using several methods, including OpenSSL, the Windows keychain, or through PowerShell. For a straightforward approach, you can use the following PowerShell command:

```
(Get-PfxCertificate -FilePath C:\Path\To\Your\File.pfx).GetPublicKey().
```

> The file corresponds to the .pfx file uploaded to your Secret Server instance. See "Configuring SAML Single Sign-on" on page 431 for details on configuring SAML SSO and uploading Certificates.

11. Once chosen, the `.cer` file displays in the **Signature Certificate** field.
12. Select the **Enable Single Logout** checkbox below the **Signature Certificate** field:



13. Configure the Single Logout (SLO) Settings as follows:

- **Single Logout URL**: your [SecretServerInstanceName] followed by the URL string: /saml/sloservice.aspx.

  Example: https://[YourSecretServerInstance.com]/saml/sloservice.aspx
- **SP Issuer**: SecretServerServiceProvider

14. Click **Next**.
15. (Optional) In the **Feedback** page, provide feedback.
16. Select **Finish**. The "SecretServer" integration has now been created.

Required SAML Claim Attributes for Secret Server

When configuring Okta as the SAML Identity Provider for Secret Server, ensure the following claim attributes are included in the SAML assertion:

- **NameID**: This is the primary identifier for the user. It should match the username format in Secret Server. For AD-synced users, this is typically SecretServerUsername@ADsyncDomain or ADsyncDomain\SecretServerUsername. For local users, it should be the Secret Server username.
- **Format**: The NameID format should be set to "Unspecified".
- **Application username**: Set to "Okta username" in the Okta SAML settings.

> If your environment uses different sAMAccountName and userPrincipalName values in Active Directory, you may need to create custom claim rules in Okta to ensure the correct username format is sent to Secret Server. See ADFS Custom Rules for Differing UPN and SAM Account Names for an example of how to handle this scenario in ADFS. For Okta, use the equivalent attribute mapping to ensure the correct username is sent.

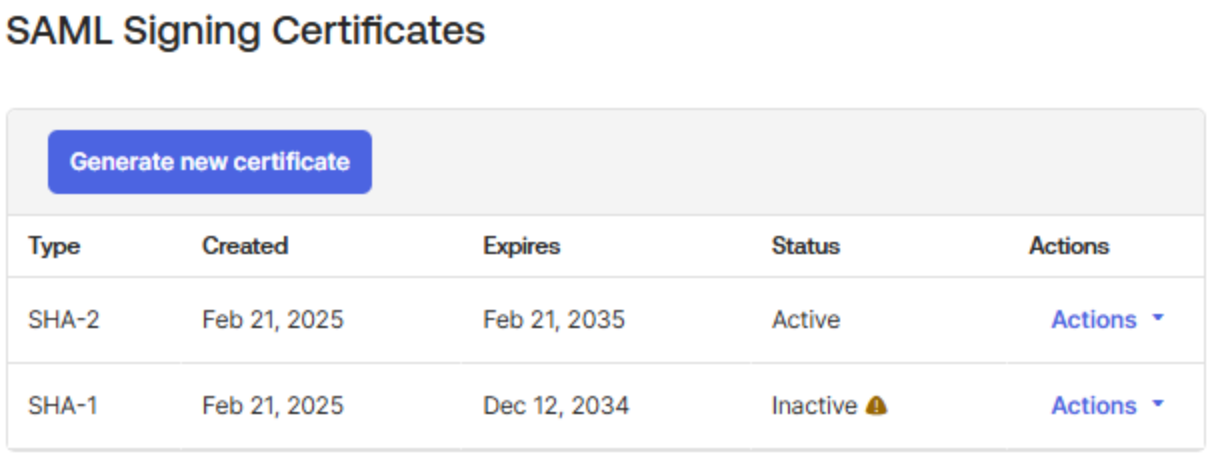
Example Attribute Mapping

- **NameID**:
  - Okta Setting: Okta username
  - Secret Server Expectation: Secret Server username
  - Notes: Format should be "Unspecified". Must match the username in Secret Server.
- **Audience URI (SP Entity ID)**
  - Okta Setting: SecretServerServiceProvider
  - Secret Server Expectation: SecretServerServiceProvider
  - Notes: Must match the SP Entity ID configured in Secret Server.
- **Single sign-on URL**
  - Okta Setting: https://[YourSecretServerInstance.com]/saml/assertionconsumerservice.aspx
  - Secret Server Expectation: Assertion Consumer Service URL
  - Notes: Use for both Recipient and Destination URL in Okta SAML settings.
- **Application username**

- Okta Setting: Okta username
- Secret Server Expectation: Secret Server username
- Notes: Set to "Okta username" in Okta SAML settings.

Downloading the IDP Metadata File

1. In your Okta instance access **Applications > Applications**, and click on the **Active** option under **Status**.
2. Select the SAML app you previously created "SecretServer". The app opens on the **Assignments** tab.
3. Select the **Sign On** tab.
4. Go to the **SAML Signing Certificates** section and look for the certificate marked **Active** in the status column.
5. Select the **Actions** dropdown menu for that certificate and click **View IdP Metadata**:



6. Once the IdP metadata page loads displaying the XML file, right-click the page and select **Save As** or **Save Page As** (depending on the browser).
7. Save the XML file as `metadata.xml`. You will need this file to create the new SAML Identity Provider in Secret Server.

Configuring SAML in Secret Server for Okta

1. Log into Secret Server.
2. Access **Settings > Configuration > SAML > Identify Providers**.
3. Select the **Create New Identity Provider** button.
4. In the Identity Provider popup, select the **Import IDP from XML Metadata** option from the dropdown. The **Import file** option appears.
5. Click the **Change** link to import the Okta metadata XML file you saved earlier.
6. Click **OK**.

Verifying the Integration

Ensure that the integration works by testing the SAML login process. Users should be able to log into Secret Server using their Okta credentials without being prompted for additional login information. This setup will allow you to use Okta as the Identity Provider for SAML-based single sign-on in Secret Server, streamlining user authentication and enhancing security.

Configuring SAML Single Sign-on

This topic is for Secret Server v10.5 and later and assumes you have a running Identity Service Provider (IDP) with a signed certificate.

Secret Server does not support using SAML when Integrated Windows Authentication (IWA) is enabled.

This topic applies to Secret Server 10.5 and later.

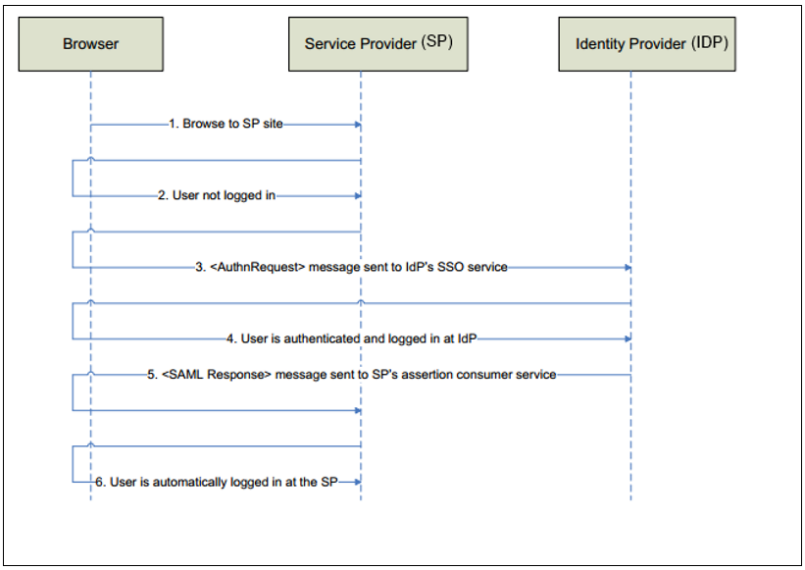
Sometimes SAML validates despite having an expired IDP Certificate. This is because the SAML certificate exchange is actually a key exchange—the SAML protocol uses the public/private keys contained within the certificate to secure the communication. Unlike a website's certificate, it is not the URL or metadata within the certificate that is used to help secure the connection, only the key exchange. If the certificate provided by the IDP has been renewed but still works without a change in Secret Server, it means the key is identical, and only the metadata, such as the expiration date, has changed. This is why it does not fail validation—the key is for validation and it has not changed. Had the key changed, Secret Server would not be able to decrypt the SAML messages, and would therefore fail. Delinea does not view this as a security problem and offers this note for clarification.

SAML Overview

Secret Server allows the use of SAML Identity Provider (IDP) authentication instead of the normal authentication process for single sign-on (SSO). To do this, Secret Server acts as a SAML Service Provider (SP) that can communicate with any configured SAML IDP.

In the diagram below, Secret Server acts as the service provider. Any configured SAML IDP can be used for this process and there are several well tested providers, including OKTA, OneLogin, Azure ADFS, and Microsoft ADFS.

Figure: Secret Server as a SAML Identity Provider



Prerequisites

Licensing and Version

Secret Server Professional Edition or higher, upgraded to version 10.5 or later. To install a new SAML license, Search for **Install New License**.

.NET Framework 4.6.2+

To use SAML 2.0, you must install .NET Framework 4.6.2 or higher on your Web server. This allows Secret Server to use Microsoft's "next generation" CryptoNG API for signing SAML requests, instead of being limited to the much older CryptoAPI. This is often necessary to use modern SSL certificates and is strongly recommended as a security best practice.

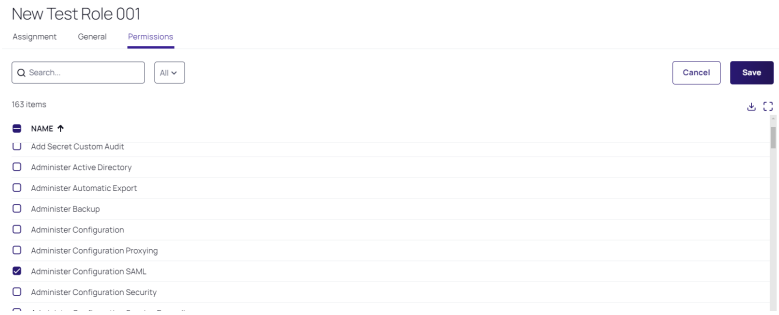
To download and install the latest version of .NET Framework: See Microsoft .NET Framework 4.8 offline Installer for Windows for the latest version as of when this topic was written. If you have already installed Secret Server on the same Web server, you have already done this.

Administer Configuration SAML Role Permission

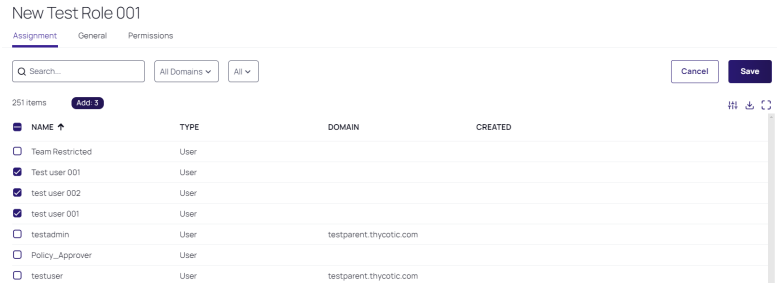
The "Administer Configuration SAML" role permission is required to configure SAML settings (no specific permission is required to access Secret Server via SAML). To grant a user this permission from an administrator account:

1. Search for **Roles**. The Roles page appears.
2. Click the **Create Role** button. The Create Role window appears:

3. Type the name, such as `SAML`, in the **Name** text box.
4. Click to select the **Enabled** check box.
5. Click **Create Role**. The role is created and the role page is now opened.
6. Under the **Permissions** tab, click the **Edit** button.
7. Select **All** next to the search box, select **Administer Configuration SAML** from the list, and click **Save**.



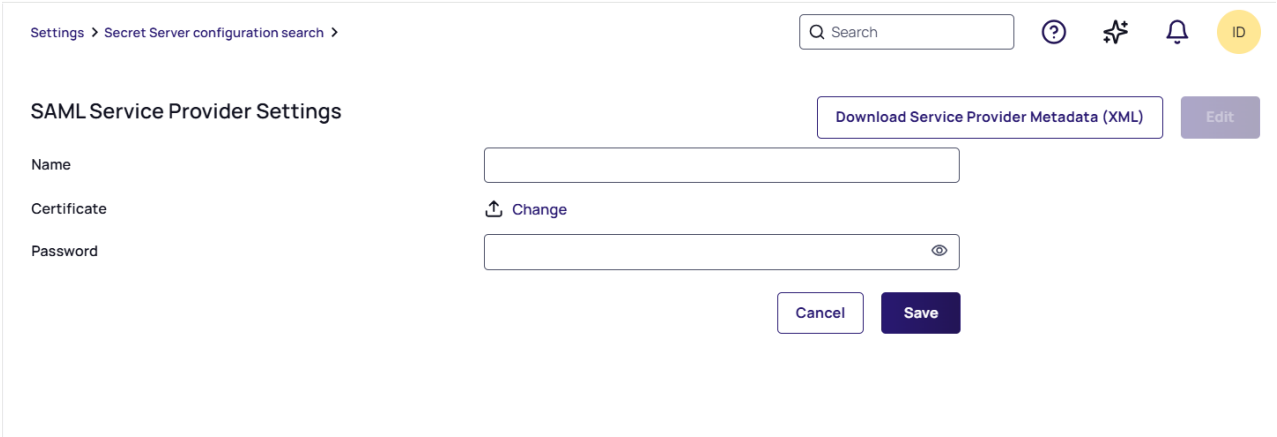
8. Under the **Assignments** tab, click **Edit**, select **All** next to the search box, select the users that you would like to assign to the role, and click **Save**.



Setting up Secret Server

1. Search for **Configuration Search**.
2. In the **SAML** section, click **General Settings**.
3. Click the **Edit** button.
4. Click to select the **SAML Enabled** check box.
5. Click the **Save** button.

6. Once you have SAML setup on our identity provider, go back to the **Settings** page and click **Service Provider Settings** in the **SAML**, section.
7. Click **Edit**.
8. Type a name for your Secret Server service provider, such as `SecretServerServiceProvider`, in the **Name** text box.
9. Click the **Change** button. The Upload Certificate popup appears:



What type of certificate can be used?

- The uploaded SAML certificate requires a `.pfx` file format.
- For on-premises instances: The uploaded certificate should match the one used for Secret Server's HTTPS configuration, **or** it can be created as a self-signed certificate using "Generating Self-Signed Certificates for Scripts" on page 1488.
- For Secret Server Cloud users: Generate your own certificate using the same PowerShell script.

> Run the referenced PowerShell script as an administrator on a machine with .NET 4.5 or above and replace the variables in the script as directed. Your certificate is created in the directory from which you run the script. The subject name on the certificate is irrelevant, though for on-premises instances it typically matches the URL of the instance.

10. Locate your certificate `.pfx` file and select it.
11. Click the **Open** button. The new certificate appears.
12. Type the access password for the private key of the certificate in the **Password** text box.
13. Click the **OK** button. The certificate is uploaded and tested, and the popup disappears. The certificate now appears in the SAML Service Provider Settings section.

> If you have an outdated version .NET Framework (earlier than 4.6.2), you may see an error recommending you upgrade to fix the error. Reload the certificate after you do so.

14. Click the **Save** button.
15. Click on **Download Service Provider Metadata (XML)** to download the `SecretServerSAMLMetatdata.xml` file. This file is needed when setting up SAML on your Identity Provider.
16. Set up your Identity Provider using the `SecretServerSAMLMetadata.xml` file from the previous step. Go to portal.azure.com and navigate to **Microsoft Entra ID**> **Enterprise Applications**.
17. Click the **Create New Identity Provider** link. An Identity Provider popup appears.
18. Click the **Import IDP from XML Metadata** button.
19. Navigate to your `SecretServerSAMLMetadata.xml` file and select it.
20. Click the **Open** button.

Setting up IDPs

IDP setup varies by provider. For Entra ID, go to "Setting up Entra ID for SAML" on page 438. For all other IDPs, go to the TDP Integration site for instructions for your provider.

The username returned from the IDP to Secret Server within the SAML Response/Assertion's subject statement must match the desired format. The format of the username passed depends upon how the user was created within Secret Server. Users must be present in the User Management section to set up SAML.

If AD Sync was used to create Secret Server users, the username returned from the IDP must match this format: `SecretServerUsername@ADsyncDomain` or`ADsyncDomain\SecretServerUsername`. If using SLO, ensure that the NameID is set correctly in the IDP as an outgoing claim for the Secret Server Service Provider. If a user has different sAMAccountName and userPrincipalName in Active Directory, custom rules in the IDP can be created. This requirement is applicable not only to Active Directory but also to OpenLDAP and Entra Integration. Regardless of the directory service used, the username or UPN values in the tbUser table must be utilized. If there is no UPN, then at least the domain\username from the tbUser table should be passed. And for the local users, it should simply pass the username value.

When using Single Logout (SLO), ensure that the NameID is correctly set in the IDP as an outgoing claim for the Verify Privilege Vault Service Provider. In cases where a user has different sAMAccountName and userPrincipalName, custom rules in the IDP can be created to address this difference.

Lockout Workaround

Locked Out? Here's how you get around SSO. If during the configuration process for SAML you lock yourself (as an administrator or a user) out of Secret Server, you can log on Secret Server without using the SSO workflow by using this URL string:

`[YourSecretServerInstanceName]/login.aspx?preventautologin=true`

The role permission needed for this is "Bypass SAML Login," which admins have by default.

Generate a Self-Signed Certificate for Secret Server Using PowerShell

The script and steps required to generate a self-signed certificate can be found at "Generating Self-Signed Certificates for Scripts" on page 1488. This script can be used for the SAML configuration in a Secret Server instance. For additional information, refer to Configuring SAML Single Sign-On.

> Replace the variables in the script, as directed, and be sure to run the PowerShell script as an administrator on a machine with .NET 4.5 or above. The self-signed certificate will be created in the directory from which the script was run (e.g., C:\Users\Administrator).

> The subject name on the certificate is irrelevant. Although for Secret Server On-Premises, it typically matches the URL of the instance.

Configuring SAML SSO with Entra ID

> For more information on how to setup SAML-based single sign-on for Secret Server in Entra ID, see Microsoft's Enable SAML single sign-on for an enterprise application .

> You must have SAML already setup in Secret Server with a valid certificate. See the Setting up Secret Server section in "Configuring SAML Single Sign-on" on page 431.

1. Log into your portal.azure.com account.
2. Navigate to **Entra ID**.
3. Navigate to **Enterprise Applications**.
4. Select **New Application**.
5. Select **Non-gallery application**.
6. Give your new IdP application a name and click **Add**.
7. Click **Single sign-on**.
8. In the dropdown, select **SAML-based Sign-on**.
9. If you haven't done so already, download the Secret Server metadata file named `SecretServerSAMLMetadata.xml` from `[YourSecretServerInstance.Name]/samlmetadata`:
   a. In Secret Server, navigate to **Administration**.
   b. Type SAML in the combination box. The Section Matches section populates with sections matching what you typed.
   c. Click the **SAML Service Provider Settings** link. The SAML Service Provider Settings page appears.
   d. Click the **Download Service Provider Metadata (XML)** button. The SecretServerSAMLMetatdata.xml file downloads to your browser's default location.

> For more information on setting SAML up in Secret Server, please see See the Setting up Secret Server section in "Configuring SAML Single Sign-on" on page 431.

10. Click **Upload metadata file** and upload the Secret Server Metadata file you previously downloaded.
11. Click **Save**.
12. Scroll down and click **Metadata XML** to download the metadata for this application.
13. Go back to **Entra ID** and click on **App registrations**.
14. Select your Entra ID Provider application.

> If you don't see the application immediately, you might need to click View all Applications.

15. Click **Settings > Properties**, then enter the Logout URL field for your instance. The form for this URL will be: https://`[YourSecretServerInstanceName]/saml/SLOService.aspx`.
16. Click **Save**.
17. Return to the **Configuration** search box and type `Identity Providers`.
18. Click on the **Identity Providers** link that appears in the **Section Matches** section. The SAML Identity Providers page appears.
19. Click the **Create New Identity Provider** button. The Identity Provider popup appears.
20. Click the **New Identity Provider** dropdown list and select **Import IDP from XML Metadata**. An Import File control appears.
21. Click the upload icon and select the XML file you downloaded earlier. If you do not see the file where it should be, ensure the file type is set to XML.
22. Click the **OK** button.

Adding Users to Single Sign-On in Entra ID

For users to be authenticated by the SSO workflow you are setting up, Secret Server usernames must match Entra ID usernames. If you manually add usernames to Secret Server or Entra ID, you must inspect them carefully to ensure that they match. You can also use Secret Server Discovery to sync Secret Server usernames in bulk with Entra ID usernames.

1. Log into your portal.azure.com account.

   Navigate to **Entra ID > Enterprise Applications** and select your IdP from the list
2. Select **Users** and groups and **Add User**.
3. Click **Users and groups/None Selected**.
4. Search for the user you want to add to your SAML workflow. (Note that any users added must also exist in your Secret Server instance. Usernames must match between the systems).
5. Click **Select** at the bottom, then **Assign**.

Once a username matches in both systems, the user should be able to use the Single Sign-On workflow. To test this, log into Entra ID as the user, then browse to your Secret Server instance. The user should be logged into Secret Server automatically without being prompted again for login credentials.

> If you have accounts in which the sAMAccountName differs from the UPN name, you can create custom rules to accommodate the differences. See "Directory Services" on page 508.

Advanced Settings

The following Secret Server Identity Provider Advanced Settings can be configured in Entra ID:

- Require Signed SAML Response
- Require Signed Assertion
- Require Signed Assertion Or Signed SAML Response

Below are the steps to configure the settings in Entra ID:

1. Log in to portal.azure.com.
2. Navigate to **Entra ID > Enterprise Applications**.
3. Select your IdP, then click **Single sign-on**.
4. Scroll down and check the box for **Show advanced certificate signing settings** checkbox.
5. Click the drop-down arrows to reveal options. These advanced options correspond with advanced options in Secret Server.
6. Click **Advanced Settings** next to your identity provider.
   - Require Signed SAML Response
   - Require Signed Assertion
   - Require Signed Assertion Or Signed SAML Response

> If you apply advanced certificate signing settings to the Secret Server IdP application in Entra ID, return to the Identity Providers page in Secret Server and click the … button next the provider and select Advanced Settings to apply the same settings.

Setting up Entra ID for SAML

For the detailed information on how to setup SAML-based single sign-on for Secret Server in Entra ID, see Microsoft's Enable SAML single sign-on for an enterprise application.

> Users must have Entra Domain Services already configured to use Entra ID.

Adding Users to Single Sign-On in Entra ID

Follow the steps in Register the user account guide to learn how to register a user account for your application.

If you have accounts in which the sAMAccountName differs from the UPN name, you can create custom rules to accommodate the differences. See "Directory Services" on page 508.

Entra ID Configuration Steps

For more information on how to setup SAML-based single sign-on for Secret Server in Entra ID, see Microsoft's Enable SAML single sign-on for an enterprise application.

You must have SAML already setup in Secret Server with a valid certificate. See the Setting up Secret Server section in "Configuring SAML Single Sign-on" on page 431

Follow the steps in Configure SAML setting to register a user account for your application.

Advanced Settings

The following Secret Server Identity Provider Advanced Settings can be configured in Entra ID:

- Advanced certificate signing options in a SAML token
- SAML Request Signature Verification
- Configure SAML token encryption

If you apply advanced certificate signing settings to the Secret Server IdP application in Entra ID, return to the Identity Providers page in Secret Server and click the **...** button next the provider and select **Advanced Settings** to apply the same settings.

Custom claims can be configured within the Azure Enterprise Application in order to match the incoming claim to the Secret Server username.

Smart Card Integration with Secret Server

Since Secret Server uses IIS to run the web application, we use IIS for smart card authentication. See Authenticate Clients Using Smart Cards for details.

We recommend enabling **Integrated Windows Authentication** in Secret Server if the users are AD users. In this way, Secret Server will not prompt for credentials if the user is authenticated to AD. IIS will authenticate users based on the smart card certificate, and Secret Server will allow the user through since they are logged in as an AD user.

To accomplish this operation, three tasks need to be completed:

1. Configure Client Certificate Authentication in IIS (Learn more).
2. Configure Windows Authentication in IIS (See "Configuring Integrated Windows Authentication" on page 389.
3. Configure Windows Authentication in Secret Server.

Configuring Windows Authentication in Secret Server

1. Install the **Client Certificate Mapping Authentication** and the **IIS Client Certificate Mapping Authentication** role services for IIS.
2. Reboot.
3. In the IIS manager, highlight the server and click **Authentication**.
4. Enable **Active Directory Client Certificate Authentication**.
5. Highlight the virtual folder for Secret Server, and click **SSL Settings**.
6. Select the **Require SSL** checkbox.
7. Select **Accept** under **Client Certificates**.
8. Edit the `%windir%\system32\inetsrv\config\applicationhost.config` file by adding the code snippet below, under the existing `<windowsAuthentication enabled="false" />` line:

```
<clientCertificateMappingAuthentication enabled="true" />
```

9. Enable **Integrated Windows Authentication** in Secret Server.

The next time a user goes to Secret Server, if a smart card is inserted, they will be prompted for smart card credentials, otherwise they are redirected to the login screen.

> If you experience a performance issue with the first login, it may be related to the **SSLAlwaysNegoClientCert** property. See "Changing IIS to Not Stop Worker Process in IIS 7.0 and Later" on page 254 for details.

SSH Key Verification Overview

SSH key verification is a process used to ensure that the SSH key you are connecting with belongs to the intended server or host. It is an essential security measure to prevent man-in-the-middle (MITM) attacks, where an attacker can intercept the connection and impersonate the server or host.

Here's how SSH key verification works:

1. **Host Key Fingerprint**: When you connect to an SSH server for the first time, the server sends its public host key to the client (your computer). This public key has a unique fingerprint or hash, which is displayed on the client's terminal.
2. **Verifying the Fingerprint**: You should compare the displayed fingerprint with the known and trusted fingerprint of the server. This trusted fingerprint can be obtained from the server administrator or from a trusted source, such as the server's website or documentation.
3. **Accepting or Rejecting the Key**: If the displayed fingerprint matches the trusted fingerprint, you can choose to accept and add the server's public key to your client's known-hosts file. This file stores the trusted public keys of the servers you have connected to before.

4. **Future Connections**: On subsequent connections to the same server, the client will check if the server's public key matches the one stored in the known_hosts file. If the keys match, the connection is allowed. If the keys do not match, the client will warn you about a potential MITM attack, and you can choose to accept the new key or abort the connection.

SSH key verification is crucial because it ensures that you are connecting to the intended server and not an impersonator. If an attacker intercepts the connection and tries to impersonate the server, the attacker's public key will not match the trusted key stored on your client, and the connection will be rejected or flagged as potentially insecure.

It is important to note that SSH key verification should be done carefully, especially when connecting to a server for the first time. You should verify the fingerprint through a trusted channel (such as, contacting the server administrator or checking the server's official documentation) to ensure that you are not accepting a rogue key from an attacker.

SSH key verification is an essential security practice that helps protect against MITM attacks and ensures the integrity and confidentiality of your SSH connections.

Server SSH Key Verification

Host SSH key verification is supported for use with heartbeat, proxied launchers, password changers, and discovery. Host SSH key verification can be used to ensure that the machine you are connecting to is a trusted host. Host SSH key verification will not pass credentials to the target machine unless the public key digest matches the SHA1 digest that Secret Server has on file. This helps prevent man-in-the middle attacks.

How to Map a Server SHA1 Digest to a Secret

To configure host SSH key verification:

1. go to Secret Templates and add a field for the host's SSH key digest.
2. Click **Configure Extended Mappings**.
3. Add a "Server SSH Key" mapping to your newly created SSH key digest field.
4. On your secrets, add the SSH Key digest of the hosts to your digest field. Verification takes effect the next time you connect to the host.

Heartbeat

If no "Server SSH Key" mapping exists for the secret or if the mapped digest field is blank, the digest will not be checked. If a digest is mapped and present and it does not match, then heartbeat will fail with a "UnableToValidateServerPublicKey" error. The heartbeat log will show the expected and actual values for the SHA1 digest.

Password Changing

If no "Server SSH Key" mapping exists for the secret or if the mapped digest field is blank, the digest will not be checked. If a digest is mapped and present and it does not match, then the password change will fail. The Remote Password Changing log will show the expected and actual values for the SHA1 digest.

Non-Proxied Launcher

When launching PuTTY, it displays a message if the server's public key digest is not yet trusted.

Proxied Launcher

If no "Server SSH Key" mapping exists for the secret or if the mapped digest field is blank, the digest will not be checked. If a digest is mapped and present and it does not match, then a message will be written to PuTTY displaying the expected and actual values for the SHA1 digest. The credentials from the secret will not be passed to the target machine.

SSH Script Dependencies

SSH Script dependencies now have a "Server Key Digest" field. When this field is blank, the server's digest will not be checked. When it is filled in, if it does not match, an error is returned indicating the expected and actual values from that server. No credentials are passed to the target machine unless the digest matches.

Unix Account Discovery

To validate SHA1 server digests for Unix account discovery, create a file named `KeyDigests.txt` in the root of the Secret Server website. Each line should contain an IP address or other computer identifier, a comma, and then the SHA1 digest (see example below). When the file exists and has data, all machines to be scanned must match one of the SHA1 hashes in the file. Any computers that do not match will still show up on the Discovery Network View page, but authenticated scanning will not take place (no credentials will be passed to the machine, and accounts will not be retrieved from the machine).

Sample `KeyDigests.txt`:

```
192.168.1.5,7E:24:0D:E7:4F:B1:ED:08:FA:08:D3:80:63:F6:A6:A9:14:62:A8:15
apollo,7A:25:AB:38:3C:DD:32:D1:EA:86:6E:1C:A8:C8:37:8C:A6:48:F9:7B
```

Be sure that your digest value which you input into `KeyDigests.txt` is not an MD5 value. MD5 values are 32 bytes, whereas a SHA1 is 40. So the above is correct whereas if you obtain a digest of your public key file and the result has 32 bytes, this is likely an MD5. One command which could be used to obtain the SHA1 digest of the public key file for use in `KeyDigests.txt` is:

```
awk '{$print $2}' id_xxx.pub | openssl base64 -d -A | openssl sha1
```

After which, you should add `:` to every two characters to the output such that it matches the above. We will try to connect to the keys which we have the strongest preference for first in the event of multiple keys and it is legal to have multiple digests for the same IP address or hostname in the file. In the event of multiple keys on your system, it is usually correct to get the digest from `/etc/ssh/ssh_host_rsa_key.pub` and put it into `KeyDigests.txt` if this public key exists.

SSL and Secret Server

Secret Server employs SSL (Secure Sockets Layer) to ensure that all communication between the user's web browser and the Secret Server application is encrypted, providing a secure channel for data transmission. By using SSL, Secret Server protects sensitive information such as passwords, secrets, and user credentials from being

intercepted by unauthorized parties during transit. SSL also helps in verifying the identity of the server, mitigating the risk of man-in-the-middle attacks. Administrators can enforce SSL by enabling the "Force HTTPS/SSL" option in the Secret Server configuration, ensuring that all access to the application is conducted over HTTPS. Additionally, Secret Server supports HTTP Strict Transport Security (HSTS) to further enhance security by instructing browsers to only interact with the server over secure connections.

Installing Self-Signed SSL Certificates

Overview

An SSL (Secure Sockets Layer) certificate greatly enhances the security between the user's browser and the server your Secret Server is installed on. It encrypts all data between the server and the client's browser so if an attacker were to look at the data being transmitted between the two, they would not be able to decipher it.

> SSL is required when using Integrated Windows Authentication.

Obtaining an SSL Certificate

You can get a certificate from various companies such as Thawte or VeriSign. If you already obtained a certificate from one of them, please follow their instructions for installing their certificates.

> Delinea does **not** provide certificates.

Installing a Self-Signed Certificate

You can create your own certificate for trial or sandbox environments:

> This requires IIS 7 or later.

Task One: Generate an IIS Self-Signed Certificate

1. Open IIS manager (**inetmgr**) on your Web server.
2. Click on the server node (one of the root nodes) in the left panel.
3. Double-click the **Server certificates** icon.
4. Click the **Create Self-Signed Certificate** link in the **Actions** panel. The Specify Friendly Name dialog box appears.
5. Type any name you desire in the **Specify a Friendly name for the certificate** text box.
6. Click the **OK** button. You now have an IIS self-signed certificate that is valid for one year. It appears under the Server Certificates panel. The certificate common name (Issued To column) is the host name of the machine running the site.

Task Two: Bind the Self-Signed Certificate to the IIS Site

1. In IIS Manager, click the server you want to bind to on the **Connections** panel tree.
2. Drill down to **Sites > Default Web Site**.
3. Click the **Bindings...** link in the **Actions** panel. The Site Bindings dialog box appears.
4. Click the **Add...** button. The Edit Site Binding dialog box appears.
5. Click the **Type** dropdown list and select **https**.
6. Click the **SSL certificate** dropdown list to select the certificate you just created.
7. Click the **OK** button. You return to the Site Bindings dialog box, where the HTTPS binding now appears.
8. Click the **Close** button. The dialog box closes.

Task Three: Test the Self-Signed Certificate

1. In a browser, go to the Website using the certificate. You should see a warning that there is an issue with the site's security certificate–specifically, the security certificate was issued for a different website's address. This occurs because IIS uses the server's name as the common name when using a self-signed certificate, which usually does not match the hostname to access the site in your browser.
2. To access the website, click the "continue to the website" link or button. You will have to do this each time you access the site. Because this is a test environment, this should not be an issue.

Note: It is possible to remove the warning by adding the self-signed certificate to the trusted root certificate authorities, but that is beyond the scope of this instruction.

Trusting an SSL Certificate on a Client Machine

For public websites, only SSL certificates issued by trusted authorities are recognized as valid. Self-signed certificates used only within a company or domain might generate security warnings but these can be ignored. The same is true of self-signed certificates installed on a server for the Secret Server website. However, these security warnings can also interfere with the use of the Secret Server Launcher and Web Password Filler. To resolve these issues, install the certificate on the client machine, either through your browser or Certificates snap-in.

To enable trust in the Secret Server self signed certificates, following these steps:

Step 1: Compare Host Names

Make sure that the host to which the certificate is issued is the same as the host name for your Secret Server website:

1. Open your browser and navigate to Secret Server.
2. Click **Continue to this website** if you are prompted.
3. Click the **Certificate Error** icon next to the navigation bar.
4. Click the **View certificate** button. The value next to **Issued to** should match the host name for your website. For example, if your website is `https://www.mydomain.local/SecretServer`, it should say **Issued to:**`www.mydomain.local`. If these fields do not match, the client will not be able to fully trust the certificate.

Step 2: Transfer a copy from your server to the client computer

Obtain a copy of the certificate file and transfer it to the client computer:

1. On the server where Secret Server is installed, find **Run** from the start menu or screen and type in `mmc`, then click the **Enter** button.
2. From the **File** menu, select **Add/Remove Snap-in**.
3. Select the **Certificates** snap-in, then click the right arrow button to add it.
4. In the window that appears, select **Computer Account**.
5. Select **Local Computer**.
6. Click **Finish**. You should now see the **Certificates (Local Computer)** node.
7. Expand the **Personal** folder and then the **Certificates** folder under it.
8. Right-click the certificate that Secret Server uses.
9. Click **All tasks**.
10. Select **Export**.
11. Keep clicking the **Next** button to accept defaults in the wizard.
12. Type in a filename.
13. Click the **Finish** button. The certificate has now been exported.

> If you have Firefox, the certificate can be saved to your client computer by viewing and exporting it after navigating to the website.

Step 3: Install the certificate on the client computer

1. On the client computer, find **Run** from the start menu or screen and type in `mmc`, then press the **Enter** button.
2. From the **File** menu, select **Add/Remove Snap-in**.
3. Select the **Certificates** snap-in, then click the right arrow button to add it.
4. In the window that appears, select **My user account**.
5. Click the **Finish** button.
6. Expand the **Trusted Root Certification Authorities** folder.
7. Right-click the **Certificates** folder and select **All Tasks > Import**.
8. Click **Next** and **Yes** to accept default settings for all steps of the wizard.
9. When prompted for the certificate file, select the file you saved in the previous Step 2.

> You may need to re-open your browser and browse to Secret Server once more to see the change reflected on the client machine.

Multi-Factor Authentication

For added security, you can add a second layer of authentication, called multi-factor authentication (MFA) or two-factor authentication (2FA), when users access the system. This section discusses several options.

MFA on Secret Access

MFA on Secret Access is only available with Secret Server Cloud on the Delinea Platform. To upgrade from stand-alone Secret Server Cloud, please contact your Delinea sales or renewal representative. You can read about the upgrade process here.

Applications for Soft Token Two-Factor Authentication

The name of the Secret Server soft token two-factor setting for Time-based One Time Password (TOTP) is “TOTP Authenticator." Any TOTP application that uses the TOTP RFC6238 algorithm, such as Microsoft Authenticator, will work with the Secret Server TOTP Authenticator. Details on the TOTP RFC6238 standard can be found at TOTP: Time-Based One-Time Password Algorithm.

> Google Authenticator support started in Secret Server version 8.6.

Duo Security Authentication

> Using this method of two-factor authentication requires that you have an active account for Duo Security.

> Secret Server supports using Duo Security as a second factor of authentication. See below for setup instructions.

> For more information on Duo and Secret Server, see the DelineaSecret Server and Duo page.

Important Duo Security Certificate Authority Changes

> This temporary section includes important information that may affect your access to Secret Server. Please read it carefully.

Cisco Duo is replacing its root certificate authority (CA) bundle. The impact on you depends on the application type configured in your Duo Admin Panel. Follow the steps below:

Determine your Application Type

In the Duo Admin Panel, go to **Applications > Applications** and check the **Application Type** column.

Application Type	Action
Delinea Secret Server or Thycotic Secret Server	Minimal—Duo granted an automatic extension until March 31, 2026
Auth API, Web SDK, or other custom application	Urgent—authentication failures may begin February 2, 2026

If You Have a Published Secret Server

Secret Server uses Windows certificate validation, not embedded certificate pinning. Secret Server Cloud integrations require no changes. Secret Server On-Premises integrations continue to function as long as the web server receives regular Windows Updates to maintain current root CA certificates.

If You Have a Custom Application

Administrators using custom applications, such as Auth API or Web SDK, must take **one** of the following actions to avoid authentication failures:

- **Either** contact Duo (support@duo.com) to request an extension.
- **Or** switch to the published Delinea Secret Server application in the Duo Admin Panel, and update the credentials in Secret Server at **Admin > Configuration > Login > Duo**.

Key Dates

Date	Event
February 2, 2026	Intermittent authentication failures begin for custom applications
March 31, 2026	Duo rotates CA roots; servers with outdated root certificates fail to connect

For details, see Duo's knowledge base article.

Setup

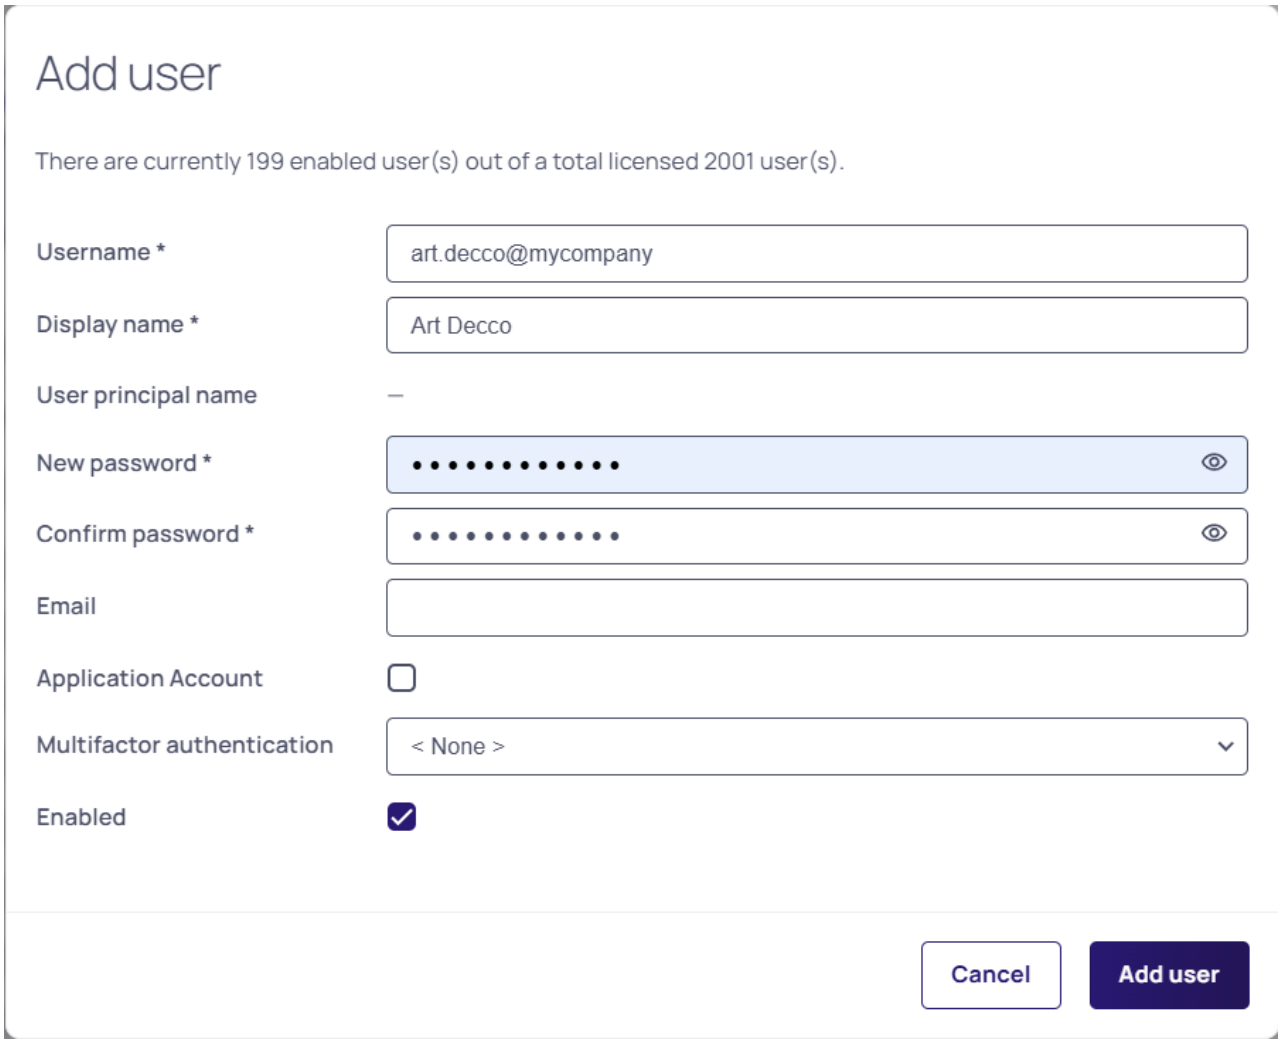
Task 1: Create a Duo Application Representing Your Secret Server (Admin)

1. Sign up for a new Duo account, or log in to an existing one at Duo Security.
2. Under **Applications**, create a new application of the **DelineaSecret Server** type. Name the application as you wish.
3. Record the API hostname, integration key, and secret key from the new Duo application you just created.

Task 2: Configure Secret Server to Use Duo (Admin)

> Because Duo is a service, the Secret Server instance must have outbound access (TCP port 443) to reach the API host to work. If there is a firewall rule preventing access to Duo's servers, two factor authentication will not work.

1. Open the Administration page in Secret Server.
2. Under Login, select **Duo**.
3. Click **Edit**.
4. Select the **Enable Duo Integration** check box.
5. Enter the **API Hostname**, **Integration Key**, **Use RADIUS Username for DUO**, and **Secret Key** values.
6. Click **Save**.
7. Search for **Users** to create a test user. The Users page appears.
8. Click the **Create New** button. The **Add User** window appears:



9. Click the **Two Factor** dropdown list and select **Duo**.
10. Type or select the other parameters for the new user.
11. Log on as the test user. If there are multiple two-factor devices available, you will be prompted to select one. If you are un-enrolled you will be given a link to perform self-enrollment. You are contacted via the Duo app, SMS, or a phone call for the second factor.
12. Add or configure actual users one at a time or by using bulk operations.

Task 3: Setting up Duo (User)

1. Log on to Secret Server.
2. After successful authentication, a new screen appears with the option to select a method to authenticate with.
3. Select one of the options (**Duo Push**, **Send SMS**, or **Phone)**, depending on your setup with Duo) and complete the selected authentication process to log in.

Email Authentication

Secret Server Email Authentication supports two methods for email connection, **SMTP** and **O365**. Use one of the methods to enter connection information required to send notifications:

Search for **Email**, and click **Edit**. In the **Send email method** field, select one of the following method and enter the required fields:

- SMTP
  - **Email Server**: Specify the domain name or IP address of your SMTP server, for example: smtp.yourcompany.com.
  - **Port**: The specific port to connect to the SMTP server.
  - **From Email Address**: This is the 'From' address for emails that are sent.
  - **Username**: The username to connect to the SMTP server.
  - **Password**: The password to connect to the SMTP server.
- O365
  - **Send Email Application Secret**: The Azure App Registration Secret for the Office365 account that will be used to send emails via the API.
  - **From Email Address**: This is the 'From' address for emails that are sent.

> Note: The Secret should be created in Secret Server prior to configuring this page. The Azure Application Secret must contain the Client ID, Client Secret, and Tenant ID detail for the Azure Application Registration with Application Permissions.

> If virus protection is running, you may need to add a firewall rule to allow aspnet_wp.exe to send e-mails.

FIDO2 (YubiKey) Two-Factor Authentication Configuration

Overview

FIDO2

FIDO2 (Fast Identity Online, second edition) is an open authentication standard that uses physical devices for authentication. Delinea uses this standard for two factor authentication (2FA) with FIDO2 providing the second authentication after a normal password entry. Any FIDO2-enabled user attempting access to a Secret Server account **must** have a FIDO2 device in hand. The device eliminates many password-related issues, such as phishing and man-in-the-middle attacks. It also speeds up the login process over callback or texting 2FA.

YubiKey

YubiKey is a FIDO2-compliant product series from Yubico, a commercial company. We recommend two of their devices, the YubiKey 5 Series and the Security Key.

Configuration

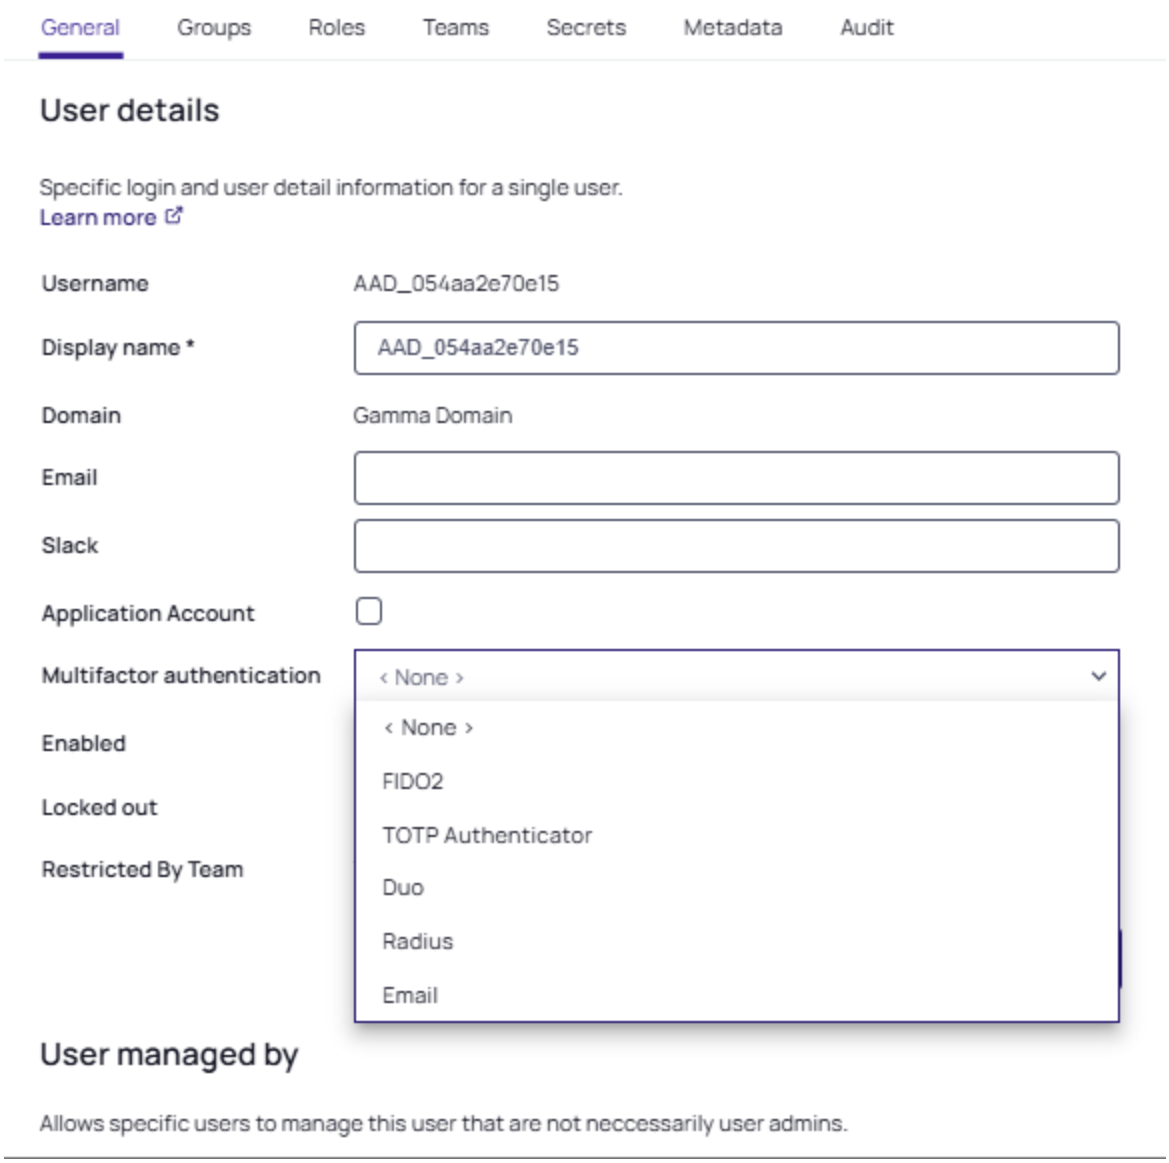
Prerequisites

- One FIDO2 device. We recommend the YubiKey series.
- A Secret Server Vault license or greater.
- Administer Users or User Owner permissions in Secret Server.
- A Firefox or Chromium browser, such as Google Chrome or Microsoft Edge.

Enabling FIDO2 for a Single User

1. In Secret Server, Search for **Users**. The **User Management** page appears.
2. Click on the user you wish to edit.
3. Click **Edit** in the **User Details** section at the top of the page (in the **General** tab).

4. Click on the **Multifactor Authentication** list and select **FIDO2**:

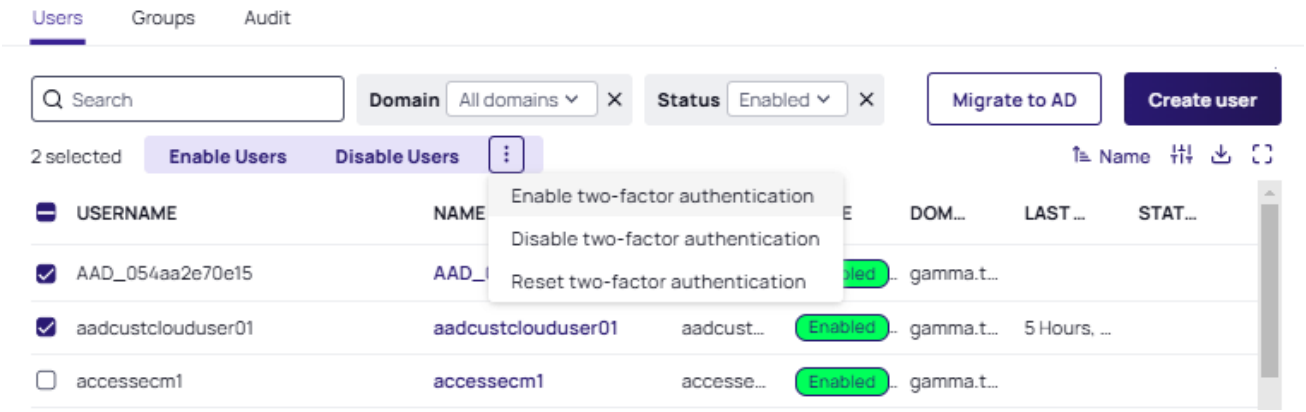


5. Click the **Save** button.

Enabling FIDO2 for Multiple Users

1. In Secret Server, Search for **Users**. The **User Management** page appears.
2. Select the check box next to each user you wish to include. The **Enable Users** link appears at the top alongside the **Disable Users**.

3. Click the three dots next to **Enable Users** and select **Enable Two-Factor Authentication** from the dropdown list:



4. In the **Enable Two-Factor Authentication** popup, select **FIDO2** in the **Two-Factor Authentication Provider** drop-down list.
5. Click the **Save** button. The **Bulk Progress** popup appears.
6. When the **Task Complete** message appears, click the **Close** button.

Disabling FIDO2 for Users

The process to disable FIDO2 for both single and multiple users is almost identical to enabling them. There are two differences:

- For a single user, select **<None>** for the **Multifactor Authentication** list on the **Edit User** page, and then**Save**.
- For multiple users:
  1. Select **Disable Two-Factor Authentication** in the drop-down list made available after selecting multiple user checkboxes in the **User Management** page, the **Disable two-factor authentication** popup appears.
  2. From the popup select FIDO2 before clicking **Save**. See the previous section for a visual example.

> Disabling FIDO2 2FA does **not** remove device registration information from Secret Server. If FIDO2 is re-enabled, the user can use the FIDO2 device without re-registering it.

Unregistering Users from FIDO2

Resetting FIDO2 serves to unregister existing users. There is no way to reverse this action, users will have re-register the FIDO2 device, even if it is the same device they used previously.

Resetting FIDO2 for both single and multiple users is very similar to enabling FIDO2 for multiple users. The only difference is that you select **Reset Two-Factor Authentication** in the drop-down list made available after selecting a single or multiple user checkboxes in the **User Management** page. See the image above for a visual example. The operation is exactly the same for single and multiple users.

Registering FIDO2 Devices (End-User Operation)

1. After an admin registers your user in Secret Server, you are prompted upon your next login to use either the "security key with the localhost" (Chrome) or that "localhost wants to register an account with one of your security keys. You can connect and authorize one now or cancel" (Firefox).

> Legacy Microsoft Edge is not supported. Edge Chromium, version 79 or higher, is required for FIDO2 support.

2. Insert your FIDO2 device into a USB port on the computer.
3. Activate it by touching the sensor on the device.
4. After a successful registration, you are **again** prompted with the same screen, which is authenticating the current session with the credentials that were just registered.
5. From then on, you will be prompted for your security key after a successful login. Once the key is authenticated, the Secret Server Dashboard appears.

> Only one FIDO2 device per user can be registered at any given time. The 2FA settings, however, can be temporarily disabled or reset in the case of a lost or forgotten FIDO2 device.

Auditing and Security

- Upon registration your FIDO2 Credential, FIDO2 Public Key JSON string, and the FIDO2 Counter are all stored in your user's audit log.
- Upon each successful FIDO2 authentication, the FIDO2 counter value is updated and noted in your audit log.

Troubleshooting and Issues

- If you encounter an error or do not complete authentication before the process times out, then you will be redirected back to the username and password login screen where the process can be reattempted.
- Authentication activities are logged in your audit log, to help with the tracking of any potential issue reproduction steps.
- System errors are logged in the Secret Server.log file in the Secret Server log directory.

RADIUS User Authentication

Secret Server allows the use of *Remote Authentication Dial-In User Service* (RADIUS) two-factor authentication on top of the normal authentication process for additional security needs. Secret Server acts as a RADIUS client that can communicate with any server implementing the RADIUS protocol.

Configuring RADIUS

Set up RADIUS on the **Login** tab of the **Configuration** page. This requires enabling RADIUS Integration, specifying the server address, the ports, and the RADIUS shared secret. The shared secret is a specific term for RADIUS clients and is not a reference to secrets in Secret Server.

You can customize the RADIUS "Login Explanation" to give users detailed instructions for entering their RADIUS information.

Once enabled, the **Test RADIUS Login** button appears on the **Login** tab for testing the communication with the RADIUS Server. If you have a failover RADIUS Server, you can specify it by clicking the **Enable RADIUS Failover** checkbox and entering the required information. If the primary RADIUS server cannot be accessed, the failover server is be used.

Enabling RADIUS for a User

After enabling RADIUS on your Secret Server, you must enable RADIUS two-factor authentication for each user on a per-user basis. On the **User Edit** page, type the **RADIUS User Name** for this user to match the RADIUS server. RADIUS can be enabled for new users by domain.

Enabling RADIUS Two-Factor Authentication

RADIUS authentication is handled by the web nodes, rather than the distributed engines, in both Secret Server Cloud and On-Premises environments.

Procedure

Secret Server allows the use of RADIUS two-factor authentication on top of the normal authentication process for additional security.

See the full RADIUS Integration Guide for additional information.

To configure RADIUS for the Secret Server instance:

1. Log on Secret Server with an account with "Administer Configuration" and "Administer RADIUS" permissions.
2. Navigate to **Administration menu**.
3. Type **RADIUS** in the search box and press **<Enter>**. The RADIUS Configuration page appears.
4. Click the **Edit** button.
5. Type the following as needed:
   - **RADIUS Login Explanation**: (custom message or instruction). Defaults to "Please enter your RADIUS passcode."
   - **RADIUS Default Username**: select the related RADIUS username from the dropdown. The default RADIUS username determines the credential Secret Server uses when attempting to authenticate against your RADIUS server. If your RADIUS server requires a UPN (User Principal Name), this setting should be

modified accordingly. The UPN is stored in the database. If a Username is used, Secret Server will send the SAM Account Name (domain\username) to the RADIUS server. This setting can be customized to meet the specific requirements of your RADIUS server by navigating to **Admin > Users** when configuring RADIUS as the two-factor authentication method.

- **RADIUS Client Port Range**: (default 1812) source ports, instructing Secret Server to send requests exclusively through the defined client port range. By entering a value of 0, you can configure Secret Server to use the ephemeral port range for outgoing requests.

  > If your RADIUS server runs on the same machine as Secret Server, the client and server ports must be different.

- **RADIUS Server Port**: (default 1812 for RSA and 1812 for AuthAnvil).
- **RADIUS Server IP**: (IP address to your RADIUS Server). See RADIUS IP Addresses.
- Leave **Use Same RADIUS Shared Secret for All Users**: selected.
- **RADIUS Shared Secret**, which must match chosen RADIUS shared secret on your RADIUS Server. (Shared Secret is a RADIUS term and not related to any Secret Server secret.)

> Attempt Silent Authentication: Silent answer is a new configuration option for RADIUS that allows setting the RADIUS response to a defined string value. This is to support push notification and other interactive variations in advanced RADIUS authentication configuration. The new setting replaces "Attempt User Password" and allows for sending the user password or another predefined string.

- **RADIUS Protocol**: select UDP or EAP-TTLS-PAP from the dropdown.
- **Time out (seconds)**: set the number of seconds for time out.
- **Enable Failover RADIUS Server**: enabling a failover RADIUS server will allow another server to fail over to.
- **Failover RADIUS Server Port**: enter the related failover server port.
- **Failover RADIUS Server IP**: enter the IP address of your failover RADIUS server.
- **Failover RADIUS Shared Secret**: enter the related secret for RADIUS failover server.
- **Failover Time Out (Seconds)**: set the number of seconds for RADIUS failover server time out.
- **Attempt Silent Authentication**: select User Password or Static Value. For Static Value, enter the value below to send to RADIUS as the password.
- **Enable RADIUS NAS-Identifier**: Check to enable and configure the NAS-Identifier that will be sent with the RADIUS Access-Request. This Attribute contains a string identifying the NAS originating the Access-Request. It is only used in Access-Request packets. Either NAS-IP-Address or NAS-Identifier MUST be present in an Access-Request packet.

> Note that NAS-Identifier must not be used to select the shared secret used to authenticate the request. The source IP address of the Access-Request packet must be used to select the shared secret.

- **Disable RADIUS NAS-IP-Address attribute**: check to disable. This Attribute indicates the identifying IP Address of the NAS which is requesting authentication of the user, and should be unique to the NAS within the scope of the RADIUS server. NAS-IP-Address is only used in Access-Request packets. Either NAS-IP-Address or NAS-Identifier must be present in an Access-Request packet.

  > Note that NAS-IP-Address MUST NOT be used to select the shared secret used to authenticate the request. The source IP address of the Access-Request packet must be used to select the shared secret.

6. Click the **Save** button.

To test RADIUS settings:

1. Click the **Test RADIUS Login** button. A popup appears.
2. Type the RADIUS username and password.
3. Click the **OK** button.
4. After enabling RADIUS on Secret Server, you must enable RADIUS two-factor authentication for each user:
   a. Sign into an account with "Administer Configuration" and "Administer RADIUS" permissions.
   b. Navigate to **Administration** > **Users**. The Users page appears.
   c. Select the desire user.
   d. Click the **Edit** button.
   e. Click to select the **RADIUS Two Factor Authentication** check box.
   f. Type the username in the **RADIUS Username** text box.

      NOTE: Secret Server defaults this value to its username. If you wish to use this default name, it must match the username on the RADIUS server.
   g. Review the settings and click **Save**.
   h. Repeat these steps for each user that needs to use RADIUS.

RADIUS IP Addresses

Please see the Secret Server Cloud Architecture Documentation for a listing of IP addresses.

TOTP

Secret Server supports using any type of soft token or mobile application authentication using the *Time-Based One-Time Password* (TOTP) RFC6238 algorithm. TOTPs are typically generated and authenticated by a mobile application using an algorithm that incorporates the current time to ensure that each one-time password (OTP) is unique. TOTP applications include tools such as Authy, Google Authenticator, and Microsoft Authenticator.

Secret Server can also serve as an OTP generator, providing TOTP authentication for RPC and launchers. The soft token two-factor function in Secret Server is the "TOTP Authenticator" and you can use any application that uses the TOTP RFC6238 standard (details on the standard can be found at the IETF Tools website. An example of a TOTP application that works with Secret Server soft token two-factor authentication is Microsoft Authenticator.

> The same 32-character key can generate different TOTP outputs based on the hashing algorithm used (SHA1, SHA256, or SHA512). It is essential to configure the Secret Server template to use the same hashing algorithm as the external system providing the key. This ensures that the generated TOTP codes are accurate and can be successfully authenticated.

Enabling TOTPs for Launchers

Most users are familiar with TOTPs that are generated by authenticator apps such as such as Google Authenticator or Microsoft Authenticator, however Secret Server can be used as the TOTP generator for RPC or launchers. Both the secret and the secret template require configuration for this use.

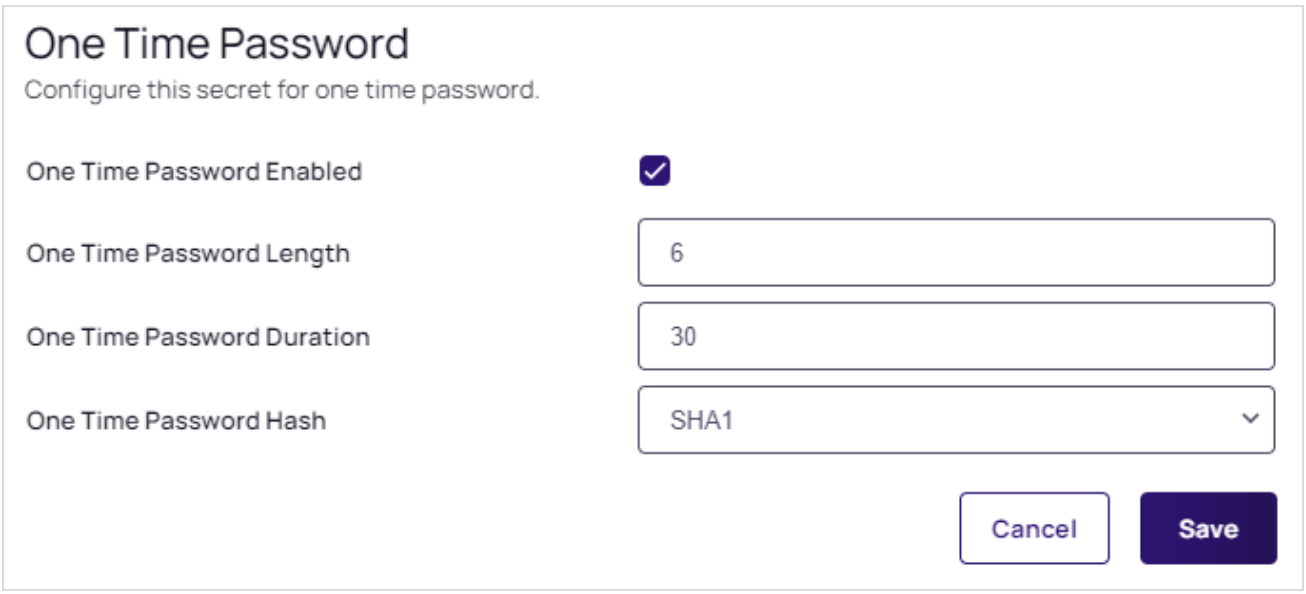
Any template type can have a TOTP code generated in the secret once TOTP is enabled in the secret template and in the secret itself. Only web password secrets have autofilling TOTPs. That is because that is based on the only template type Web Password Filler (WPF) is looking at. See Autofilling OTP in Using WPF for details.

> When configuring TOTP on a Secret Server template, make sure that the hashing algorithm specified in the template matches the algorithm used by the external system providing the key. The same 32-character key can produce different TOTP outputs depending on whether SHA1, SHA256, or SHA512 is used. Failure to match the hashing algorithms can result in incorrect TOTP codes and authentication failures.

Secret Template Setup

To enable TOTP on a Secret Server template:

1. Go to **Administration button > Secret Templates**.
2. Select the desired template, and click the **Edit** button. The Secret Template Designer appears.
3. Navigate to the **One Time Password** section of the page, and click the **Edit** button.
4. Click to select the **One Time Password Enabled** check box. This enables the option with default settings:



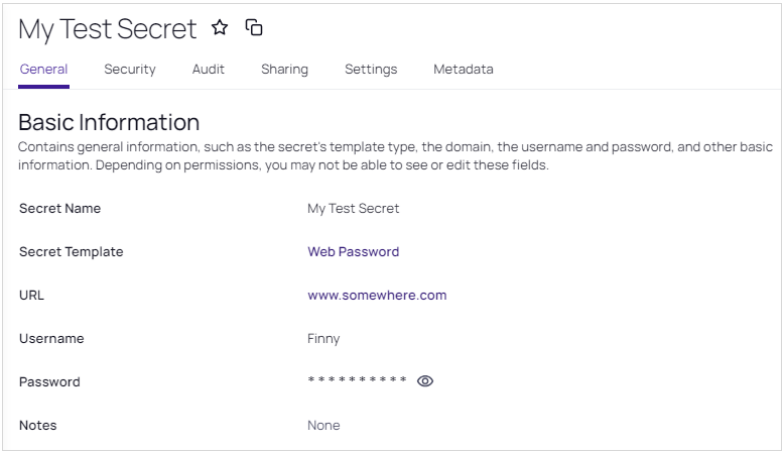
These are the values that most one-time password instances, such as Google and Microsoft Authenticator, use today. If you use these settings with another OTP provider and are unable to successfully use generated codes to authenticate, please review their documentation and adjust these settings as required.

5. Save the secret template. Any web password secret based upon this template can now use TOTP.

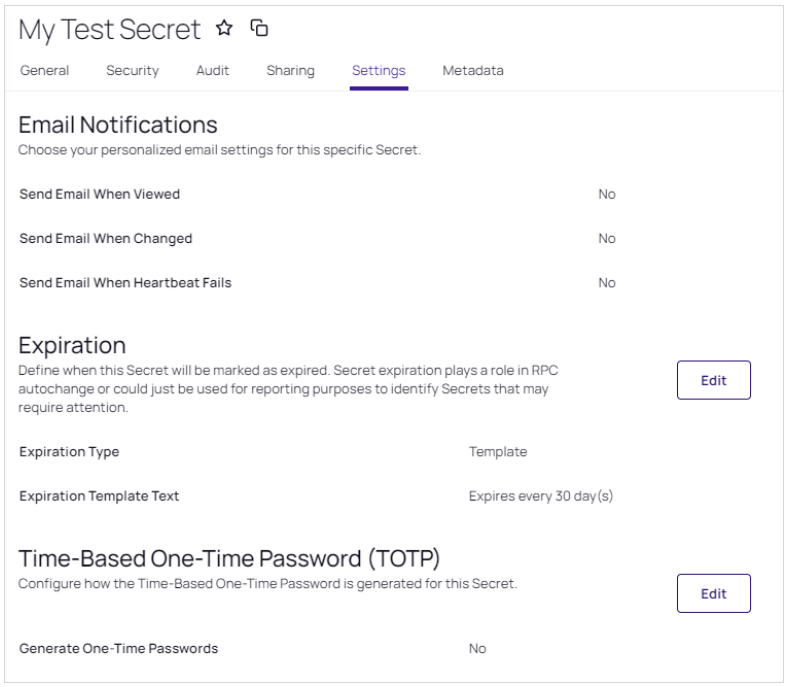
TOTP Secret Setup

Once a secret template is set up for TOTP, each secret based on that template also needs to be set up:

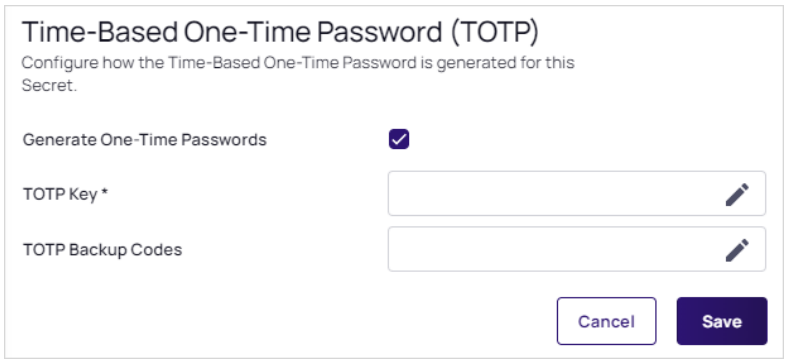
1. Click the **Secrets** menu item in the dashboard.
2. Open the desired secret.



3. Click the **Settings** tab:



4. Click the **TOTP** section's **Edit** button
5. Click to select the **Generate One-Time Passwords** check box in the **TOTP** section. This exposes two text boxes:



6. Type the TOTP key in the **TOTP Key** text box. The TOTP Key is generated by the OTP-protected asset when you set up your account to use TOTP. Usually, you are prompted with a QR barcode that you can scan with a mobile device, or you can expose the key that the QR code represents by selecting the **Manual Setup** link when performing the initial TOTP setup for a user. The TOTP Key is found in the **Key** field. This text string is the value that is placed into the TOTP Key field.

> Treat the TOTP key and backup codes like you would any other password! If anyone obtains the key, it can be used to set up a valid TOTP generator for that account on any device, allowing that person to bypass the protection. Similarly, the backup codes allow users to temporarily bypass protection.

> If you have an account that has been TOTP protected and you did not save the TOTP key upon creation, you must deactivate TOTP on that account and then reactivate it to retrieve the TOTP key to set up Secret Server.

7. Type the TOTP backup codes in the **TOTP Backup Codes** text box. The TOTP Backup Codes are often presented to a user while initially setting up an account for TOTP. These backup codes are single-use codes for use if a TOTP generator is not available or working. Again, these codes will be valid and allow the holder to get past the two-factor authorization to access an account, so protect them as you would a password!

Enabling TOTP for Secret Server Users

Upon logging into Web Password Filler and Delinea Credential Manager (DCM), users will be prompted to enter a Time-based One-Time Password (TOTP) code if their login configuration requires it. Once authenticated, users can view the TOTP code within the secret details in the popup when accessing a secret configured with a TOTP code. Additionally, when autofilling credentials into a website using a secret with TOTP enabled, the system will automatically populate the TOTP field on the login page and ensure synchronization if the TOTP code changes prior to submission.

To enable TOTP:

1. From the **Admin** menu, select **Users**.
2. Select the check box beside each user to enable two-factor authentication for.
3. From the **< Select Bulk Operation >** drop-down menu, select Enable TOTP Auth Two Factor.
4. Click **OK** in the dialog that appears, confirming the operation.
5. The user(s) are now required to complete the soft token setup with a mobile device the next time they log into Secret Server. See Onboarding the Mobile App for details on the account and mobile app setup that follow.

For information on installing Web Password Filler or Delinea Credential Manager, see "Installing Browser Extensions" on page 707.

Disabling TOTP for Users

To disable soft token two-factor authentication, follow almost the same process as enabling soft token two-factor authentication for a user, select **Disable TOTP Auth Two Factor** from the bulk operation drop-down menu instead of **Enable TOTP Auth Two Factor**.

Resetting TOTP for Secret Server Users

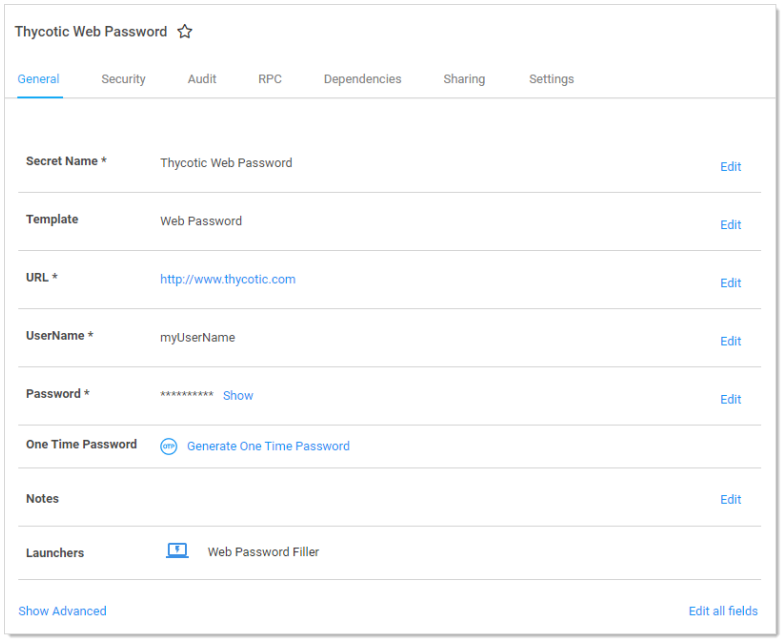
1. From the **Admin** menu, select **Users**.
2. Select the check box beside the user to reset two-factor authentication for.

3. Click select **Reset TOTP Auth Two FactorFrom** on the **< Select Bulk Operation >** drop-down menu.
4. Click **OK** in the dialog that appears, confirming the operation.
5. The user is now required to complete the soft token setup with a mobile device the next time they log into Secret Server. See **User Setup of Soft Token Two-Factor Authentication** for further details on the account and mobile app setup that follow.

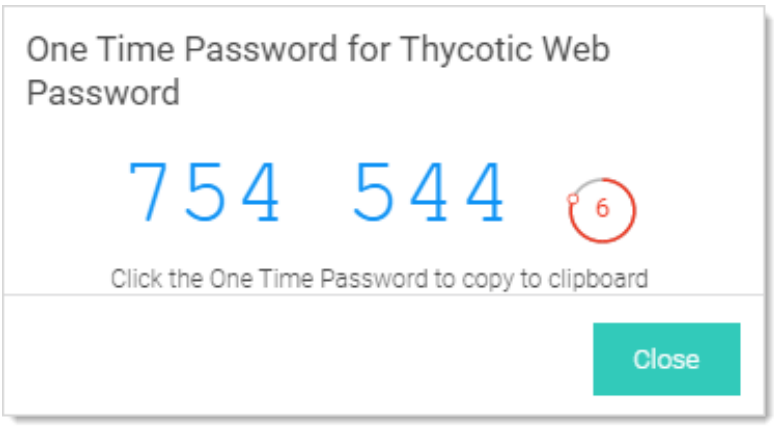
Viewing a TOTP for a Web Secret

To view or copy the TOTP generated for an account:

1. Navigate to and open the desired secret.
2. Click the **General** tab:



3. Click the **Generate One Time Password** link next to the **One Time Password** setting.
4. A dialog box appears with an OTP:



5. Click the OTP to copy it to the clipboard.
6. Click the **Close** button.

> The "Generate One Time Password" link also appears on the preview pane when you click a secret on the All Secrets page.

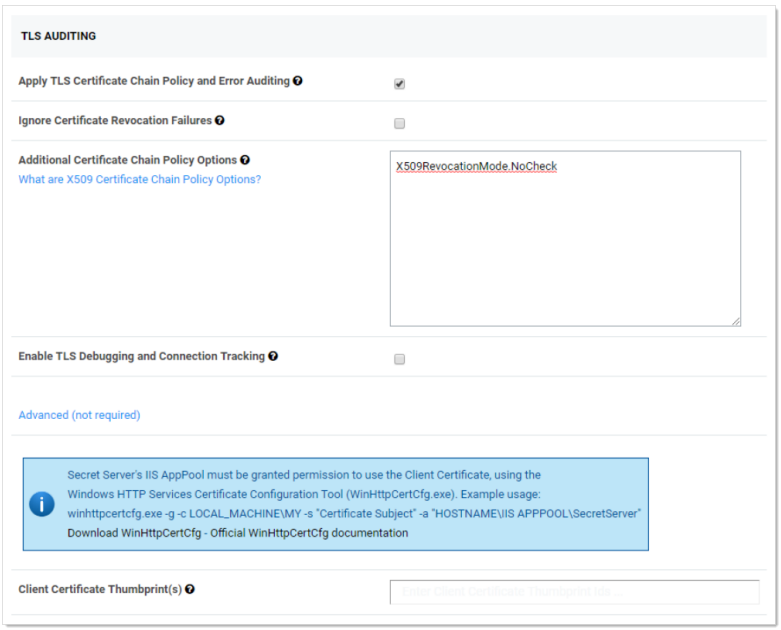
X.509 Certificate Security Chain Options

Secret Server allows you to define a policy for validating X509 Certificates. This applies to all Active Directory domains using LDAPS. It also applies to any connections to syslog servers over TLS. Certificates that do not meet the policies specified in Secret Server are rejected, denying connections to the server. All certificate validation failures are logged in the security audit log, which is available by going to **Admin > See All** and then **Security Audit Log**.

Setting the Certificate Verification Policy

To set a verification policy:

1. Search for **Configuration**.
2. Click the **Security** tab.
3. Click the **Edit** button
4. Click to select the **Apply TLS Certificate Chain Policy and Error Auditing** check box. The TLS Auditing options appear:



5. To change the policy, type a semi-colon delimited list of policy options in the **Additional Certificate Chain Policy Options** text box. To use a policy, enter the `<full_enumeration_name>.<enumeration_item>`. For example, to validate the entire certificate chain, add `X509RevocationFlag.EntireChain` to the semi-colon delimited list of options. See Certificate Validation Options for details.
6. If you wish to ignore certificate revocation warnings and allow revoked certificates, click to select the **Ignore Certificate Revocation Failures** check box.

Certificate Validation Options

The following Microsoft enumerations are the available certificate chain policy options. For detailed descriptions of each option, see the linked documentation.

X509RevocationMode

Specifies the mode used to check for X.509 certificate revocation.

Enumeration Item	Value	Description
NoCheck	0	No revocation check is performed on the certificate.
Offline	2	A revocation check is made using a cached certificate revocation list (CRL).
Online	1	A revocation check is made using an online certificate revocation list (CRL).

See X509RevocationMode Enum for details.

X509RevocationFlag

Specifies which X.509 certificates in the chain should be checked for revocation.

Enumeration Item	Value	Description
EndCertificateOnly	0	Only the end certificate is checked for revocation.
EntireChain	1	The entire chain of certificates is checked for revocation.
ExcludeRoot	2	The entire chain, except the root certificate, is checked for revocation.

See X509RevocationFlag Enum for details.

X509VerificationFlags

Specifies conditions under which verification of certificates in the X.509 chain should be conducted. These values can be bitwise combined to indicate multiple flags.

Enumeration Item	Value	Description
AllFlags	4095	All flags pertaining to verification are included.
AllowUnknownCertificateAuthority	16	Ignore that the chain cannot be verified due to an unknown certificate authority (CA).
IgnoreCertificateAuthorityRevocationUnknown	1024	Ignore that the certificate authority revocation is unknown when determining certificate verification.
IgnoreCtlNotTimeValid	2	Ignore that the certificate trust list (CTL) is not valid, for reasons such as the CTL has expired, when determining certificate verification.
IgnoreCtlSignerRevocationUnknown	512	Ignore that the certificate trust list (CTL) signer revocation is unknown when determining certificate verification.
IgnoreEndRevocationUnknown	256	Ignore that the end certificate (the user certificate) revocation is unknown when determining certificate verification.
IgnoreInvalidBasicConstraints	8	Ignore that the basic constraints are not valid when determining certificate verification.
IgnoreInvalidName	64	Ignore that the certificate has an invalid name when determining certificate verification.
IgnoreInvalidPolicy	128	Ignore that the certificate has invalid policy when determining certificate verification.

Enumeration Item	Value	Description
IgnoreNotTimeNested	4	Ignore that the CA (certificate authority) certificate and the issued certificate have validity periods that are not nested when verifying the certificate. For example, the CA cert can be valid from January 1 to December 1 and the issued certificate from January 2 to December 2, which would mean the validity periods are not nested.
IgnoreNotTimeValid	1	Ignore certificates in the chain that are not valid either because they have expired or they are not yet in effect when determining certificate validity.
IgnoreRootRevocationUnknown	2048	Ignore that the root revocation is unknown when determining certificate verification.
IgnoreWrongUsage	32	Ignore that the certificate was not issued for the current use when determining certificate verification.
NoFlag	0	No flags pertaining to verification are included.

See X509VerificationFlags Enum for details.

Troubleshooting

If you enable certificate policy validation and logging, you may have server connections rejected due to certificates that violate the set policies. These errors are recorded in the security audit log. If the information logged there is not enough to determine why a certificate was rejected, you can get additional log details by enabling TLS Debugging. This adds detailed information to the logs about each certificate checked.

Due to the possibility of exposing sensitive information in the logs, TLS debugging requires two steps to enable:

1. Click to select the **Enable TLS Debugging and Connection Tracking** check box.
2. Change the global logging level to DEBUG. To do this, edit the `web-log4net.config` file in the root folder of your Web application. Follow the comments in the file to comment out the current log level line (the default is INFO), and uncomment the line that sets the value to DEBUG.

> Only enable TLS debugging when you are actively troubleshooting a certificate validation issue. Disable this option when you are not to prevent logging of certificate details.

Backup, Disaster Recovery, and Glass Break

Backups

Backups are routine copies of critical data that protect against accidental deletion, corruption, or other data-loss incidents. Secret Server supports both manual and scheduled backups of the database and IIS directory, providing a reliable way to safeguard the data itself. These backups ensure that individual records or files can be restored even if the production system remains intact. Administrators can also export secrets to a CSV file as an additional precaution to strengthen data protection. See the Backup section for details.

Disaster Recovery

Disaster recovery is the broader strategy for restoring the entire Secret Server environment after a major outage or catastrophic event. While backups preserve the data, disaster recovery focuses on bringing the full application and all related services back online. Secret Server enhances this capability through SQL mirroring and automatic failover, which minimize downtime and keep privileged access secure and accessible. These measures enable rapid restoration of both the application and database, ensuring operational continuity when a disaster occurs. See the Disaster recovery section for details.

Break Glass Access

The Break Glass concept provides emergency access when standard methods are unavailable because of infrastructure failures or other emergencies. It ensures continuity and access to essential information during outages or disasters. Secret Server supports several Break Glass options, including exporting secrets for secure retrieval when systems are down, maintaining resilient secrets that remain accessible during outages, allowing mobile app offline caching so authorized users can retrieve cached secrets without connectivity, and enabling PCS/Server Suite Agent offline operation, which uses policy-cached authentication and machine-specific MFA for secure access when servers cannot be reached. See the Break Glass Concepts section for details.

Secret Server Backup

This topic only applies to **Secret Server On-Premises**.

Secret Server offers robust backup features to ensure data integrity and availability in case of system failures or disasters. It supports both manual and scheduled backups of the database and IIS directory, allowing administrators to configure automatic backups at specified intervals. These backups can be stored locally or on a network share, providing flexibility in storage options. Secret Server also supports SQL mirroring and automatic failover for enhanced disaster recovery. Additionally, administrators can export secrets to a CSV spreadsheet as an extra precautionary measure. The backup settings include options to specify file paths, set retention periods for operational logs, and configure notifications for backup failures, ensuring comprehensive backup management.

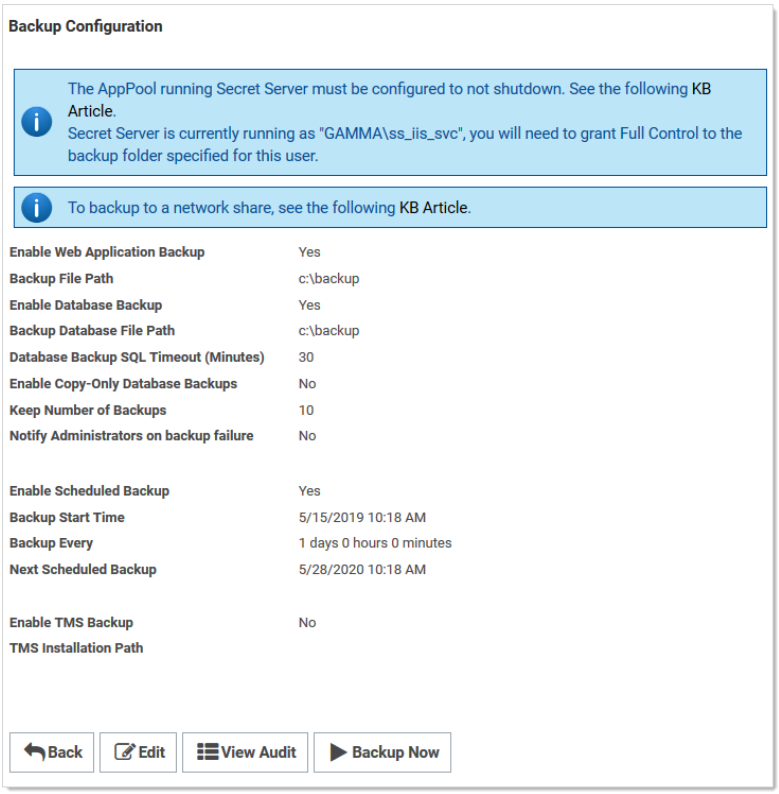
Backing up Secret Server to a Network Share

This topic only applies to **Secret Server On-Premises**.

Secret Server can be configured to backup to a network share instead of a local folder on the server. For example, you may want to do this such as when the Secret Server database (SQL) is located on a different server than the web application server (IIS).

To back up:

1. Ensure the Secret Server IIS Application Pool is running as a service account if it is not already. See Secret Server"Running the IIS Application Pool As a Service Account" on page 63.
2. Grant access to the network share (using Windows ACLs) to the account running the Secret Server IIS Application Pool (so that Secret Server can backup the application folder and zip it to the network share).
3. Grant access to the network share (using Windows ACLs) to the account running Microsoft SQL Server service. (so that Microsoft SQL Server can backup the Secret Server database to the network share). You can change the service account running Microsoft SQL Server by going to SQL Server Configuration Manager.
4. Search for **Backup**. This may require you to Search for **All** and search for **Backup**.



5. Note that the two file paths are from two different perspectives–Backup File Path is from the ASP.N ET application server and Backup Database Path is from the Microsoft SQL Server (these may be on the same box in your environment, or they might not be depending on how you have configured Secret Server).
6. Click the **Edit** button.
7. Type the Secret Server backup path, such as \\server01\backup\secretserver\, in the **Backup File Path** text box.
8. Type the database backup path in the **Backup Database Path** text box.
9. Click the **Save** button.

Backup Settings

> This topic only applies to **Secret Server On-Premises**.

Overview

The following configuration options are available on the **Tools > Backup** page of Secret Server:

- **Backup Database File Path:** This folder must be accessible by the SQL server and stores the `database.bak` file. See File Path Settings.
- **Backup File Path:** This directory must exist on the Web server and stores the zip file of the application directory. See File Path Settings.
- **Database Backup SQL Timeout (Minutes):** Number of minutes that Secret Server waits for the database backup to complete successfully before timing out.
- **Enable Scheduled Backup:** Enables automatic backups on a set schedule.
- **Days to Keep Operational Logs**: Sets the period to keep backup-related logs that might contain PII. Secret Server automatically deletes logs older than that (in days).
- **Keep Number of Backups:** Number of previous backups to keep.
- **Notify Administrators on Backup Failure:** Users with the Administer Backup role permission are notified if the backup fails.

File Path Settings

There are two file path settings on the **Admin > Backup** page (`ConfigurationBackup.aspx`). The "Backup File Path" setting corresponds to the application backup. The "Backup Database Path" setting corresponds to the SQL server backup.

Generally, the "Backup File Path" setting can be set to a path local to the application server for backing up of application files. If Secret Server is running under an account that does not have permission to write to a local path, then a network share can be used. If the SQL server is located on the same server as the Web application server, the "Backup Database File Path" setting can be set to a local path.

If the SQL server is not located on the same server as the Web application server then a network share should be used. The account under which SQL server service is running either must have modify rights to that path or must be a member of a group with modify rights to that path. You must use UNC (Universal Naming Convention) notation to write to a network path. For example: `\\TESTVM0\c$\backupDirectory`.

If you get an error stating "Cannot open backup device... Operating system error 3," this is often due to an invalid path value.

> For Secret Server to delete old database backups, the backup database path must also be accessible by the Secret Server Application Pool account.

Backup Folder Permissions

> This topic only applies to **Secret Server On-Premises**.

From the Backup Administration page, specify the correct directory paths for the IIS Secret Server file directory and the database backups to be stored. The backup path must be local to the server where the Secret Server database or file directory exists. The directories must also have the proper folder permissions to allow Secret Server to automatically store backups at those locations. The account that requires permission is displayed as an alert on the Backup page.

Common Backup Errors

This topic only applies to **Secret Server On-Premises**.

Cannot open backup device... Operating system error 3

This is often due to an invalid path value for the "Backup Database File Path" setting. For more information on the proper values for this setting, see "File Path Settings" on the previous page.

Timeout expired. The timeout period elapsed prior to completion of the operation or the server is not responding.

This is often due to an overly-large database. The Secret Server database likely contains too many log entries. To clear these, within Secret Server, select System Log from the Administration menu. Click the "Clear" button below the data grid that contains the log entries. If the timeout occurs with the clear as well, an upgrade to the latest version should resolve this. If the timeout issue persists with the backup, additional SQL database clean-up may be necessary. Contact Delinea Support for instructions on shrinking the reserve database size.

The process cannot access the file... because it is being used by another process

The cause of this message is typically multiple backup threads running simultaneously with all attempting to write to the same file. To fix this, open IIS Manager and ensure the "Maximum Worker Processes" setting for Secret Server's application pool is set to 1. If it is not, set the value to 1 and then either recycle the application pool or perform an `iisreset`.

Unable to complete backup. The following exception occurred: System.Threading.ThreadAbortException: Thread was being aborted

If this error message appears in combination with the application backup files not completed or the size of the file is unusually small, the backup process may have been interrupted by anti-virus software. Disabling scanning of the backup folder should resolve the issue.

Manually Backing up Secret Server

This topic only applies to **Secret Server On-Premises**.

To back up your Secret Server installation:

Your Secret Server instance may be running during this procedure.

1. Navigate to the directory where Secret Server is installed.
2. Copy the folder (holding the application) to your back up location.
3. Open your SQL Server Management Studio.

4. Right click the database your Secret Server is running on, and select **Tasks > Backup**.
5. Click the **Add** button. You will be prompted to enter a file path.
6. Make sure SQL Server has permissions for this location.
7. Copy the resulting database backup file to your backup location.

> You can also automate steps 2-4 using the command: `osql -S myserver\SQLEXPRESS -E - Q "BACKUP DATABASE SECRETSERVER TO DISK = 'c:\backup\ss.bak'.`

Restoring Secret Server from a Backup

> This topic only applies to **Secret Server On-Premises**.

To restore your Secret Server from a backup:

Restoring the Application

1. Extract your backup zip file of the Secret Server application directory, or copy the files from your other backup location to the physical file path that your virtual directory is pointing to.
2. If you have configured encryption of your `encryption.config` using EFS or DPAPI, you will need to replace the file from the backup with the unencrypted one.
3. Check that FIPS mode is not enabled on the server to avoid an error during the process.

Restoring the SQL Server Database

Choose one of the following scenarios:

Scenario One: Database and Secret Server Are in the Same Location

1. Open SQL Server Management Studio and connect.
2. Right click **Databases** and click the **Restore Database** button.
3. In the **To database** text box, type the database name or select it from the drop down list.
4. Click to select the **Device** radio button.
5. Browse to your database backup file.
6. In the **Restore Database** window Options section, ensure the **Force Restore over Existing Database** check box is checked.
7. Click the **Ok** button.
8. If you get an error saying that Management Studio was unable to get exclusive access to the database:
   a. Right click on the Secret Server database and go to **Properties**.
   b. At the very bottom, change the **Restrict Access** property to "SINGLE_USER". This closes all other

connections to the Secret Server database.

c. Re-attempt the restore.

9. Disable **Force SSL** if there is no certificate installed on the server you are restoring to.
10. In SQL Server Management Studio, expand the databases and select the database for Secret Server.
11. Select **New Query** at on the menu bar to open a query pane.
12. Copy the following command: `UPDATE [dbo].[tbConfiguration] SET ForceHttps = 0` into the query pane
13. Click **Execute** on the menu bar.
14. After the query executes successfully, restart Internet Information Server (IIS) by running `iisreset` from the command line.

> If you are prompted for database credentials when accessing Secret Server and are unable to re-connect, you may need to remap the user.

15. Expand the **Security > Users** folder under the Secret Server database.
16. Remove the user that Secret Server will use to access the database.
17. Expand the **Security > Logins** folder under the SQL Server root.
18. Right click on the log on corresponding to Secret Server and select **User Mappings**.
19. Re-map the log on to the Secret Server database.
20. If necessary, activate your licenses by going to the **Licenses** page.

Scenario Two: The Database and Secret Server Are in Different Locations

1. Delete the `database.config` file from the Secret Server folder.
2. Restart Internet Information Server (IIS) by running `iisreset` from the command line.
3. Use your Web browser to navigate to the new instance of Secret Server. This redirects you to the Web installer because the `database.config` file is missing and it thinks you have not installed yet.
4. Open SQL Server Management Studio and connect.
5. Right click **Databases** and click the **Restore Database** button.
6. In the **To database** text box, type the database name.
7. Click to select the **Device** radio button.
8. Browse to your database backup file.
9. In the Restore Database window options make sure the Force Restore over Existing Database Check box is checked.
10. Click **Ok**.
11. If you get an error saying that Management Studio was unable to get exclusive access to the database:

a. Right click on the Secret Server database and go to **Properties**.

b. At the very bottom, change the **Restrict Access** property to "SINGLE_USER". This closes all other connections to the Secret Server database.

c. Re-attempt the restore.

12. Disable **Force SSL** if there is no certificate installed on the server you are restoring to.
13. Copy the following command: `UPDATE [dbo].[tbConfiguration] SET ForceHttps = 0` into the query pane
14. Click **Execute** on the menu bar.
15. Navigate through the Web installer to Step 3.
16. Type the new database credentials (new server location, username, and password).
17. If you are unable to re-connect you may need to remap the user.

> If you are prompted for database credentials when accessing Secret Server and are unable to re-connect, you may need to remap the user.

18. Expand the **Security > Users** folder under the Secret Server database.
19. Remove the user that Secret Server will use to access the database.
20. Expand the **Security > Logins** folder under the SQL Server root.
21. Right click on the log on corresponding to Secret Server and select **User Mappings**.
22. Re-map the log on to the Secret Server database.
23. Once past Step 3, you are finished. Go to the `home.aspx` page (click the Secret Server logo). There is no need to go any further with the install because the `database.config` has been recreated with the new information.
24. If necessary, activate your licenses by going to the **Licenses** page.

Scheduled Backups

> This topic only applies to **Secret Server On-Premises**.

There are numerous options to consider when backing up Secret Server. Backups can be scheduled to run on a specific time interval. To prevent the directory from growing too large, the number of backups to keep can be defined as well. Depending on size constraints or preferences of the DBA, the database backup can either truncate the transaction log or keep it intact. The additional schedule settings are available when "Enable Schedule Backup" is enabled, and the view page indicates the time and date of the next scheduled backup.

Secret Server Disaster Recovery

The Disaster Recovery (DR) feature is a tool for emergency access to critical systems in the event of an emergency, such as a network outage. DR generates updates at regular intervals from one Secret Server instance (the data source) to another, or many other, instances (the replicas). A select set of folders and the secrets they contain will have any changes sent securely to the configured replicas so that, in the event the data source becomes inaccessible, the replicas can be quickly used for emergency access to vital systems.

General Disaster refers to generic DR concepts (clustering, SQL mirroring, etc.) while Resilient Secrets refers to specific features for replicating secrets data.

Disaster Recovery and Resilient Secrets

On-premises systems involved in Disaster Recovery/Resilient Secrets, acting as either a Source or a Replica, require a Site Connector using RabbitMQ.

Resilient Secrets Coverage

Resilient Secrets feature is available with Secret Server Professional and Platinum editions. It is not available with other Secret Server editions.

The Resilient Secrets (RS) feature is tailored to replicate data from a primary data source to a secondary data replica. The features and specific data replicated **do not** constitute the entirety of an instance of Secret Server. Instead, Resilient Secrets replicates the prioritized vital data and functionality needed so that, in the event of an outage of the primary data source, the most important information and functionality can be accessed on the secondary data replica to aid restoring the primary data source while keeping minimal operations running.

See Working With Resilient Secrets for more information about using Resilient Secrets with the Delinea Platform.

For more information on the login options available to users depending on service availability and internet connectivity, see Resilient Secrets Login Options for Delinea Platform.

The following features are what RS replicates, denoting what data is and is not replicated:

Excluded Features

The following features not replicated at all:

- Advanced LDAP Connection Settings
- Advanced Session Recording
- Audits
- Auto Export
- Backup Configuration
- Custom Reports
- Dev Ops Secret Vault
- Disaster Recovery Configuration
- Discovery
- DoubleLock
- Dual Controls
- Event Pipelines
- Event Subscriptions

- HSM Configuration
- Inbox Information and Rules
- IP Address Restrictions
- Jumbox Routes
- Licenses
- Node Information
- RDP Proxy Settings
- Remote Password Changing
- SAML Configuration
- Scripts
- SDK Client Configuration
- Secret Policies
- Session Recordings
- SSH Commands
- Ticket Systems
- Workflows

Conditionally Replicated Features

Configuration

Secret Server

Covered Features

The only global configuration settings replicated are:

- Enable directory service integration.
- Allow authentication against directory services.
- Application hardening state
- Allow quantum state encryption

The SSH cipher suite configuration is replicated.

Exceptions

Any configuration settings not listed above are not replicated.

Delinea Platform

The Platform configuration and Delinea permissions are replicated to allow the replica to communicate with Platform when needed, so Platform users can authenticate.

> In the event that everything fails, you will need to have created “break glass” local accounts on the Replica Secret Server. See Resilient Secrets Best Practices for more information. Delinea recommends creating these local accounts as soon as you provision the Replica instance.

> For a complete list of login options available depending on service availability and internet connectivity, see Resilient Secrets Login Options.

> Platform login on on-prem Disaster Recovery replicas is not supported in Secret Server versions earlier than 11.7.49.

Folders and Secrets

Covered Features

Folders are replicated, along with extended values associated with their function:

- Subfolders and the entire tree structure, as specified by the RS configuration.
- Any Delinea permissions associated with the folder, including whether or not to inherit them from its parent folder.
- For personal folders, the associated user.
- Secret template restrictions placed on folders.

Secrets are replicated along with essential information relating to them:

- The template, active status, name, and the folder the secret is in.
- Several secret settings, including:
  - Multi-factor authentication required
  - Check out enabled or RPC interval
  - Require comment
  - SSH proxy enabled
  - Web launcher requires incognito mode
  - Hide launcher password
- The secret field, item value, and whether or not it is a file attachment. If it is a file attachment, its contents are replicated as well
- Any Delinea permissions associated with the secret, including whether to inherit them from the folder.
- Audits are not replicated, but, for data integrity, secret item history, including the history of file attachments, *is* replicated.

Exceptions

These are not covered:

- Password change, heartbeat, and custom expiration information is not replicated because we do not allow RPC to happen from a replica.
- Secret policy information is not replicated.
- Secret dependencies, checkout hooks, and one-time-password settings are not replicated.
- Although TOTP codes are not replicated, you can obtain the MFA code from the source instance and configure TOTP on the replica without any issues.

Launchers and Mappings

Covered Features

All launchers are replicated, along with:

- Their fields.
- Mappings to secret templates.
- Any default associated and privileged secrets.

Exceptions

Custom icons for launchers are not replicated.

Lists

All list information is replicated, including:

- Categories
- Item values
- Team restrictions
- Secret item mappings

Metadata

All metadata on secrets and folders that are configured for replication are replicated. All Metadata on users and groups will be replicated. This includes:

- Metadata field sections.
- Metadata fields.
- Metadata item data.

Roles and Permissions

Roles and permissions are replicated, as are their assignments to users and groups.

Secret Templates

Covered Features

These are covered:

- Secret templates, their settings, permissions, and secret fields are replicated.
- Password requirements, associated rules, and their character sets are replicated.

Exceptions

These are not covered:

- Remote password changing and expiration-related settings are not replicated. Replicas are not intended to run RPC.
- One-time-password settings are not replicated.

Sites

Covered Features

All sites are replicated.

Exceptions

Site connector information is not replicated, and engine information is not replicated. This is because the encryption information related to the site is not replicated.

Launchers that rely on site connectors and engines will not function on the replica. To restore launcher functionality, you must:

- Manually configure Site Connectors on the replica.
- Manually install and configure Distributed Engines for the replica.

Launchers that rely on site connectors and engines will not function on the replica. To restore launcher functionality, you must: Manually configure Site Connectors on the replica. - Manually install and configure Distributed Engines for the replica.

Teams

All teams are replicated, along with their group and site mappings.

Users and Groups

Covered Features

All users and groups in the system are replicated and, for licensing purposes, we recommend the RS configuration be set to having users inactive by default and only enable the ones needed for vital access. User accessibility is maintained between source and replica. Group memberships are replicated and any associated roles and Delinea permissions mapped to them will come across as well.

Any directory services on the source is replicated to the data replica, and all users and groups mapped to these services retain system accessibility, provided the data replica is on a network that can reach the service endpoint.

Exceptions

These are not covered:

- Two-factor-authentication (2FA) configuration or details are not replicated. Users are not automatically configured for 2FA on the replica.
- User passwords are not replicated. Local users need to have their passwords manually reset by an administrator on the replica.

Setup

Secret Server Database Preparation

Overview

We provide several SQL scripts to help you identify any data duplication you may have that could cause issues with DR. We recommend that you run all of them.

> These searches will be built into future DR installations. We provide these as an interim measure till that happens.

They are:

- Secret Template Names: Searches for duplicates
- Secret Field Slug Names: Searches for duplicates
- Character Set Names: Searches for duplicates
- Password Requirements Names: Searches for duplicates
- Domain Names: Searches for duplicates of formal domain names (those in URLs)
- Domain Friendly Names: Searches for duplicates of human-readable domain name equivalents
- Folder Paths: Searches for duplicates of secret folders
- Group Names: Searches for duplicates of user group names
- Role Names: Searches for duplicates of user role names

Procedure

Copy and paste each query into a "Creating and Editing Reports" on page 887 and run it. Alternatively, database admins can run the scripts directly on the Secret Server On-Premises database. After running the queries, if you receive any results, that indicates duplicates to address before enabling the DR feature. Most issues can be resolved by simply renaming or removing the duplicate items.

SQL Scripts

Secret Template Names

```
SELECT
    SecretTypeName
FROM
    tbSecretType
GROUP BY
```

```
    SecretTypeName
HAVING
    COUNT(*) > 1
```

Secret Field Slug Names

```
SELECT
    st.SecretTypeName,
    t.FieldSlugName
FROM
(
    SELECT
        sf.SecretTypeId,
        sf.FieldSlugName
    FROM
        tbSecretField AS sf
    JOIN
        tbSecretType AS st2
    ON
        st2.SecretTypeID = sf.SecretTypeID
    GROUP BY
        sf.FieldSlugName, sf.SecretTypeId
    HAVING
        COUNT(*) > 1
) AS t
JOIN
    tbSecretType AS st
ON
    st.SecretTypeID = t.SecretTypeID
```

Character Set Names

```
SELECT
    cs.Name
FROM
    tbCharacterSet AS cs
GROUP BY
    cs.Name
HAVING
    COUNT(*) > 1
```

Password Requirement Names

```
SELECT
    pr.Name
FROM
```

```
    tbPasswordRequirement AS pr
GROUP BY
    pr.Name
HAVING
    COUNT(*) > 1
```

Domain Names

```
SELECT
    Domain
FROM
    tbDomain
GROUP BY
    Domain
HAVING
    COUNT(*) > 1
```

Domain Friendly Names

```
SELECT
    FriendlyName
FROM
    tbDomain
GROUP BY
    FriendlyName
HAVING
    COUNT(*) > 1
```

Folder Paths

```
SELECT
    FolderPath
FROM
    tbFolder
WHERE
    UserID IS NULL
GROUP BY
    FolderPath
HAVING
    COUNT(*) > 1
```

Group Names

```
SELECT
```

```
    GroupName
FROM
    tbGroup
WHERE
    IsPersonal = 0
    AND IsPlatform = 0
    AND SystemGroup = 0
    AND DomainId IS NULL
GROUP BY
    GroupName, DomainId
HAVING
    COUNT(*) > 1
```

Role Names

```
SELECT
    r.Name
FROM
    tbRole AS r
WHERE
    r.RoleType = 1
    AND r.IsSystem = 0
GROUP BY
    r.Name
HAVING
    COUNT(*) > 1
```

Duplicate Launcher Type Fields

Duplicate launcher type fields in the source database can cause a DR sync failure. This script detects them.

```
SELECT
  ltf.Name AS LauncherTypeField,
  lt.ConcurrencyId AS LauncherTypeConcurrencyId
FROM
  tbLauncherTypeField ltf WITH (NOLOCK)
  INNER JOIN tbLauncherType lt WITH (NOLOCK) ON lt.LauncherTypeId = ltf.LauncherTypeId
GROUP BY
  lt.ConcurrencyId,
  ltf.Name
HAVING
  COUNT(*) > 1
```

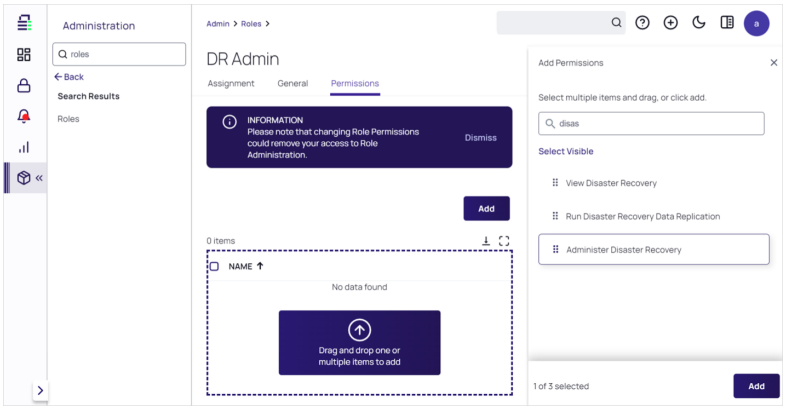
It is possible to use Disaster Recovery with Integrated Windows Authentication enabled on Secret Server Cloud. See "Configuring Integrated Windows Authentication" on page 389 for more information.

Role Assignment

Assign the "administer disaster recovery" role permission:

Do this on both the data source and replica instances.

1. Click **Administration** in the main menu. The Secrets Administration page appears.
2. Click the **Roles** link in the **Users, Roles, Access Management** section. The Roles page appears.
3. Select or create the role you want to configure this feature with.
4. Click the **Permissions** tab.



5. Click **Add** or **Edit**.
6. If you do not see the role in the **Add Permissions** list, type `Administer Disaster Recovery` in the search box.
7. Drag the **Administer Disaster Recovery** role from the **Add Permissions** list and drop it in the unlabeled permissions box. The role now has the permission.

Data Source DR Configuration

Configure the data source DR configuration:

1. Click **Administration** in the main menu. The Secrets Administration page appears.
2. Search for and click **Disaster Recovery**. The Disaster Recovery page appears.
3. Click the **Outgoing Configuration** tab.
4. Click **Outgoing Setup Steps**. A popup appears.
5. Click **Copy** to copy the URL from the **Data Source URL** and save it where you can easily access it.
6. Click **Copy Data Source Key** to copy the key to the clipboard. The popup disappears.
7. Copy the key and save it to the same location you used for the URL. It should look something like this:

```
https://mydomain.com/Playground
                                        BgIAAACkAABSU0ExABAAAAEAAQAPeEYJLZ3u1F26EF+bBiRwokrGusSAICUpR
2/lo3Ad7dpTEl7j3rvG9+T+j8DKTsmi6Xfj

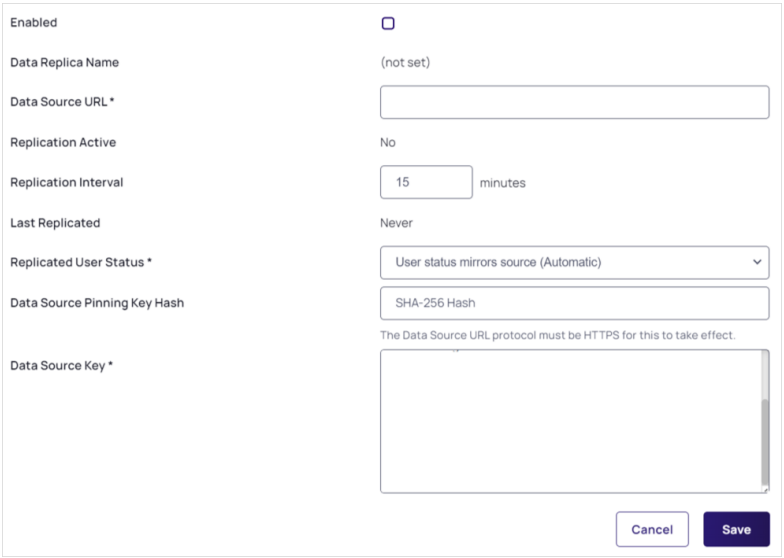
xRLJ/f/SMdxfmIcTqxLr/r9k6RAiJo8DiBoWMkjk4VUCFIL4rYpUIJb/aKmx9npg==

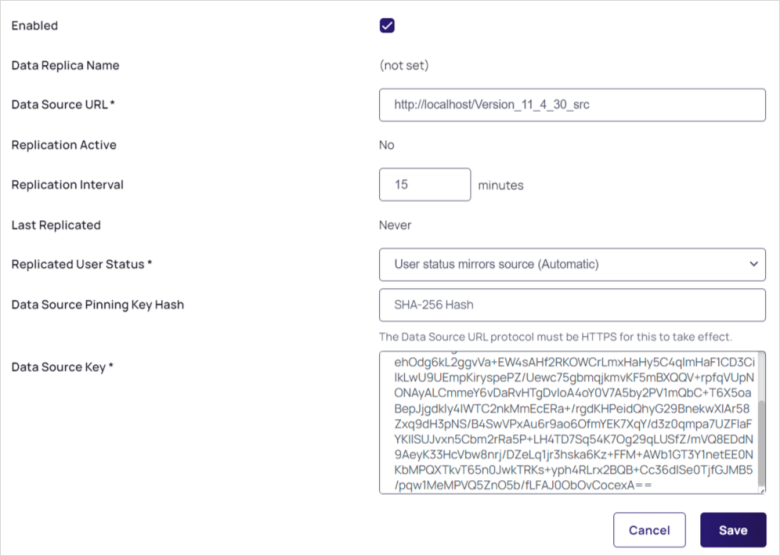
> If you have a On-Premises source instance with multiple webnodes, you will need to enter the storage path where files related to data replication will be temporarily stored. All servers must have a shared path to store the replication packages, otherwise replication errors may occur.

Replica DR Configuration

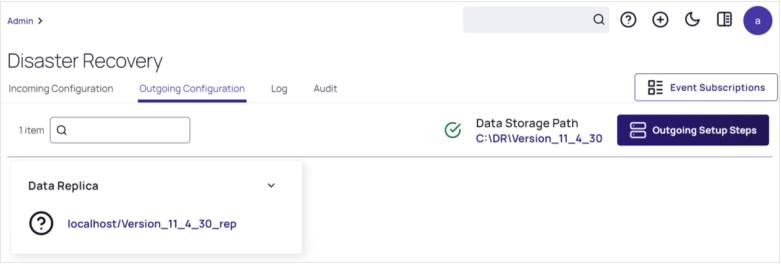
1. Click **Administration** in the main menu. The Secrets Administration page appears.
2. Search for and click **Disaster Recovery**. The Disaster Recovery page appears.
3. If necessary, click the **Incoming Configuration** tab.
4. Click **Edit**. The page becomes editable.



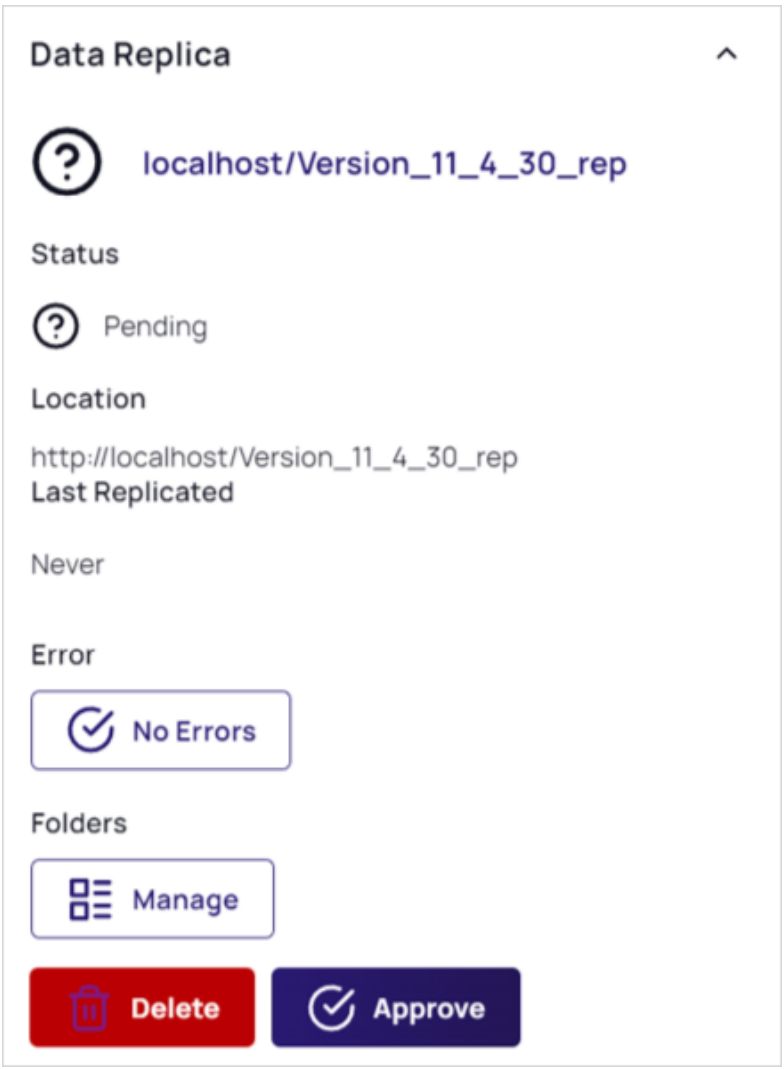
5. Click to select the **Enabled** check box.
6. Type or paste the data source URL you saved before.
7. Type or paste the data source key you saved before.



8. Click **Save**.
9. Refresh the **Disaster Recovery** page showing the **Outgoing Configuration** tab on the Data Source Disaster Recovery page. A new block appears for the new replica connection:



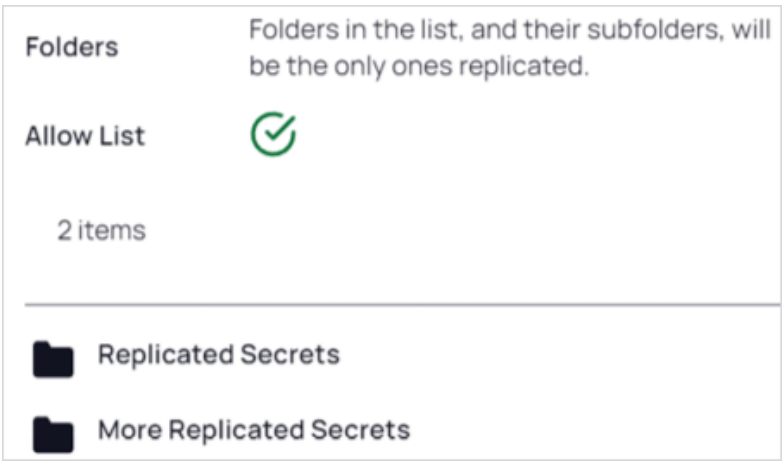
10. Click the **v** on the block to expand it.



11. Click the **Approve** button.
12. Returning to the **Ingoing Configuration** tab, click the **Test Connection** button to verify everything is configured correctly.

Finishing up

1. Once configuration is complete, return to and refresh the **Outgoing Configuration** tab.
2. We recommend expanding the block and clicking the **Manage** button for folders.



This enables you to select which folders, subfolders, and secrets get replicated. This reduces the scope of the replicated data, enabling faster replication and a smaller duplicated data footprint.

This will enable the regular interval synchronization

For more configuration information on configuring your source and replica instance, see Setting Up Resilient Secrets

Replication

By design, the first time a replication from the data source to the replica occurs, all data is replicated. This is likely the slowest DR operates and can take up to 20 minutes to replicate a data source containing 100,000 secrets.

All subsequent replications are significantly smaller. Only information that has been changed since the previous replication is replicated again.

Replica Mode

When you configure a Secret Server instance as a replica, it is automatically placed in replica mode. While in replica mode, the following features are disabled

- ConnectWise synchronization
- Discovery
- DoubleLock
- Heartbeat
- Pipeline and bulk operations on secrets
- Remote password changing
- Secret import
- Secret policy changes to secrets

Replicated User Status

The "replicated user status" setting determines how the "enabled" status for users is handled during replication. The setting is used primarily when the source and replica user counts do not match—that is, new users are on the source that are not on the replica. Delinea strongly recommends both source and replica user counts match so all users and their access is replicated to the DR instance.

> When these settings are changed, they impact any new users from that point forward. Existing user statuses do not change.

The possible settings are:

- User status mirrors source (automatic): This is the default setting. Any new users in the source are replicated as enabled.
- New users from source are disabled by default (manual): This setting is for admin special cases and must be manually set. New users are replicated as disabled.

Recommendations

We recommend placing a Secret Server replica into maintenance mode. This further reduces the possibility of data changes to the instance. See Maintenance Mode section for more details.

Disaster Recovery Best Practices

- Backup Data with Resilient Instances - Resilient instances refer to the capability of replicating secrets data to another cloud or on-premises instance of Secret Server with automated one-way synchronization from the source instance to the replica. Replicas should be kept in read-only mode to avoid loss of integrity. This ensures continuous access to secrets, even during emergencies, thereby reducing the risk of downtime or disruption in privileged access. See Working with Resilient Secrets section of the Delinea Platform documentation to learn more.
- Using Multifactor Authentication (MFA) - For disaster recovery planning, the relevant MFA consideration is ensuring that critical secrets remain accessible during a disaster scenario—either by configuring MFA methods that will function in a disaster recovery event or by establishing break-glass procedures for emergency access. Refer to "Multi-Factor Authentication" on page 446 for more information.
- Security Hardening - Security hardening for Secret Server involves implementing a series of best practices and configurations to enhance the security of your Secret Server instance. This includes securing the operating system, application settings, database, and network communications. Hardening must be applied to both primary and replica instances. Refer to the "Security Hardening Guide" on page 1419 for more information.

> Please be sure to test the items in the Security Hardening Guide one at a time as multiple simultaneous changes can cause issues in case you need to test or revert the changes.

- Setting Up Event Alerting - provides robust alerting and notification features to help administrators stay informed about critical events and actions. Refer to "Event Subscription Overview" on page 320 for information.

- (**Secret Server On-Premises only**) Leverage Rabbit MQ's Disaster Recovery Capabilities - The Best high availability/disaster recovery multi-site deployment for RabbitMQ Helper in Secret Server is designed to provide high availability and disaster recovery across multiple locations, typically a primary and a secondary disaster recover site. This setup ensures that RabbitMQ Helper clusters are available in multiple locations, providing robust failover capabilities. Learn more about Rabbit MQ.

  For failover to a secondary location, configure SQL Server with an availability group (either standard or basic availability groups). This allows the database to fail over alongside your Secret Server instance.

Version Compatibility

Although there is typically no stringent requirement to align the releases between the source and replica, it is considered best practice to maintain the replica at the same release version of Secret Server as the source to ensure compatibility.

For Resilient Secrets, the source and replica versions do not need to match exactly, though newer features won't be available on the older instance. Keep versions as close as possible. Note that cloud and on-premises versions will never align exactly due to different release schedules.

For traditional disaster recovery (non-Resilient Secrets): On-premises to on-premises configurations must run identical Secret Server versions.

> Individual releases may necessitate upgrading, and customers should refer to the release notes for specific requirements. Additionally, customers are advised to always upgrade to ensure their release is within Delinea Support's stated policy.

Server Clustering

> This topic only applies to **Secret Server On-Premises**.

Secret Server can run with multiple front-end Web servers. For a critical instance, clustering offers a redundant system to limit potential down time from a single point of failure. Clustering also allows users to load balance for better performance. For instructions on enabling clustering in Secret Server, see "Secret Server Clustering" on page 775.

SQL Server Mirroring

> This topic only applies to **Secret Server On-Premises**.

This topic describes the process of configuring Secret Server and SQL Server for a high-availability environment using Mirroring. The contents of this paper include:

- Configuring SQL Server 2016 for database mirroring with a failover partner and a witness
- The encryption used between the primary database and the mirror database
- Configuring Secret Server to use mirroring to achieve high availability

> This topic uses SQL Server 2016, but it is very similar to earlier versions.

SQL Server Mirroring is deprecated as of SQL Server 2016 and is not supported in SQL Server 2022. For environments using SQL Server 2022, it is recommended to use Always On Availability Groups (AAG) instead. If the SQL Server edition does not support full AAG, consider using Basic Availability Groups as an alternative. For more information on configuring Basic Availability Groups, refer to the Microsoft documentation on Basic Availability Groups.

Introduction

Three different SQL Server instances are required to implement this scenario:

- **Primary database:** The main application database
- **Mirror database:** Replicates all of the data on the primary database in a transactional manner
- **Witness database:** Monitors the health of the primary and mirror databases and initiates failover if necessary

In the setup described here, mirroring operates in synchronous mode, which means that a transaction does not commit on the primary database until it has committed on the mirror.

See Prerequisites, Restrictions, and Recommendations for Database Mirroring for more on synchronous mirroring.

Procedures

Setting up Databases for Mirroring

To initiate database mirroring, the databases on the primary and secondary machines must have the same name. We recommend doing this before installation. To initially set up mirroring, in Microsoft SQL Server Management Studio, take a full backup of the database on the primary and then restore it onto the database on the secondary. When restoring the database, the "RESTORE WITH NORECOVERY" option must be selected.

SQL Server Configuration

The three SQL Server instances should all be running under the same domain account. It is possible to run under different accounts but the configuration is more complex and not supported by Delinea technical support. Each SQL Server instance should be configured to listen on TCP.

Configuring Mirroring

To configure mirroring:

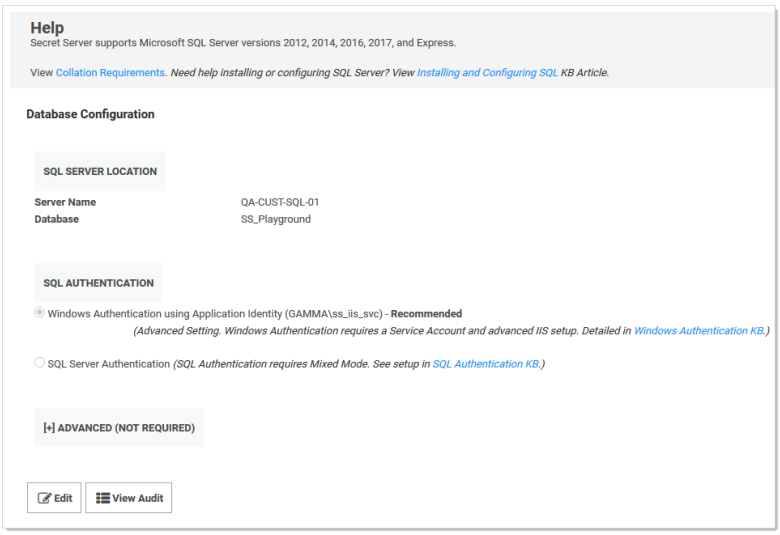
1. In Microsoft SQL Server Management Studio, drill down to the primary database in the Object Explorer.
2. Right click the primary database and select **Properties**. The Database Properties window appears.
3. Select the **Mirror** page.
4. Click on the **Configure Security** button. The Configure Database Mirroring Security Wizard appears on the introduction page.
5. Click the **Next** button. The Include Witness Server page appears.

6. Click to select the **Yes** selection button.
7. Click the **Next** button. The Choose Server to Configure page appears.
8. Click to select all three interface check boxes (principal, mirror, and witness servers).
9. Click the **Next** button. The Principal Server Instance page appears.
10. Click the **Principal server instance** dropdown list to select the current (primary) server.
11. Type a port number for connecting to the other servers in the **Listener port** text box. The port must be open for TCP communication on the machine's firewall and on any network devices that restrict access to this machine.
12. Click to select the **Encrypt data sent through this endpoint** check box. This enables RC4 encryption on data sent through this endpoint.
13. Type `Mirroring` in the **Endpoint name** text box. The endpoint name is for referencing the endpoint later.
14. Click the **Next** button. The Mirror Server Instance page appears.
15. Repeat the exact same configuration you set for the primary server instance with only the server instance name different (choose the mirror instance).
16. Click the **Next** button. The Witness Server Instance page appears.
17. Repeat the exact same configuration you set for the primary server instance with only the server instance name different (choose the witness instance).
18. Click the **Next** button. The Service Accounts page appears.
19. Type the domain user that SQL Server runs under for each instance's Service Accounts text box. For example `mydomain\sql_svc`.
20. Click the **Finish >>** button. Logins are created for each account and are given CONNECT permission on each endpoint, if needed. The Complete the Wizard page appears.
21. Click the **Finish** button

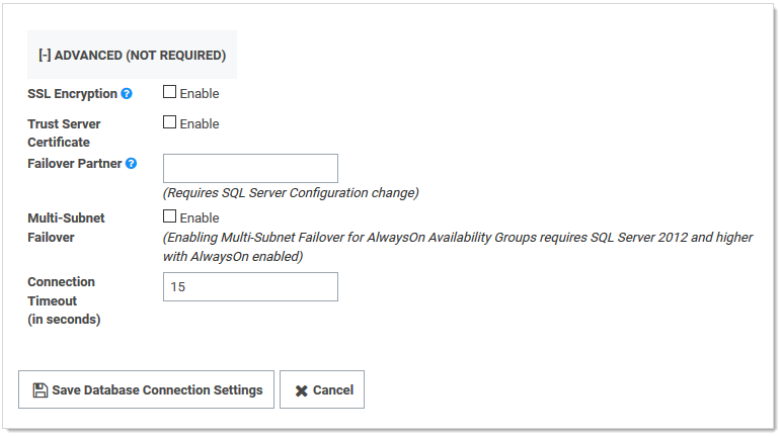
Configuring Secret Server for Mirroring

The credentials used to access the primary database must also be valid on the mirror database for failover to work.

1. Search for **See All**. The admin panel appears.
2. Type Database in the **Search** text box and select **Database**. The Database Configuration page appears:



3. Click the **Edit** button.
4. Click the **Advanced (Not Required)** link. A new section appears:



5. Click the select the **SSL Encryption** check box.
6. Type the mirror server name in the **Failover Partner** text box.
7. Click the **Save Database Connection Settings** button.

Testing Mirroring

This procedure is necessary to verify that failover will function correctly in the event that the primary server is unavailable or inoperable:

1. Open SQL Server Enterprise Manager.
2. Right click the primary database and select **Properties**.
3. Click the **Mirroring** tab.

4. Click the **Failover Now** button. This causes the database on primary to switch roles and become the mirror database. The mirror database becomes the primary. Clients using the application should be able to continue as before.

> One request may fail before Secret Server begins making requests to the new primary database.

Database SSL Configuration

> See Enable encrypted connections to the Database Engine for instruction on configuring SSL for SQL Server.

The certificate authority used for the SSL certificates must be trusted on all of the machines that are a part of Secret Server's installation. The SQL Server service account must be granted access to the certificate.

Procedure:

1. Open Microsoft Management Console by running `mmc` on the Windows command prompt.
2. Drill down to **Console Root > Certificates > Personal > Certificates** in the navigation tree.
3. Right click the certificate and select **All Tasks > Manage Private Keys**.
4. Grant the user account that SQL Server uses read permission.
5. Ensure SSL is enabled for both the primary and mirror database server. See Configuring Secret Server for Mirroring. It is not necessary to configure SSL on the witness server.

SQL Server Replication Best Practices

> This topic only applies to **Secret Server On-Premises**.

> **Geo replication is deprecated. It is no longer a feature of Secret Server and is not supported by Delinea.** When it was active, Geo Replication upgrades were outside the scope of technical support and were scheduled through Professional Services. Due to improvements in AlwaysOn technology, we recommend using it instead for most use cases.

Overview

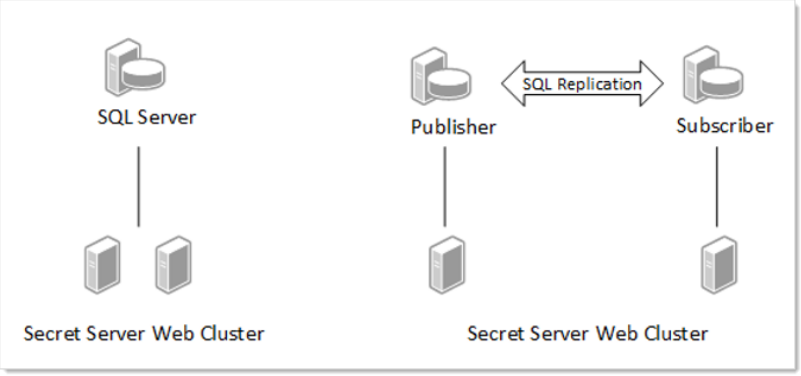
Secret Server geo replication is SQL Server replication using a set of technologies for copying and distributing data and database objects from one database to another and then synchronizing between databases to maintain consistency across geographically distributed data centers.

> Secret Server uses merge replication. The only version validated is pull-based merge replication. Push based replication has not been validated.

SQL timeouts are a known error condition when SQL Server Always On is configured to use synchronous replication. We recommend using asynchronous replication to mitigate or avoid the timeouts. Secret Server does hundreds of transactions per minute from all web nodes, any of these SQL operations can timeout if the replication takes too long blocking other operations to complete in a timely manner. Asynchronous replication will not block other operations from completing in a timely manner.

SQL Server Replication

Figure: SQL Server Replication



Benefits of Replication

Enabling SQL Server replication allows a database and application to be hosted closer together and this allows for the mitigation of network latency and outages.

- Decrease application server to database network latency
- Resolve issues with unreliable network connectivity
- Allows for distribution of workload in a scale out fashion
- Works across large distances

In a typical web-clustered version of Secret Server, all application servers access a centralized database. In the event of a network outage, any users on affected application servers are not be able to use Secret Server until network access was restored. In addition, poorly performing networks can introduce latency that may decrease the responsiveness of Secret Server. This technology provides additional options when designing the network topology behind Secret Server that can help alleviate these issues.

High Availability

SQL Server replication is *not* an option for high availability, but it can be coupled with other technologies like SQL Server AlwaysOn Availability Groups to provide high availability. Any architecture should be reviewed and designed with your database group.

Architecture

The SQL Server Replication technologies do all the work of ensuring data consistency between each database, and Secret Server is designed to work well with this technology. When SQL Server replication is enabled on a specified database several system tables, views, stored procedures, and SQL Server jobs are added to the database schema. These tables store information about the data replication, and the procedures contain most of the code needed to perform the synchronization between databases.

Data Synchronization

This is the process through which SQL Server replication integrates changes from each database node. These changes include data changes as well as schema changes. Each subscribing database node has a synchronization interval that defines when it will synchronize any changes between the main publication node and itself. Secret Server has been tested using pull-based subscriptions where a scheduled job on each SQL Server subscriber runs at a specified interval to trigger the synchronization.

Data Conflicts

Enabling SQL Server replication introduces the possibility of data conflicts occurring in the Secret Server environment. This can happen when two people in different regions attempt to update the same set of data. Due to the disconnected nature of the technology, the system is unaware of this conflict until a data synchronization occurs. During synchronization, SQL Server attempts to resolve any conflicts based on a defined set of parameters. Secret Server provides a setup script to help define optimal parameters for each article (table, view, and stored procedure) in the Secret Server database.

SQL Server Replication Monitor and Conflict Viewer

For more information:

- Replication Monitor
- Conflict Viewer and Interactive Resolver

Tracking level

SQL Server replication tracks changes to each node by either row or column:

For more information on row- and column-level tracking, see Row-Level Security

Conflict Resolvers

SQL Server replication uses resolvers to determine the outcome of data conflicts between two database nodes. For example, the same row or column was updated on different nodes. These can be as simple as the publisher database always wins, last change by date wins, and many others.

Switch nodes over to subscriber databases. Any nodes that are configured to run background, engine, or session recording roles must remain on the publisher database.

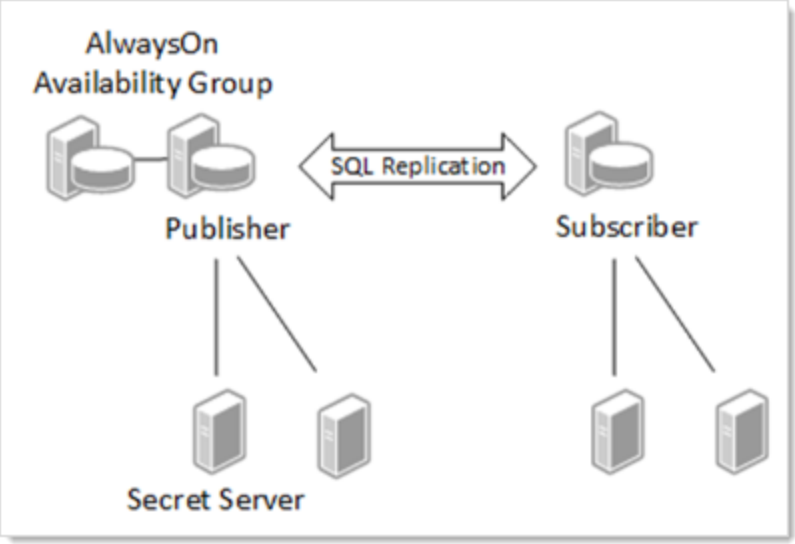
For more information see:

- Advanced Merge Replication Conflict Detection and Resolution
- Specify Merge Replication Properties

Secret Server and SQL Replication

There are many architectures for how SQL Replication can be setup. Determining the correct configuration requires proper planning with a good understanding of how SQL Replication works and the intended goals of using this technology. Here are a few examples.

Figure: Web Cluster with SQL Server Replication



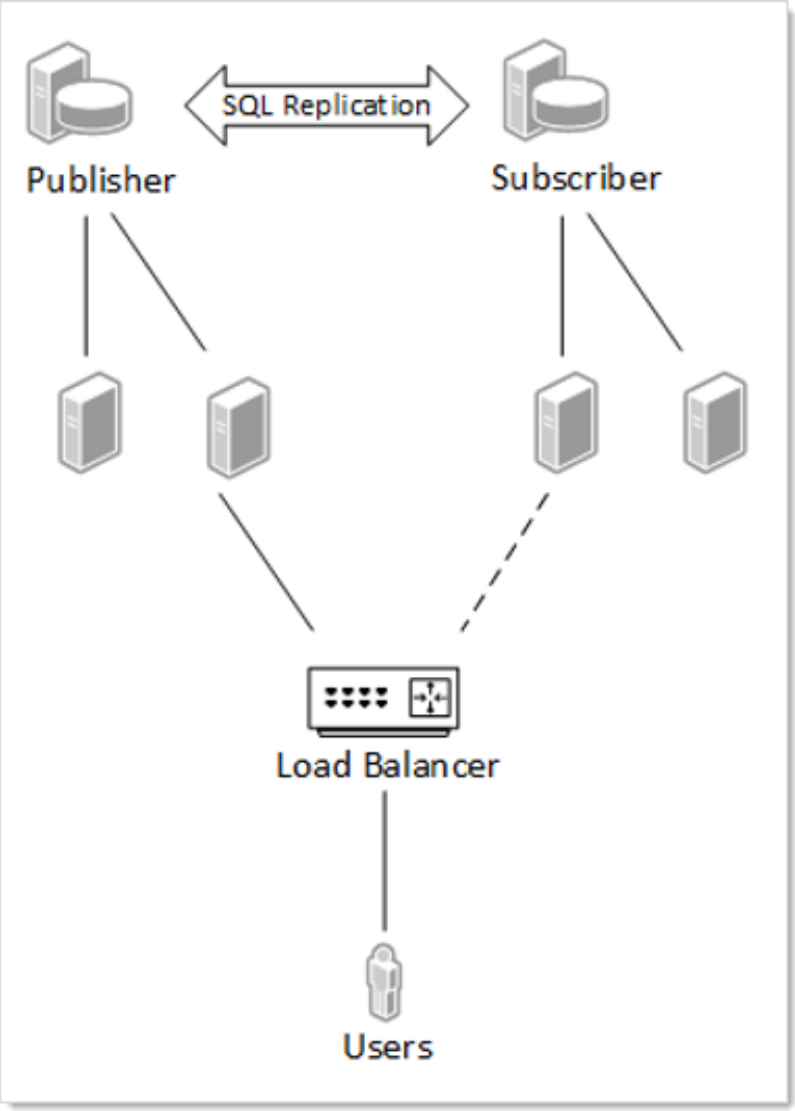
Some key points about designing the right architecture:

- Multiple web application servers can connect to the same database server.
- Secret Server allows you to configure various roles (background, engine, session recording) that perform various services, such as heartbeat and password changing. These roles can only function on a node that has a connection to the publisher database and will not run on other nodes even if configured to do so. If no suitable node is available that has roles enabled and is connected to the publisher database, then certain activities such as secret heartbeat and remote password changing will be offline until such a node becomes available.
- Secret Server Engines are an effective means to distribute workload to different networks or sites. Each engine must call back to a Web application node that connects to a publisher database.
- The diagram shows the publisher in an AlwaysOn availability group, but this is just an example. Depending on the needs of the organization, AlwaysOn could run on both the publisher and the subscribers or on neither. Many other high availability options could be leveraged alongside SQL

  Replication.

Using a Subscriber When the Publisher Is Offline

Figure: Using a Subscriber When the Publisher Is Offline

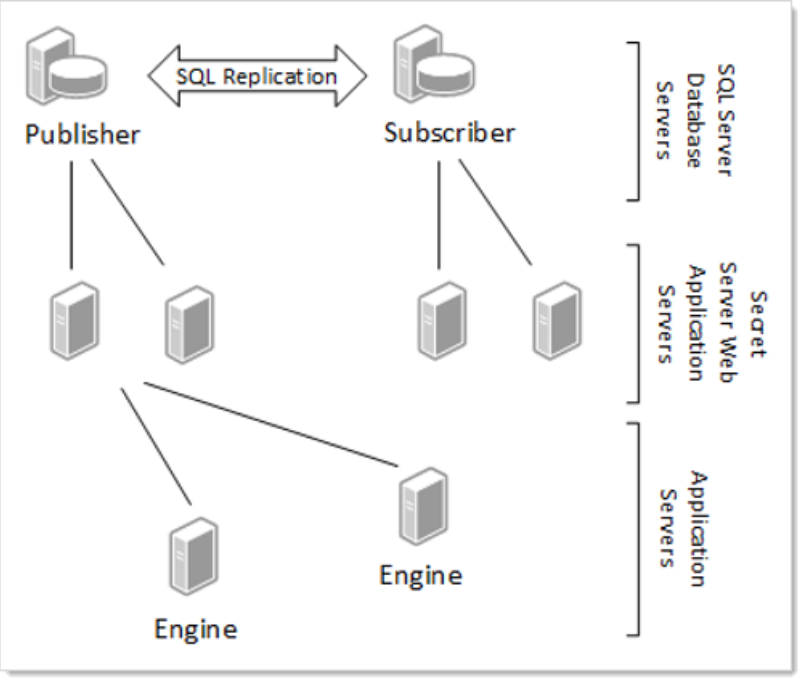


In the event of a network outage, a load balancer could be configured to fail over to the subscriber nodes. The data on the subscriber would be as up to date as the last synchronization, and when network connectivity is restored all data activity will be synchronized again. Obviously, if the issues of network latency or disconnects occur too frequently, this may not be a workable solution.

Secret Server Distributed Engine

You can add Secret Server distributed engines to different network segments, but you must still be able to call back to a Secret Server Web application server that is connected to a publisher database node. This helps to ensure that heartbeats and password changes occur with the most up to date dataset.

Figure: SQL Replication and Distributed Engines



Secret Server Replication Settings

Keep in mind that this is a disconnected technology, so there are required decisions when setting it up:

- How often should synchronization occur?
- Should any resolvers override the provided defaults?
- Are there any operational considerations based on the type of secret data?

Publications

- Events: These are things that need to occur on a timely schedule, such as updating secrets. The events publication should be set to synchronize every minute. This means that if a secret were created in one region, it would not appear in another region for one minute. By default, this publication is called *SSPubEvents*.
- Logs: Information from each audit log is available on its server. We do not recommend setting log synchronization to less than hour. If this happens too frequently, the database could create deadlocks by constantly updating large sets of data. Once the logs merge, the events will appear in the order in which they occur and show on the server on which they took place. By default, this publication is called *SSPubLogs*.

Using the default Secret Server implementation, most conflicts are resolved by taking the change made on the publication server as the winner (using the "publisher wins" resolver). It is assumed that the publication server is most likely the main server in an environment and therefore, most likely, the decider in a case of a conflict. Thus, we recommend doing functions, such as configuration changes or secret template definition changes, on the publication node. This is only an issue if two people update the same data on two different servers before a synchronization occurs.

There are some exceptions to the "publisher always wins" rule:

Data Element	Resolver or Tracking Level	
Secret Fields	Last Update Wins	If two people change a password on a secret to a new password, then the last person to make the change will win.
Secret Access Request Approval	Last Update Wins	If two people are in a group that is requested to approve access, then the last person to approve or disapprove access would set that approval.
File Attachment	Last Update Wins	
tbConfiguration	Column Level	Configuration changes are resolved by table column, not the default row-level where the entire row is resolved. This allows different configuration options to be set on different servers and not conflict with each other, but changing the same option would create a conflict.

Always remember that the conflict is only resolved when synchronization occurs. If there is a synchronization window of 24 hours, there could be very different data on different servers for that entire 24-hour period. The risk of data conflicts increases with larger synchronization windows. The default recommended synchronization is every minute for most items and every hour for system logs.

For a complete listing of recommended settings navigate to the **SQL Replication Administration** page in an installed version of Secret Server at **ADMIN > Nodes > SQL Server Replication > Show Articles**.

Conflict Auditing

When conflicts occur during synchronization, Secret Server writes an event to the system log on the server that it has detected these conflicts. Depending on the type of conflict, more-specific information maybe written to the audit log for a specific data entity, such as a secret or folder. Notification of the conflict is written to the system, secret audit, folder audit, and other logs. To view complete details of the conflict, the SQL Conflict Viewer tool needs to be used to review the conflict by right clicking on the publication and choosing to View Conflicts.

As an example, if the same field changed on two different servers, resulting in a conflict, then the Secret Server audit log will indicate the field was changed twice and then denote that there was a data conflict.

Operational Latency

Give consideration to how your Secret Server data is setup and managed. This is most easily described by an example where a manager uses a Secret Server node in Europe and their employee works on a node in Australia. Due to network latency, the organization has changed the default event log synchronization interval from every minute to every five minutes. The employee requests access to a secret in Australia, but due to the synchronization window, the manager is not alerted until five minutes later because the manager is using the server in Europe. You can mitigate this issue by having operational groups work on data for their region or decreasing the synchronization window.

Options to manage data latency if data conflicts occur regularly:

When setting up the SQL Replication Publication certain articles need settings other than the default settings. The recommended settings can be found within Secret Server by accessing the SQL Server Replication page located at

Admin > Nodes > SQL Server Replication > Show Articles. This page can also be used to generate a setup script for both the Publication and Subscribers that uses these default settings. A Distributor will need to be created before running these scripts. For more information, see Configuring Distribution.

Compensate for Errors

When conflicts occur, an article that has the compensate_for_errors attribute set to true will automatically try to resolve the conflict. When false, a SQL Server administrator can use the SQL Server Conflict Viewer to review and resolve conflicts.

Identity Range

SQL Server replication manages table identities by assigning ranges to the publisher and subscribers. Certain tables (logging or auditing) require larger assigned identity ranges. New ranges are only assigned when a data synchronization occurs. For more information, see Replicate Identity Columns.

Variations

How SQL Server replication is setup can vary greatly and there may be reasons to not use the standard setup. Consult with your database group for approaches that may work well in your environment. The architecture diagrams contained within this document are just high-level examples.

Installation

There are a multitude of configuration options for SQL Server replication. At a high level, these are the steps to setup Secret Server in a SQL Server replicated environment:

This can run on the same database as the publication database or on a separate one on another server.

1.
2. Review what settings are appropriate for the distributor setup with your on-premise database group or with a database consultant.
3. Download the SQL publication script.
   a. In Secret Server select **ADMIN > Nodes > SQL Server Replication >Get SQL Publication Script**.
   b. Review this script and update the variables according to your environment.

Advanced users can use the article list on that same page to configure SQL replication differently than this script to suit your environment.

1. Run this script on the Secret Server Database. A DBA with administrative privileges is needed to run this. Please consult with your on-premise database group or review your configuration with a database consultant.
2. Create snapshots for each publication:

   a. Open SQL Server Management Studio
   b. Right click on each publication under **Replication > Local Publications**
   c. Select **View Snapshot Agent Status**.
   d. Click **Start**
3. Download the SQL subscriber script:
   a. In Secret Server select **ADMIN > Nodes > SQL Server Replication >Get SQL Subscriber Script**.
   b. Review this script and update the variables to match your environment
4. Create a new database on the database server you intend to be your subscriber. Ensure the script uses this database and machine name. Set up permissions for the user or network account that Secret Server uses to connect to this database.
5. Run the subscriber script on the publication database first and then on the subscriber database. If your variables are set properly, it will execute the appropriate part of the script.
6. Expand the **SQL Server Jobs** on the subscriber, and you should see two jobs named for each publication.
7. Right click these jobs to start them. After they complete, your subscriber database should have replicated the schema objects from the publication.
8. Switch Secret Server nodes over to subscriber databases. The primary node *must* remain on the Publisher database, as must any node that an engine calls back to, but all other nodes can be reconfigured to use subscriber databases. Which nodes to switch depends on your specific needs as described in the previous sections. To switch an existing node to a subscriber database, log into that node and go the DbConnectionReset.aspx page by entering that page name in the URL field of your browser (`http[s]://<your_secret_server_name>/DbConnectionReset.aspx`). Step through the wizard, entering the name of the new server and database when prompted. After completing this step, recycle the node's application pool.

Troubleshooting the Installation

Replication Setup Scripts Fail

Make sure that the SQL Server replication feature is enabled before running the script. Check the error messages in the script output. Make sure you set all of the variables in the top of the script correctly (such as publisher server, database names, and subscriber server).

SQL Replication Job Fails

To see the error message, it is easiest to right click on the job and choose to view history. This error message can indicate the actual problem.

Removing SQL Server Replication

Certain operations such as upgrading Secret Server, adding or removing DoubleLocks from secrets, and enabling or disabling HSM cannot be performed while SQL Server replication is enabled. In order to perform these operations you must remove SQL Server replication. When you are done with the action that required you to remove replication you can install and configure it again by repeating the previous instructions.

You only need to remove replication from the Publisher and all Subscribers. The Replication Distributer does not need to be removed. These are the steps to remove SQL Server replication from your publisher and subscriber databases.

On Each Subscriber

1. Stop the websites of all nodes using the subscriber database.

> You can see what database each node is using from **Admin > Server Nodes**.

1. In SQL Server Management Studio, go to , right-click **Local Subscriptions** and choose
2. In the dialog, click to select "Subscriptions in the following data sources" and select the Secret Server subscription databases.
3.
4. Click **Generate Script > Open in new query window**.
5.
6. The script contains sections to be run on both the subscriber and the publisher. Run the sections on the subscriber by uncommenting them and commenting those for the publisher.
7. Copy the script to a query window on the publisher server.
8. The script contains sections to be run on both the subscriber and the publisher. Run the sections on the publisher by uncommenting them and commenting those for the subscriber.
9. Perform any maintenance actions needed on the subscriber database and nodes.

On the Publisher

1. Stop the websites of all nodes using the publisher database.
2. On the publisher, go to **Replication**, right-click **Local Publications** and choose **Generate Scripts...**
3. In the **Generate SQL Script** dialog **check Publications in thefollowing data sources** and select the Secret Server database.
4. Click to deselect the **Distributor Properties** check box.
5. Select **To drop or disable the components**.
6.
7. Click **Close** to close the dialog once the script is created.
8. Run the script.
9. Perform any maintenance actions needed on the subscriber database and nodes.
10. After all maintenance tasks are done, restore replication as described in "Disaster Recovery and Resilient Secrets" on page 474.

Managing SQL Server Replication

Once replication is setup and working certain considerations should be given to managing it along with conflicts that can occur. The recommended settings for the publication have been tested to limit conflicts, but they can still occur. Here are some scenarios you might encounter:

Scenario	Solution
Conflict automatically resolved	SQL Server was able to determine how to resolve the conflict. Secret Server will log and audit this conflict. To see the specific details for the conflict, use the **SQL Server Conflict Viewer** in SQL Server Management Studio.
Conflict unable to be automatically resolved	A user with SQL Server access needs to open the conflict in SQL Server Management Studio. Access these by right-clicking on the publication and choosing to view conflicts.
Some data stops replicating	A table could become blocked if there are conflicts. Other data may continue to synchronize. If data in one region or database node is different than another after a synchronization, there could be conflicts that need to be reviewed and resolved.
SQL Replication Synchronization Times	The status of each publication and subscribing server along with the last time of synchronization can be located in Secret Server by selecting .

Web Server Nodes

The **Web Server Nodes** page now includes a column that lists the database server name and database name. This column also indicates whether the database is the publisher or a subscriber. To see the page:

1. Open Secret Server.
2. Click the **Admin** menu item and select **All**.
3. Click the **Server Nodes** button. The Server Nodes page appears (not shown).
4. If you click the **SQL Server Replication** button, you can see more information about your SQL Server replication. The page pulls from the replication data and shows the:
   - Publication name
   - SQL server
   - Database
   - Subscription type (push or pull)
   - Status of the last sync
   - Last time that subscription was synced
   - Date of the last sync

The same information is available within SQL Server Management Studio, but this page gathers all of the subscription information together in one place.

As mentioned earlier, the **Get SQL Publication Script** and **Get SQL Subscriber Script** buttons will download replication script templates that you can use to set up replication for Secret Server. You can fill in the variables at the top of each script to match your environment and run them as-is or modify them further if you need to customize the default scripts.

The **Show Articles** button lists each article in Secret Server that should be included in replication along with the recommended settings for SQL Server replication. These are *recommended settings* and do not show the current state of replication on the publisher.

Upgrade Scenario

New versions of Secret Server may issue schema changes including indexes, column changes, and views. In some cases, SQL merge replication will not automatically replicate these schema changes. For this reason, we recommend removing any publications and subscriptions targeting the Secret Server database, redirecting users to the web server at the primary site before performing any upgrade, and recreating the publication and subscriptions from new versions of the replication scripts.

In the following scenario, there are Secret Server web servers installed at a site in Australia, the U.S., and the U.K. The U.K. is the publisher node and Australia and U.S. nodes are the subscribers.

1. Redirect all users to the U.K. Secret Server URL.
2. Stop IIS at the Australia and U.S. sites.
3. Manually force a synchronization between the Australia subscriber and the U.K:
    a. Open SQL Server Management Studio and connect to the Australia subscriber database server.
    b. Go to **Replication > Local Subscriptions**.
    c. Right-click on one of the Secret Server subscriptions (if you used the scripts provided by Secret Server, they are called *SSPubLogs* and) and select **View Synchronization Status**.
    d. Click the **Start** button to force a synchronization.
4. Repeat sub-steps 3 and 4 for all Secret Server subscriptions.
5. Repeat sub-step 3 for the U.S. subscriber database.
6. Resolve any replication conflicts:
    a. Open SQL Server Management Studio and connect to the UK publisher database server.
    b. Go to **Replication > Local Publications**.
    c. Right-click on one of the Secret Server publications (if you used the scripts provided by Secret Server they are called SSPubLogs and SSPubEvents) and select **View Conflicts**.
    d. Examine and resolve any unresolved conflicts.
7. Generate the script to remove replication on the subscriber databases as specified above.
8. Run it to remove replication.

9. Generate the script to remove replication on the publisher database as specified above.
10. Run it to remove replication.
11. Restart IIS on the Secret Server web server in the U.K.
12. Run the Secret Server web upgrade wizard.
13. Copy the website application directory to the web servers in Australia and the U.S.
14. Use the scripts generated from the Secret Server UI to recreate replication on the publisher.
15. Push a snapshot to the Australia and U.S. subscriber databases.
16. Recreate replication at the subscribers.
17. Restart the jobs on the subscriber databases as described above.
18. Start IIS on the Australia and U.S. web servers.
19. Change redirection rules for Australia and U.S. users so they access the local WithWeb server as normal.

Other Information about SQL Server Replication

- Upgrading Secret Server with SQL Replication
- SQL Server Replication (MS Books Online)
- Snapshot Replication

Regional Availability

Below are the geo-locations and regions where Secret Server is currently deployed:

Geography	Primary Region	Failover Region
Southeast Asia	Southeast Asia (Singapore)	East Asia (Hong Kong)
Europe	Germany West Central (Frankfurt)	West Europe (Netherlands)
Canada	Canada Central (Toronto)	Canada East (Quebec City)
Australia	Australia Central (Canberra)	Australia East (New South Wales)
United Arab Emirates	UAE North (Dubai)	UAE Central (Abu Dhabi)
United Kingdom	UK South (London)	UK West (Cardiff)
United States	East US (Virginia)	West US (California)

Break Glass Scenarios

The Break Glass concept is a strategy for gaining emergency access to critical systems and secrets when standard access methods are unavailable due to infrastructure issues or other emergencies. This concept ensures continuity and access to essential information during outages or disasters. The Secret Server Break Glass options include:

- Export Secrets
- Resilient Secrets
- Mobile App Offline Caching
- PCS/Server Suite Agent Offline Operation

Export Secrets

Enable offline access to secrets by exporting them to an encrypted file (CSV/XML).

See Automatic Secret Export feature to export secrets securely for offline access.

Resilient Secrets

- Create local accounts with necessary Windows permissions for emergency access, and store the credentials securely. Use these accounts only during emergencies and ensure they are audited.
- Set up Role-Based Access Control (RBAC) to manage Windows permissions effectively. Enable access audit logging to track all activities during break glass scenarios.

See Secret Server Resilient Secrets Architecture for details.

Mobile App Offline Caching

The mobile app can cache secrets for offline use, providing access even if the main infrastructure is down. Enable offline caching in the mobile app settings to access secrets without a live connection, and sync secrets regularly to keep the cache updated with the latest information.

See Setting Maximum Time for Secret Server Mobile Offline Caching for details.

PCS/Server Suite Agent Offline Operation

Configure policy caching to allow operations without a live connection, set up machine-specific MFA (OTP) for secure offline authentication, and ensure policies are regularly updated and tested to confirm offline functionality.

See the Privilege Control for Servers documentation for offline operation details.

Diagnostics

The Diagnostics section provides all the necessary information on your current Secret Server version, Operating System Configuration, Database and Secret ServerEnvironments, your current application settings, running and scheduled jobs, allows viewing and exporting logs, clearing cache, testing events log, and exporting diagnostics.

Select **Settings>Diagnostics**, or **Admin>Diagnostics** to proceed to the Diagnostics section.

- Click **Clear Cache** at the top right to request cache clearance. Cache will be cleared in few seconds.
- Click **Test Event Log** at the top right to request test of events log.
- Click **Export diagnostics** to download the diagnostics on your local drive in *txt format.

Specifications

Select the Specification tab to find all the information about your current running Secret Server application version, including:

- Operating System Configuration - Operating System, System Type, Up Time, Memory Use, Server Name, Server Time, Server Time Zone, Domain Controller, and .NET Framework Version.
- Database Environment - SQL Server Name, Database Name, SQL Server Version, SQL Server Edition, SQL Server Collation, SQL Server Time, SQL Server Connection String, Is Replication Enabled, Replication Publisher, Replication Subscriber, and Is Synchronizing.
- Internal Site Connector Configuration - Backbone Site Connector and Backbone Class.
- Secret Server Environment - Secret Server URL, Search Indexer Background Processor, Product Version, Proxy Configuration, Max Degrees of Parallelism, Maintenance Mode, and Cached language files.
- Upgrade Information - Latest Version, Last Upgrade Details, Upgrade In progress.

App settings

Select the App settings tab to find all the settings configured on your Secret Server instance with their keys and values displayed in the grid. You can download the settings list in *csv format by clicking the download button at the top right.

See Export/Import Settings for more information.

Background Processes

Select the Background Processes tab to view all the processes running on the background displayed in the grid with the related Host and Environment names, Thread name and identity, and their last activity time specified. Click on a process in the grid to expand its details to the right. You can download the processes list in *csv format by clicking the download button at the top right.

Click Recycle Background processes at the top right to request processes recycle.

Long Running Tasks

Select the Long Running Tasks tab to view all the long running tasks displayed in the grid with the related information. You can download the tasks list in *csv format by clicking the download button at the top right.

Scheduled Jobs

Select the Scheduled Jobs tab to view all the jobs scheduled on your Secret Server instance with their last and next trigger time and current trigger state. Click on a job in the grid to expand its details to the right. You can download the jobs list in *csv format by clicking the download button at the top right.

Export logs

This feature is used to gather various logs and diagnostic information from Secret Server. It is particularly useful when troubleshooting issues or when preparing to open a support case. Collecting logs helps in identifying symptoms that match known problems, resolving non-defect issues, identifying defects, and locating root causes for faster fixes. Select the Export logs tab to collect and download collected logs for your Secret Server instance. All the latest logs are listed here in the grid with their type and status.

- Click **Collect** at the top right to collect the latest log.
- Click **Download collected logs** to download the log you have just collected on your local drive for further analysis or to provide them to Secret Server Support. The log will be downloaded as a zip file with Node log and Engine log inside.
- Click **Clear** at the top right to clear the collected log if you need to collect a fresh one.

Directory Services

Directory services are integral components of network operating systems that map the names of network resources to their network addresses. They provide a shared information infrastructure to locate, manage, and organize network resources, including volumes, folders, files, users, groups, devices, and more. Active Directory is Secret Server's native directory service.

Active Directory

Secret Serverintegrates with Active Directory (AD) to streamline user authentication and management. Key features include user authentication, user and group synchronization, Role-Based Access Control (RBAC), and Azure Active Directory Integration.

View Active Directory section for details.

Azure Active Directory

Azure Active Directory (Azure AD) is a cloud-based identity and access management solution that provides a robust and scalable way to manage user identities, authentication, and authorization. Azure Active Directory integration with Secret Server facilitates SAML-based single sign-on, streamlining user authentication and access control. It requires .NET Framework version 4.8 or later and supports advanced certificate signing settings.

View Azure Active Directory for details.

LDAP

Lightweight Directory Access Protocol (LDAP) is a widely-used protocol for accessing and managing distributed directory information services over IP networks. LDAP enables organizations to store and manage user identities, groups, and other data in a centralized repository, allowing for efficient authentication, authorization, and directory

management. Secure LDAP (LDAPS) extends the protocol to provide encryption and authentication using TLS or SSL.

View LDAP for details.

Active Directory and Secret Server Overview

> Before synchronizing or creating users, you need to create a secret to be used as the "sync secret." This secret should contain Domain Admin credentials (or an account with appropriate AD permissions to search and view the attributes to all your organization's users and groups).

Secret Server integrates with Active Directory (AD) to streamline user authentication and management. Here are some key points about this integration:

- User Authentication: Secret Server allows users to log in using their Active Directory credentials. This simplifies the login process and enhances security by leveraging existing AD authentication mechanisms.
- User and Group Synchronization: Before synchronizing or creating users, a "sync secret" containing Domain Admin credentials (or an account with appropriate AD permissions) must be created. This enables Secret Server to search and view attributes for all users and groups within the organization.
- Role-Based Access Control (RBAC): Secret Server uses RBAC to control user rights and privileges. This feature allows administrators to enforce least privilege and segregation of duties on privileged accounts. Users and groups are assigned to roles that define their permissions within the system, ensuring that access is granted strategically and securely.
- Azure Active Directory Integration: Secret Server can also integrate with Azure Active Directory, requiring .NET Framework version 4.8 or later. This integration allows for seamless management of users and groups in cloud environments.
- User Lockout Protection - When enabled, synchronization will not disable the domain's users if it would result in every user in this domain being disabled.

Active Directory Automatic User Management

Overview

When Active Directory (AD) Sync is run with the "User status mirrors Active Directory (Automatic)" option, it creates groups and users in Secret Server to mirror the organization's configured AD groups and users. A Secret Server user is created or enabled for every enabled AD user in the selected groups.

Thus, every enabled AD user in every synched group consumes a Secret Server license, whether or not they use Secret Server. As a result, an organization can end up paying for far more Secret Server licenses than they need.

AD Automatic User Management addresses this issue by automatically disabling the accounts of users who have not logged in to Secret Server in a specified number of months. This saves unnecessary licensing costs as inactive users do not count against the number of user licenses required by Secret Server.

You can configure the setting on the Edit Active Directory Configuration page. See "Configuring Active Directory" on page 520 There is a checkbox to enable or disable the feature and a textbox to set the number of months before a user is auto-disabled. The default is three, but you can set it from one to 12.

Newly-added users remain enabled until the first synchronization after the configured number of months have passed. When a user whose account has been disabled by this feature attempts to log in they automatically have their account enabled, provided there are licenses available.

Examples

Example One

1. Maria joined the company today.
2. The next AD synchronization creates a Secret Server account for Maria.
3. Maria never logs in to Secret Server because she does not need it for her job.
4. Once the defined number of months have passed, the next AD synchronization disables Maria's Secret Server account.
5. The Secret Server license used by Maria's account becomes available for use.

Example Two

> This only pertains to users who have never logged into Secret Server and their account was disabled (never enabled). It does not apply to previously enabled users who have been disabled due to inactivity.

1. Joe gets added to Secret Server but never logs in.
2. The defined number of months later, Automatic User Management disables his account, freeing his license.
3. Joe gets promoted to a job that requires Secret Server.
4. Joe logs into Secret Server.
5. His account is automatically re-enabled, and he now takes up a license.
6. Joe gets demoted to his old job, which does not require Secret Server.
7. A defined number of months later, Automatic User Management disables his account, and the license is freed up once again.
8. Joe has no idea any of this has happened–the automated process is hidden from him.

Example Three

1. Rupert logs in to Secret Server several times per month.
2. The defined number of months for Automatic User Management to disable his account is never reached.
3. Rupert's account stays current and his license remains his. The entire process is invisible to Rupert.

Active Directory Credential Caching

Overview

Active Directory credential caching enables users to access Secret Server even when the domain controller is unavailable. When caching is enabled, Active Directory credentials are cached for 30 days in the on-premise

editions, and for 90 days in Secret Server Cloud.

With credential caching enabled, whenever a domain user successfully logs into Secret Server, their domain password is hashed using PBKDF2, and stored in the Secret Server database along with the current time stamp.

If a domain user attempts to log in but Secret Server is unable to contact a domain controller, it falls back to the cached credentials to attempt to provide access. If the hash of the entered password matches the hash of the cached credentials and the time has not expired, the authentication will be successful.

Active Directory Caching Configuration

AD credential caching is disabled by default, but an administrator can enabled or disable it at any time using the steps below:

1. Search for **Login settings**to get to the Login page, and click **Edit**.
2. To enable caching, click to select the **Cache AD Credentials for when Engines are offline** check box.
3. To disable caching, click **Clear Cached AD Credentials** at the top right.

Auditing

Audit logs are recorded in the system log whenever cached credentials are found to be expired or when a successful login attempt has been made using cached credentials.

Active Directory Rights for Synchronization Account

Below is a listing of the Active Directory permissions required by the account used for synchronization. See "Configuring Active Directory" on page 520 for more on selecting this account.

> The locations discussed below are part of the Active Directory Administrative Center (ADAC). See Advanced AD DS Management Using Active Directory Administrative Center for information on using the ADAC.

Recommended AD Permissions

Object Tab

This object and all descendant objects:

- List contents
- Read all properties

Minimum Required AD Permissions

> These all require ADSI Edit - Allow (Active Directory Service Interfaces Editor) permission.

Object Tab

This object and all descendant objects:

- Read E-mail-Address
- Read objectGUID
- Read Logon Name
- Read Logon Name (pre-Windows 2000)

Descendant Group objects:

- Read displayName
- Read Distinguished Name
- Read Group name (pre-Windows 2000)
- Read groupAttributes
- Read memberOf
- Read Members
- Read objectGUID

ADFS Custom Rules for Differing UPN and SAM Account Names

Overview

In Active Directory, when a user's sAMAccountName and UserPrincipalName (UPN) differ, you must take some steps to accommodate those differences in Secret Server. For example, suppose a user's sAMAccountName is `jsmith` and the user's UserPrincipalName is `john.smith@somedomain.com`. When Secret Server syncs with Active Directory, it obtains `jsmith` as the Secret Server login user name. However, with its standard ADFS rule passing in the UPN, Secret Server will receive `john.smith@somedomain.com` and it will not find the user.

To rectify this situation you must configure the SAML Username Attribute in Secret Server to be `customvalue`, and use three custom claim rules described below.

Change the SAML Username Attribute

To change the SAML Username Attribute in Secret Server, perform the following steps:

1. Click **Admin > SAML identity providers**.
2. Click **Create New Identity Provider**.

3. In the Identity Provider dialog, select **Enter IDP Information** from the New Identity Provider dropdown.
4. In the next Identity Provider dialog, specify all the required fields, and in the **Username Attribute** type `customvalue`, and click **OK**.

Create Three Rules

To create the three rules you need, open the Active Directory application and follow these steps:

1. In the **Edit Claim Rules** window, select **Add Rule**.
2. Choose **Send Claims Using a Custom Rule** as the rule template.
3. Create each rule using the information below, in the order presented.

> If you copy code directly from the webpage for pasting, please ensure that you have copied everything you need, or correct the text after pasting it.

Rule 1: Query AD for UPN and sAMaccountname Attributes

```
c:[Type == http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname,
Issuer == "AD AUTHORITY"]
 => add(store = "Active Directory", types = ("ssupn", "sswindowsaccountname"), query =
";UserPrincipalName,sAMAccountName;{0}", param = c.Value);
```

Rule 2: Obtain the Domain from the UPN

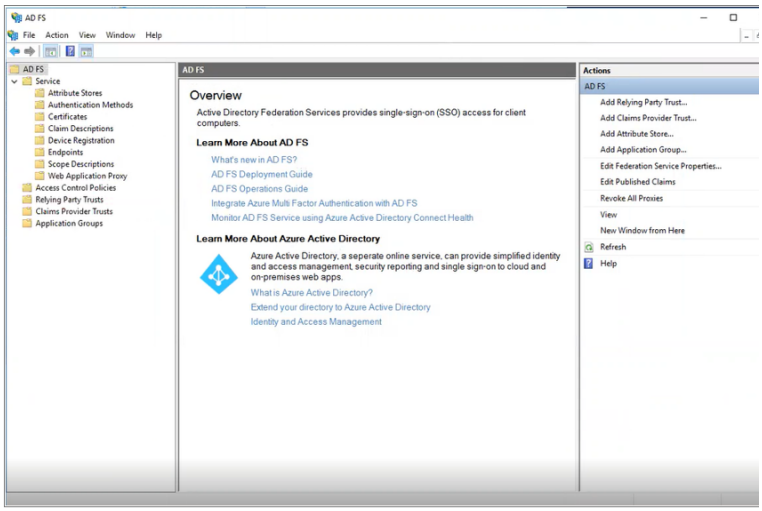
```
c:[Type == "ssupn"]
 => add(Type = "ssnewupn", Value = RegExReplace(c.Value, "^(.*?)@", ""));
```

Rule 3: Combine the sAMaccountname with the Domain

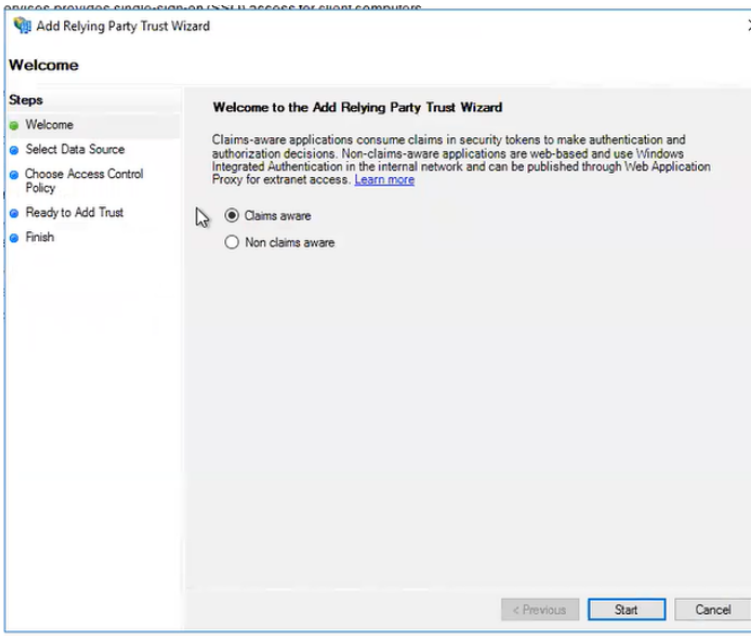
```
c1:[Type == "ssnewupn"]
 && c2:[Type == "sswindowsaccountname"]
 => issue(Type = "customvalue", Value = c2.Value + "@" + c1.Value);
```

Configuring ADFS 4.0 (Windows Server 2016)

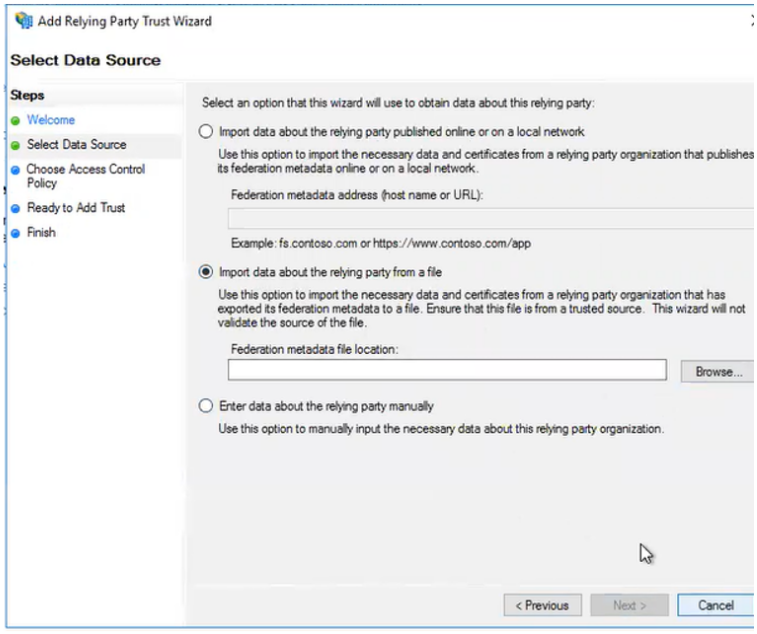
1. Go to the server on which ADFS is installed and launch the AD FS Management application.
2. Expand the Trust Relationships node and click on the Relying Party Trusts node.
3. Click on the **Add Relying Party Trust** link in the right pane to start the *Add Relying Party Trust* wizard



4. Select the **Claims aware** radio button and click the **Start** button to continue.

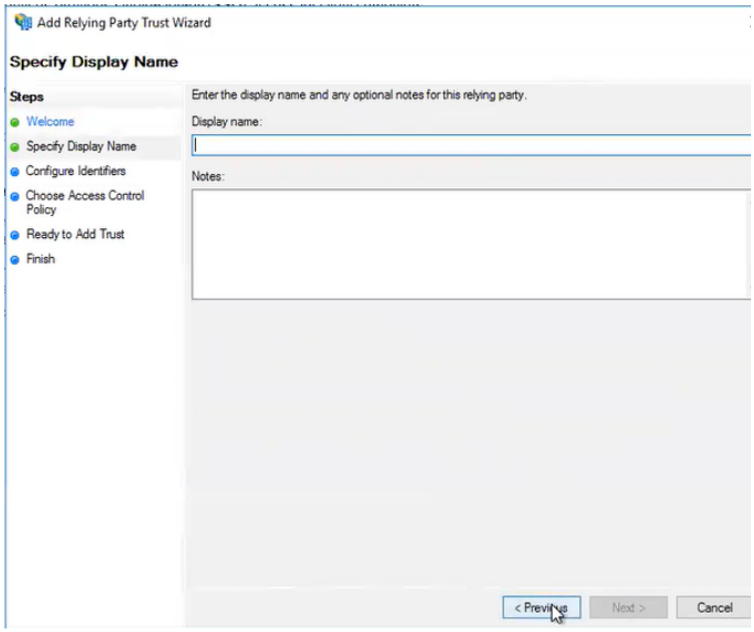


5. Select the **Import data about the relying party from a file** radio button. Browse to select the Metadata XML file you downloaded from Secret Server in earlier steps. Once uploaded, click Next to continue

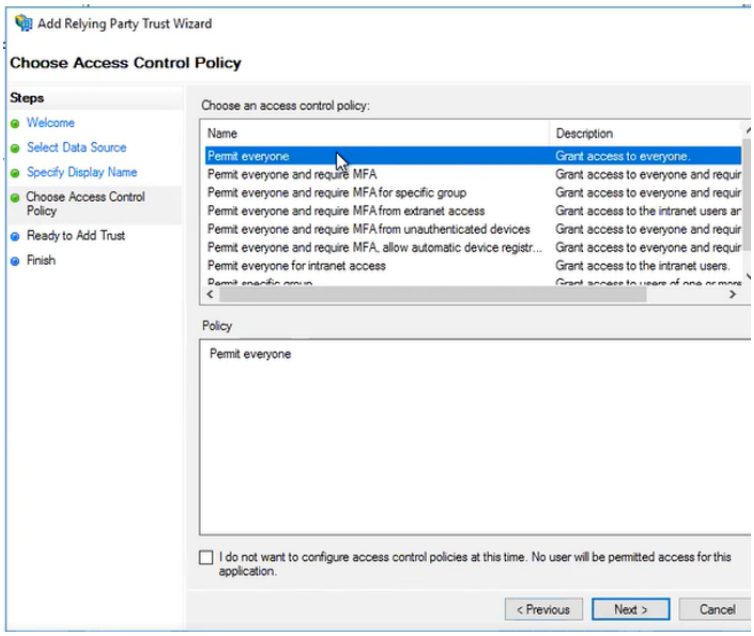


.

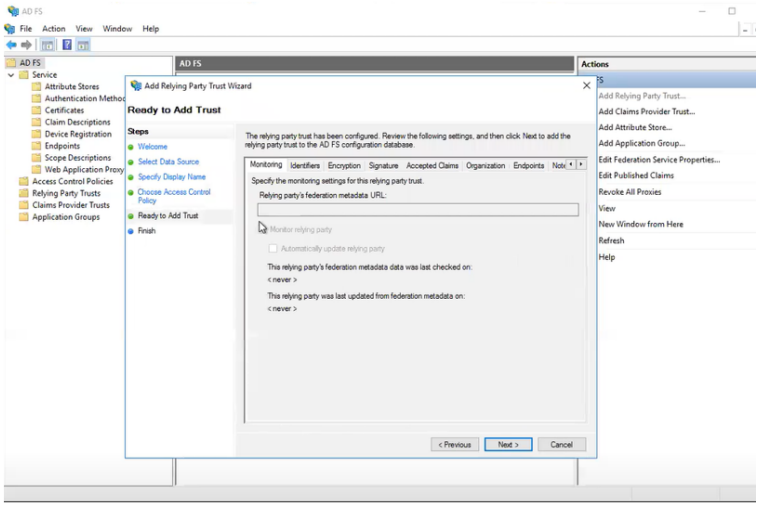
6. Choose and enter a **Display Name** for this Relying Party and any additional notes you may want. Click **Next** to continue.



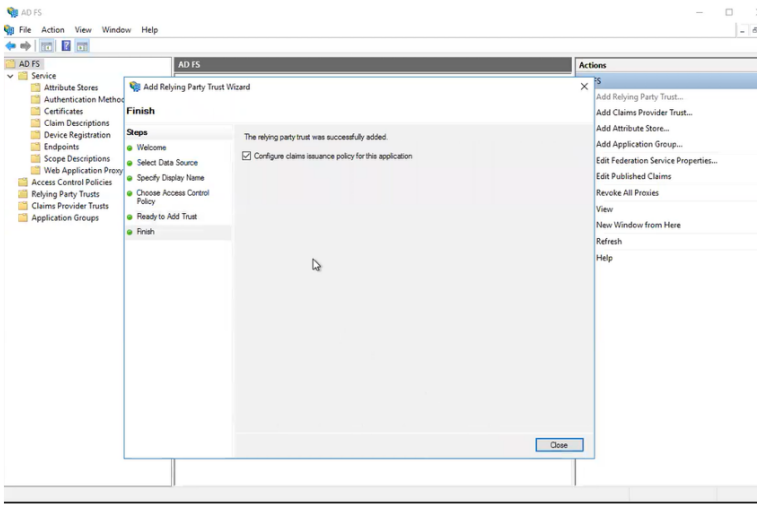
7. Choose the **Permit everyone** access control policy and then click **Next** to continue. You may optionally select another access control policy to permit only a smaller subset of users and/or require multi-factor authenticator (MFA), if needed; however, these other access control policies will not be covered in this configuration.



8. Click **Next** in the next window.



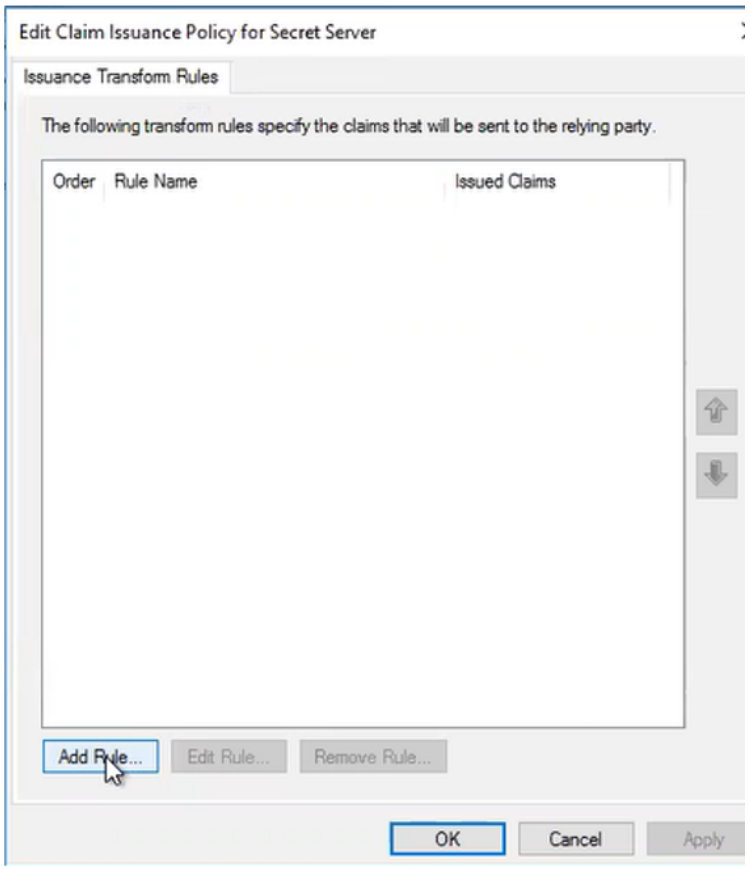
9. On the **Finish** page, make sure the **Configure claims issuance policy for this application**



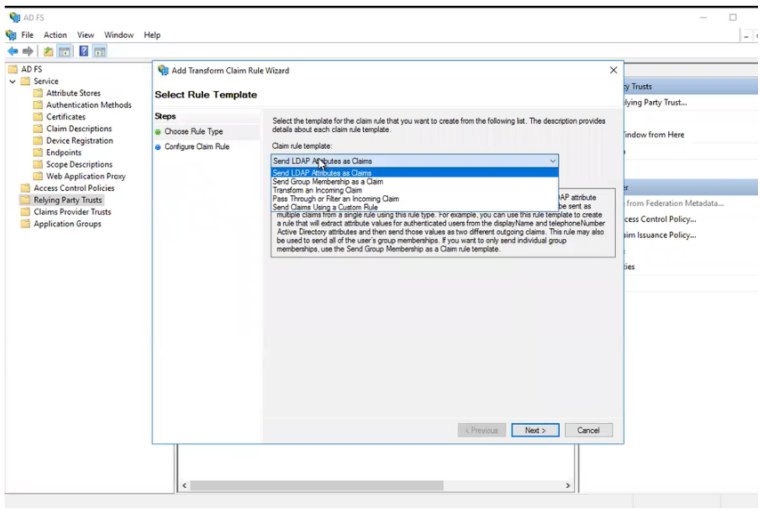
Create Claim Rules for the Secret Server Relying Party

We have now created the Relying Party trust in ADFS for Secret Server; however, we must set a claim rule so that ADFS relays information to Secret Server to describe the user's identify and authenticate.

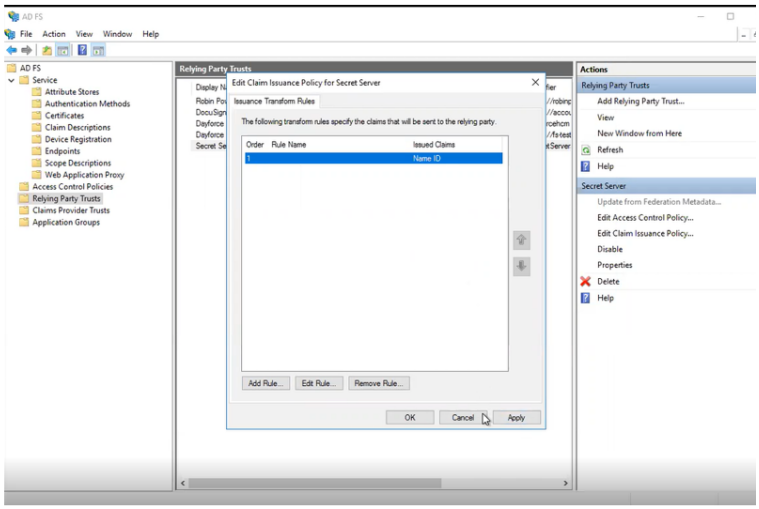
1. Let's turn our attention to the "Edit Claim Issuance Policy..." dialog window that comes up after the prior steps.



2. Click the **Add Rule** button.
3. Under **Claim rule template**, select **Send LDAP Attributes as Claims**. Click **Next** to continue.



4. Fill out the information:
    a. **Claim rule name**: Optional
    b. **Attribute Store**: select Active Directory
    c. Add an **LDAP Attribute of User-Principal-Name**
    d. Outgoing **Claim Type of Name ID**
    e. Click **Finish**
5. Click on **Apply** and **OK**.



6. Download your Metadata for the Relying Party Trust you created for Secret Server. There are several methods
    a. Navigate to **https://[YOURSERVERNAME]/FederationMetadata/2007-06/FederationMetadata.xml** to download the Metadata for your ADFS IDP. The file will automatically download.
    b. Run the PowerShell script on this page.

Configuration Parameters

Active Directory configuration can be enabled by a user with the Administer Active Directory role. To change these settings, select **Directory Services** from the **Administration** menu and then click the **Confederation** tab. Then click **Edit**.

The configuration screen offers several options:

- **Enable Active Directory Integration:** Enable or disable the Active Directory Integration feature.
- **Enable Integrated Windows Authentication:** Enable or disable the Windows integrated authentication feature.
- **Enable Synchronization of Active Directory:** Enable or disable the automatic synchronization of the selected Synchronization Groups from Active Directory. If you have manually added users and will not use the Synchronization group, do not enable this setting or manual users can be locked out.

- **Synchronization Interval for Active Directory:** Set the interval that Secret Server synchronizes its users and groups with the Active Directory.
- User Account Options:
  - **Users are enabled by default (Manual):** Secret Server users are automatically be enabled when they are synced as new users from Active Directory. If they were disabled explicitly in Secret Server, they are not be automatically re-enabled. If creating a new user causes the user count to exceed your license limit, the user is created as disabled. Secret Server
  - **Users are disabled by default (Manual):** Secret Server users are automatically disabled when they are pulled in as new users from Active Directory. If they were enabled explicitly in SS, they are not automatically re-disabled.
  - **User status mirrors Active Directory (Automatic):** When a new user is pulled in from Active Directory, they are automatically enabled if active on the domain. The exception is when this causes you to exceed your license count. For existing users, they are automatically be disabled if they are removed from all synchronization groups, deleted in AD, or disabled in AD. They are automatically re-enabled when they are part of a synchronization group and are active in AD.

Configuring Active Directory

To allow users to log in with their Active Directory (AD) credentials, you can configure your AD domain settings in Secret Server and then add users either individually or by group.

Step 1: Enabling Active Directory Integration

1. Search for **Directory Services**. Alternatively, click **Access** to the left and select **Directory Services**. The Directory Services page appears.
2. Click the **Configuration** tab.
3. If **Enable Directory Services** says **No**:
   a. Click the **Edit** link next to **Directory Services**.
   b. Click the **Enable Directory Services** check box.
   c. Click **Save**.

Step 2: Adding a Domain

1. Search for **Directory Services**. The Domains tab of the Directory Services page appears.
2. Click the **Add Domain** button and select **Active Directory Domain** from the dropdown. The Active Directory popup appears.
3. Type the Fully Qualified Domain Name and Friendly Name in their text boxes.
4. Enable the Active checkbox. This determines whether the domain can be used to authenticate against. A domain also needs to be active for synchronization to occur. You can inactivate a domain that is no longer used and all user accounts will remain keeping your audit history intact.
5. If you wish to use Secure LDAP, enable the **Use LDAPS** checkbox.

6. If you have an existing sync secret, click the **No Secret Selected** link next to **Synchronization Secret** to select the secret containing the username and password for connection. Otherwise, click the **Create New Secret** link to create one.
7. Click the **Site** dropdown list to select the site for the AD location.
8. Click the **Multifactor Authentication** dropdown list to select the desired MFA, if any.
9. Click **Validate & Save**.

Now you are ready to add individual users or groups of users for access to Secret Server with AD credentials. See the relevant section below for instructions.

Step 3: Setting Up Synchronization Groups

Once you add a domain, add the applicable synchronization groups users from these groups are available for login, subject to synchronization settings. These groups can also be used to assign AD permissions, roles, and sharing. To add groups:

> If the specific group does not exist, one can be created by your Active Directory administrator. If you create domain users manually or want to convert local users to domain users, see the corresponding sections below before setting the synchronization group.

1. Click the **Domain Name** link on the **Domains** tab. The page for that domain appears.
2. Under the **Groups** tab, click **Edit** next to **Synchronized Groups**. The top Synchronized Group table and search box represent the available sync groups. The Select Groups list shows all the groups belonging to the domain (those with selected check boxes).
3. Type the name of the desired group in the **Search domain for groups** search text box or scroll down the list to find a group.
4. Click the group. The users belonging to the group appear below in a list to provide a preview to aid selecting groups.

Step 4: Adding or Removing Groups

1. Click the check box in the **Select Groups** list to add or remove groups from the domain.
2. If you want to remove an entire group instead of not selecting it (leaving it for later use), click the **Remove** link next to the group name in the **Synchronized Groups** table.
3. Click the **Save** button.

> Enabled users count towards your Secret Server user licensing.

Step 5: Enabling Active Directory Synchronization

> Two safeguards are built into the synchronization process to prevent the system from erroneously disabling users as a result of receiving incomplete information from the directory server. If communication with a directory server returns an error, then no membership changes are made to users from that directory. Similarly, if communication with a directory server returns zero users, no membership changes are made to users from that directory.

1. Return to the **Directory Services** page.
2. Under the **Configuration** tab, click **Edit**in the **User Synchronization** section, and click to select the **Enable User Synchronization** check box. Additional settings appear.
3. Choose how often you want Secret Server to sync with AD by configuring the **Synchronization Interval**. The default value is one day.
4. Click the **User Account Options** Dropdown list to select a default status for users. See below for a description of each option. We recommend selecting **Users are disabled by default (Manual)** for initial testing. The options are:
   - **Users are enabled by default (Manual)**: Secret Server users are automatically enabled when they are synced as new users from AD. If they were disabled explicitly in Secret Server, they are not automatically re-enabled. If creating a new user will cause the user count to exceed your license limit, the user created disabled. Secret Server
   - **Users are disabled by default (Manual)**: Secret Server users are automatically disabled when they are pulled in as new users from AD. If they were enabled explicitly in SS, they are not automatically re-disabled.
   - **User status mirrors Active Directory (Automatic)**: When new users are pulled in from AD, they are automatically enabled if active on the domain. The exception is when this will cause you to exceed your license count. For existing users, they are automatically disabled if they are removed from all synchronization groups, deleted in AD, or disabled in AD. They are automatically re-enabled when they are part of a synchronization group and are active in AD. See "Active Directory Automatic User Management" on page 509.
5. Change the **Days to Keep Operational Logs** text box to set the period to keep AD-related logs that might contain PII. Secret Server automatically deletes logs older than that (in days).
6. Click **Save**.

Step 6: Running Active Directory Synchronization

From the **Directory Services** page, click the **Sync Now** button to run a sync. As the sync progresses, you can click the **Refresh** button to monitor the logs until you see the message **Completed Domain synchronization for all domains**.

Converting Local Users to Domain Users

Local users can be converted to a domain user in a one-way irreversible process. This feature helps existing customers with extensive groups and Delinea permissions setup for a local user that they want to convert to an Active Directory user.

To convert users to the domain users, Search for **Users**, select the related users from the list and click **Migrate to AD**. For the conversion to work, the domain user must not exist within Secret Server. The username is changed to match the domain user throughout the system.

Creating Active Directory Users

Active Directory users can be created manually by a user that has the Administer Users role. You can do this by going to **Admin > Users**, then clicking the **Create New** button. See "Creating Users" on page 1304.

Enabling and Disabling Active Directory Users

If you selected a manual setting for **User Account Options**, you can now enable or disable your AD users' access to Secret Server:

1. Search for**Users**to get to the Users page appears.
2. To enable users:
   a. Select the **Inactive** users from the Status dropdown.
   b. Click to select the check box next to the users to enable.
   c. Click **Bulk Operation** and select **Activate** in the Bulk Operation pop up.
3. To disable users, use the same process, selecting **Deactivate** from the **Bulk Operation** pop up.

Setting up SAML SSO for Active Directory

How to set up Single Sign-On (SSO) for users synced between an Active Directory domain server and a Secret Server user list.

The interface and workflows for Active Directory Federation Services (ADFS) Server are subject to change. For more current workflow and interface references, please refer to the Microsoft ADFS Server documentation.

ADFS Server

1. On your ADFS server, browse to your Secret Server instance and sign in.
2. Download the `SecretServerSAMLMetadata.xml` file from `[YourSecretServerInstance.Name]/samlmetadata`.
3. Open **Active Directory Federation Services Management**.
4. Under **Trust Relationships**, click **Add Relying Party Trust** to add your service provider information.
5. In the **Add Relying Party Trust** wizard, click **Start**.
6. Click **Import data about the relying party from a file**.
7. Browse to select the metadata XML file you downloaded earlier and click **Next**.
8. Enter a display name of your choice and click **Next**.
9. Decide whether to configure multi-factor authentication and click **Next**.

Secret Server

1. In Secret Server, search for **SAML Identity Providers**, and click **Create New Identity Provider**.
2. Select **Import IDP from XML Metadata** from the dropdown and select the ADFS metadata you downloaded. If you don't see the file, you might need to change the metadata filetype to xml.

Adding Users to ADFS

For users to be authenticated by the SSO workflow you are setting up, Secret Server usernames must match domain AD usernames. If you manually add usernames to Secret Server or AD, you must inspect them carefully to ensure that they match. You can also use Secret Server Discovery to sync Secret Server usernames in bulk with AD usernames.

Once a username matches in both systems, the user can log into their desktop computer using their AD credentials and then browse to Secret Server without being prompted again for authentication.

If you have accounts in which the sAMAccountName differs from the UPN name, you can create custom rules to accommodate the differences. See the Directory Services section of the Secret Server documentation.

Common Errors

If you encounter any of the errors below, check that the **RelyingPartyTrust Rule** on the ADFS server has both the message and assertion signed. By default, only the assertion is signed.

- "Attempt to login via SAML from identity provider had no signed responses or assertions"
- "Attempt to login via SAML with unsigned request"
- "Attempt to login via SAML with unsigned assertion"

If you encounter the error, "SAML Response signature message from IDP failed verification," it means that Secret Server cannot decrypt the assertion message from the IDP (ADFS) because the public certificate thumbprint is incorrect. To fix this issue, follow the steps below.

1. Download the ADFS certificate, upload it to Secret Server (search for **Configuration** and select **SAML** tab) and edit the IDP configuration.
2. Check the token-decrypting in ADFS to verify the certificate.
3. Use the Get-AdfsCertificate cmdlet to retrieve the certificates listed below that ADFS uses, and check that they are appropriately identified as primary (**IsPrimary** is set to **True**):
   - A primary token-signing certificate is used to digitally sign outgoing claims.
   - A primary token-encrypting certificate is published in federation metadata for use by trusted claims providers.
   - Information card signing and service communications certificates are always primary.

Entra ID

Microsoft Entra ID is a cloud-based identity and access management solution that provides a robust and scalable way to manage user identities, authentication, and authorization. As a critical component of Microsoft's cloud ecosystem, Entra ID enables organizations to securely manage access to applications, services, and data, both on-premises and in the cloud.

With features like single sign-on (SSO), multi-factor authentication (MFA), and conditional access, Entra ID helps protect against cyber threats and ensures that only authorized users have access to sensitive resources. Additionally, Entra ID provides advanced tools for identity governance, risk detection, and compliance, making it an essential platform for businesses seeking to strengthen their security posture and streamline user management.

To integrate Entra ID with Secret Server, follow these steps:

- Configuration Parameters: Learn about the various configuration parameters required for integrating Entra ID with Secret Server.
- Create Azure App Registration: Set up an application registration in Azure to allow Secret Server to communicate with Entra ID.
- Configure Azure Active Directory Domain: Adjust settings in Entra ID to enable integration with Secret Server.
- Set Up Entra ID for SAML: Configure SAML authentication using Entra ID for secure access.
- Configuration Steps for Entra ID: Detailed configuration steps for setting up Entra ID with SAML.

You can also enhance your password management and security by utilizing various Remote Password Changer (RPC) templates. These templates are designed to automate password changes and ensure secure access across different directory services. For more info see:

- Azure Active Directory Secret Template for RPC - a template designed for managing Entra ID account secrets, allowing for automatic password changes when a secret expires, ensuring efficient and secure password management.
- Entra ID Secret Template for RPC - a template designed for Entra ID accounts, providing automated password management and enhancing security by ensuring that passwords are updated regularly and securely.
- Microsoft AD Secret Template for RPC - specifically for Microsoft Active Directory accounts, this template facilitates the automatic updating of passwords, helping maintain security and compliance within your organization's AD environment.

Additionally, Active Directory Remote Password Changing (RPC) in Secret Server allows for the automated management of AD account passwords, ensuring they remain synchronized with Secret Server policies. For details see:

- RPC for Active Directory - facilitates seamless password changes and management, reducing the risk of unauthorized access and enhancing overall security

Setting Up Entra ID

> These are instructions specifically for Entra ID setup in Secret Server as a SAML provider, not Entra ID setup in Secret Server as a Directory Source.

Creating an Entra ID Application Registration

Task 1: Create the Application Registration in Entra

> Additional Microsoft Documentation for this step can be found at Register an application in Microsoft Entra ID.

1. Navigate to the Microsoft Entra Admin Center.
2. Log in. At a minimum, you must be logged in as an Application Developer.
3. If you have access to multiple tenants, click the settings icon (a cog) in the top menu to switch to the tenant where you want to register the application.
4. On the left side of the page, click **App Registrations**.
5. Click **New Registration**.
6. Name the application "Delinea Secret Server."
7. Under **Supported account types**, specify who can use the application. We recommend you select **Accounts in this organizational directory only** for most applications. Refer to the table on Register an application in Microsoft Entra ID for more information on each option.
8. Under **Redirect URI** choose **web** from the dropdown and set the URL to `https://<Your Secret Server URL>/signin-oidc`
9. Click **Register**.

Task 2: Adding a Client Secret to the Entra Application Registration

> Additional Microsoft Documentation for this step can be found in the Add a client secret tab of Add and manage application credentials in Microsoft Entra ID page.

1. Navigate to the Microsoft Entra Admin Center.
2. Log in. At a minimum, you must be logged in as an Application Developer.
3. If you have access to multiple tenants, click the settings icon (a cog) in the top menu to switch to the tenant where you want to add the client secret.
4. On the left side of the page, click **App Registrations**.
5. Select the **All applications** tab on the page to see the application that was created in the section above.
6. Select the application that was created in the section above.
7. In the **Manage** section of the application, click **Certificates & secrets**.
8. Click **New client secret**.

9. Add a description for the secret and set its expiration time.
10. Click **Add**.
11. Once the client secret is added, copy the **Value** for the client secret.

> You must copy this value at this time. This secret value is never displayed again after you leave this page.

Task 3: Adding API Permissions to the Entra Application Registration

> Additional Microsoft Documentation for this step can be found at Configure an application to expose a web API.

> This requires a local Secret Server account with at least one of these roles: Administer Active Directory, Unlimited Vault Access, or Administer Configuration Unlimited Admin.

1. Navigate to the Microsoft Entra Admin Center.
2. Log in. At a minimum, you must be logged in as an Application Developer.
3. If you have access to multiple tenants, click the settings icon (a cog) in the top menu to switch to the tenant where you want to add the permissions.
4. On the left side of the page, click **App Registrations**.
5. Select the **All applications** tab on the page to see the application that was created in the section above.
6. Select the application that was created in the section above.
7. In the **Manage** section of the application, click **API Permissions**.
8. There will be a single permission listed on this page, click on the three dots to the right of that listed permission, click **Remove Permission**.
9. Click **Yes, remove**.
10. Click **Add a permission**.
11. Select **Microsoft Graph**.
12. Click **Delegated permissions**.
13. Search for and select **Group.Read.All**, which appears in the Group section.
14. Click **Application permissions**.
15. Search for and select the following:
    - **Group.Read.All** in the Group section
    - **GroupMember.Read.All** in the GroupMember section
    - **Member.Read.Hidden** in the Member section
    - **User.Read.All** in the User section

16. Click **Add permissions**.
17. Click **Grant admin consent for Delinea**.
18. Click **Yes**.

Creating an Application Registration Secret in Secret Server

> Secret Server will throw an error if you attempt to use the Secret ID of the Entra ID application secret instead of the value of the Entra ID application secret. For example:
> `- tenantId: Failed to validate Azure domain credentials. A configuration issue is preventing authentication) - check the error message from the server for details. You can modify the configuration in the application registration portal. See https: /aka. ms/msal-net-inva I id-client for details. Original exception: AADSTS7000215: Invalid client secret provided. Ensure the secret being sent in the request is the client secret value, not the client secret ID, for a secret added to app '98fec3da-la 12-429f-8ecf-0e803b5c39d9'. Trace ID: d7d2e5e6-c817-4d7d-8cd5-fddd2a985100 Correlation ID: 7cb5fl8e-7401-4af8-be39-4512169ea99b Timestamp: 2026-01-15 21:20:00ZH`

This procedure syncs Entra ID to Secret Server via Directory Services.

1. If you don't have one already, create a folder where the Secret will be stored in Secret Server.
2. Click on the **+** button at the top right of Secret Server.
3. Select **New Secret**.
4. Click **Change** next to the folder name to choose the folder that you have created and select the proper folder.
5. Choose the **Azure Application Registration** Secret Template.
6. Provide the secret name.
7. Provide the client ID:
   a. Navigate to the Microsoft Entra Admin Center.
   b. If you have access to multiple tenants, use the settings icon (a cog) in the top menu to switch to the correct tenant.
   c. On the left side of the page, click **App Registrations**.
   d. Select the **All applications** tab on the page to see the application that was created in the section above.
   e. Select that application.
   f. On the **Overview** page, in the **Essentials** section, look for and copy the **Application (client) ID**.
8. Provide the client secret. This should have been copied during the **Add Client Secret to the Application Registration in Entra** section of this topic. If it wasn't, you need to delete the client secret and recreate a new one as that value will never be exposed after it is initially created.
9. Provide the tenant ID:
   a. Navigate to the Microsoft Entra Admin Center.
   b. The tenant ID should be visible on the home page in the first tile. It can also be found by clicking on the **Overview** page.

10. Add notes as needed.
11. Select a site if needed.

Configuring an Entra ID Directory Source in Secret Server

1. Navigate to the **Directory Services** page.
2. Click the **Domains** tab.
3. Click **Add domain**.
4. Select **Microsoft Entra domain**.
5. Provide the following information:
   - **Domain Name**: This can be whatever you would like, this name in particular has no impact on synchronization.
   - Check the **Active** checkbox if you want to use the Entra ID directory source immediately after creation.
   - **Synchronization Secret**: Click **No Secret Selected** and choose the secret created in the "Create an Application Registration Secret in Secret Server" section above.
   - **Multifactor Authentication:** If you want to force your users to perform multifactor authentication when logging into Secret Server, select the proper option here.

> This is not the same as the multifactor for the Entra ID accounts themselves. This is specific to Secret Server. So, if this is enabled, and you also have multifactor enabled for your user in Entra ID, their sign in process will be: Sign into Entra > Enter Multifactor for Entra > Redirect to Secret Server > Enter additional Multifactor for Secret Server.

6. Click **Validate & Save**. A popup appears that shows the groups within Entra ID that are available to sync to Secret Server.
7. Select the groups you would like to sync.
8. Click **Save**.
9. If you want to sync those users right now, click **Sync now**.
10. If you navigate to the **Log** tab, you should see the users from the groups you chose listed as being added. For instance: `Domain.onmicrosoft.com: There are 3001 licensed users and user "[euser0001@Domain.onmicrosoft.com](mailto:euser0001@Domain.onmicrosoft.com)" will be user #2375`.

LDAP

Lightweight Directory Access Protocol (LDAP) is a widely-used, open-standard protocol designed for accessing and managing distributed directory information services over IP networks. It enables organizations to store and manage user identities, groups, and other data within a centralized repository, facilitating efficient authentication, authorization, and directory management.

Secure LDAP (LDAPS) enhances the protocol by incorporating encryption and authentication through Transport Layer Security (TLS) or Secure Sockets Layer (SSL), ensuring the confidentiality and integrity of data in transit. For more details on secure LDAP, refer to the Secure LDAP Overview.

OpenLDAP, a popular open-source implementation of the LDAP protocol, offers a scalable and customizable directory server solution that supports a variety of platforms and applications. To learn more about syncing with OpenLDAP, visit Syncing with OpenLDAP Directory Service.

With its flexibility, scalability, and security features, LDAP continues to be a fundamental technology for identity management, authentication, and authorization in modern computing environments.

Syncing with OpenLDAP Directory Service

Introduction

OpenLDAP is a free, open source version of the Lightweight Directory Access Protocol (LDAP) developed by the OpenLDAP Project. This topic describes syncing OpenLDAP to Secret Server.

> This feature is only supported by the new interface. The classic interface does not support OpenLDAP Directory Services.

Unsupported and Difficult Use Cases

Anonymous User Authentication

We do not support anonymous user authentication:

When creating an OpenLDAP directory service, "Anonymous" is a supported authentication method. When this is chosen, Secret Server connects anonymously to the OpenLDAP directory service as configured during the synchronization process and creates any users found on the directory service.

When anonymous is selected, a secondary authentication option, "User Authentication," appears, which is the method used when the synchronized users attempt to authenticate to Secret Server. In short, user authentication cannot be anonymous because Secret Server does not allow anonymous access.

The valid options for user authentication when anonymous is selected for the synchronization process are "Basic," "Kerberos," or "No Authentication." "No Authentication" supports using an OpenLDAP directory service as a user directory while enabling alternative methods of authentication, such as SAML.

Duplicate User Attributes

We do not support configurations where using different attributes yield users with the same username, GUID, or user principal name (email address format–not necessarily an actual email address). These must all be unique to each user. If a duplicate exists, it may result in odd, unpredictable behavior from the application.

OpenLDAP Password Changer Servers Using a DNS ANAME Record

Overview

Any OpenLDAP server that uses a DNS ANAME alias record in its Transport Layer Security (TLS) certificate requires an additional registry entry for the Microsoft ADSI library to successfully do a TLS handshake. For example, this problem directly impacts connections with Okta LDAP servers.

Registry Entry

The registry entry is:

```
(DWORD) HKLM\SYSTEM\CurrentControlSet\Services\ldap\UseHostnameAsAlias = 1
```

Example

We want to integrate with dev-99352743.ldap.okta.com (or any variation). We run Nslookup:

> Nslookup is a command-line tool used for querying the Domain Name System (DNS) to obtain the mapping between a domain name and its IP address or other DNS records. It is commonly used to retrieve detailed information about a specified domain, which is essential for troubleshooting DNS-related problems.

```
C:\Program Files\SafeNet\LunaClient>nslookup
dev-99352743.ldap.okta.com
Server: dns-cac-lb-02.rr.com
Address: 2001:1998:f00:2::1

Non-authoritative answer:
Name:   ok12-ldapi-6062af7f5304741c.elb.us-west-2.amazonaws.com
Addresses: 44.234.52.16
44.234.52.15
44.234.52.17
Aliases: dev-99352743.ldap.okta.com
ok12.ldap.okta.com
```

From this we glean:

ANAME record: dev-99352743.ldap.okta.com

CNAME record: ok12-ldapi-6062af7f5304741c.elb.us-west-2.amazonaws.com

> A "non-authoritative answer" means that the answer is not fetched from the authoritative DNS server for the queried domain name. Instead, it is obtained from a DNS server that has the information in its cache or has obtained it from an authoritative server and is providing the information as a best guess.

Thus, without the registry entry, the Microsoft library connects to the CNAME, and the TLS handshake fails. With the registry entry, the Microsoft library connects to the ANAME and the TLS handshake succeeds.

Procedure

1. Create a secret in Secret Server of type **OpenLDAP Account**. This sync secret is used to synchronize users and groups. It requires permission to search and view the attributes of the users and groups. If you plan on using Secret Server discovery, the account will also need LDAP permissions to scan computers on the network for accounts. Complete these parameters:
   - Domain. Example: `ldap.omega.thycotic.com`
   - Username. Example: `cn=ldap,dc=omegaldap,dc=local`
   - Password
2. Search for **Directory Services**. The Directory Services page appears:

3. Click the **Add Domain** dropdown list and select **OpenLDAP Domain**. The OpenLDAP popup appears.
4. Type the domain's FQDN in the **Fully Qualified Domain Name** text box. For example: `ldap.omega.thycotic.com`.
5. Type any name you desire in the **Friendly Name** text box.
6. Ensure the **Active** check box is selected.
7. Type the distinguished name (node path) in the **Distinguished Name** text box. For example: `dc=omegaldap,dc=local`
8. Click the **Authentication** dropdown list to select either the **Basic**, **Anonymous**, or **Kerberos** authentication method.
   - Basic authentication requires that valid credentials are assigned as the sync secret. Those credentials are used to authenticate to the OpenLDAP system on each sync.
   - Anonymous authentication does not require valid credentials and removes the Synchronization Secret section. Instead, it exposes a User Authentication field.

   The Kerberos authentication method probably works but has not been tested by Delinea.
9. **Basic** authentication:
   - Click the **No Secret Selected** link in the **Synchronization secret** section. The Select Secret popup appears.
   - Navigate to and select the secret you created earlier. The moment you click it, the popup disappears and the secret name appears in the Synchronization Secret section.
10. **Anonymous** authentication:
    - Click the **User Authentication** list to select **Basic** or **No Authentication**. This sets which authentication method to use when users who are synced anonymously try to authenticate:
    - Basic authentication requires valid OpenLDAP account credentials.
    - No authentication is for when customers want users synced from OpenLDAP but use authentication through another service, such as SAML. We do *not* support anonymous authentication for security reasons.
11. Click to select the **Use LDAPS** check box if you intend to use secure LDAP.
12. Click the **Site** dropdown list to select your site.
13. Click the **Multifactor Authentication** dropdown list to select the desired authentication method.
14. Click the **Validate & Save** button. The information is validated. If there are any connectivity issues, an error message will appear stating what field is the likely cause. If the Active check box is not selected no validation occurs. If you chose anonymous authentication, no secret is needed and no credential validation occurs; however the distinguished name and FQDN are still used. Upon a successful save, a new box appears, prompting the user to select their initial synchronization groups. If groups appear in the search box that also indicates the connection was successful.

Secure LDAP

Overview

By default, Secret Server uses normal LDAP on port 389 to communicate with Active Directory. Although passwords are still transmitted using Kerberos or NTLM, user and group names are transmitted in clear text. In contrast, secure LDAP (LDAPS) requires that both port 389 and 636 are open.

If you want all information to be encrypted, then you can enable Secure LDAP (LDAPS) in Secret Server via the Advanced link on the Edit Domain page.

When LDAPS is used, Secret Server transmits and receives Active Directory data through port 636 (with port 389 open). A certificate on the domain controller is used to negotiate encryption, and no information is transmitted in clear text.

LDAPS requires that port 636 is open and a valid certificate is installed on the domain controller. Ensure that the certificate is trusted by the Secret Server environment.

Make sure that UDP port 389 is available for LDAP operations, as it is used for essential services like the Domain Controller Locator.

If you want to use Integrated Windows Authentication and Secure LDAP, that is only supported in Windows Server 2008 R2 or greater.

Troubleshooting LDAPS Connection Issues

Common problems with LDAPS and Secret Server:

- When you turn on LDAPS you will get a "domain name is invalid" error.
- Users are suddenly unable to log on Secret Server.

Both issues are caused by LDAPS to Secret Server communication issues, usually one of the following:

- The certificate is expired (this is the client certificate, not the SSL on the Secret Server website).
- LDAPS is not enabled in your environment.
- A port is blocked that is denying successful communication between the server and AD.

To troubleshoot, use the free LDP tool to test LDAPS connections from the Secret Server Windows server to your AD server. If you are unable to establish a connection on port 636 (with 389 open too), then we recommend consulting with your AD or security team.

Sometimes the Secret Server event viewer has information regarding invalid certificates.

Ensure that all relevant certificates are trusted within the Secret Server environment, especially when dealing with multiple domains. This is crucial for establishing secure LDAPS connections.

Secret Server Discovery

Secret Server Discovery is a powerful feature that scans an environment to identify accounts and associated resources, known as dependencies. This process helps in creating new secrets within Secret Server by automatically discovering and importing accounts, thereby reducing the administrative burden of manually tracking computers and accounts. Discovery can find various types of accounts, including Windows local admin, Windows domain, and Unix non-daemon accounts, as well as dependencies like scheduled tasks, application pools, and services running under domain accounts. It supports multiple discovery types, including Active Directory, ESX/ESXi, AWS, Google Cloud Platform, and Unix. Additionally, Secret Server allows for extensible discovery through custom PowerShell scripts, enabling the discovery of account and dependency types not supported out-of-the-box. This feature ensures continuous monitoring and management of privileged accounts, enhancing security by identifying and securing backdoor accounts and other potential vulnerabilities.

For details, refer to the "Discovery Overview" below.

Understanding Discovery

"Discovery Overview" below

"Discovery Glossary" on page 537

"Introduction to Discovery Sources, Scanners, and Templates" on page 538

Discovery Overview

Discovery is the process where Secret Server scans an environment to find accounts and associated resources called *dependencies*. Once accounts are found, they can be used to create new secrets in Secret Server. Users with the "administer discovery" role permission can either manually import accounts or can create an automated process to do so. Using discovery does not stop users from manually creating their own secrets.

Some typical accounts that discovery can find include Windows local admin, Windows domain, and Unix non-daemon. Some typical dependencies discovery can scan for include scheduled tasks running as a domain user, application pools running as a domain user, and services running as a domain user.

> Account and dependency types not supported out-of-the-box in Secret Server can still be discovered by writing PowerShell scripts that you can run as custom scanners. See "Extensible Discovery" on page 584.

In a Hurry?

We suggest reading (in order):

- "Discovery Glossary" on page 537
- "Introduction to Discovery Sources, Scanners, and Templates" on page 538
- "Running and Interpreting Active Directory Discovery" on page 608

Discovery Benefits

Importation of Network Credentials

By using discovery, your Secret Server offsets the burden of keeping track of computers and accounts on your network. This can be especially beneficial when getting started for discovering and importing accounts in bulk, as well as having Secret Server find accounts and create secrets whenever a new machine or account is provisioned.

Protection Against Backdoor Accounts

When Secret Server is configured to discover new accounts, it provides added protection by regularly running discovery on your network to identify those accounts. Secret Server adds the new accounts to its records and resets the accounts password to values that meet your security policy. Consequentially, if someone is setting up backdoor admin accounts on the network, they cannot use those accounts very long before they are imported into Secret Server and their passwords are changed with Remote Password Changing (RPC).

Discovery Types

Active Directory Discovery

Secret Server AD discovery scans for AD machines, AD user accounts, local Windows accounts, and dependencies on an AD domain. First, SS discovers machines from your domain. Next, SS scans each machine for local Windows accounts and dependencies **that depend on domain accounts**. By default, SS scans for local accounts, domain accounts, scheduled tasks, Windows services, and IIS application pools. You can discover additional accounts and dependencies by creating PowerShell scanners. PowerShell scanners are an advanced topic described in the "Extensible Discovery" on page 584 section.

ESX/ESXi Discovery

Secret Server provides a wizard to help configure ESX/ESXi discovery. You name the discovery Source, define the host ranges of the desired IP addresses, and choose a secret to use as credentials when scanning.

Secret Server provides a "Generic Discovery–Only Credentials" secret type that stores a simple username and password pair for Unix or ESX/ESXi discovery. It is intended only for discovery and is incapable of RPC.

AWS Discovery

Secret Server can scan Amazon Web Services (AWS) for accounts that can access the cloud resource. Two types of secrets can be discovered and managed through Secret Server:

- AWS Access Key: Keys used for programmatic integration with AWS.
- AWS Console Account: User login accounts for AWS.

Google Cloud Platform Discovery

Secret Server can manage Google Cloud Platform (GCP) service accounts and VM instances. This feature allows users to run discovery to pull and manage VM Instances, as well as import and manage GCP service accounts.

Unix Discovery

Secret Server provides a wizard to help configure Unix discovery. You name the discovery Source, define the host ranges of the desired IP addresses, and choose a secret to use as credentials when scanning. The default command sets that Secret Server ships with discovers machines and accounts in most Unix environments.

By default, the "Find Non-Daemon Users (Basic Unix)" command set is used first. If a built-in account is discovered, you must modify the discovery source to use the "Find All Users (Basic Unix)" command set. You can create new command sets by clicking the Configure tab on the Discovery Sources page.

Extensible Discovery

You can customize discovery by changing parts of it to use PowerShell. The information a discovery scanner outputs is defined by its scanner template. For standard templates, the input and output information types are fixed. Extensible discovery allows you to customize or replace the unmanaged account, IP address and OU, account, and dependency discovery steps above. Extensible discovery does still have limitations on what information is passed between discovery scanners. For more information, see "Extensible Discovery" on page 584.

Discovery Performance

Please see our "Discovery Best Practices" on page 562 to learn about optimizing discovery performance.

Example Discovery Process

A typical automated discovery process for Active Directory domains, running on an interval, looks like this:

> The majority of current discovery processes are for AD discovery source type. The others types differ by input and output but follow a similar process.

> Even though automatic discoveries run on a set interval, you cannot schedule when those occur. The interval is from whenever the discovery last ran.

1. Discovery matching runs. The discovery matcher creates a link between existing active secrets and any existing secrets in Secret Server based on their machine names, accounts and dependencies. The matcher is automatic. When matches are found, the corresponding existing discovery results appear as "managed" in the discovery network view with a link to the existing secret or dependency.
2. Discovery rules run and attempt to match any unmanaged discovery results to the rule's parameters. If a rule matches the results, discovery automatically imports the results using the settings in the discovery rule. Once finished, discovery begins.
3. The Find Host Ranges scanner (using the Windows Discovery base scanner) runs with an Active Directory Domain input template. The scanner determines which OUs are to be scanned and populates its Organizational Unit output template with a list of those OUs. The output template will be used by the following Find Machine scanner and also by the Find Local Accounts scanner, which does not require machine information.
4. The Find Machine scanner (using the Windows Discovery base scanner) examines OUs from its Organizational Unit input template via LDAP and creates a list of machines with which it populates its Windows Computer output template. This is the list of computers to run a dependency scan on. The Find Dependencies scanner

uses this instance of the output template as its input template.

5. The Find Local Accounts scanner (using the File Load Discovery base scanner) examines OUs from its Organizational Unit input template via LDAP and creates a list of all AD admin accounts with which it populates its Active Directory Account output template. This is the list of discovered admin accounts.
6. The Find Dependencies scanner (using the Windows Discovery base scanner) examines a list of machines from its Windows computer input template using various technologies. For example, application pools use Microsoft Web Administration (WMA) or, failing that, Windows Management Instrumentation (WMI). Services use WMI, and scheduled tasks use Windows' task scheduler interfaces. The Find Dependencies scanner can return any number of output templates as desired. These include: Com+ Application, Computer Dependency (Basic), PS Dependency, Remote File, SQL Dependency (Basic), SSH Dependency (Basic), SSH Key Rotation Dependency, Windows Application Pool, Windows Scheduled Task, and Windows Service.

The discovered dependencies for local accounts are displayed at **Admin > Discovery > Discovery Network View > Local Accounts**. Returned accounts for AD users are displayed at **Admin > Discovery > Discovery Network View > Domain > Cloud Accounts**.

Any dependencies that were discovered in prior discovery runs that are no longer present are removed from the discovery results, and their secret dependencies are deactivated.

Manual Discovery

You can also run discovery manually by going to **Admin > Discovery** and clicking the **Run Now** button and selecting **Discovery Scan**. We recommend waiting for any automatic discovery to idle before starting a manual discovery run. A discovery scan runs the first four of the automated steps above. When you click the "Run Now" button on the Scan Computers tab, the last two are run. These steps are the most time intensive steps because many machines may be scanned.

Discovery Glossary

- Command sets: An SSH script that runs on Unix machines and produces a specific set of output to be consumed in a discovery source flow.
- Discovery scan template: A scan template simply defines an object and what properties the object contains. For example, a computer account has a name, machine, and domain. Think of a scan template as an interface that describes an object.
- Discovery scanner: This item defines how to take that information and runs code to produce collection outputs. Scanners can be system out-of-the-box code that runs natively in the system or completely custom scripts that can do anything.
- Discovery scripts: In the scripting section, you can define a script for a discovery scanner. While scripts are not specific to discovery, they are an important piece to help use the power of extensible discovery.
- Discovery source flow: A collection of scanners that work in a common pipe and filter architecture where each scanner inputs a certain type of item and then outputs a different type of item. For example, a scanner takes an input of a host IP range and outputs multiple computers that can then be consumed by another scanner which can input computer information and output computer accounts.

- Discovery source: This defines the definition for how items are discovered. One discovery source may discover Active Directory items, and one may discover Unix machines. It is common to have multiple discovery sources. Each source defines credentials, scanners, and settings specific to your network.
- Secret search filters: Certain scanners and import rules can leverage a filter that uses the name of the machine to find or use an associated Secret. For example, you may have a pattern of naming the local account on a machine including the machine name. A secret search filter allows you to find secrets using the name of the current machine in the pattern to find the matching secret.
- Discovery Import: Import performs the task of creating new Secrets or linking dependencies to existing Secrets based on discovered account objects. It is available as both a manual option and an automated process (dependent on licensed features).

Introduction to Discovery Sources, Scanners, and Templates

Discovery Source

A *discovery source* is a named collective, ordered system that conducts discovery. There are five broad types: Active Directory, Amazon Web Services, Unix, VMware ESX\ESXi, and Google Cloud Platform.

Configuring discovery is defining the parameters of the discovery source, once the general type is chosen.

Each discovery source is a configurable definition of how to scan for computer assets in a given environment. A subcomponent of discovery source, called a scanner, details how to perform those scans.

Discovery Scanner

A *discovery scanner* is a component of a discovery source that collects information during a discovery. There are four general types of scanners, called *scan templates* (in their sequential running order):

- Find host ranges
- Find machines
- Find (local) accounts
- Find dependencies

They are called scan *templates* because when you create an instance a discovery source, it includes scanners based on a standardized set scanners specific to the platform the discovery source is designed for and the type of performed scan. That is, when you create a discovery source, you are instantiating a set of of scanner objects copied from a set of static templates. You cannot modify the templates, but you can modify the scanners based on them.

Thus, a discovery source consists of an ordered sequence of discovery scanners, along with some data specific to the whole discovery source. Each scanner has a defined input and output, which are also based on object templates. A discovery source can have more than one scanner of a given type.

Discovery Input Template

The defined input type for a discovery scanner. An instance of the template contains the data needed to conduct the scan. The input template is often, but not always, an output template of the preceding scanner in the sequence.

Some examples include Active Directory domain, AWS discovery source, organizational unit, and Windows computer.

Discovery Output Template

The defined output type for a discovery scanner. An instance of the template contains the data produced by the scan. The output template is often, but not always, an input template of the next scanner in the chain. Other times, the output may be used by another non-adjacent scanner in the discovery source.

You can also have more than one scanner of the same type in the same discovery source. For example, you could have both the Windows Local Accounts and Active Directory User Accounts scanner active in the Find Accounts section. Click the **+** icon next to the scanner section to see what other scanners are available there.

Some examples include: Active Directory account, AWS access key, ESXi local account, host range, organizational unit, and Windows local account.

Example

The following figure shows the data flow through the discovery source as the scanners receive and output data via input and output templates. The dataflow is as follows:

1. The original input, the domain, comes from the discovery source and was manually inputted.
2. The Active Directory Organizational Units (of type Find Host Ranges) scanner receives the domain via the Active Directory Domain input template.
3. The scan discovers the OUs of the inputted domain and returns those OUs via the Organizational Unit output template.
4. The Active Directory Computers (of type Find Machines) scanner receives the OUs from the Organizational Unit output template.
5. The scanner discovers the Windows computers belonging to the inputted OUs and returns those Windows computers via the Windows Computer output template.
6. The Windows Local Accounts (of type Find Accounts) scanner receives the Windows computers from the Windows Computer output template.
7. The scanner discovers local accounts belonging to the inputted Windows computers and returns those local accounts via the Windows Local Account output template to Secret Server*and* to the Windows Service scanner.
8. The Windows Service (of type Find Dependencies) scanner receives the Windows computers from the Windows Computer output template. This is the same input received in the last step by SS.
9. The scanner discovers Windows services belonging to the inputted Windows computers and returns those Windows services via the Windows Service output template to SS.

Editing and Adding Discovery Scanners

Many of the discovery scanners can be edited after instantiation by the discovery source. Sometimes the editable data is the same as was originally inputted for the discovery, and sometimes it is something else altogether.

The Secret Credentials section is the same as the credential secret defined when creating the discovery source. The Advanced Settings section contains settings that were not initially configurable in the discovery scanner.

In this case, you see many default configuration settings that were not originally settable in the discovery source. For example, you can use a different credential secret or change the ports scanned by the scanner. Please be advised that if a privileged account is set under specific OUs, that the account will override any accounts set on the individual Discovery Scanners (Service, Scheduled Task, Local User, etc.) As mentioned above, you can also add entire scanners too–that is, more than one scanner of the same type.

Account Permissions for Discovery

Entra ID

The Application Registration (mapped to an Azure Application Registration Secret) used for Entra ID Discovery must be assigned to the following roles:

- EntitlementManagement.Read.All
- RoleManagement.Read.Directory
- User.Read.All

> These Microsoft Graph API permissions must be added as Application Permissions not Delegated Permissions.

Unix

Local Accounts

The scanning account needs to be able to connect over SSH and read the contents of `/etc/passwd`. If Discovery needs to take over an account then the scanning account will also need the ability to run `sudo passwd <username>`

During a remote password change, the `passwd` command is also used and the default local settings will apply.

SSH Public Keys

The scanning account needs the ability to login and execute `sudo` without a password prompt.

Please see "Discovering SSH Public Keys" on page 635 for more information.

ESXi

The scanning account needs the ESXi **Shell Access** and the vSphere **Query VRM Policy** permission.

Local Windows Accounts

The scanning account needs the **Access this computer from the network** permission (and possibly one more) on the endpoint:

1. Access the windows command line and run `gpedit.msc`. The **Local Group Policy Editor** window will open.
2. Go to **Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment**.
3. Double-click the **Access this computer from the network** policy. The properties for the policy appear.
4. Ensure the scanning account is one of the listed users. If not, click the **Add User or Group** button to add it.

   Modifying this policy may overwrite or remove access to the device for remote processes. This policy is not usually configured by default, so any existing inherited Windows permissions could be overwritten.

5. Look at the following list of operating systems and updates to determine if any of them match your system:
   - Windows 10, version 1607 and later
   - Windows 10, version 1511 with KB 4103198 installed
   - Windows 10, version 1507 with KB 4012606 installed
   - Windows 8.1 with KB 4102219 installed
   - Windows 7 with KB 4012218 installed
   - Windows Server 2019
   - Windows Server 2016
   - Windows Server 2012 R2 with KB 4012219 installed
   - Windows Server 2012 with KB 4012220 installed
   - Windows Server 2008 R2 with KB 4012218 installed

> For more information on this security issue, see Network access: Restrict clients allowed to make remote calls to SAM.

6. If you found a match, do the following:
   a. Go to **Computer Configuration > Windows Settings > Security Settings > Local Policies > Security Options**.
   b. Double-click the **Network access: Restrict clients allowed to make remote calls to SAM** policy. The policy properties appear.
   c. Click the **Edit Security** button to select an account for the Security descriptor text box. The **Security Setting for Remote Access to SAM** dialog box appears.
   d. Ensure the scanning account is present (if not add it).
   e. Click the account in the **Group or user names** list. The Windows NTFS permissions for that account appear.
   f. Ensure the **Allow** checkbox next to the **Remote Access** permission is selected.
   g. Click the **OK** button.

> The discovery account must be a part of the local admin's group to be able to pull back any local accounts.

Windows Services, Scheduled Tasks, App Pools, and COM+ Applications

> There are special considerations for discovering service accounts running COM+ Applications, please see "Windows Services" on page 930.

To scan for service accounts, the account entered must be a domain account that is in the Administrators group on the target machine(s). Follow the instructions below in either case to ensure your account has the appropriate privileges to run a successful scan:

1. Access the windows command line and run `gpedit.msc`. The **Local Group Policy Editor** window will open.
2. Go to **Computer Configuration > Preferences > Control Panel Settings**.
3. Right-click **Local Users and groups** and select **New > Local Group**.
4. Leave the **Action** dropdown list set to **Update**.
5. Click to select **Administrators (Built-in)** in the **Group Members** drop-down list.
6. Click the **Add...** button.
7. Search for the account you will use for Discovery scanning.
8. Click the **OK** button to save your changes.

   The next time the group policy updates across your environment, the discovery account will be a part of the local administrators group.

9. For stronger security, we suggest configuring the group policy to limit the login privileges of the Discovery account:

   > This will also require you to use a different account (separate from the discovery account) to rotate dependencies.

   a. Access the windows command line and run `gpedit.msc`. The **Local Group Policy Editor** window will open.
   b. For your domain policy, go to **Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment**.
   c. Add your discovery account to the **Deny log on locally** policy.
   d. Add your discovery account to the **Deny log on through Remote Desktop Services** policy.
   e. (Optional) Ensure the account is not part of the remote desktop users group.
10. Do not put dependency changers in these policies:
    - Deny access to this computer from the network.
    - Deny log on Locally.
11. We recommend putting dependency changers in these policies:
    - Deny log on as a batch job.
    - Deny log on as a service.
    - Deny log on through Remote Desktop Services.

Application Pool Discovery Over Distributed Engines

Overview

Application pools cannot directly perform discovery over distributed engines, but a work around can be made by using impersonation of a discovery source's identity.

> The distributed engine service must be run as an account with sufficient privileges to scan the application pools on its own.

For discovery to work on application pool service accounts on IIS 7+, the **IIS Management Scripts and Tools** feature must be installed on both the DE and the web server running the scan and the target machine hosting the application pool.

Check that the following privileges are set:

1. Enable the account to log in as a service.
2. Grant the account read, write, and execute privileges to the entire distributed engine installation directory and sub-folders.
3. Add the account to the administrators group on each computer that will be scanned.

80070005 Error

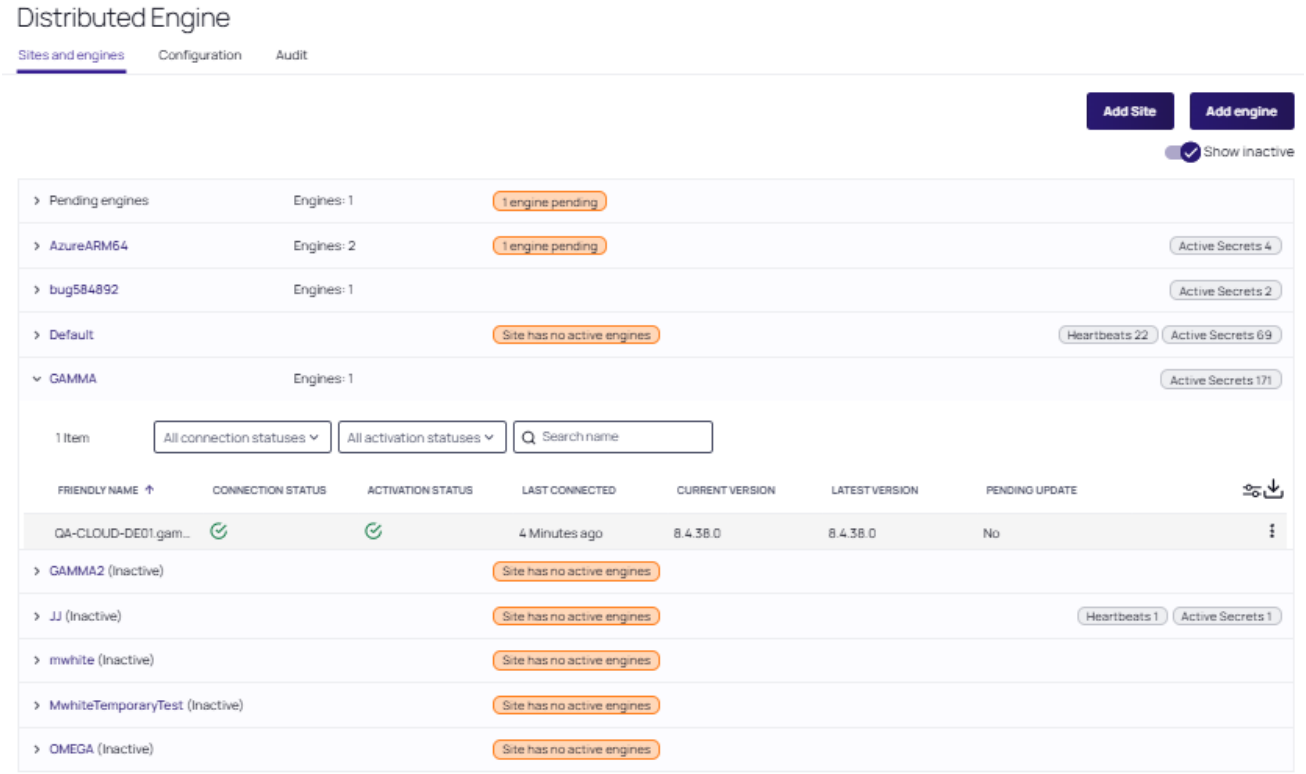
An 80070005 error indicates that the distributed engine service account does not have sufficient privileges on the machine being scanned:

```
Exception: Retrieving the COM class factory for remote component with CLSID {2B72133B-3F5B-4602-8952-803546CE3344} from machine <MACHINE> failed due to the following error: 80070005
```

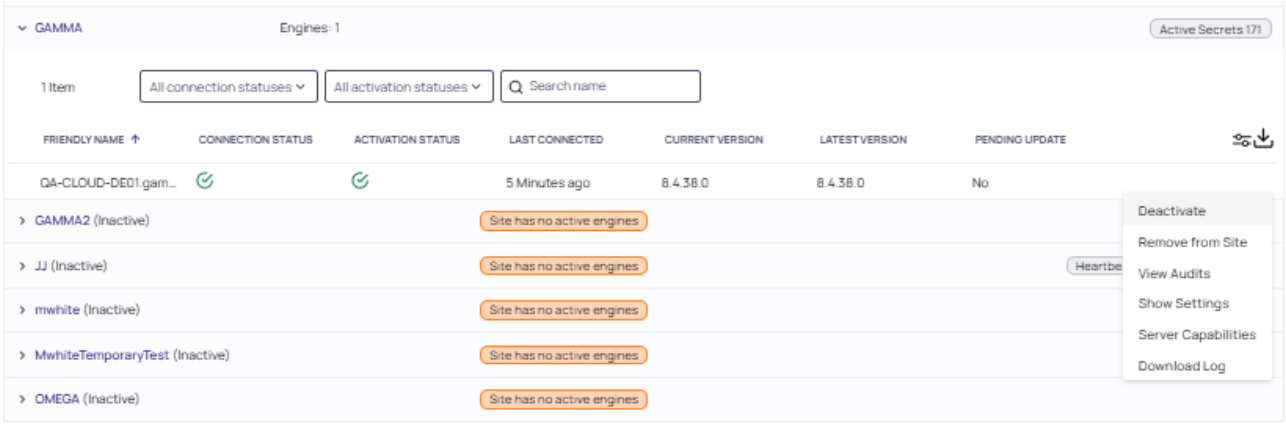
To resolve the error, add the account to the administrators group on that machine. When changing the user of the distributed engine service, Secret Server interprets the service as a new engine. Delete the old engine and activate the new engine in secret-server.

The typical workflow for changing the account login for the distributed engine service is as follows:

1. Hover over **Settings** and under **Distributed Engine** select **Sites and engines**. The **Distributed Engine** page appears.
2. From the list of sites with active engines displayed by default, select the site whose engine you want to deactivate and click the arrow to expand the selection:



3. To deactivate the DE, hover over the far right of the screen on the line of the engine under the download button, a vertical 3-dot option will appear. Click the option to open a drop-down list and select the first option:



4. When prompted, confirm the deactivation by clicking **Ok**.
5. Delete the engine by reselecting the 3-dot menu and choosing **Remove from Site**.
6. When prompted to confirm this action click **OK**. This will place the engine under the **Pending engines** dropdown at the top of the page. In order to see it in that section a refresh of the page is necessary.
7. Once the deactivated engine can be seen in the list, hover over the line again until you see the 3-dot option menu, and click on it. The **Delete** option is second on the list, choose it and confirm the action. The page will refresh automatically and the engine will vanish from the **Pending engines** list.
8. Go to the distributed engine server and stop the distributed engine service or end the process from the Task Manager.
9. Change the Log On option – this must be the same account used for your discovery.
10. Start the distributed engine service.
11. In the Secret Server application, Search for **Sites and engines** and check if the engine is under **Pending engines**.
12. If so, activate the DE by clicking the 3-dot menu and selecting **Activate** and assigning it to a site when prompted. You should see a successful connection. **Activation Status** should also have the green checkmark.

Managing IIS Application Pool Dependencies

Overview

To manage IIS Application Pools effectively, the same requirements that apply to Discovery must also be met. This includes ensuring that the necessary IIS permissions and configurations are in place, even for customers who create dependencies manually. See Application Pool Discovery Over Distributed Engines for more details.

To manage IIS dependencies, the Distributed Engine service must be run as a service account with administrator rights on the target workstations. This is crucial because:

- Administrator rights ensure that the service account can access and manage all necessary components of the IIS Application Pools.

- Without these rights, the service may not function correctly, leading to potential issues in managing dependencies.

Configure the Distributed Engine Service

1. Create a Service Account with administrator rights on the target workstations and the necessary Windows permissions to access IIS components.
2. Configure the Distributed Engine:
   - Open the Distributed Engine configuration settings.
   - Set the service account credentials.
   - Save the configuration and restart the service to apply changes.
3. Check the logs to ensure the service is running without errors.
4. Test the management of IIS Application Pools to confirm successful configuration.

Creating a Discovery Source

Introduction

A *discovery source* is a named collective, ordered system that conducts discovery. There are six broad types to choose from:

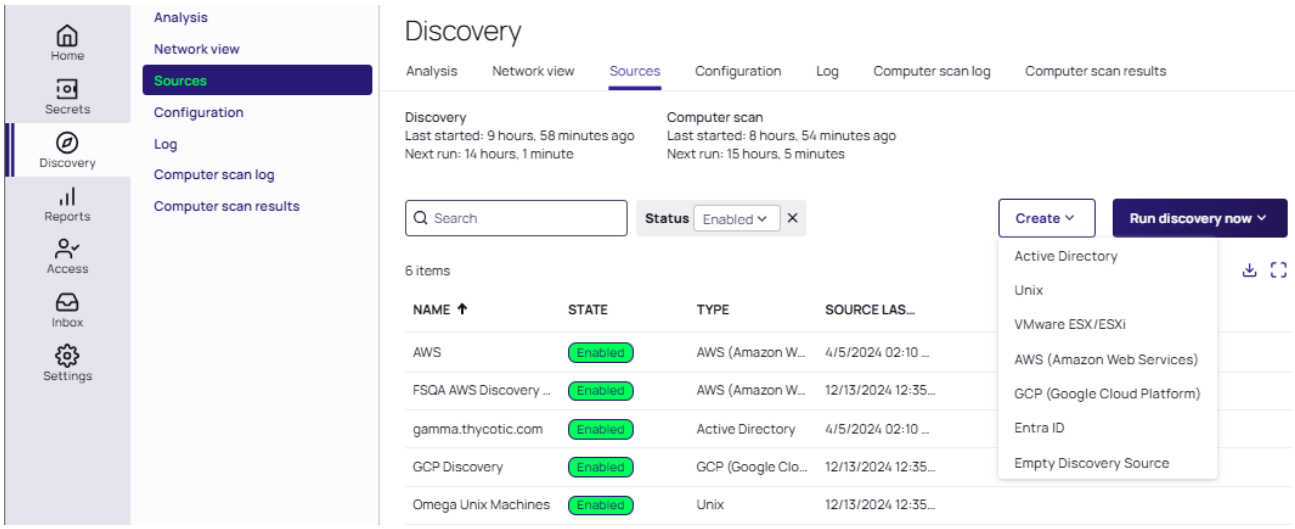
- Active Directory
- Unix
- VMware ESX\ESXi
- AWS (Amazon Web Services)
- GCP (Google Cloud Platform)
- Entra ID

Configuring discovery is defining the parameters of the discovery source. Each discovery source is a configurable definition of how to scan for computer assets in a given environment. A subcomponent of a discovery source, called a scanner, details how to perform those scans.

There is also an **Empty Discovery Source** option that creates a new discovery source that does not contain any scanners. This is useful for extensible discovery as you can add any custom scanners.

Procedure

1. Search for **Discovery Sources** on the main page and select it.
2. Select the **Create** dropdown list and select the type of source you need:

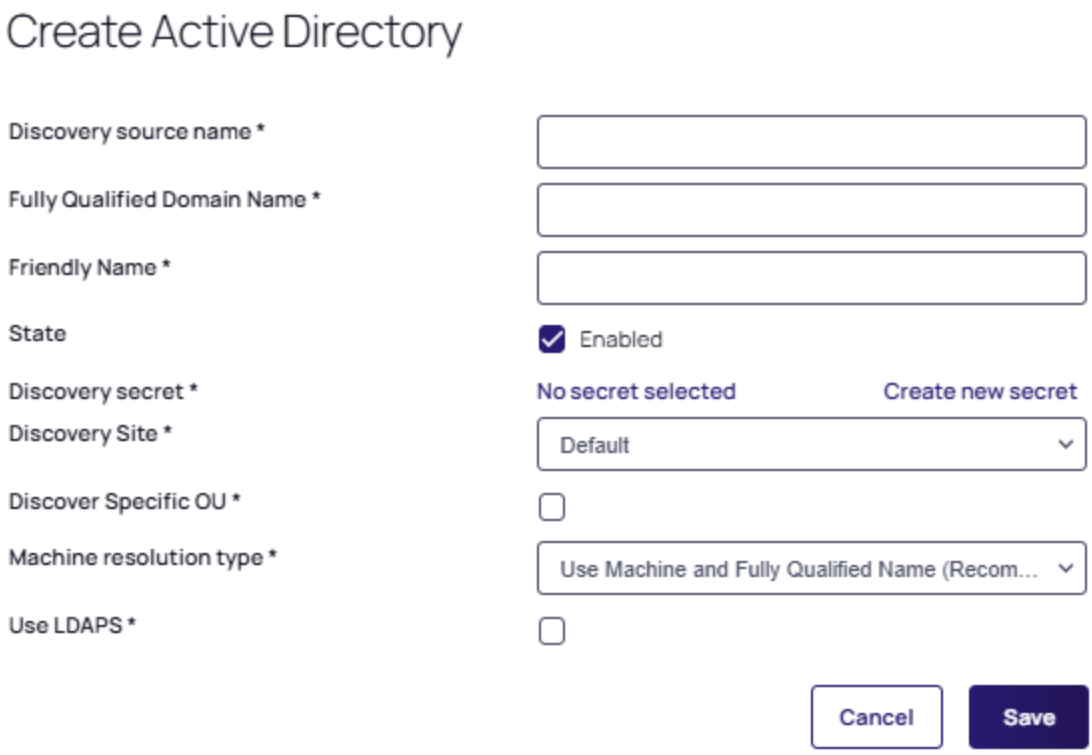


For all sources except for Active Directory you are prompted for a name, site, source type, and secret. Active directory has a specific dialog which allows for some advanced validation and customization.

> Active Directory discovery scans Active Directory (AD) machines, AD user accounts, local Windows accounts, and their dependencies within an AD domain. The discovery process begins by identifying machines within your domain, followed by scanning each machine for local Windows accounts and associated dependencies. By default, the scan includes local accounts, domain accounts, scheduled tasks, Windows services, and IIS application pools. To further enhance the discovery process, you have the option to create PowerShell scanners, which allow for the identification of additional accounts and dependencies. PowerShell scanners are an advanced topic covered in detail within the Extensible Discovery section.

a. If the **Active Directory** option is chosen:

i. The **Create Active Directory** discovery source page appears:



If you upgraded from an earlier version of Secret Server and have created an AD domain within it, a corresponding discovery source is displayed on this page. If discovery was not enabled on that domain, the discovery source Active column is not checked for that discovery source.

ii. Type in values for the following mandatory fields:

- Discovery source name
- Fully Qualified Domain Name
- Friendly Name
- Discovery secret
- Discovery Site
- Discover Specific OU
- Machine resolution type
- Use LDAPS

iii. Ensure the **State** checkbox is set to **Enabled**.

This activates the discovery source for scanning. Enabled discovery sources are scanned at the defined discovery interval. If you have multiple discovery sources, the discovery source with the most un-scanned computers is scanned first.

iv. Click the **No Secret Selected** link. The **Select Secret** popup page appears.

v. Select a secret that will be used as the credentials for discovery scanning and AD synchronization. These credentials must have the proper rights to scan the remote machines.

vi. Once you've selected a secret the popup page closes. The name of the secret you chose replaces the *No Secret Selected* link name.

vii. Alternatively, you can create a new secret for the credentials:

  i. Click the **Create New Secret** link. The **Create New Secret** popup dialog appears.

  ii. Search for and select the **Generic Discovery Credentials** secret template. Another Create New Secret popup appears.

  iii. Type or select the parameters needed for the discovery operation. Parameters with asterisks are required.

  iv. Click the **Create Secret** button.

viii. Click the **Discovery Site** dropdown list to select the desired site for the discovery source.

If distributed engines are set up, the list shows all active sites. If no distributed engines are set up, the list defaults to local, and you cannot change it.

ix. Select the **Discover Specific OU** checkbox to limit your discovery to an OU.

See "Enabling Specific OU Domain Discovery" on page 580 to define the scanned OU. When you select this option, a **Domain Scope** tab appears on the Discovery Source page for the created AD discovery source.

x. Leave the **Machine Resolution Type** dropdown list set to **Use Machine and Fully Qualified Name** unless you have a specific reason to change it.

xi. Check the **Use LDAPS** checkbox to if you want this server to connect to the LDAP server using SSL.

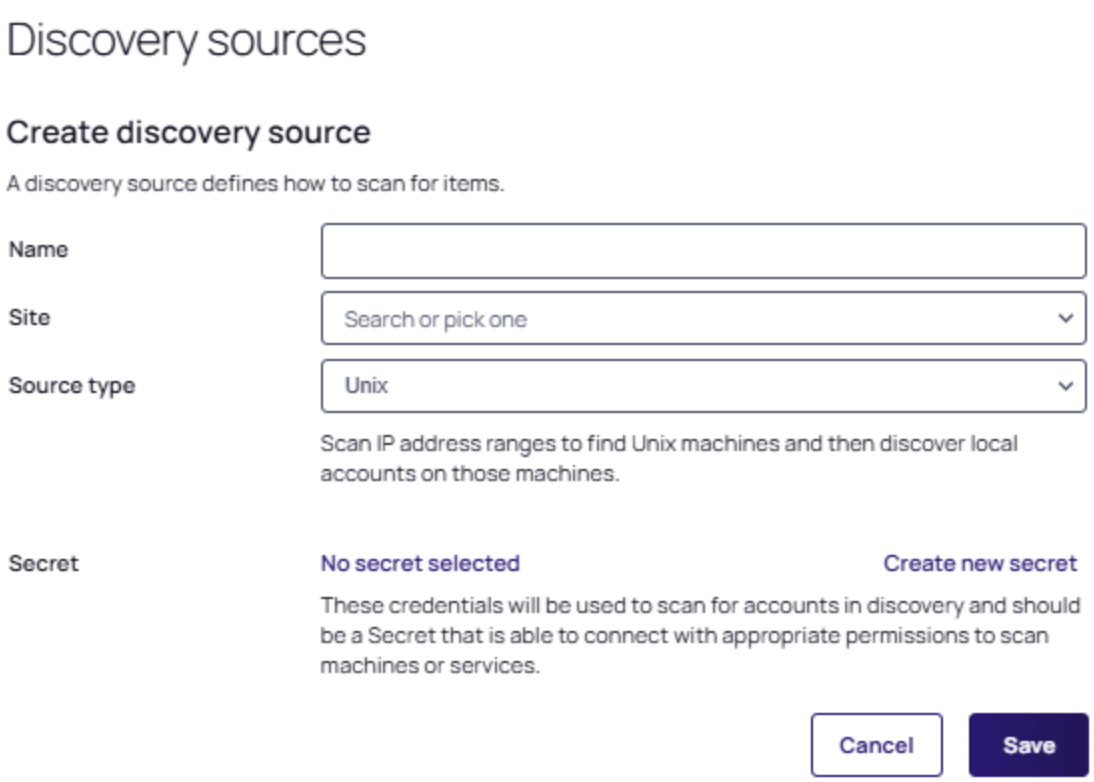
xii. Click the **Save** button.

Secret Server attempts to access the domain with your specified credentials to ensure the configuration is correct. Secret Server must have access to the domain provided, and the account credentials must work.

3. For other source types when selected:

For Unix, the default command sets efficiently discover machines and accounts in a wide range of Unix environments. By default, the "Find Non-Daemon Users (Basic Unix)" command set is used for discovery. If you wish, however, to include the built-in account in the discovery process, you will need to update the discovery source to use the "Find All Users (Basic Unix)" command set. For further customization, you can create new command sets by accessing the "Configure Command Sets" option on the Discovery Sources list page. Additionally, you can modify the secrets employed during the discovery by accessing the scanner settings.

a. The discovery sources page appears:



b. Type the name of the discovery source in the **Name** field.

c. Click the **Site** dropdown list to select the domain.

d. Click the **Source Type** dropdown list and choose one of the following:

- **Empty**: An empty discovery source does not have any scanners in it and after it is created you will need to add scanners before it can be activated. Creating an empty source is for when you have specific scanners in mind or want to build it from scratch.
- **Unix**: Scan IP address ranges to find Unix machines and then discover local accounts on those machines.

- **AWS**: Scan Amazon Web Services for keys, users, windows and non-windows machines. You will be prompted after saving to select which items.
- **GCP**: Scan Google Cloud Platform for users, windows and non-windows machines. You will be prompted after saving to select items.
- **VMware ESX/ESXi**: Scan IP address ranges to find VMware ESX/ESXi hosts and discover local accounts.
- **Entra ID**: Scan an Entra ID tenant for Roles and Role Members.

e. Click the **No Secret Selected** link. The **Select Secret** popup page appears.

Select a secret that will be used as the credentials for discovery scanning and AD synchronization. These credentials must have the proper rights to scan the remote machines.

Once you have selected a secret the popup page closes. The name of the secret you chose replaces the *No Secret Selected* link name.

i. Alternatively, you can create a new secret for the credentials:

i. Click the **Create New Secret** link. The **Create New Secret** popup dialog appears.

ii. Search for and select the **Generic Discovery Credentials** secret template. Another Create New Secret popup appears.

iii. Type or select the parameters needed for the discovery operation. Parameters with asterisks are required.

iv. Click the **Create Secret** button.

f. Click the **Save** button.

4. The **Add Flow** popup appears. Select the flow that matches the source type you just created.
5. The source details page loads automatically with the **Scanners** tab selected. Make any adjustments to the source scanner flow as needed.
6. All scanners for the source are listed in this tab. Click on one to see its settings in a panel that appears on the right.
7. Select **Edit Scanner** to make any changes to the scanner secret or its IP ranges.

> Your discovery source may not be ready to run yet and may require additional properties to be configured for your network. Some scanners will have required properties such as an IP address range and will indicate this by a red exclamation coupled with "Review needed" on the discovery flow on the Scanners tag. Some settings may be specific to your network and require customization. We recommend that you review each scanner and each setting to see which settings apply to you.

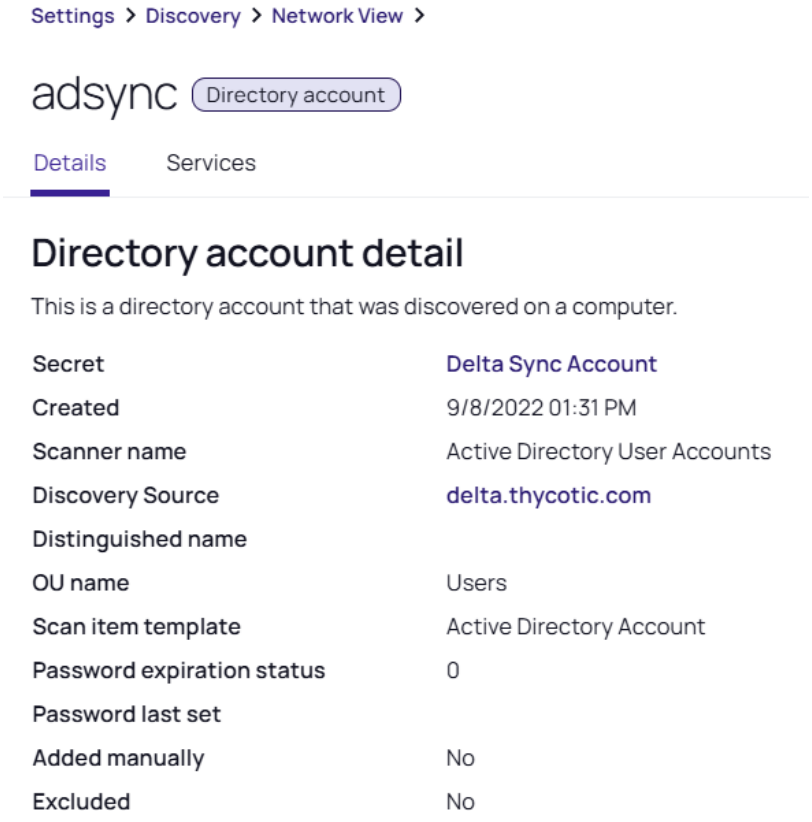
Discovery Account Details

To view the Discovery Account Details:

1. Select **Discovery > Network view**.
2. In the **Item Type** dropdown list, select **Directory Accounts**.

3. Click the related account from the list. The account details expands to the right (for a full page view click the **View details** button in the expanded menu).

The account details show the Type, Full Name, Created date and time, Active Directory Account, Delta Sync Account, Discovery Source Name, Managed, Password expiration status. Click **View details** to proceed to the Directory Account details.



Here the following details are displayed:

- **Secret**: refers to the secret associated with the directory account.
- **Created**: the timestamp that indicates when the account was created. It is important for tracking the account lifecycle and understanding its history within the system.
- **Scanner name**: the name of the account as identified during the discovery scan.
- **Discovery Source**: the origin or the source from which the discovery process is initiated. See Discovery Source for more details.
- **Distinguished name**: the unique identifier for the account within a directory service like Active Directory. It provides the full path to the account within the directory hierarchy, which is essential for locating and managing the account.
- **OU name**: refers to the Organizational Unit (OU) within which the account resides. OUs are used to organize accounts and resources within a directory service, making it easier to apply policies and manage Active

Directory (OU-level) permissions.

- **Scan item template**: defines the criteria and properties used during the discovery scan to identify and categorize the account.
- **Password expiration status**: indicates whether the account's password is set to expire and when.
- **Password last set**: the timestamp that shows when the password for the account was last changed.
- **Added manually**: indicates whether the account was manually added to the system, as opposed to being discovered automatically through a scan. Manually added accounts might require additional verification to ensure they are correctly configured.
- **Excluded**: shows whether the account has been excluded from certain processes or scans. Exclusion might be used to prevent specific accounts from being managed or altered by automated systems, often for security or operational reasons.

Creating Discovery Rules

Introduction

Secret Server discovery rules play a pivotal role in automating the process of finding, importing, and managing passwords, API keys, and other credentials throughout an IT environment.

Discovery rules offer several advantages:

- **Automated Discovery**: Discovery rules simplify identifying potential secrets across various platforms and environments, ensuring that no sensitive credentials remain unmanaged or unprotected.
- **Policy Enforcement and Risk Reduction**: Discovery rules help enforce consistent security policies across an IT environment. This consistency is crucial for minimizing security breaches and ensuring compliance with regulatory standards.
- **Efficient Secret Management**: Discovery rules reduce the administrative burden on IT teams by automating secret candidate discovery and importation.
- **Dynamic Adaptation**: Discovery rules help to flexibly adapt to IT environments, which are constantly changing with the addition of devices and applications.

secret-server offers a feature related to discovery rules that allows you to see what accounts would match a rule. This is part of the discovery process where discovery rules are used to automate the identification and management of credentials across various platforms. Here's how it works:

- **Discovery Account Rules**: These rules are search queries against the accounts found by discovery. When these rules are created and run, accounts that match the rules can be automatically imported as secrets. This means you can define criteria for accounts, and the system will identify which accounts matches these criteria.
- **Viewing Discovery Results**: After running a discovery scan, you can view the results in the **Discovery Network View**. This view allows you to see which accounts have been discovered and whether they match any existing rules. You can filter and search through these results to identify specific accounts that meet the criteria set by your discovery rules.

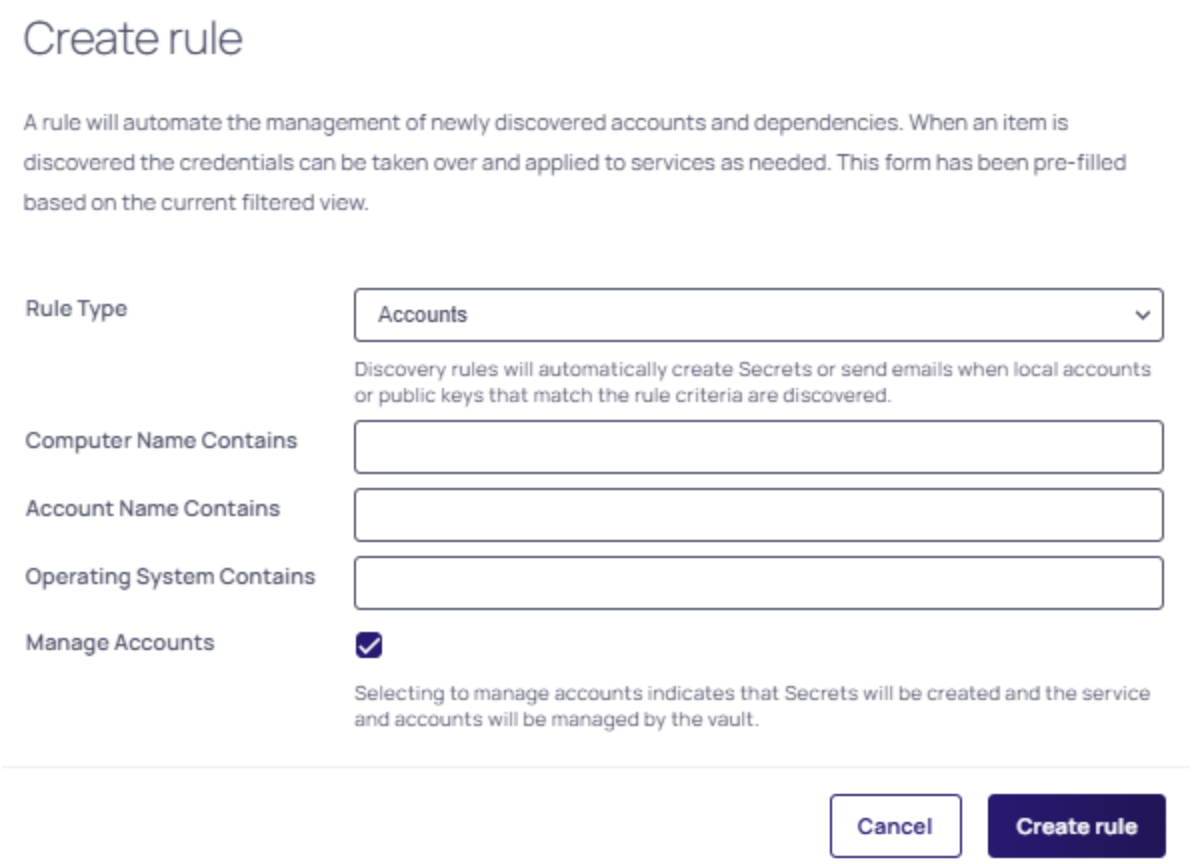
Creating Local Account Rules

Discovery account rules are search queries against the accounts found by discovery, visible in the Discovery Network View. When these rules are created and run, accounts that match the rules can be automatically imported as secrets. When matches are found, email notifications can also be sent out.

The rule order determines the rule application order. Drag rules to reorder them. Rules can specify a combination of the domain or OU, the computer name and the account name.

To create a rule:

1. Select **Discovery**. The Discovery **Analysis** tab of the Discovery page appears.
2. Select the **Network View** tab.
3. Click the **Create Rule** button. The Create Rule popup appears:



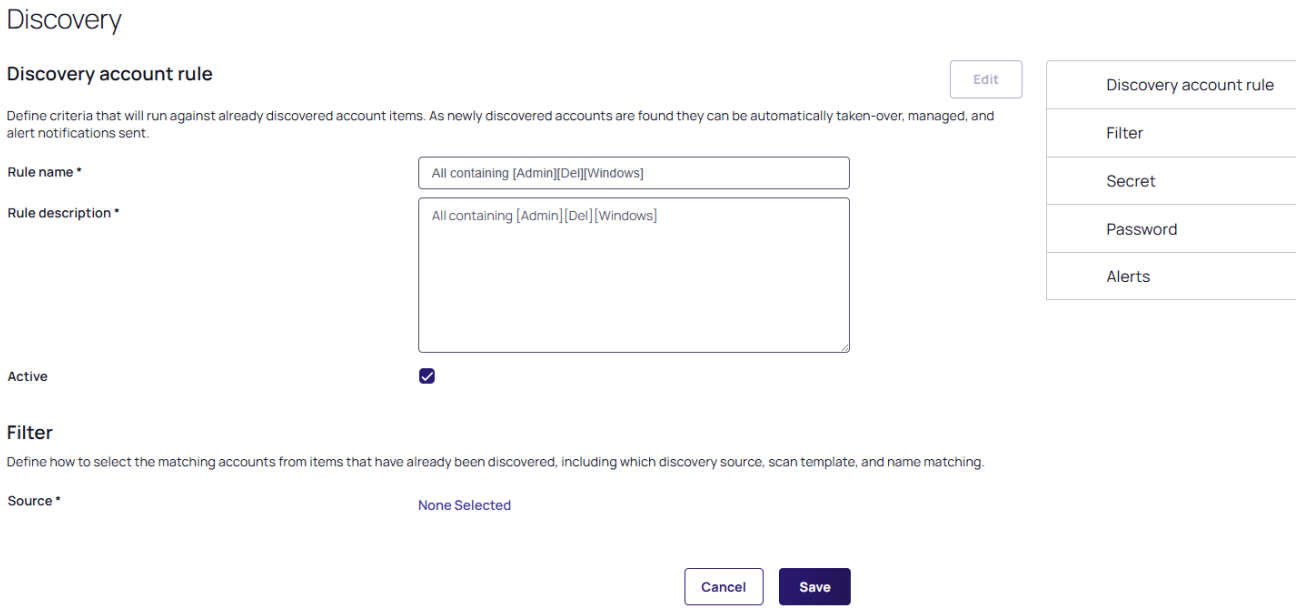
4. From the **Rule Type** dropdown list, select **Accounts**.
5. (Optional) Type in text strings for the following if you want to limit the scope of the rule:
   - Computer Name Contains
   - Account Name Contains

- Operating System Contains

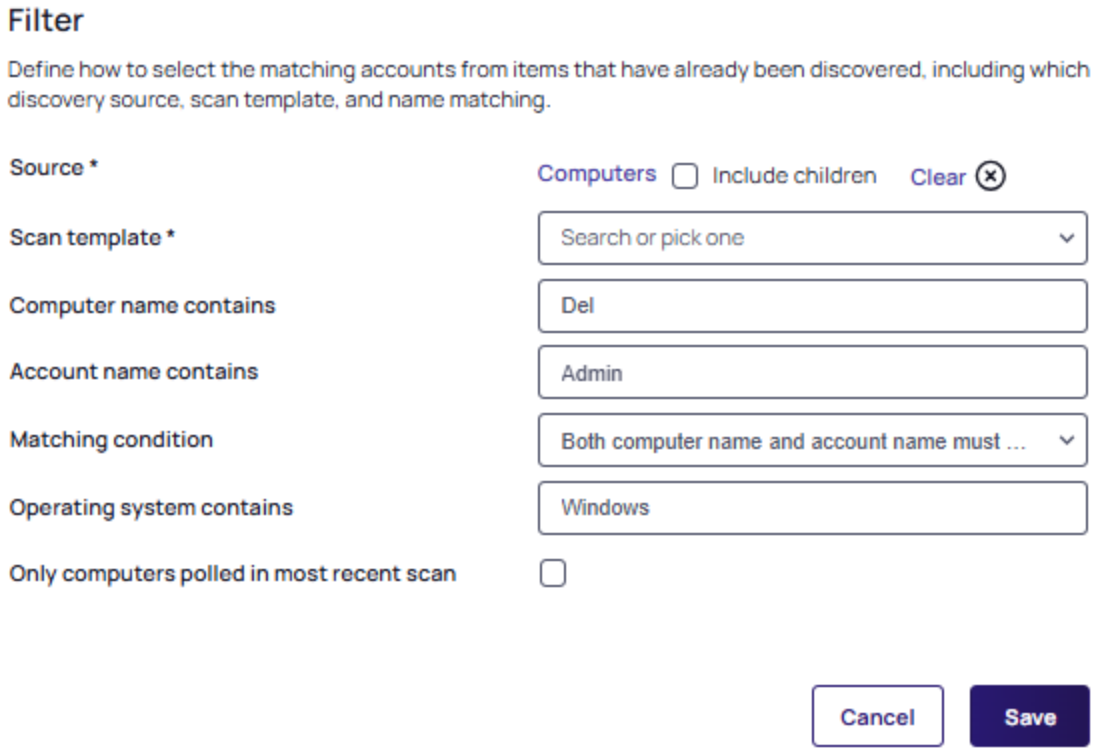
For this example, `Del`, `Admin`, and `Windows` have been entered.

> Discovery rules automatically create secrets or send emails when local accounts or public keys that match the rule criteria are discovered.

6. Select the **Manage Accounts** checkbox if you want secrets to be created and the service and accounts to be managed by Secret Server.
7. Click the **Create Rule** button. The Discovery account rule page appears with the values you typed:



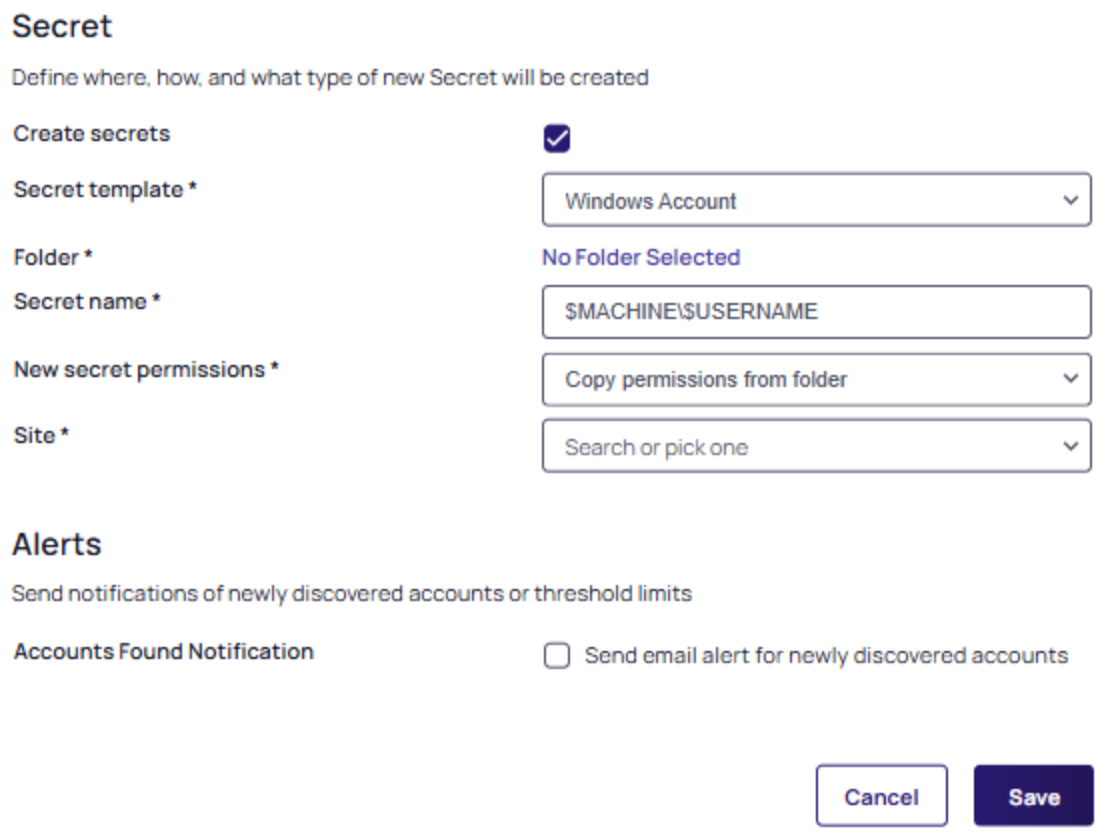
8. Type the name of the new rule in the **Rule Name** textbox if you want to change the suggested name.
9. Click the **None Selected** link in the **Filter** section to choose a discovery source. The Pick OU popup appears.
10. Navigate to and select the OU of your choice, this appears as your source. Additional controls also appear, which differ with each source. For this example the following source was used:



11. Select the **Include Children** checkbox if you want to include any child OUs in the scan.
12. From the **Scan Template** dropdown list, select an output template. The Secret and Alerts sections appear below the Filter section.
13. From the **Matching Condition** dropdown list, pick which of the filtering parameters must match.

    The completion checklist updates to show that you completed the Filter section.

14. Scroll to the **Secret** section:



15. The **Create Secrets** checkbox is selected by default.
16. From the **Secret Template** dropdown list, select the secret template the new secret will originate from if a default is not available automatically.
17. Click the **Folder** link to select a folder for the new secret to belong to.

    You cannot use personal folders for this purpose.

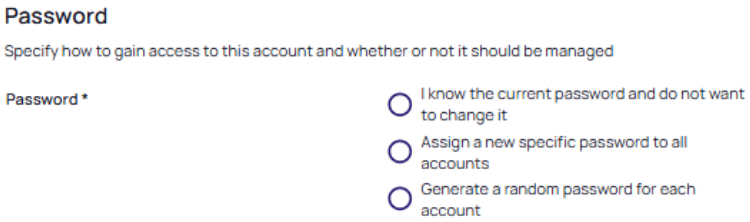
18. Type the naming convention for the new secret in the **Secret Name** text box.

    A naming convention is automatically suggested based on the hostname and username, such as `$DOMAIN\$USERNAME`.

19. From the **New Secret Permissions** dropdown list, select whether you want secrets to *copy* (standalone) or *inherit* (change with the folder) the permissions from the folder.
20. From the **Site** dropdown list, select the Secret Server local installation or a distributed engine to run the rule from. The Password Section appears.

    The completion checklist updates to show that you completed the Secret section.

21. Scroll to the **Password** section:



> Remote password changing must be enabled to change the password.

22. Select the **I know the current password...** option if you do not want Secret Server to change the account password when the secret is created.

    Complete the following:

    a. In the **Current Password** text box, type the password.

    b. Leave the **Password Changing** dropdown list set to **Use privileged account**.

    c. Click the **No Secret Selected** link to choose a secret for the privileged account for ongoing use.

23. Select the **Assign a new specific password to all accounts** option if you want all the new secrets to have the same password, which you can later change.

    Complete the following:

> This option will change the password on the remote machine for any newly discovered accounts.

    a. (Optional) Type a value in the **Takeover Threshold** text box.

> If the number of accounts that will be taken over exceeds the maximum threshold, the import is canceled and the subscribed users are notified by email.

    b. Type the new password in the **New Password** text box.

    c. From the **Password Type** dropdown list, select the desired type.

    d. For **Initial Takeover Secrets**, you have the option of selecting the **No Secret Selected** link and choosing a secret for the privileged account for the initial takeover.
    Or if you want to have a set of secrets that can be tried until one works, click the **(Switch to Multiple Reset Secrets)** link, and select **Add Secret** to choose a secret. The name of the secret appears. Repeat as needed.

    e. Leave the **Password Changing** dropdown list set to **Use privileged account**.

    f. For **Password Changing Privileged Account**, click the **Add Secret** button to choose a secret or secrets for the privileged account for ongoing use.

24. Select the **Generate a random password for each account** option if you want to have Secret Server create a strong password for the secret.

    This option will change the password on the remote machine for any newly discovered accounts.

    a. (Optional) Type a value in the **Takeover Threshold** text box.

       If the number of accounts that will be taken over exceeds the maximum threshold, the import is canceled and the subscribed users are notified by email.

    b. From the **Password Type** dropdown list, select the desired type.

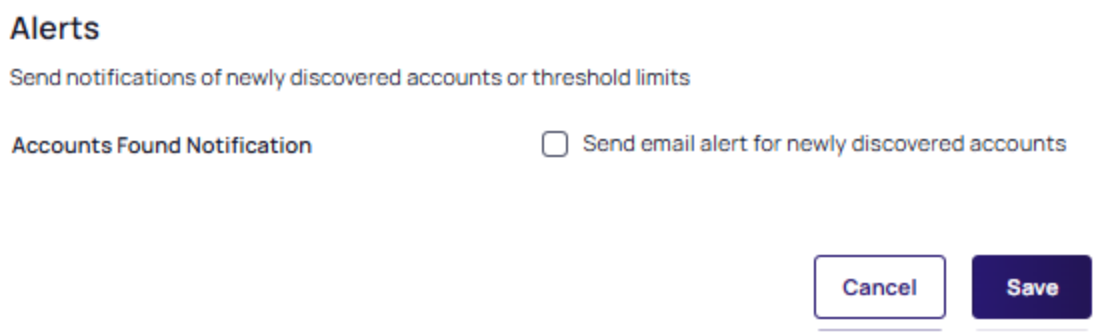
    c. For the **Initial Takeover Secrets**, click the **Add Secret** button to choose a secret or secrets for the privileged account.

    d. Leave the **Password Changing** dropdown list set to **Use privileged account**.

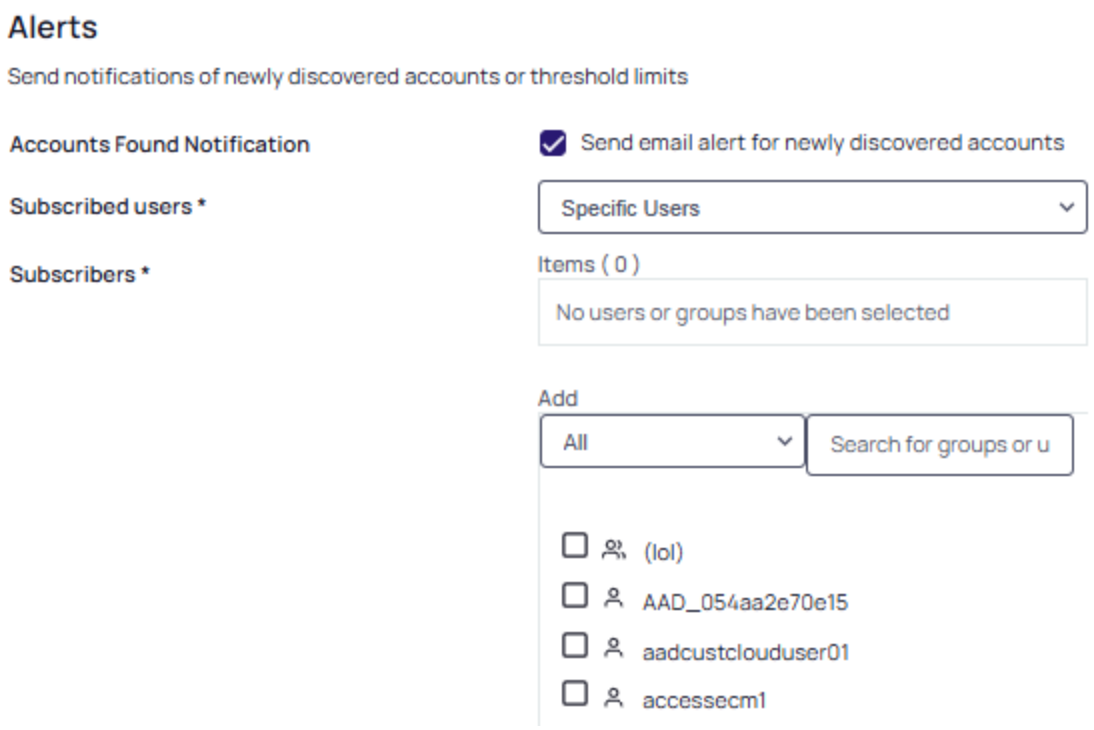
    e. For **Password Changing Privileged Account**, click the **Add Secret** button to choose a secret or secrets for the privileged account for ongoing use.

       Note that the completion checklist updates with a check mark to show that you completed the Password section.

25. Scroll to the **Alerts** section:



26. Select the **Send email alert for newly discovered accounts** checkbox to enable the **Subscribed Users** dropdown list.
27. From the **Subscribed Users** dropdown list, select one of the following:
    - **Discovery Administrators**, if you only want to notify admins.
    - **Specific Users**, if you want to define a list of people to notify.
28. If you chose **Specific Users**, new controls appear:



29. In the **Add** section, select or search for users and groups. As you click each one, they appear in the **Items** text box.

> The completion checklist updates to show that you completed the Alerts section.

30. Select **Save** at the bottom of the page to keep your changes.

Creating Dependency Rules

Dependency rules automatically add dependencies (Windows services, schedule tasks, application pools) to existing secrets. You can receive email notifications of linkages by adding an event subscription in the **Event Subscriptions** page. Rules can specify a combination of the domain or OU.

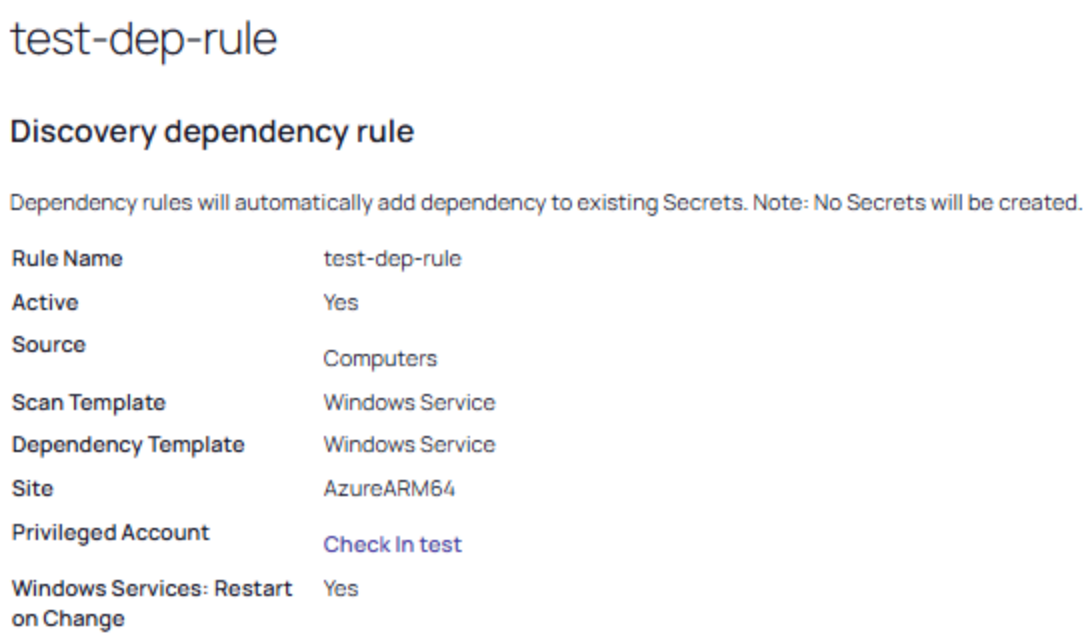
> The rule order determines the order in which the rules are applied. Drag rules to reorder them.

> You must have a discovery scanner and dependency template configured to apply a dependency rule.

> If you run discovery against Windows Server 2016 or 2019, scheduled tasks are not discovered unless your instance or engine are on the same domain as the target server. On Windows Server 2016 and up, scheduled task discovery only gets a security identifier (SID) for the user that runs the task. Secret Server has code to convert the SID to a username, but this only works if the code is being executed on the same domain as the scheduled task. If the SID cannot be translated, the scheduled task will not be saved with discovery.

To create a rule:

1. Access **Discovery**. The Discovery Analysis tab appears.
2. Select the **Network View** tab.
3. Click the **Create Rule** button. The Create Rule popup appears.
4. From the **Rule Type** dropdown list, select **Dependencies**.
5. Click the **Create Rule** button. The New Rule page appears.
6. Type the name of the new rule in the **Rule Name** text box.
7. Click the **None Selected** link to choose a discovery source. The Pick OU popup appears.
8. Select the OU of your choice, it will appear as the source. The Scan Template dropdown list appears.
9. From the **Scan Template** dropdown list, select an output template. For this example, the Windows Service template was chosen.
10. From the **Dependency Template** dropdown list, select a dependency template. Once again, we chose Windows Service.
11. From the **Site** dropdown list, select the local installation of Secret Server or a distributed engine to run the rule from.
12. For **Privileged Account**, click the **No Secret Selected** link to choose a secret for the scanning account. The chosen secret appears as a link.
13. Select the **Windows Services: Restart on Change** checkbox if you want the services restarted after discovery.
14. Select **Save** to keep your changes. The page for your new rule appears:

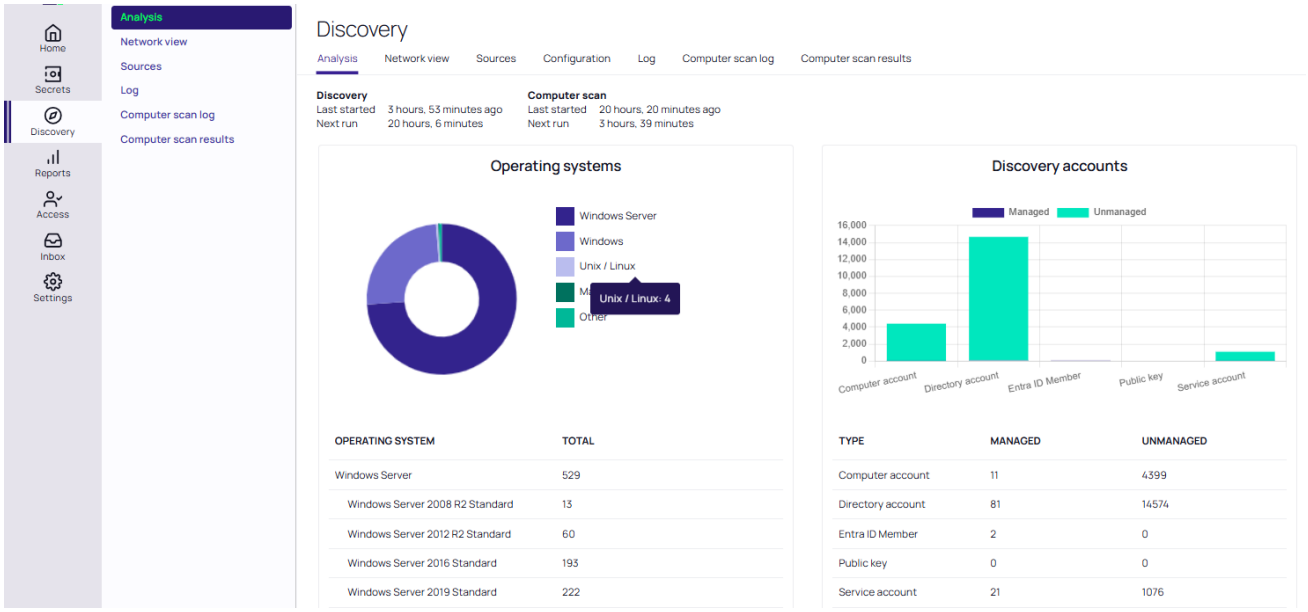


Discovery Analysis

After discovery has been configured, the Analysis tab shows high level discovery statistics, including when it last ran and what the process has discovered. The chart indicates which items are managed or unmanaged. A *managed* item has a secret associated with it. *Unmanaged* items can be discovered on the network but have not been imported into the vault.

Procedure

1. Click the **Discovery** feature from the left-side menu.
2. The **Analysis** tab loads automatically. A graphical summary of your discovery activity appears:



3. Click on an item count link to open the network view tab filtered to only show those items.

> Click in the Discovery scan results table to be redirected to the Computer Scan Results tab.

Discovery Best Practices

Overview

This document covers the most common settings to tune to make discovery more efficient. Environmental factors contribute to some these settings.

Global Settings

The settings below might make discovery more efficient, regardless an organization's size.

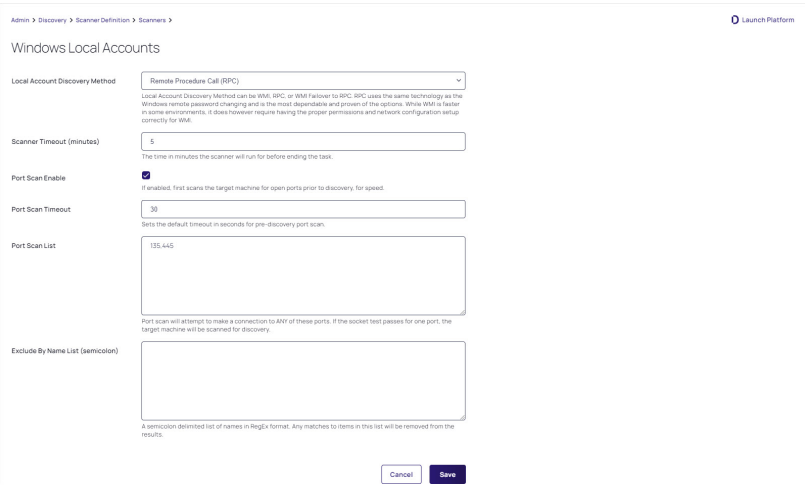
Enabling Port Scanning

Note: During a Port Scan, if the connection attempt fails due to a network failure prior to the port scan timeout another attempt will be made with the remaining time. This means that port scans will run a minimum of the time specified. Also the operation can take up about 20 seconds longer than the port scan timeout to complete. This applies to Secret Server version 11.6 and later.

Introduction

Port scanning is a scan that can be conducted before the regular discovery scan to potentially reduce discovery time—if specified ports are unavailable on a given machine, the standard discovery scan will eventually timeout (the default is five minutes). Port scanning eliminates that timing out process, which saves time.

Figure: Edit Discovery Scanner for Windows Local Accounts



Port scanning for discovery has three configurations or controls:

- Port Scan Enable: Whether to port scan at all. Defaults to unchecked.
- Port Scan Timeout: How long (in seconds) the port scan will try before giving up. Defaults to 30.
- Port Scan List: A comma-delimited list of ports to scan. These depend on the configuration of the systems you will scan. Defaults to NetBIOS (135) and Active Directory services (445).

Examples of scanners that have a port-scanning timeout option for Active Directory include:

- Windows local accounts
- Active Directory user accounts
- All dependency scanners

Accessing Port Scanning

Simply Search for **Accounts (tab)**, and then click the pencil icon for the desired scanner. If the configurations are on that page, that scanner supports port scanning. See the previous figure.

Additional Reasons to Consider Discovery Port Scanning

Lowering the Discovery Scanner Timeout May Cause Issues

If you lower the regular discovery scanner timeout, without port scanning enabled, you may kill a running scan. In addition, non-Active-Directory discovery scanners, such as a custom PowerShell scanner, that are slow or prone to hanging may also be disrupted or even crash if the regular discovery scanner timeout is set too low. As a best practice, we recommend enabling port scanning and not lowering the regular scanner timeout, which defaults to five minutes, unless Delinea Support asks you to. Do not lower the port scanning timeout below 15 seconds.

Secrets with Multiple Dependencies May Create Especially Long Timeouts

Without discovery port scanning enabled, discovery scanners rely on the standard timeout, which defaults to five minutes. If a secret has multiple dependencies, the system may have a chain of discovery timeouts to process, one at a time. With the default five-minute timeout on all the systems, timing out can take a long time, especially if you have a lot of machines turned off or unavailable. Discovery port scanning greatly reduces that.

To calculate the maximum timeout for discovery use this formula (with all systems using the same timeout value and each secret having the same number of dependencies):

```
(number of secrets) × (number of dependencies) × (timeout value) = (maximum minutes for discovery scans)
```

For example, using the default five-minute timeout value for 35 secrets, each with three dependencies:

```
35 × 3 × 5 = 525
```

Thus, 8.75 hours (525 ÷ 60) of timeout are possible and enabling discovery port scanning becomes a really good idea, especially if you have a lot of machines down at any given time.

> We can ignore clustered objects as part of a discovery scan, but we cannot ignore disabled computer objects, so Secret Server tries to scan each object that exists within AD. If you have a centralized area for disabled computer objects, consider configuring discovery to be OU specific and excluding your disabled computers OU to make discovery more efficient.

- Windows enforces a maximum time limit for a response to TCP Syn.
- The first attempt runs 3 seconds, then it retries with increasingly long limits.
- The number of retries is determined by MaxSynRetransmissions which can have a value of 2-8.
- MaxSynRetransmissions Maximum Time Windows will wait:
  - 2: 7 sec
  - 3: 15 sec
  - 4: 21 sec
  - 5: 63 sec
  - 6: 123 sec
  - 7: 183 sec
  - 8: 243 sec

- To prevent timeouts, the customer should update to Secret Server 11.6 or greater and execute "netsh interface tcp set global MaxSynRetransmissions=N" on the Windows server the Delinea Distributed Engine is executing on.
- Choose a value for N that corresponds to a Windows timeout greater than the Discovery Port Scan Timeout.
- Example: a Discovery Pre Scan Timeout of 30 seconds, MaxSynRetransmissions should be set to MaxSynretransmissions=5 which will cause the Windows TCP stack to wait up to 63 seconds (which is the lowest value which is greater than or equal to 30 seconds).

When to Run Discovery

Currently, you cannot set when discovery runs via a control or setting. You can, however, approximately set when it runs by disabling and enabling it at the desired time. It runs daily around the same time as when it was first enabled and then again according to whatever the discovery scan offset hours interval was set to. If you are running discovery once per day, we suggest:

- Choosing a start time outside your normal business hours, such as midnight.
- First running several ad-hoc discoveries when your network traffic normally drops at the end of the day. Record how long each discovery process takes. Remember, this can vary greatly if a lot of machines are down, which is why we suggest conducting more than one discovery.

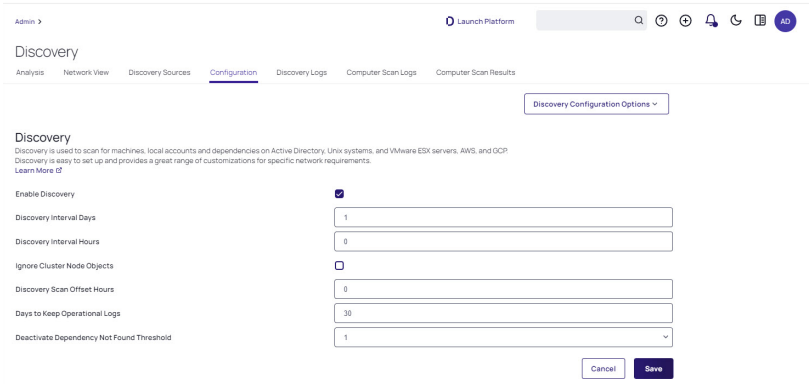
  > Running a test with discovery port scanning disabled may provide valuable insights into the differences in performance or results.

- Using the average time the test runs took, calculate when to start discovery at a time when no anticipated portion of the discovery period is during your high-traffic times. We suggest having an end buffer as long as possible to account for variability, so if your average discovery time is fairly long, it might be best to start discovery soon after your network traffic drops off for the evening. This is especially true if your machine pool is growing.

For example, if your tested average discovery time was four hours and your network traffic is busy between 0600 and 1800, you should run discovery between 1800 and 0200, the closer to 1800 the better.

Discovery Settings

Figure: Discovery Settings Page



The settings are:

- Discovery interval for days and hours: How often you want the regular discover scan to occur.
- Ignore Cluster Node Objects: Tells Secret Server to not run discovery on machines identified as "msclustervirtualserver." Do not change this setting.
- See Discovery Scan Offset Hours for a discussion of the last setting.
- Deactivate Dependency Not Found Threshold: If set to 0, this setting means we will never disable dependencies if they are not found during a scan. If set to a higher number, it would indicate the number of failed attempts to find the dependency before finally disabling it". The threshold can be set to *Never* to prevent disabling, or a count for times a dependency is not found.

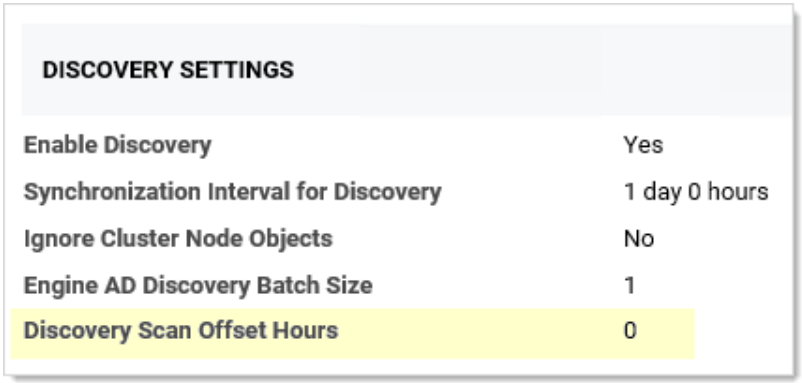
> There is another "Discovery Batch Size" setting on the Advance Settings page, which is usually only available to Delinea Customer Support. This setting, too, is legacy, and should not be set.

Environment-Specific Considerations

Discovery Scan Offset Hours

This section discusses a setting that allows you to quickly discover changes without greatly increasing traffic.

Figure: Discovery Settings Page in View Mode



The "discovery scan offset hours" (DSOH) setting is for customers that need to detect new (to the network) systems quickly without excessive network traffic during business hours. For example, you might need this feature if you have lots of server testing (systems are up and down) or laptops (systems are connected or not). The trick is doing this while minimizing the networking load.

We accomplish this with discovery scan offsets. With these, you have multiple synchronization scans per day, rather than just one, where Secret Server attempts to scan each and every system, but first Secret Server looks up each system to see if that system is flagged for scanning. The process goes like this:

1. Initially, Secret Server scans each discovered system and resets its DSOH timer, which is set to the number of hours defined by the DSOH setting value. Secret Server has a separate timer for each scanned system.
2. Once set, each timer starts counting down. Until that timer runs out, Secret Server ignores the scanned system if it runs a discovery scan.
3. When the timer is finished, the system is again flagged for scanning.
4. The next time Secret Server does a discovery scan, it sees the flag is present and scans the system.

The period the "scan me" flag is down (the period the timer is running) is defined by the DSOH setting. Thus, DSOH essentially tells Secret Server how long before scanning that discovered system again.

For example, if you have a discovery scan offset of 12 hours and a discovery interval of four hours:

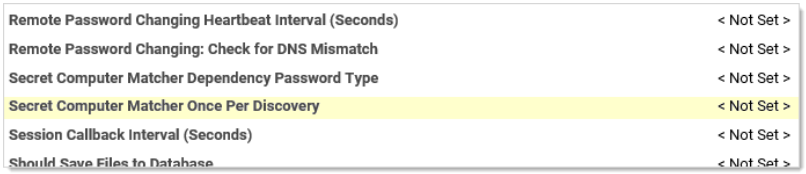
1. Start: The first time discovery runs, it scans every object because each one's timer is zeroed out, which makes it flagged for scanning. After scanning, each object's timer starts to count down, which makes it unflagged for scanning.
2. At four-hours: The next time discovery runs , it ignores the objects that were scanned the first time (because their timer was set to 12 hours), but it does process any newly discovered objects.
3. At eight-hours: In four more hours the same happens—only new objects are processed.
4. At 12 Hours: In four more hours, the scan runs again. This time, the 12-hour scan offset has expired, and all the timers of the original objects are zeroed out. The process begins anew—discovery scans every object because its timer is zeroed out, which makes it flagged for scanning. After scanning, each object's timer starts to count down, which makes it unflagged for scanning.

Advanced Settings

These settings reside in the ConfigurationAdvanced.aspx file, which you should not edit unless Delinea Support asks you to.

Run Secret Computer Matcher Once per Discovery

Figure: Secret Computer Matcher Once per Day

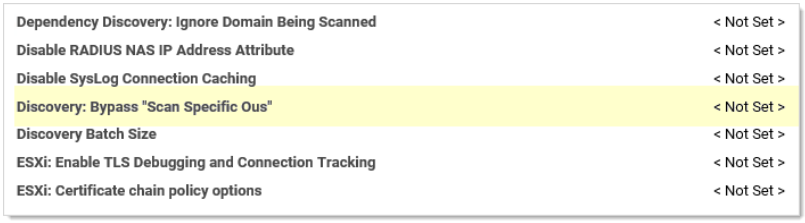


During the discovery process, secrets are matched with their machine. For smaller customers, this likely has little performance impact. For very large customers, the performance impact is noteworthy. We recommend that large businesses enable this option to decrease matcher resource use.

By default, the secret computer matcher runs once every five hours (this is non-configurable). This means the matcher runs four times per day, and only one of those times could coincide with discovery running at four-hour intervals. The other three will not run in tandem with discovery and thus will increase network traffic. If you enable this setting, the matcher will instead run after each discovery completes. If discovery only runs once, the matcher only runs once too. This more efficient because discovery can take hours to run, and having the matcher run several times during that period wastes processing.

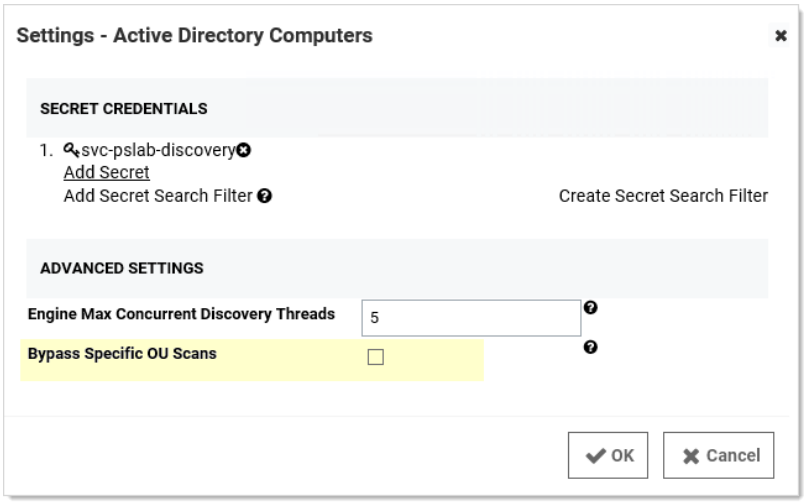
Limit the Network Traffic Caused by Nested Organizational Units

Figure: Discovery: Bypass "Scan Specific OUs"



If you configure discovery for Active Directory to scan by separate OUs and not by the entire domain, nested OUs can overwhelm your message bus. This occurs because each OU generates its own message unless you enable this setting. So if your enterprise has a complex tree of nested OUs, as many large businesses do, you could experience this issue. Smaller enterprises with single or a small number of nested OUs can ignore it. If you change the configuration in the Advance Configuration page file, it will affect all discovery source settings (some scanners have a similar configuration that only affects them). Alternatively, for more flexibility, you can configure this individually at the scanner level by checking the Bypass Specific OU Scan check box on the Settings - Active Directory tab for the scanner:

Figure: Tuning Active Directory Settings



Engines and Engine Workers

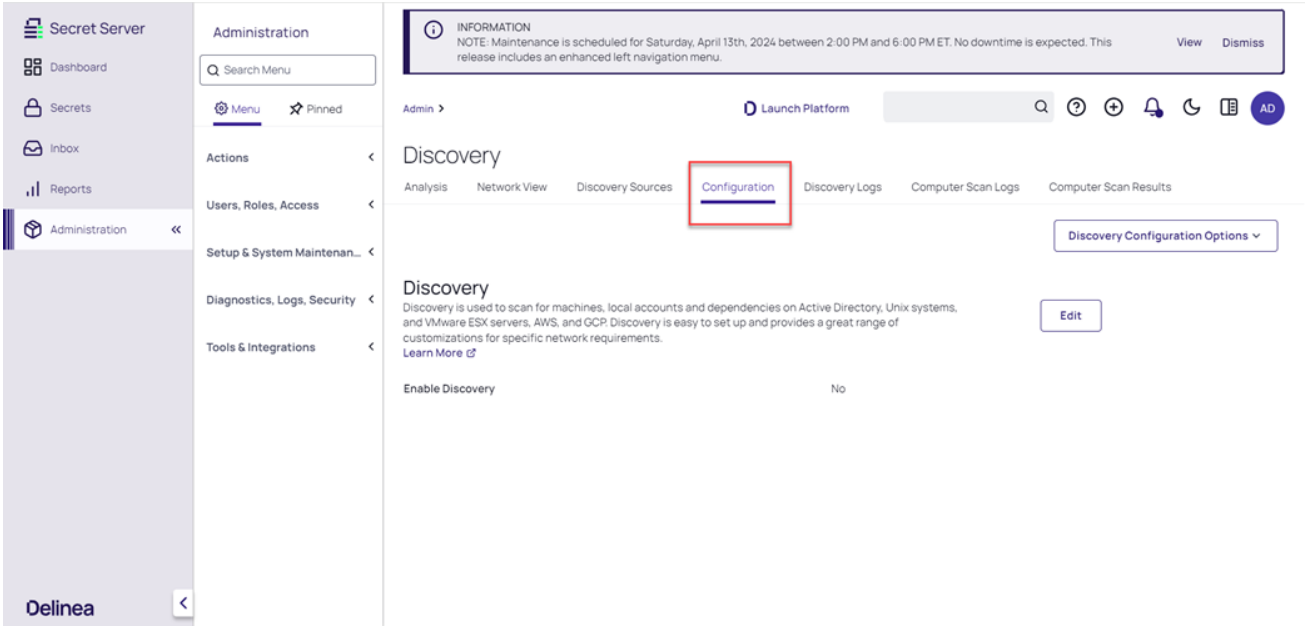
The number of distributed engines and engine workers within your environment can affect how fast discovery completes. Increasing CPU counts on your existing engines may help them to complete a diverse set of tasks more efficiently but might not have much effect on discovery processing time. If an engine is doing discovery, only a subset of consumers run and they will run into a prefetch count limit (30 messages per engine). Thus, increasing the number of engines and engine workers might decrease total discovery time by increasing that prefetch limit.

Domain Name Index

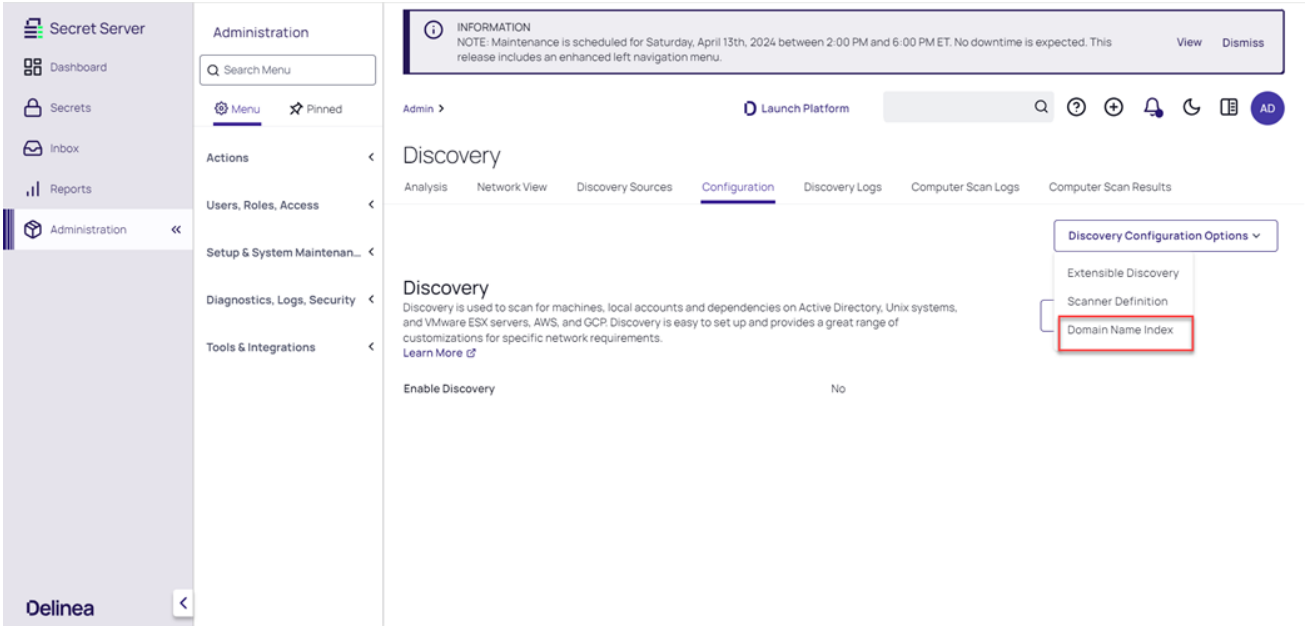
During Discovery, Secret Server needs to associate discovered accounts with domains and secrets. Discovery may return different forms of the domain name, so doing various forms of lookup to try and get the Discovery domain is frequently required. The Domain Name Index page exposes this list of mapped names to the admin and allows the admin to add their own known mappings. This helps to reduce the number of lookups required and therefore improves Discovery's speed and accuracy.

To access the Domain Name Index functionality:

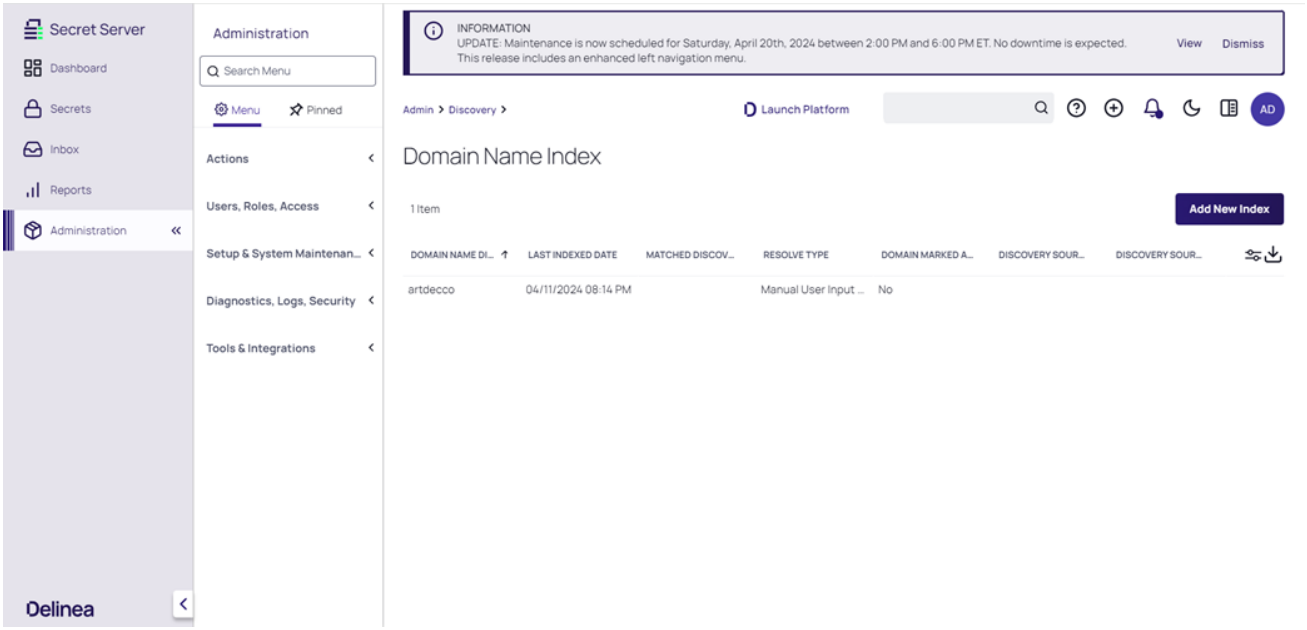
1. Search for **Discovery.**
2. Click the Configuration tab.



3. Open the *Discovery Configurations Options* menu and click **Domain Name Index**.



4. A list of list of mapped names to the admin will be displayed



5. **Optional:** Admins can add their own known mappings

Discovery Error Messages

The following are common error messages received when performing discovery and their possible causes:

Error	Cause
User credentials cannot be used for local connections	This error typically occurs when attempting to run discovery on the server that Secret Server is running on, due to WMI restrictions.
No AD Account Services	No services run by Active Directory accounts have been found on the machine.
Computer is inaccessible or does not exist	Port 135 is blocked.
The target computer could not be reached	The machine is not connected to the network.

Error	Cause
Access Denied	The account used to sync the domain with Secret Server does not have domain admin or local admin privileges for the machine it is attempting to scan for accounts.
Bad parameters - Script Error: Cannot bind argument to parameter 'Message' because it is null.	There is a mismatch between parameters referenced by the script and the arguments passed in. Check the script arguments on the scanner or dependency changer against the script.

Discovery Network View

Overview

The discovery network view allows users to view the results of completed discovery after defining the discovery sources. This view is crucial for managing the discovered items and provides information about each item.

Items from disabled discovery sources will not be visible.

To filter items, users can select the type: computers, computer accounts, public keys, service accounts, or directory accounts. The network view tree and advanced filters can be used to view the organizational structure.

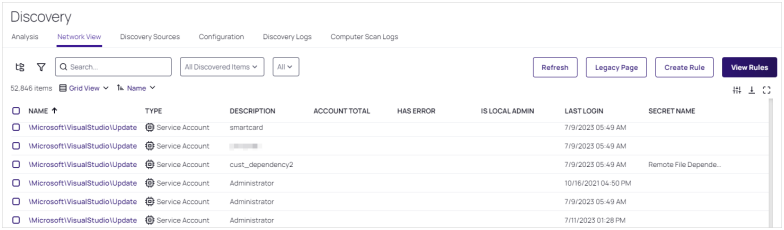
By selecting any row, users can open a preview pane that displays a summary of the item. The preview panel also allows expanding to see items discovered on that specific item. For example, expanding a computer will reveal all local computer accounts. Users can initiate a rescan of certain items like computers by clicking the scan button. Additionally, a link is provided to access a full details view of the computer.

Viewing the details of an item provides more information about related items. In the case of a computer, there is an option to connect to the computer if it is managed or has an associated secret.

All items are interlinked with their respective details. For instance, while viewing a computer, users can access information about all the services and check if any service is running as a directory account. The directory account is also linked, allowing users to view all computers with services running under that directory account.

Procedures

1. Click the **Administration** button on the main menu. The All Settings page appears.
2. Click the **Discovery** link in the **Core Actions** section. The Discovery page appears on the Discovery Sources tab.
3. Click the **Network View** tab. A graphical summary of your discovery activity appears:



4. **Filtering by network view source:** By default, all types or sources are displayed. To filter that, click the folder icon on the top-left of the page. The Network View panel appears. Drill down in the tree to choose what source you want to limit the view to.

   If you close the panel, the view stays in effect–you must click **All Sources** to clear the view.

5. **Filters panel:** Click the funnel icon at the top-left of the page. The Filters panel appears. You can filter by:
   - **Item type:** Click to select one of the **Item Type** selection buttons: computers, computer accounts, public keys, service accounts, or directory accounts.
   - **Management status:** Click to select one of the **Managed** selection buttons.
   - **Created date:** Click the left side of the calendar box to enter or select the start date. Click the right side of the calendar box to enter or select the end date.
   - **Last polled date:** Click the left side of the calendar box to enter or select the start date. Click the right side of the calendar box to enter or select the end date.
   - **Lasted reached date:** Click the left side of the calendar box to enter or select the start date. Click the right side of the calendar box to enter or select the end date.
   - **Scan Template:** Click to select one of the scan template selection buttons. Scan templates are secret templates that define the criteria needed for discovering a given type of asset, such as an account type or host range.
6. **Grid or card view:** Click the **Card/Grid View** dropdown to toggle between views.
7. **Sorting:** Click the sorting dropdown (on the left) to choose what to sort the list or cards by. Click the same choice again to toggle between ascending and descending. Alternatively, in grid view, you can click the column heading to do the same thing. The dropdown provides sorting in card view and allows you to sort on hidden columns.
8. **Hiding and ordering displayed columns:** Click the displayed columns icon on the top far right of the page. The Displayed Columns panel appears. Click any of the checkboxes to hide or display a column. Drag the icon on the left to change the display order of the columns. Click the **Save** button when you are done.
9. **Creating Rules:** As mentioned above, rules define criteria that run against already discovered accounts and dependencies. As newly discovered accounts are found, rules can automatically take them over, manage them, or send alert notifications. To create a rule:
   a. Click the **Create Rule** button. A Create Rule dialog box appears.
   b. Click the **Rule Type** dropdown list to select a type:

- Accounts: Automatically create secrets or send emails when local accounts or public keys that match the rule criteria are discovered.
- Dependencies: Automatically add a dependency to existing secrets. No Secrets are created.

c. (optional) Type a text string that appears inside the computer's name in the **Computer Name Contains** text box (account rules only).

d. (optional) Type a text string that appears inside the account's name in the **Account Name Contains** text box (account rules only).

e. (optional) Type a text string that appears inside the operating system's name in the **Operating System Contains** text box (account rules only).

f. Click to select the **Manage Accounts** check box to indicate that secrets will be created and the service and accounts will be managed by the vault.

g. Click the **Create Rule** button.

10. **Viewing existing rules:** Click the **View Rules** button.

Discovery on Non-Domain Joined or Unix Targets

Overview

When running Discovery on non-domain joined targets or Unix targets, there are two methods of finding local administrator credentials to authenticate to the target:

> The two methods can be used together.

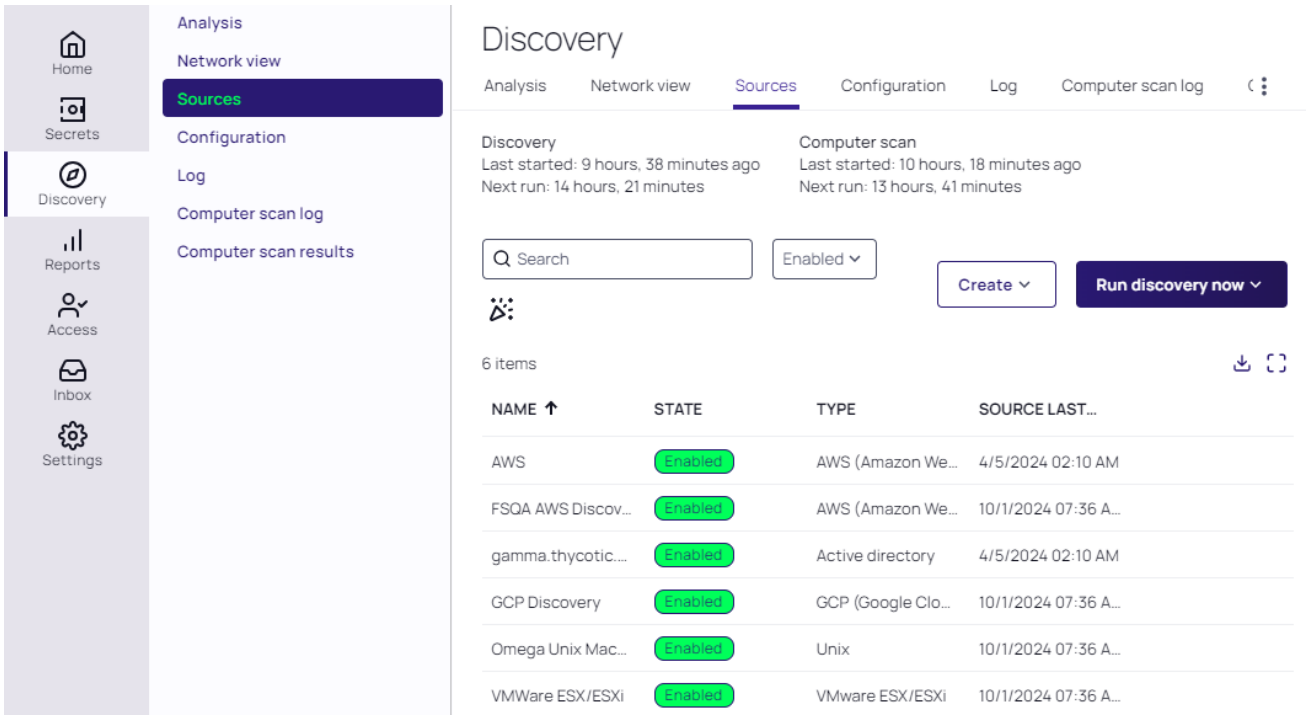
- **Specify a secret with an expected default password** - recommended for performing an initial scan if you have a known password or key for a privileged account.
- **Specify a Secret Search Filter** - recommended when you cannot use a default password because each machine's account password is unique.
  A **Secret Search Filter** dynamically searches for a secret with a name or folder location that corresponds to the target scanned. If a matching secret is found, Secret Server will authenticate to the target using the administrator credentials in the secret.

> To use a secret search filter, the administrator account names must exist as secrets in Secret Server and they must follow a regular naming pattern.

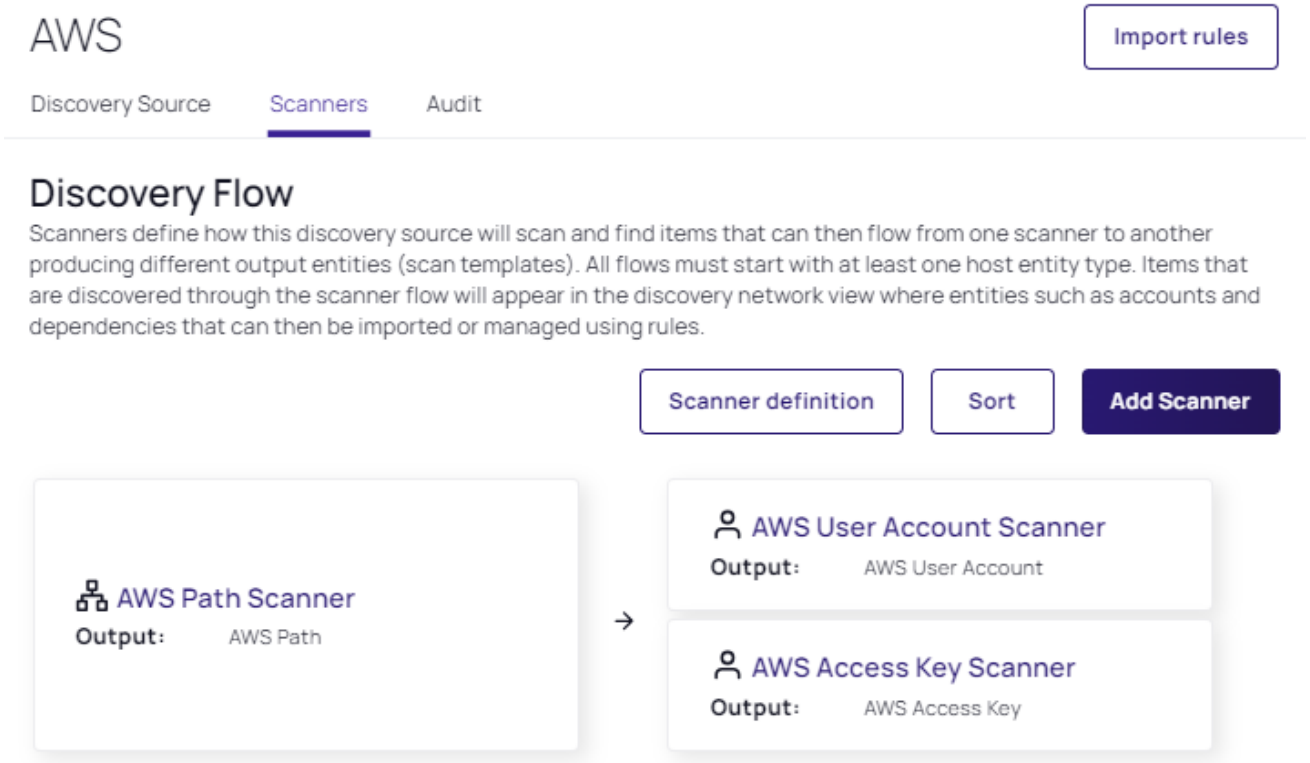
> The discovery secret search filter is available in Secret Server 10.0.000006 and newer.

Setting Credentials on a Discovery Scanner

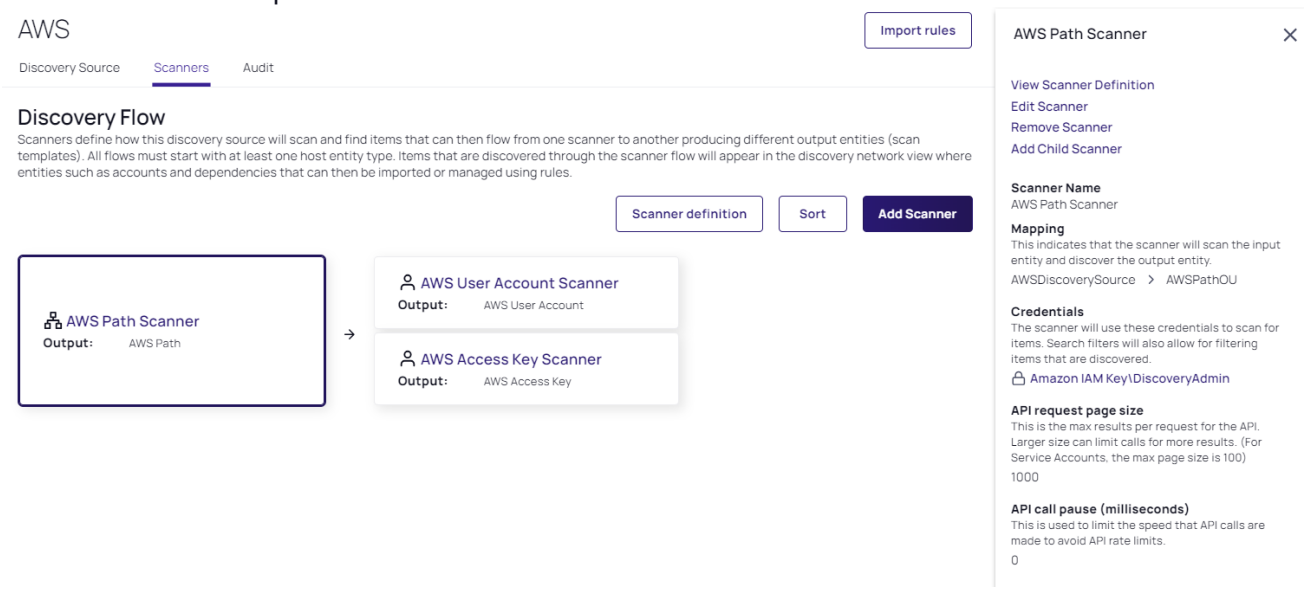
1. From the left menu-bar, hover over **Discovery** and select **Sources**, the page will open by default on the **Sources** tab:



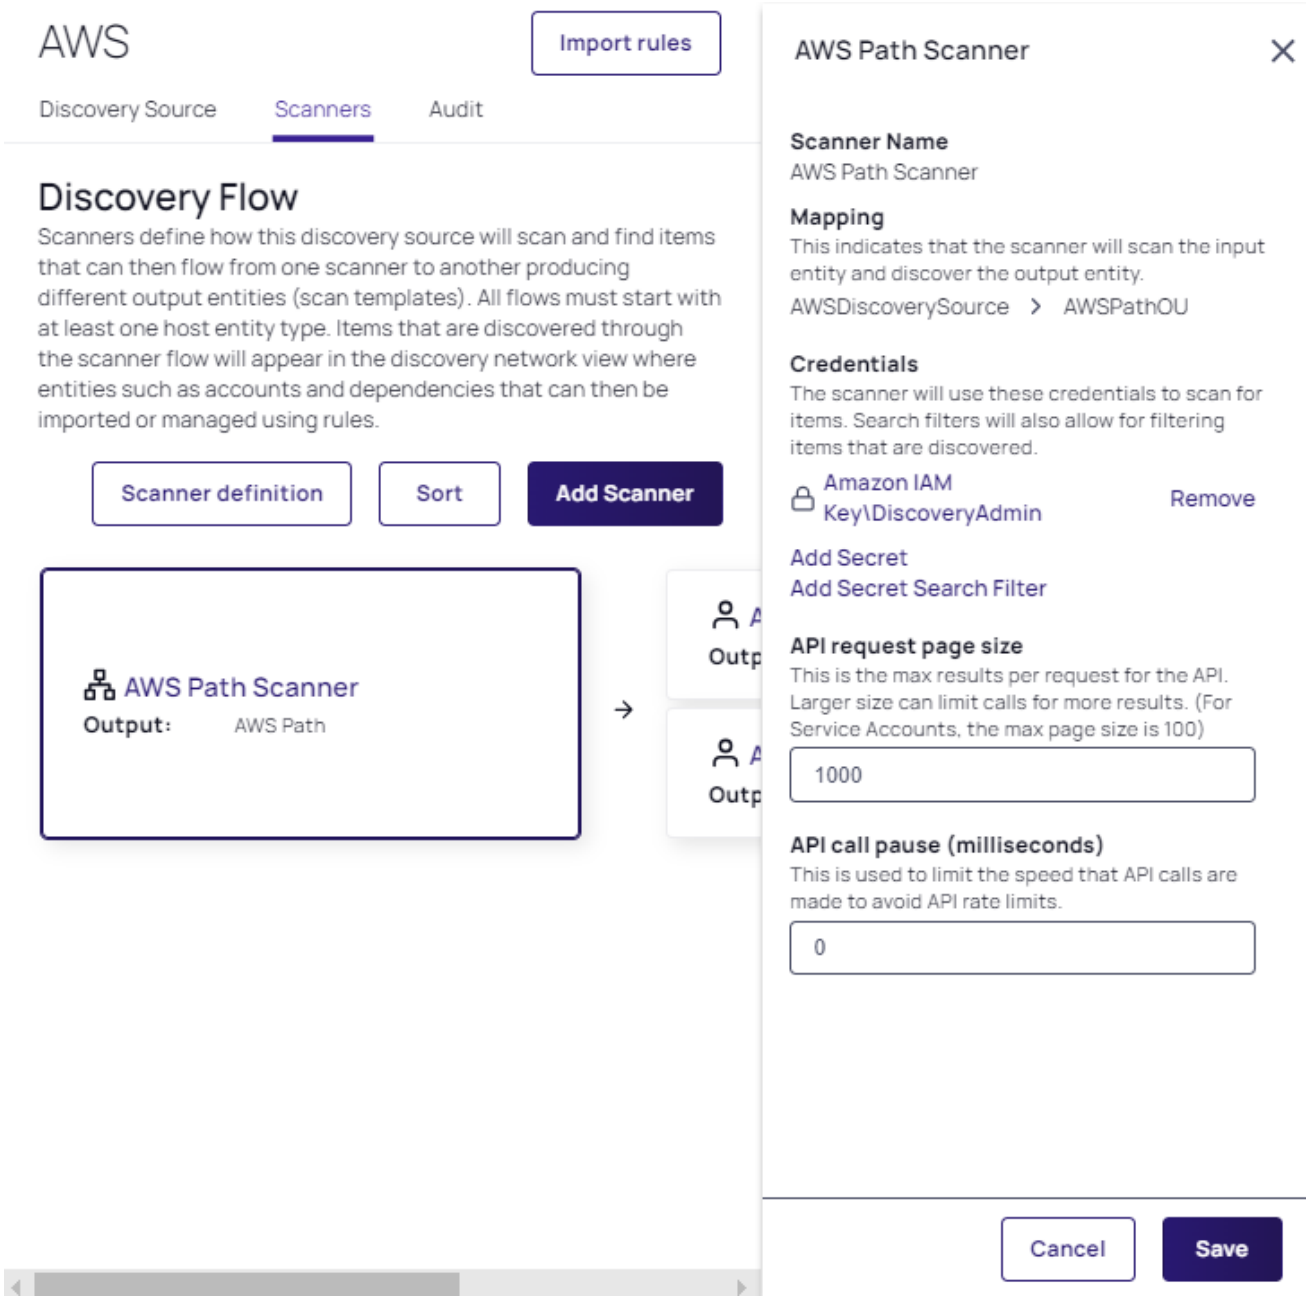
2. Select one of the enabled discovery sources as shown above, and inside that page, click on the **Scanners** tab:



3. Select a scanner from the ones available, a details page will popup on the right side of the screen where you will see the **Edit Scanner** option:



4. Select the **Edit Scanner** option and here you will see different settings for that scanner. Under **Credentials**, choose among the following options:
   - Click **Add Secret** to specify a default credential.
   - Click **Add Secret Search Filter** to specify an existing secret search filter.

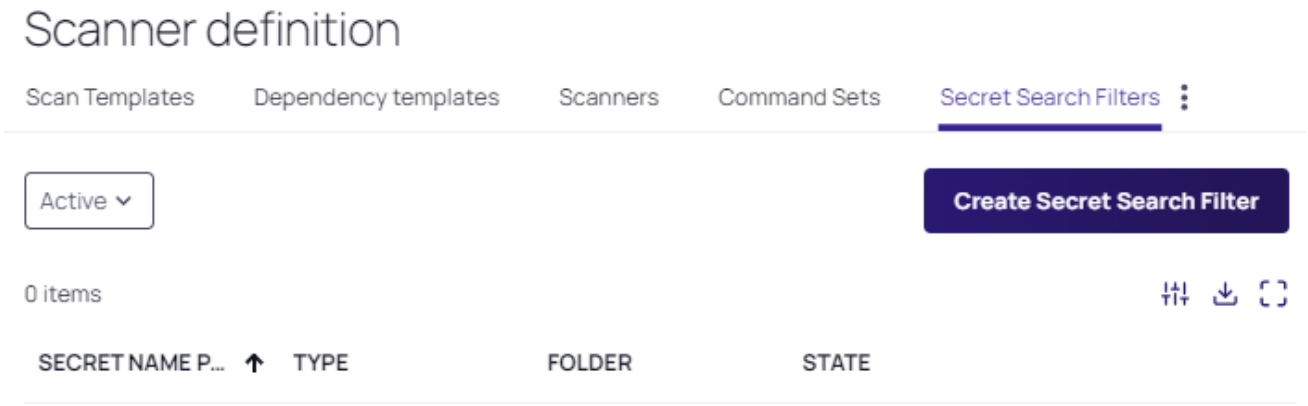


Secret Server will try the secrets and secret search filters in sequence until it finds a match.

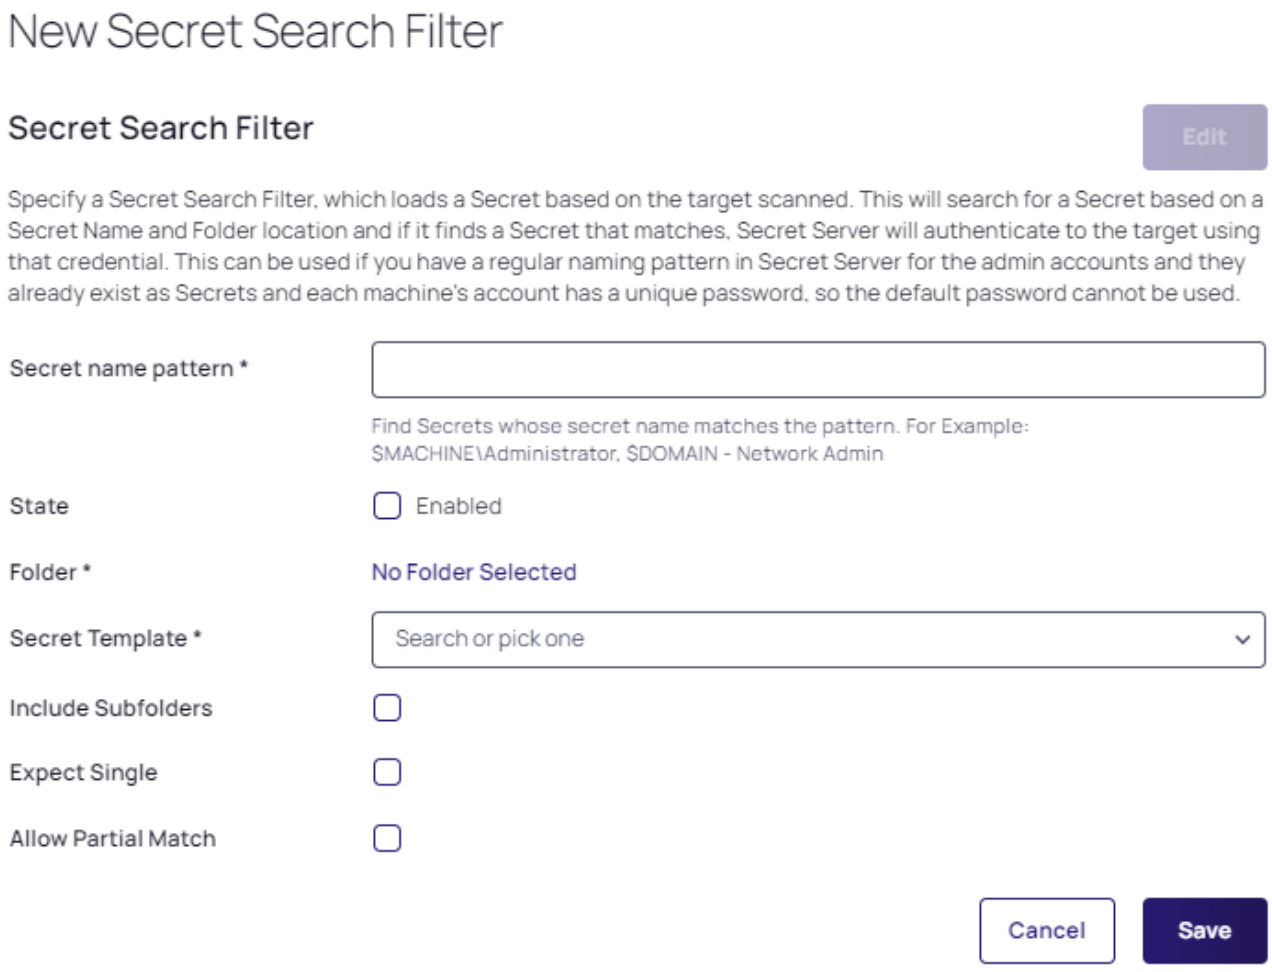
Creating a Secret Search Filter

If you decided to create a secret search filter, perform the following:

1. In the search bar type **Discovery secret search filters**, this will cause the **Scanner definition** page to appear:



2. Select **Create Secret Search Filter** and the following options will appear:



3. Specify all the mandatory* settings along with any others you need, as described below:

- **Secret Name Pattern**: Specifies the pattern that Secret Server will search for. The search is dynamic based on the target. For example, if scanning a machine named `appserver01`, Secret Server will also search for a secret named `appserver01\system`.
- **State**: Enabled or not.
- **Folder**: Specifies the folder to search within.
- **Secret Template**: Specifies the template that returned secrets should be based on.
- **Include Subfolders**: Specifies that the search should include the specified folder as well as subfolders.
- **Expect Single**: Specifies that only one result should be returned. If more than one is returned, Secret Server will log an error to the discovery log.
- **Allow Partial Match**: Specifies that secret names will be returned if they partially match the pattern. By default the secret name must be an exact match to the secret name pattern.

4. Click **Save** when all your settings have been speciffor exampled and go back to your discovery source, ie. back to the **Edit Scanner** page.
5. Click **Add Secret Search Filter** and select the filter you just created.

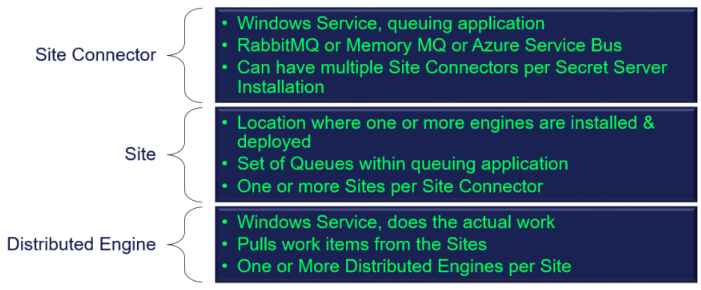
Now, when scanning a machine, Secret Server will try a default credential, and then it will try the secret returned by the search filter.

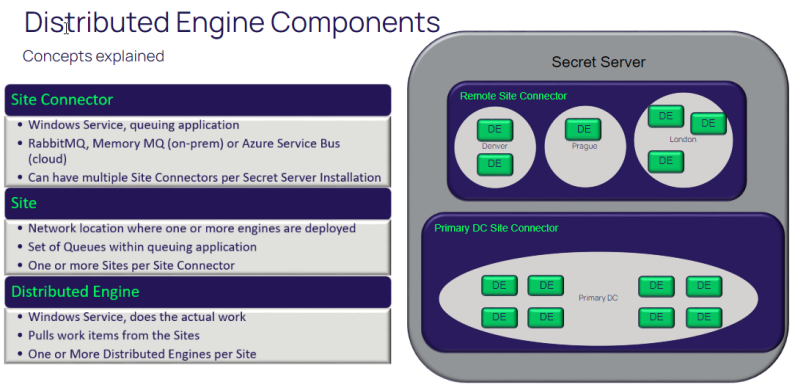
Discovery and Sites–Where Does Secret Server Run Discovery Scans?

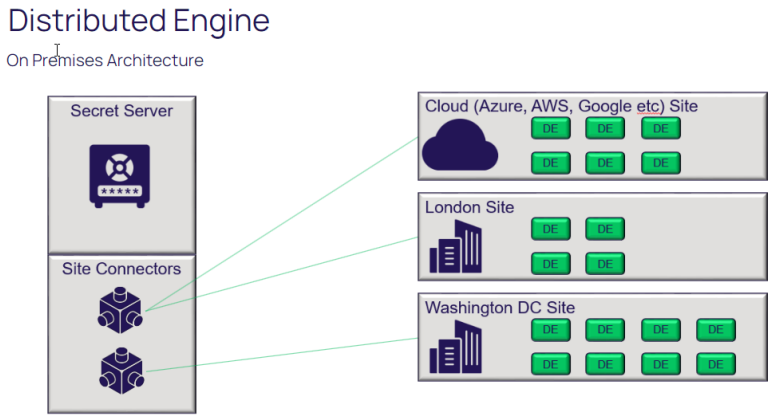
Like many operations in Secret Server, you can configure discovery to run locally on IIS machines running Secret Server using website processing or by running through a distributed engine. Distributed engines are agents that you can deploy to remotely process work. They are useful for scenarios where performance is an issue or the work must take place in a remote network where the ports required by discovery are not available. You can configure discovery to use a single site location per discovery source or on a per-OU basis for AD.

- A site refers to a collection of Distributed Engines. Secret Server interacts with the site, allowing any available Distributed Engine within the pool to execute tasks as needed.
- A site also denotes the network of queues utilized by a pool of Distributed Engines to facilitate communication with Secret Server. This setup ensures efficient task distribution and management across the engines.

Distributed Engine Components

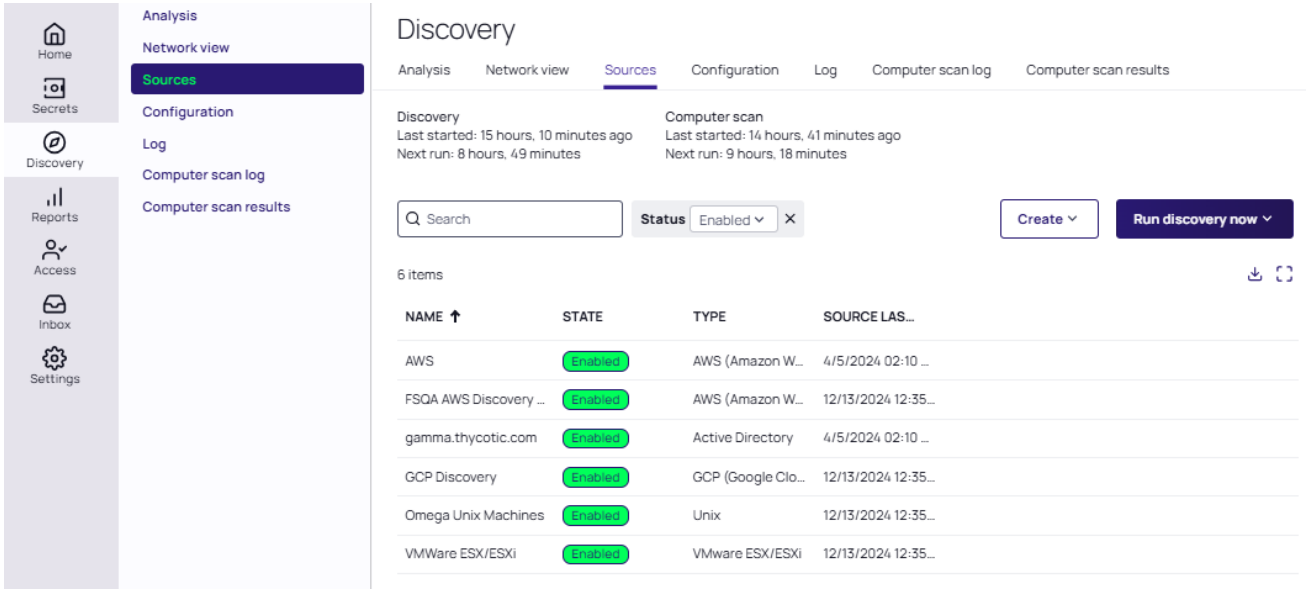




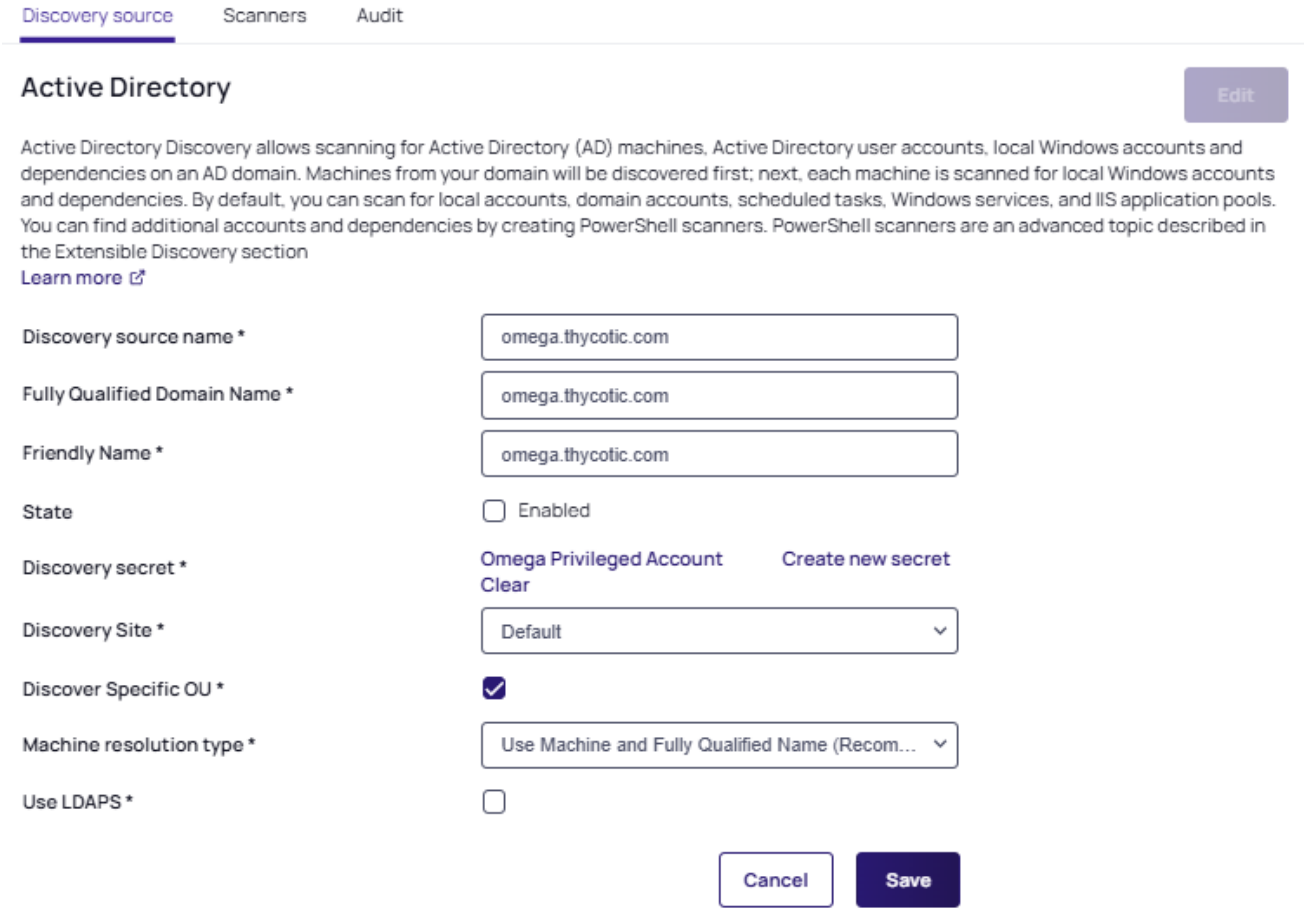


Enabling Specific OU Domain Discovery

1. In the left-hand menu select **Discovery > Sources**. The Discovery **Sources** tab appears:



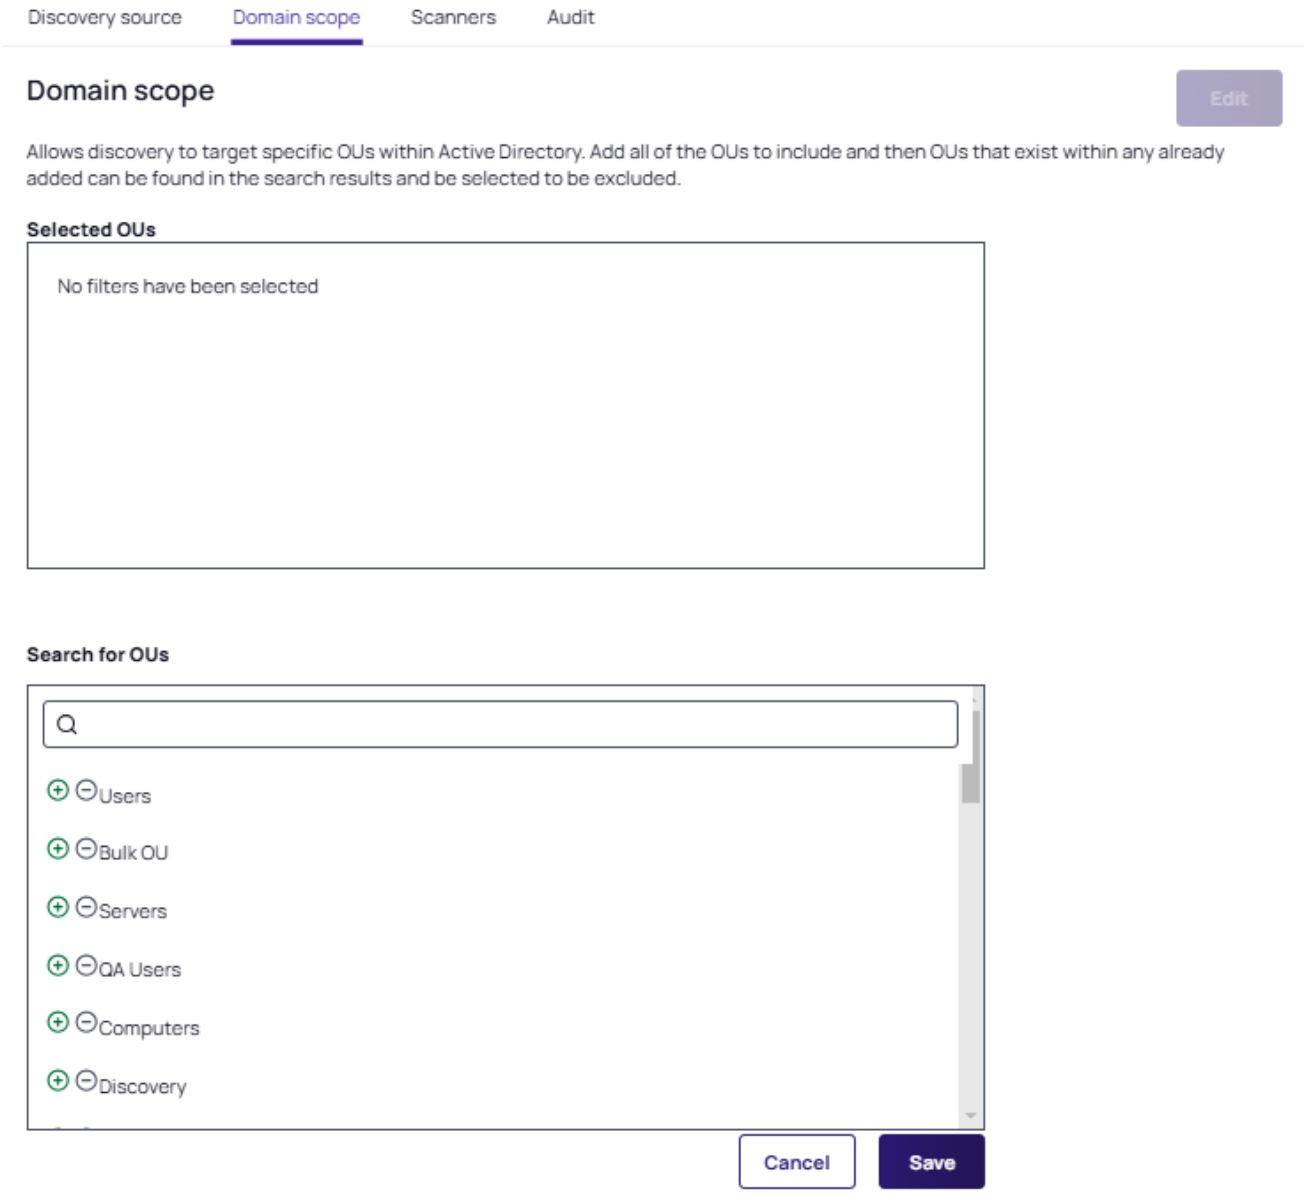
2. Select one of the discovery sources listed which you want to configure. The **Discovery Source** page and tab for that source appears, with all its details. These include a brief description, the Discovery source name, Fully Qualified Domain Name, Friendly Name, State, Discovery secret type, Discovery Site, Discover Specific OU, Machine resolution type, and if Use LDAPS has been selected.
3. Click the **Edit** link next to the discovery source name. The page becomes editable.
4. Click to select the **Discover Specific OU** check box:



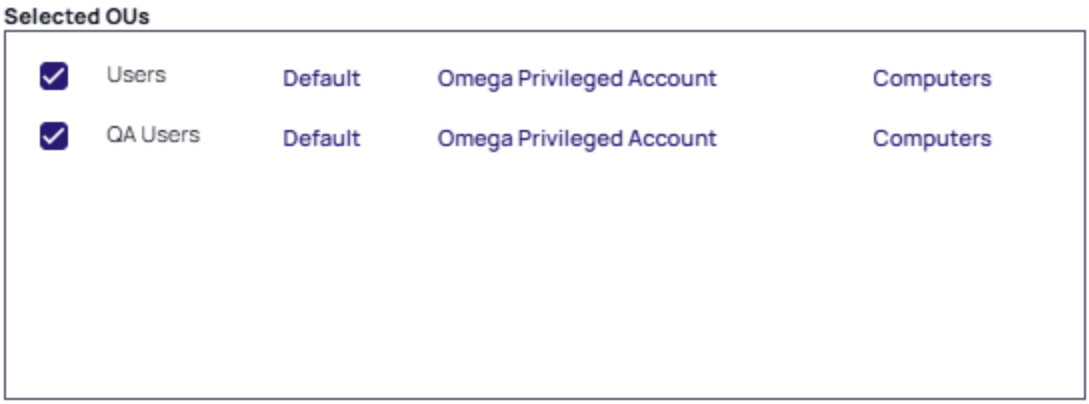
> When **Discover Specific OU** is enabled, unmapped secrets are not added.

5. Click the **Save** button. The **Domain Scope** tab appears.
6. Select the **Domain Scope** tab.

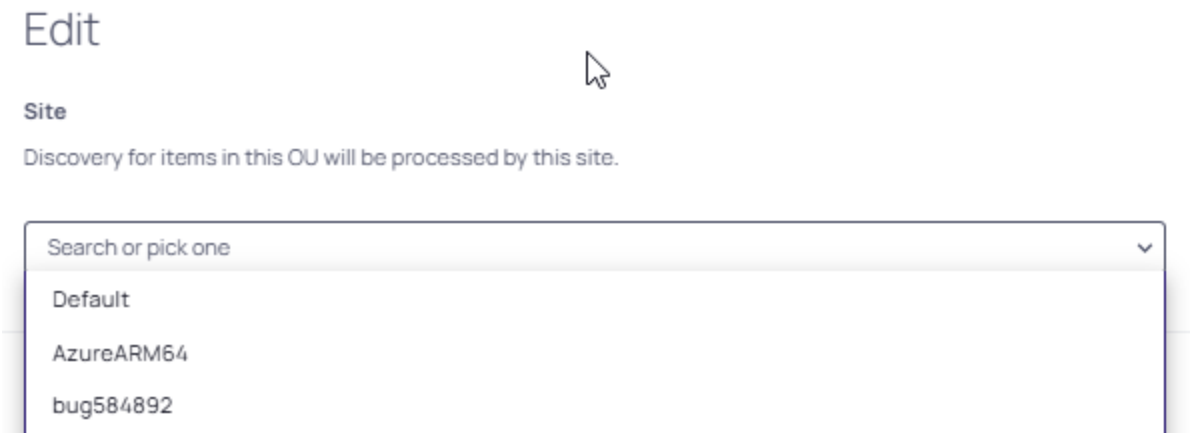
7. Click the **Edit** link next to **Domain Scope**. The page becomes editable:



8. In **Search for OUs** type the name of the desired OUs. Matching OUs appear.
9. Click the circled plus button to add an OU. Upon addition, OUs appear automatically in the **Selected OUs** box above the search list. Clicking the checkbox next to Selected OUs removes them:



10. Click the site link (e.g. Default, shown above) to edit the site (distributed engines) included. A popup appears with a dropdown allowing you to choose what type of site will process the Discovery for items in this OU:



> Please be advised that if a privileged account is set under specific OUs, that the account will override any accounts set on the individual Discovery Scanners (Service, Scheduled Task, Local User, etc)

11. Click the credential secret link (e.g. Omega Privileged Account) to edit the secret that should be used when scanning items within this OU.
12. Click the scan target link (e.g. Computers) to specify what filter should be applied after the items are discovered within this OU.

> If Computers is specified for all OUs no filtering will be applied with User scanners configured.

13. Repeat the previous steps for any additional OUs.
14. Click the **Save** button.

> The ports required for Discovery are documented in "Ports and IP Addresses Used by Secret Server" on page 765.

Extensible Discovery

Extensible discovery is not covered by Delinea Support.

Overview

It is important to have an understanding of built-in discovery scanning before attempting to create your own custom scanner. Please see "Introduction to Discovery Sources, Scanners, and Templates" on page 538 for more details.

Extensible discovery lets you extend the already powerful scanning abilities of Secret Server by creating custom scanners that run PowerShell. You can use either built-in or custom scanners and templates at each step of the extensible discovery process.

If the built-in discovery sources, scanners, or input and output templates, cannot meet your needs, you can use PowerShell scripts to perform any part of discovery. Doing so requires that you define your own input and output templates, as well as scanners, and then add them to a new or existing discovery source.

When to Use Extensible Discovery

Creating a discovery source using scripted scanners can be a lot of work to set up, so when should you consider it? If you only need to discover domain administrator accounts with standard dependencies (Windows services, application pools, and scheduled tasks), our built-in scanners will do the job, and extensible discovery is not necessary. However, your network probably contains other items you want to discover and bring under managed control. Here are some examples:

- Discover configuration files containing passwords and automatically add them as dependencies.
- Scan computers not joined to the domain.
- Create dependencies that run a SQL, SSH, or PowerShell script when a secret's password changes to log events to an external source, such as an external auditing or monitoring system.
- Record information not currently imported by local account discovery or custom fields in a secret template.
- Discover SQL Server logins as local accounts and import them as SQL Server account secrets.

To run PowerShell scanners against machines for local account and dependency discovery, you may need to configure WinRM and CredSSP. See "Configuring WinRM for PowerShell" on page 1500 and "Configuring CredSSP for WinRM with PowerShell" on page 1502.

Extensible Discovery Tutorial

Extensible discovery can be a long process for new users. It has many hands-on steps. As such, we believe a step-by-step tutorial is the best way to learn it.

Discovery scanners can run custom PowerShell scripts, as well as our built-in scanners for Active Directory, UNIX, and VMware ESXi. You can use one or more built-in or custom scanners at each step of the discovery process: host range, machine, local account, and dependency discovery.

Roughly, this tutorial has four tasks:

- Understanding the process
- Setting up scripts
- Creating scan templates
- Setting up discovery scanners and sources. You define dependency templates to change items manually added to secrets and added through discovery rules.

The tutorial shows you how to take full advantage of extensible discovery by creating an Active Directory discovery source that replaces each of the built-in scanners with a PowerShell script.

For simplicity, we will only create a Windows service dependency scanner in the dependencies step, but you can add additional built-in or custom PowerShell scanners to scan for application pools, scheduled tasks, or any other item that requires an action triggered when a secret's password is changed.

Task One: Understanding the Process

For most of this tutorial we will use the **Extensible Discovery Configuration** page as our launch page into each of the features that needs to be configured. Setting up extensible discovery requires making changes on several pages. The Extensible Discovery Configuration page has buttons linking to each of these pages as well as short explanations of what you need to do on them. The high-level process is as follows:

1. Create the scripts for each discovery step.
2. If necessary, create scan templates to define the information to return from the objects discovered at each step.

   > You want to avoid altering scan templates unless you absolutely need to. First, ensure the regular scanners cannot do the job. Once you change a template, you cannot use out-of-the-box scanners and must maintain your own PowerShell scripts for the local account and dependency scanners.

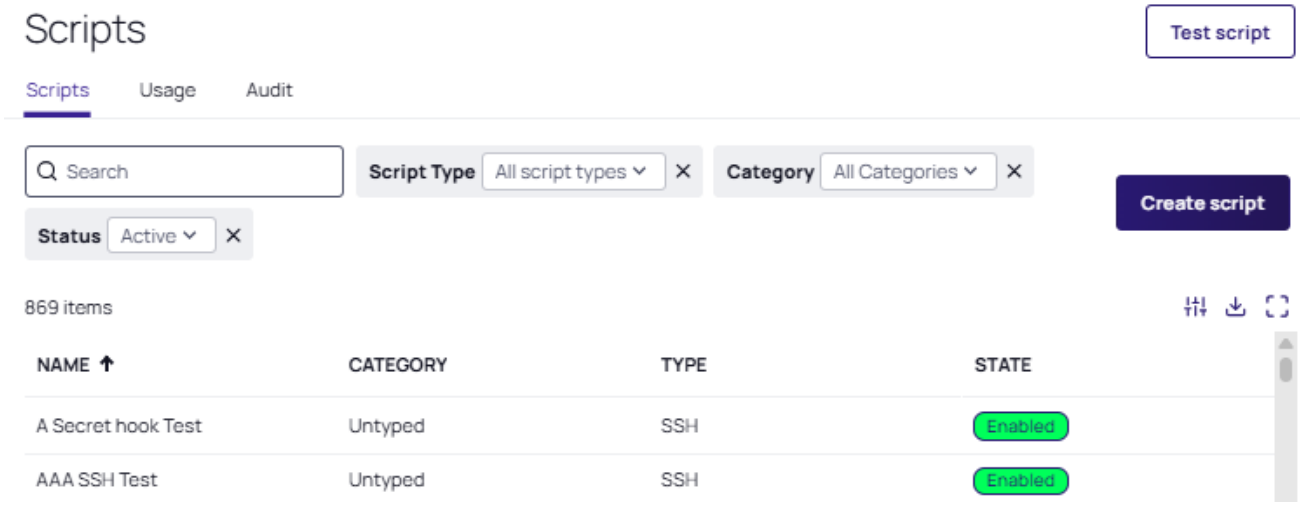
3. Create discovery scanners for each step to define:
   a. Which script to use for scanning.
   b. Which scan template represents the objects used as the source of data for the script.
   c. Which scan template represents the object returned from the script.
4. Create a discovery source that is configured to use discovery scanners in lieu of the default scanners.
5. Create a dependency changer for the type of dependency we want to manage.
6. Create a dependency template for the changer.
7. Manually add a dependency to a secret using the dependency changer.
8. Create a local account rule to import discovered accounts as secrets.
9. Create a dependency rule to import discovered dependencies as secrets.

Task Two: Creating the Scripts for Each Discovery Step

First, we add the scripts that we will use as our scanners to Secret Server:

To use extensible discovery, you must use a Secret Server edition that supports scripts or has an "Advanced Scripting" add-on license.

1. Search for **Scripts: PowerShell, SQL, SSH**. The **Scripts** tab of the Scripts page appears:



2. Select the **Create script** button. The **New Script** page appears.
3. For the Host Range Scanner, Machine Scanner, Local Account Scanner, and Windows Service Dependency Scanner scripts, fill in the following fields:
   a. Use the script name in the **Name** text box.
   b. Fill in the **Description** text box with relevant details about the script.
   c. Select the **State** checkbox to make the script **Enabled**.
   d. Pick the **Script Type** from the dropdown list.
   e. In the **Category** dropdown list use the **Discovery Scanner** category for each script.
   f. Copy and paste each script listed below in code snippets into the **Script** code text box for each of the four scripts.
   g. Click the **OK** button and repeat the process for each script.

Include the following code snippets for each script mentioned above.

Script Name: Host Range Scanner

```
$passwordArg = $args[2]
               $username = $args[1]

               $domain = $args[0]

               write-debug "$domain $username $passwordArg"

               $distingisheddomain = "DC=" + ($domain.Split('.') -join ",DC=");
```

```
                $Spassword = ConvertTo-SecureString "$passwordArg" -AsPlainText -Force
#Secure PW

                $cred = New-Object System.Management.Automation.PSCredential
("$domain\$username", $Spassword) #Set credentials for PSCredential logon

                $ous = Get-ADOrganizationalUnit -filter 'Name -like "*"' -Server $domain
-Credential $cred | select-object -property Name, ObjectGUID, @{Name =
'DistinguishedName'; Expression = {$_.DistinguishedName.Replace
(",$distingisheddomain",'')}}, ObjectClass

                return $ous

                # Script Args: $[1]$Domain $[1]$username $[1]$Password
```

Script Name: Machine Scanner

```
$Ou = $args[0];

                $domain = $args[1];

                $distinguisheddomain = "DC=" + ($domain.Split('.') -join ",DC=");

                if ($distinguisheddomain.ToLower() -eq $Ou.ToLower()) {

                $searchbase = $distinguisheddomain

                } else {

                $searchbase = "$Ou,$distinguisheddomain"

                }

                $FoundComputers = @()

                $ComputersinOU = Get-ADComputer -Filter 'Name -like "*"' -Server $domain
-SearchBase $searchbase -properties *

                foreach ($comp in $ComputersinOU) {

                $object = New-Object -TypeName PSObject

                $object | Add-Member -MemberType NoteProperty -Name ComputerName -Value
$Comp.Name

                $object | Add-Member -MemberType NoteProperty -Name DNSHostName -Value
$comp.DNSHostName

                $object | Add-Member -MemberType NoteProperty -Name ADGUID -Value
$comp.ObjectGuid
```

```
                $object | Add-Member -MemberType NoteProperty -Name OperatingSystem -Value
$comp.OperatingSystem

                $object | Add-Member -MemberType NoteProperty -Name DistinguishedName -
Value $comp.DistinguishedName.Replace(",$distinguisheddomain",'')

                $FoundComputers += $object

                }

                return $FoundComputers

                # args: $target $[1]$domain
```

Script Name: Local Account Scanner

```
$ComputerName = $args[0]

                $username = $args[1]

                $domain = $args[2]

                $password = $args[3]

                $objComputer = New-Object System.DirectoryServices.DirectoryEntry
("WinNT://$ComputerName", "$domain\$username" , $password)

                $children = $objComputer.Children | select-object SchemaClassName, Path,
Name, Properties, userflags, SIDType, Disabled

                $results = @()

                foreach ($child in $children){

                Write-Debug $child

                if ($child.SchemaClassName -eq 'User'){

                write-debug "adding to results"

                $object = New-Object -TypeName PSObject;

                $object | Add-Member -MemberType NoteProperty -Name Username -Value
$[child.Name](http://child.name/)[0];

                $object | Add-Member -MemberType NoteProperty -Name Resource -Value
$ComputerName;

                $object | Add-Member -MemberType NoteProperty -Name Disabled -Value
$child.Disabled;
```

```
                $results +=$object;

                }

                }

                return $results

                # Arguments $target $[1]$username $[1]$Domain $[1]$Password
```

Script Name: Windows Service Dependency Scanner

```
$ComputerName = $args[0]

                $accounts = Get-WMIObject Win32_Service -ComputerName $computername |
Where-Object{($_.StartName -like "*\*" -or $_.StartName -like "*@*") -and $_.StartName -
notlike "NT *"}

                if ($accounts) {

                $dependencyaccounts = @()

                foreach($dependency in $accounts)

                {

                $object = New-Object -TypeName PSObject;

                $object | Add-Member -MemberType NoteProperty -Name ServiceName -Value
$dependency.DisplayName;

                $object | Add-Member -MemberType NoteProperty -Name Enabled -Value
$dependency.Started;

                if ($dependency.startname.contains('@'))

                {

                $accountinfo = $dependency.startname.split('@')

                $username = $accountinfo[0]

                $domain = $accountinfo[1]

                }

                else

                {
```

```
                $accountinfo = $dependency.startname.split('\')

                $username = $accountinfo[1]

                $domain = $accountinfo[0]

                }

                $object | Add-Member -MemberType NoteProperty -Name Username -Value
$username;

                $object | Add-Member -MemberType NoteProperty -Name Machine -Value
$ComputerName;

                $object | Add-Member -MemberType NoteProperty -Name Domain -Value $domain;

                $object | Add-Member -MemberType NoteProperty -Name DependencyType -Value
'Powershell Script';

                $object | Add-Member -MemberType NoteProperty -Name AccountStatus -Value
'Expired';

                $dependencyaccounts += $object

                $object = $null

                }

                return $dependencyaccounts;

                }

                throw "Error - no service accounts found"

                return $null

                # args: $target
```

Task Three: Creating Scan Templates

The second task is to create scan templates for each object to be discovered. Scan templates define the types of objects that can be retrieved by discovery scanners. The goal of discovery scanning is to retrieve the following:

- Accounts that can be imported and managed as secrets.
- Entities (dependencies) requiring knowledge of password changes to managed secrets.

The process of finding these accounts and entities usually involves running the following scans beforehand:

- Host ranges where machines containing accounts can be found.

For Active Directory, this usually involves scanning a domain for organization units or defining which organization units in a domain to check. For Unix and ESXi, this usually involves defining one or more lists of IP address ranges to scan.

- Machines to be scanned for accounts.

Each of these items–host ranges, machines, accounts, and dependencies–is defined by a scan template. The scan template specifies:

- At which step of the scanning process the item is created (scan type).
- The scan template from which the current template gets its required fields (Parent scan template).
- A list of fields that the item contains.

The **Fields** section describes the list of properties that will be returned by the built-in scanner or script for the item. At a minimum, you need to define one field for each of the fields on the parent scan template. For items that are returned from a script, you can define additional fields that the script will return on the object. These are mapped by name to the corresponding field on the scan template. These additional fields can then be used by future scanners.

Secret Server defines scan templates for all of its built-in scanners. Whenever possible, you should use these as input and output sources for your scripted scanners. Create your own scan templates if you need to capture additional information as data for your scripts or if you need to use specific input and output templates on the discovery scanners to drive multiple discovery workflows on a single discovery source. For this tutorial, we will create new scan templates for the output of each of our scripts.

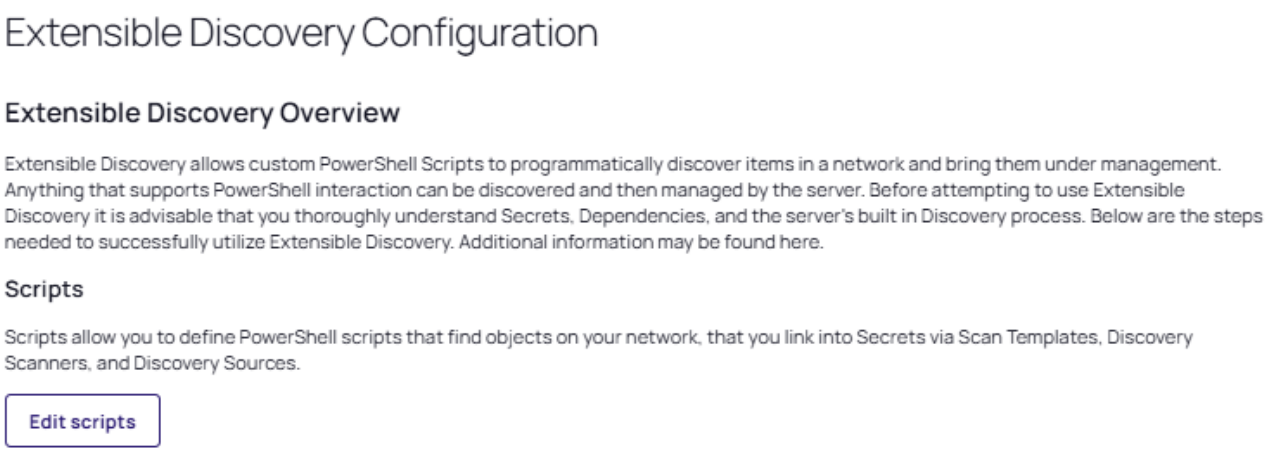
Host Range

The first scan template is the one that stores the results from our Host Range Scanner script. The script outputs an object with the following properties:

- Name
- ObjectGUID
- DistinguishedName

Our scan template must hence, have fields to store the values of these three properties:

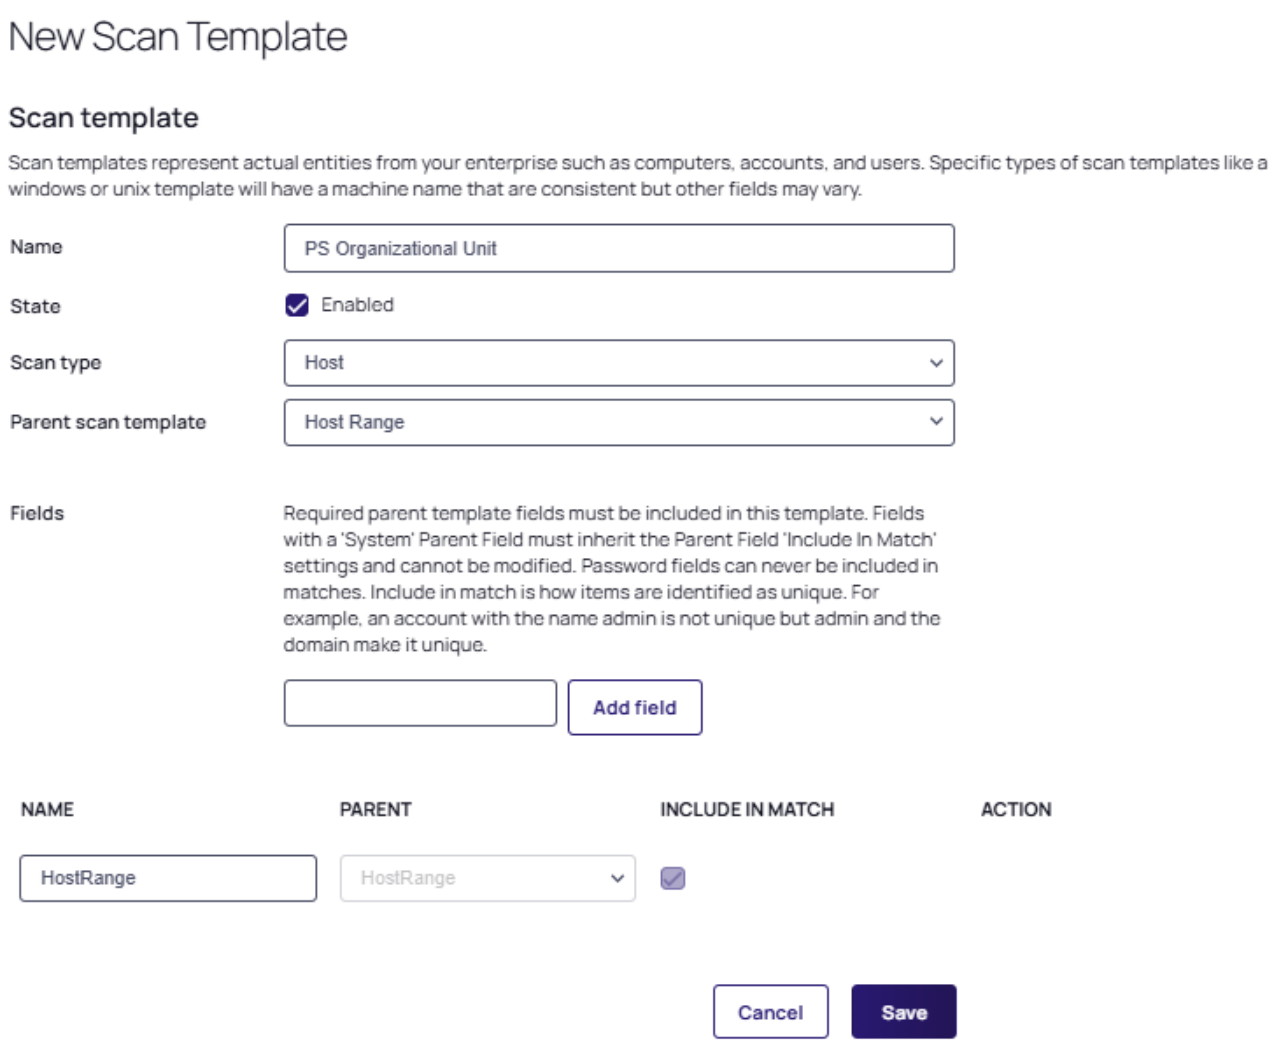
1. Go to **Discovery**.
2. Select the **Configuration** tab.
3. Click the **Discovery Configuration Options** dropdown and select **Extensible Discovery**. The Extensible Discovery Configuration page appears:



4. Click the **Configure Scan Templates** button. The Scanner Definition page appears on the **Scan Templates** tab.
5. Click the **Create Scan Template** button. The New Scan Template page appears.
6. Type `PS Organizational Unit` in the **Name** text box.
7. Select the **State** checkbox to make the template **Enabled**.
8. Leave the **Scan Type** set to **Host** in the dropdown list. The Parent Scan Template dropdown appears.
9. Leave the **Parent Scan Template** set to **Host Range** in the dropdown list. A field is automatically generated for this value when selected.
10. In the **Fields** section, add a field for each of our script output object's properties by typing the following in the text box and clicking the **Add field** button:

Field Name	Parent Field
DistinguishedName	<None>
Name	HostRange
ObjectGUID	<None>

A field with the name value HostRange for the parent HostRange is automatically created and needs to be renamed to "Name":



11. When done, click the **Save** button.

Machines

Create the scan template to contain the output from the Machine Scanner script. This script takes the name of an OU retrieved from our previous step, scans that OU for computers, and returns a list of custom objects containing certain properties of each computer. In this tutorial we are capturing these properties:

- ADGUID
- ComputerName
- DistinguishedName
- DNSHostName
- OperatingSystem

If future scanners need more information about the computer, you can easily modify this script to return additional properties.

1. Click the **Create Scan Template** button. The New Scan Template page appears.
2. Type `PS Machine` in the **Name** text box.
3. Select the **State** checkbox to make the template **Enabled**.
4. Set the **Scan Type** dropdown list value to **Machine**.
5. The **Parent Scan Template** dropdown list automatically appears, set to **Computer**, leave it unchanged.
6. In the **Fields** section, two fields automatically appear, one for Machine which needs to be renamed to "ComputerName" and another for "OperatingSystem" which will be left as is.
7. Add a field for each of our remaining script output object's properties by typing the following in the text box and clicking the **Add field** button:

Field Name	Parent Field
ADGUID	<None>
ComputerName	Machine
DistinguishedName	<None>
DNSHostName	<None>
OperatingSystem	OperatingSystem

8. Click the **Save** button.

Local Accounts

Our Local Account Scanner script takes the computer name of a computer retrieved from the previous step, scans that computer for local accounts, and returns a list of custom objects containing the following properties from each account:

- Disabled
- Name
- Resource

The setup of these fields in the Local Account scan template is different than the other templates that we have created so far. The parent template for local accounts is "Account" and it has three fields: Username, Password, and Resource. Our script is not able to return the password on the account, so the objects returned do not have that as a property. We need to map this parent field to a field on our template, but it is only used internally.

1. Click the **Create Scan Template** button. The New Scan Template page appears.
2. Type `PS Account` in the **Name** text box.
3. Select the **State** checkbox to make the template **Enabled**.
4. Set the **Scan Type** to **Account** in the dropdown list.
5. The **Parent Scan Template** dropdown list automatically appears set to **Account (Basic)**. Leave it unchanged.
6. In the **Fields** section, three fields automatically appear. Leave Resource and Password as they are. Rename Username as shown below.

   Add a field for each of our remaining script output object's properties by typing the following in the text box and clicking the **Add field** button:

Field Name	Parent Field
Disabled	<None>
Name	Username
Password	Password
Resource	Resource

Dependencies Scan Template

The final scan template to set up is the one used to find Windows Service dependencies. The script will return a list of all Windows Services on a computer along with account information for that service. The properties returned by the script for each service are:

- AccountStatus
- DependencyType
- Domain
- Enabled
- Machine
- ServiceName
- Username

The complete the setup:

1. Click the **Create Scan Template** button. The New Scan Template page appears.
2. Type `PS Dependency` in the **Name** text box.
3. Select the **State** checkbox to make the template **Enabled**.
4. Set the **Scan Type** to **Dependency** in the dropdown list.

5. The **Parent Scan Template** dropdown list automatically appears set to **Computer Dependency (Basic)**. Leave it unchanged.
6. The **Account Scan Template** dropdown list automatically appears, set it to **PS Account**.
7. In the **Fields** section, four fields appear automatically, leave them all unchanged:
   - Machine
   - ServiceName
   - Username
   - Domain

   Add a field for each of our remaining script output object's properties by typing the following in the text box and clicking the **Add field** button:

Field Name	Parent Field
AccountStatus	None
DependencyType	None
Domain	Domain
Enabled	<None>
Machine	Machine
ServiceName	ServiceName
Username	Username

Task Four: Setting up Discovery Scanners and Sources

Discovery Scanners

Now that you have created the scan templates that our scripted discovery source will need, you can create the discovery scanners.

When creating a new scanner you must specify:

- Which step the scanner runs on.
- What type of base scanner to use (for example, Manual Input, Windows Discovery, or PowerShell Discovery).
- Which scan provides the input for the scan.
- Which scan template represents the output of the scan.
- When using a PowerShell base scanner, you also select what script to run and any arguments to pass to the script.

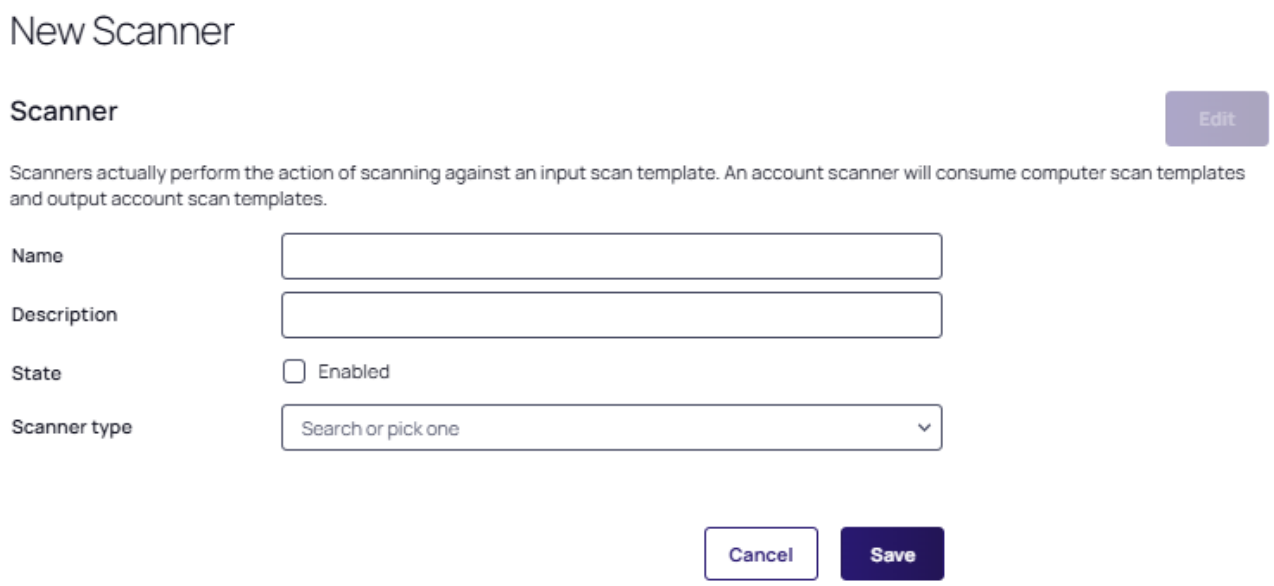
To get started:

1. Access **Discovery** and select the **Configuration** tab.
2. Click the **Discovery Configuration Options** dropdown and select **Extensible Discovery**.
3. Select the **Configure Discovery Scanners** button. The Scanners Definition page appears on the **Scanners** tab.

   The page is similar to the scan templates tab page, but with a list of configured scanners displayed. Secret Server comes with discovery scanners for each built-in scanner. Add a new PowerShell scanner for all four scanner types, using the scripts and scan templates we set up in the previous sections.

Host Ranges

1. Click the **Create Scanner** button. The New Scanner page appears:

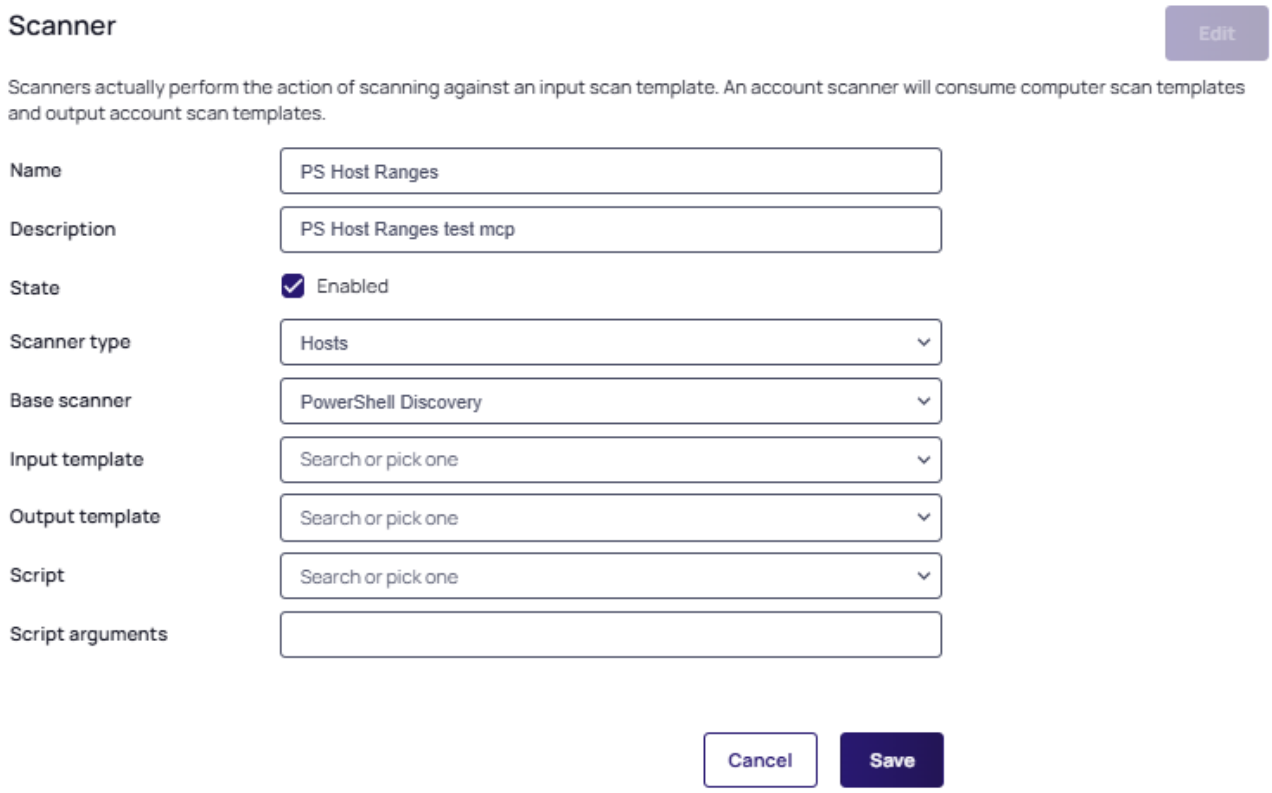


2. Type `PS Host Ranges` in the **Name** text box.
3. Type a description in the **Description** text box.
4. Select the **State** checkbox to make the scanner **Enabled**.
5. Set the **Scanner Type** dropdown list set to **Hosts**.

> Discovery scanning always proceeds in the following order: Host Ranges > Machines > Local Accounts > Dependencies. The scan templates, scanners, and source pages all organize their contents in the same order.

> Although the discovery scanning process proceeds in the order just mentioned, it is important to realize the output of each step *may* not be the input of the next step. Machines take host ranges as their input, and local accounts take machines as their input, but dependencies do not take local accounts as their input. Like local accounts, dependencies are on machines, so they also take machines as their input.

6. The **Base Scanner** dropdown list appears automatically, select **PowerShell Discovery**. A selection of template and other fields appears:



> For any scripted scanner, choose **PowerShell Discovery** as the **Base Scanner**. This tells the discovery process that this scanner is running a script. Other base scanner options are available based on the discovery type. If you do not need to run a script for a specific step of discovery but do need to use a custom scan template for the input, output, or both to create a specific workflow, you can choose an option other than "PowerShell Discovery".

7. In the **Input Template** dropdown list, select **Active Directory Domain**.

   The input and output templates are where you define the information flow for the discovery process. Each scanner uses the output of a previous step as its input. Each scanner returns a list of results as its output. The input template defines what to use as the input data for the scanner. The output template defines what is returned from the scan and used elsewhere. To see what scanner consumes the output of another given scanner, look for the one that has the same input template as the original scanner's output.

> You can have multiple scanners in each step with the same input template, but each scanner has to have a unique output template. When a scanner runs, it compares the results of the current scan with the results of the previous scan that was stored in the database. It updates any existing records, adds new records for new items, and removes any records that do not match items found during the current scan. If there were more than one scanner with the same output template, the second scanner would overwrite the results of the first scan, making it pointless. This is why each output template must be unique.

8. In the **Output Template** dropdown list, select **PS Organizational Unit**.

   This is the Host Range template we created in the previous section. Generally, each output template feeds a single scanner at the next level, but you can have multiple scanners using the same input template, with each using the results to find different things. For example, you could have two local account scanners defined that both use the input from the previous find machines step—one for finding Windows local accounts and the other for finding AD accounts that have rights on the computer. In turn, each scanner returns its results to its own output scan template—one creating Windows account secrets and the other creating Active Directory account secrets.

9. In the **Script** dropdown list, select **Host Range Scanner**, the first script you created in the previous section.

   The script runs for each object matching the input template, using the arguments in the next step, to return an object defined by the output template.

10. Type the following in the **Script Arguments** text box, separating each with a space: `$[1]$Domain $[1]$username $[1]$Password`.

    Script arguments can be a combination of literal values and tokens. When the script runs, these tokens are replaced with values from the input object and any privileged accounts associated with the scanner. Privileged accounts are assigned to scanners when the scanners are added to a discovery source. The table below lists the tokens that can be used as script arguments.

11. Click the **Save** button to save the scanner.

Table: Script Tokens

Token	Description
$target	A generic placeholder for the input object. This is not used when scanning for host ranges because there is no previous scanner input source. For machine scanners, $target refers to either the OU (for Active Directory discovery sources) or the IP address (for Unix and ESXi discovery sources) from the host range input. For local account and dependency scanners, $target is the name of the scanned computer.
$[x]$Username	The username of the xth privileged account associated with the scanner. Each scanner can have one or more privileged accounts associated with it. If you need to use the username of the first privileged account in your script, you would type in $[1]$Username. The second would be $[2]$Username and so forth. You can have as many privileged accounts as necessary.

Token	Description
$[x]$Password	Similar to $[x]$Username, this is the password of the xth privileged account associated with the scanner.
$[x]$Domain	Similar to $[x]$Username, this is the fully-qualified domain name of the xth privileged account associated with the scanner.

Machines

Once you set up one discovery scanner, the rest should be straight-forward:

1. Click the **Create Scanner** button. The New Scanner page appears.
2. Type `PS Machines Ranges` in the **Name** text box.
3. Type a description in the **Description** text box.
4. Select the **State** checkbox to make the scanner **Enabled**.
5. Set the **Scanner Type** dropdown list to **Machines**.
6. In the **Base Scanner** dropdown list that automatically appears, select **PowerShell Discovery**. A selection of template and other fields appears.
7. In the **Input Template** dropdown list, select **PS Organizational Unit**. This is the same as the output template from the last scanner.
8. In the **Output Template** dropdown list, select **PS Machine**. This is the Host Range template we created in the previous section.
9. In the **Script** dropdown list, select **Machine Scanner**. The script runs for each object matching the input template, using the arguments in the next step, returning an object defined by the output template.
10. Type the following in the **Script Arguments** text box, separating each with a space: `$target $[1]$domain`.
11. Click the **Save** button to save the scanner.

Local Accounts

Repeat the process for the local accounts scanner:

1. Click the **Create Scanner** button. The New Scanner page appears.
2. Type `PS Accounts` in the **Name** text box.
3. Type a description in the **Description** text box.
4. Select the **State** checkbox to make the scanner **Enabled**.
5. Set the **Scanner Type** dropdown list to **Accounts**.
6. In the **Base Scanner** dropdown list that automatically appears, select **PowerShell Discovery**. A selection of template and other fields appears.
7. In the **Input Template** dropdown list, select **PS Machine**. This is the same as the output template from the last scanner.

8. In the **Output Template** dropdown list, select **Account (Basic)**.
9. In the **Script** dropdown list, select **Local Account Scanner**. The script runs for each object matching the input template, using the arguments in the next step, returning an object defined by the output template.
10. Type the following in the **Script Arguments** text box, separating each with a space: `$target $[1]$username $[1]$Domain $[1]$Password`.
11. Click the **Save** button to save the scanner.

Dependencies

Repeat the process for the dependencies scanner:

1. Click the **Create Scanner** button. The New Scanner page appears.
2. Type `PS Windows Services` in the **Name** text box.
3. Type a description in the **Description** text box.
4. Select the **State** checkbox to make the scanner **Enabled**.
5. Set the **Scanner Type** dropdown list to **Dependency**.
6. In the **Base Scanner** dropdown list that automatically appears, select **PowerShell Discovery**. A selection of template and other fields appears.
7. In the **Input Template** dropdown list, select **PS Machine**. This is the same as the output template from the PS Machines scanner.
8. In the **Output Template** dropdown list, select **Computer Dependency (Basic)**.
9. In the **Script** dropdown list, select **Windows Service Dependency Scanner**.
10. Type the following in the **Script Arguments** text box: `$target`.
11. Click the **Save** button to save the scanner.

Discovery Sources

The final step is to create a discovery source and assign the discovery scanners we just made to it:

1. Select **Discovery > Sources**. The Discovery Sources tab loads.
2. Note the list of existing discovery sources.

> If you upgraded from an earlier version of Secret Server and have created an AD domain, a corresponding discovery source is displayed on this page. If discovery was not enabled on that domain it will appear in this list under the Disabled status.

3. Click the **Create** dropdown button and select the **Active Directory** type. The Create Active Directory discovery source page appears.
4. Type in values for the **Discovery source name**, **Fully Qualified Domain Name** (FQDN), and **Friendly Name** parameters.

> All parameters with asterisks are required.

5. Select the **State** checkbox to make the source **Enabled** for scanning.

> Active discovery sources are scanned at the defined discovery interval. If you have multiple discovery sources, the discovery source with the most un-scanned computers is scanned first.

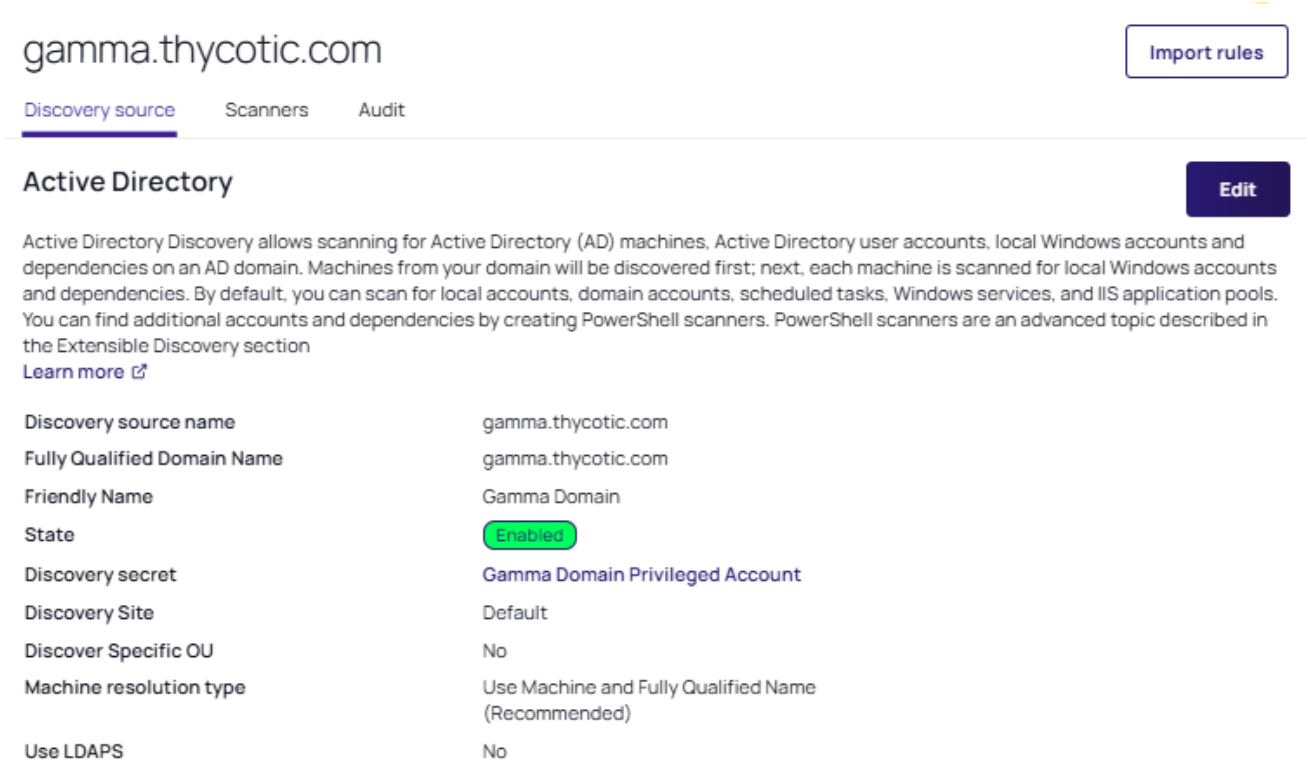
6. For the **Discovery secret** option click the **No Secret Selected** link. The Select Secret popup page appears.
7. Choose one of the following options:
   a. Option 1: Search for and select a secret that is used as the credentials for discovery scanning and AD synchronization. These credentials must have the proper rights to scan the remote machines. The popup page closes. The name of the secret you chose replaces the No Secret Selected link.
   b. Option 2: Create a new secret to be used as the credentials:
      i. Click the **Create New Secret** link. The Create New Secret page appears.
      ii. Search for and choose the **Generic Discovery Credentials** secret template. Another Create New Secret page appears.
      iii. Type or select the parameters needed for the discovery operation. Parameters with asterisks are required.
      iv. Click the **Create Secret** button.
8. In the **Discovery Site** dropdown list, select the desired site for the discovery source.

   If distributed engines are set up, the list shows all active sites. If no distributed engines are set up, the list defaults to local, and you cannot change it.
9. Select the **Discover Specific OU** checkbox to limit your discovery to an OU.

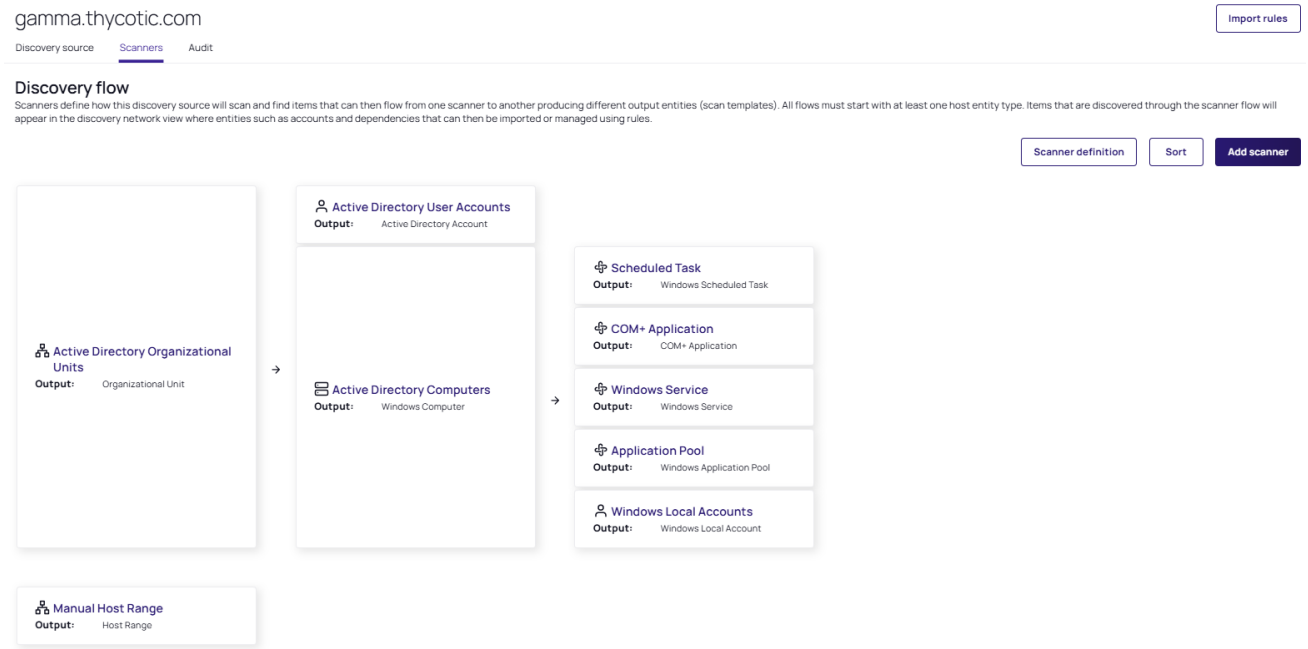
> See "Enabling Specific OU Domain Discovery" on page 580 to define the scanned OU. When you select this option, a Domain Scope tab appears on the Discovery Source page for the created AD discovery source.

10. Leave the **Machine Resolution Type** dropdown list set to **Use Machine and Fully Qualified Name** unless you have a specific reason to change it.
11. Select the **Use LDAPS** checkbox to use secure LDAP for the discovery.
12. Click the **Save** button.

    Secret Server attempts to access the domain with your specified credentials to ensure the configuration is correct. Secret Server must have access to the domain provided and the account credentials must work. Once the new discovery source is created it appears in the **Sources** tab of the Discovery page.
13. Click the newly created discovery source. The Discovery Source tab for the source appears:



14. Access the **Scanners** tab. The Discovery Flow page appears, for example:



> Note that a discovery source with default scanner options is already created. For this tutorial, we are not using any of those scanners.

15. Click on each scanner, and in their details panel, which opens on the right side of the screen, select **Remove Scanner**. In the verification popup, click the **Remove Scanner** button.
16. Click the **Add Scanner** button. The Add Scanner popup appears. It displays by default only scanners that can be added.
17. Set the **Scan Type** to **Hosts**.
18. Add the **PS Host Ranges** scanner.
19. Click on the **PS Host Ranges** scanner to open its details panel.
20. Click **Edit Scanner** to make it editable.
21. Click the **Add Secret** link. The Select Secret popup appears.
22. Select a secret that has permissions to scan the domain, such as the account you linked to the domain when adding the discovery source.
23. Click the **Save** button to save your settings, and exit out of the details panel.
24. Now that you have defined the host range scanner, repeat the process for the machine scanner, **PS Machines**, with the appropriate secret. Repeat any advanced settings from the last scanner.
25. Repeat the process for the local account scanner, **PS Accounts**, with the appropriate secret. Repeat any advanced settings from the last scanner.
26. Finally, repeat the process for the dependency scanner, **PS Window Services**, with the appropriate secret. Repeat any advanced settings from the last scanner.
27. Your scripted discovery source is now complete. You can go to the main discovery page to run discovery followed by a computer scan.
28. When both are done, you should see identical results in your discovery network view to what you would get if you ran discovery with our built-in scanners.

Manually Importing Local Accounts

Importing local accounts is the process of bringing in discovered local accounts for management by Secret Server:

1. Click **Administration** button on the side bar. The Secrets Administration page appears.
2. Click the **Discovery** link in the **Configuration > General** section. The Discovery Sources tab of the Discovery page appears.
3. Click the **Network View** button, which is not the same as the Network View tab. The Discovery Network View page appears. This page shows the computer accounts that have been found by Discovery. Clicking a domain name in the domain tree on the left displays the OUs available in that domain. Clicking on an OU displays the computers in that OU in the search grid.

> By default, this process uses the Import All discovery account rule.

4. Click a domain in the tree. The tree expands to show the domain's OUs.
5. Click an OU from that domain. The table on the right populates with the computers in that OU.
6. Click to select the computer accounts you want to import. Only accounts that have been assigned a secret can be selected. In fact, that is largely what import does—takes a discovered computer account and assigns it a secret so that Secret Server can manage it.
7. Select or fill in the scan template, secret type, folder for the new secrets, secret naming convention, and site (if this discovery uses distributed engines).
8. Click the **Next** button. The Password tab of the wizard appears.
9. Choose whether you have existing passwords for the accounts or wish to create new ones. If you choose the latter you can choose whether you want to manually create the new passwords or automatically create them based on the secret template's password settings.

   Remote password changing must be enabled to change the password. If that is the case, you will not see any selection buttons and a message appears instead.

10. Click the **Next** button. The Initial Takeover tab of the wizard appears.
11. If you chose to change the passwords, you need to select secrets to provide the initial password to do so—otherwise, discovery cannot access the account to change the password.
12. Click the **Next** button. The Password Changing tab of the wizard appears.
13. Select whether you want to use a secret credential or a privileged account to change the password in the future.
14. Click the **Finish** button. The final page of the wizard appears, and your choices are applied.
15. When the operation is complete, click the **Close** button. The Network View page reappears.
16. You can now see that the accounts you selected have secrets associated with them. You can click the secret name to go to that secret, which should indicate a successful heartbeat was conducted.

Vendor-Specific Topics

- "Active Directory Discovery" below
- "AWS Account Discovery" on page 611
- "Entra ID Discovery" on page 615
- "Google Cloud Platform Discovery" on page 621
- " Local Account Discovery Methods" on page 621
- "Unix Account Discovery" on page 633
- "VMware ESX/ESXi Account Discovery" on page 648

Active Directory Discovery

Secret Server queries AD domains to obtain a list of Organizational Units (OUs) and Windows computers on the domain. These OUs and computers are recorded in the Secret Server database. Secret Server then attempts to connect to each computer and query for the following:

- **Domain Accounts:** AD user accounts
- **IIS Application Pools:** IIS application pools run by AD accounts
- **Local Accounts:** Local Windows accounts
- **Windows Services:** Windows services run by AD accounts
- **Scheduled Tasks:** Windows scheduled tasks run by AD accounts

Setting Permissions for Active Directory Scans

See "Account Permissions for Discovery" on page 540 for additional information about local account and dependency discovery.

The default configuration of Active Directory should allow you to scan computers and users. However, if your IT department has implemented security hardening measures, you may need to adjust your AD permissions accordingly.

Local Windows Accounts

The scanning account needs the "Access This Computer From the Network" permission (and possibly one more) on the endpoint:

1. Open the local group policy editor (gpedit.msc).
2. Go to **Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment**.
3. Double-click the **Access this computer from the network** policy. The properties for the policy appears.
4. Ensure the scanning account is one of the listed users. If not, click the **Add User or Group** button to add it.

   These settings apply only to the configurations listed below. Check the following list of the operating systems and updates to see if any match your system. If your system configuration is not in this list, then none of the settings above required to be set for you.

   - Windows 10, version 1607 and later
   - Windows 10, version 1511 with KB 4103198 installed
   - Windows 10, version 1507 with KB 4012606 installed
   - Windows 8.1 with KB 4102219 installed
   - Windows 7 with KB 4012218 installed
   - Windows Server 2022
   - Windows Server 2019
   - Windows Server 2016
   - Windows Server 2012 R2 with KB 4012219 installed

- Windows Server 2012 with KB 4012220 installed
- Windows Server 2008 R2 with KB 4012218 installed

> For more information on this security issue, see Network access: Restrict clients allowed to make remote calls to SAM.

Windows Services, Scheduled Tasks, App Pools, and COM+ Applications

> There are special considerations for discovering service accounts running COM+ Applications, please contact Delinea for more information.

> If you run discovery against Windows Server 2016 or 2019, scheduled tasks are not discovered unless your instance or engine are on the same domain as the target server. On Windows Server 2016 and up, scheduled task discovery only gets a security identifier (SID) for the user that runs the task. Secret Server has code to convert the SID to a username, but this only works if the code is being executed on the same domain as the scheduled task. If the SID cannot be translated, the scheduled task will not be saved with discovery.

To scan for service accounts, the account entered must be a domain account that is in the Administrators group on the target machines. Follow the instructions below in either case to ensure your account has the privileges to run a successful scan:

1. Open the group policy editor for your domain policy.
2. Go to **ComputerConfiguration** > **Preferences** > **Control Panel Settings**.
3. Right-click **Local Users and groups** and select **New** > **Local Group.**
4. Leave the **Action** dropdown list set to **Update**.
5. Click to select **Administrators (Built-in)** in the **Group Members** dropdown list.
6. Click the **Add…** button.
7. Search for the account you will use for discovery scanning.
8. Click the **OK** button to save your changes. The next time the group policy updates across your environment, the discovery account will be part of the local administrators group.
9. For strong security, configure the group policy to limit the logon privileges of that account:
    a. Open the group policy editor
    b. For your domain policy, go to **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Local Policies** > **User Rights Assignment**.
    c. Add your discovery account to the **Deny log on locally** policy.
    d. Add your discover account to the **Deny log on through Remote Desktop Services** policy.
    e. (Optional) Ensure the account is not part of the remote desktop users group.

Running and Interpreting Active Directory Discovery

This topic discusses how to configure, run, and interpret discovery scans on Active Directory systems. After the initial configuration, normally the discovery source is set to active, which runs the follow-on tasks automatically. You can also manually run either a discovery (locate computers on the domain) or computer (inspect the individual computers) scan.

Step One: Discovery Configuration

Running a discovery on an AD system is easy, assuming everything was configured correctly. To that end, follow these instructions first:

- "Setting Permissions for Active Directory Scans" on page 606
- "Creating a Discovery Source" on page 546
- "Enabling Specific OU Domain Discovery" on page 580 (optional)

Step Two: Discovery Scan

> When running discovery with a one way trust, make sure to use a user secret from the domain that has the universal trust.

When you complete the configuration and there is at least one active discovery source and discovery is enabled (the Active check box is selected), you can run a discovery scan manually or wait for an automatic one to start. A typical scan:

1. Runs discovery matching: The discovery matcher creates a link between existing active secrets and any existing secrets in Secret Server based on their machine names, accounts and dependencies. The matcher is automatic. When matches are found, the corresponding existing discovery results appear as "managed" in the discovery network view with a link to the existing secret or dependency.
2. Runs discovery rules: Secret Server attempts to match any unmanaged discovery results to the rule's parameters. If a rule matches the results, discovery automatically imports the results using the settings in the discovery rule. Once finished, discovery begins.
3. Runs the find host ranges scanner: The scanner (using the Windows discovery base scanner) runs with an Active Directory domain input template. The scanner determines which OUs are to be scanned and populates its organizational unit output template with a list of those OUs. The output template will be used by the following find machine scanner and also by the find local accounts scanner, which does not require machine information.
4. Runs the find machine scanner: The scanner (using the Windows Discovery base scanner) examines OUs from its organizational unit input template via LDAP and creates a list of machines with which it populates its Windows computer output template. This is the list of computers to run a dependency scan on. The find dependencies scanner uses this instance of the output template as its input template.

> You can see logs of this process by going to the Discovery Logs tab on the Discovery page.

To run a manual discovery scan, on the **Admin** menu, click the **Run Discovery Now** button and select **Run Discovery Scan**.

Step Three: Computer Scan

Once the computers in the desired AD domain or OU are discovered, a computer scan runs AD queries on each machine found during the discovery scan to attempts to the collect the information the discovery source was configure to collect, which can include local accounts, Windows services, scheduled tasks, and IIS application pools.

> If you run discovery against Windows Server 2016 or 2019, scheduled tasks are not discovered unless your instance or engine are on the same domain as the target server. On Windows Server 2016 and up, scheduled task discovery only gets a security identifier (SID) for the user that runs the task. Secret Server has code to convert the SID to a username, but this only works if the code is being executed on the same domain as the scheduled task. If the SID cannot be translated, the scheduled task will not be saved with discovery.

Specifically, the scan:

1. Runs the find local accounts scanner: Using the file load discovery base scanner, Secret Server examines OUs from its organizational unit input template via LDAP and creates a list of all AD admin accounts with which it populates its Active Directory account output template. This is the list of discovered admin accounts.
2. Runs the find dependencies scanner: Using the Windows discovery base scanner, Secret Server examines a list of machines from its Windows computer input template using various technologies. For example, application pools use Microsoft Web Administration (WMA) or, failing that, Windows Management Instrumentation (WMI). Services use WMI, and scheduled tasks use Windows' task scheduler interfaces. The find dependencies scanner can return any number of output templates as desired. These include: com+ application, computer dependency (basic), PS dependency, remote file, SQL dependency (basic), SSH dependency (basic), SSH key rotation dependency, Windows application pool, Windows scheduled task, and Windows service.

> You can see logs of this process by going to the Computer Scan Logs tab on the Discovery page.

To run a manual computer scan, on the **Admin** menu, click the **Run Discovery Now** button and select **Run Computer Scan**.

Step Four: Viewing Discovery Results

Browsing Discovery Results

1. Search for **Discovery**. The Discovery Sources tab of the Discovery page appears.
2. Click the **Network View** tab.

   The Discovery Network View page shows any discovered computer accounts. The domain tree on the left displays the domains as folders with OUs for that domain presented as folder contents. Clicking on a folder and then on an OU displays the computers in that OU in the table on the right.

   > For large numbers of domains you can type the domain name in the unlabeled search box over the domain folder tree and press <Enter> to narrow what domains are presented to you.

The discovery page has tabs for local account, service accounts, and domain or cloud accounts. All are very similar and draw from the same network tree on the left.

Searching Discovery Results

To search for a specific discovery source or OU, type the source or OU name in the search bar displayed at left. If results are found, click the result shown below the search field to highlight it. Now, only machines from that source or OU will be displayed at right.

To search for a specific computer name, account, or service name, type the search term in the search field on the right. Matching results are filtered below the search field.

To use advanced search settings, click the filter icon beside the search field. The filters panel appears.

Select an option in the **Filters** panel to match an account, computer, operating system, or rule.

> "Rule" only appears in the list box if discovery rules exist for local accounts. When you select it, another menu appears for selecting a rule. For more information about creating and searching with rules, see "Creating Discovery Rules" on page 553.

Click the **Managed** option buttons to select accounts managed or unmanaged by Secret Server.

Understanding Discovery Results

The table below describes the contents of each column:

Table: Discovery Results

Column	Description	Account Type (Local, Service)
Account	Username of discovered account.	Both
Computer	Computer name of the machine scanned. This is obtained from AD during the first part of the discovery process.	Both
Last Connected	Last date a user logged into the machine.	Local
Last Scanned	Last date that the machine was scanned by discovery.	Both
Org Unit	Organizational Unit the machine is joined to. This information is obtained from AD during the first part of the discovery process.	Local
Secret	If a secret name appears here, a credential secret already exists for the account listed in the account column. Otherwise, this column is blank.	Both

Column	Description	Account Type (Local, Service)
Service Name	Name of a discovered dependency.	Service
Status	Indicates that an account is managed by Secret Server, connectivity issues, or no accounts detected. For more information about error messages, see "Discovery Error Messages" on page 571.	Both
Type	Discovered dependency type icon. See the following table.	Service

Table: Service Account Dependency Types

Type	Icon	Service Name
Application Pool		IIS application pool name
Scheduled Task		Scheduled task name
Windows Service		Service name

To correctly identify and import IIS application pools for IIS 7 or higher, Secret Server requires a trust relationship between the scanned domain and domain that the Secret Server Web server is joined to.

AWS Account Discovery

Discovery must be enabled in Secret Server to discover AWS accounts.

Secret Server can scan Amazon Web Services (AWS) for accounts that can access the cloud resource. Two types of secrets can be discovered and managed through SS:

- AWS Access Key: Keys used for programmatic integration with AWS.
- AWS Console Account: User login accounts for AWS.

AWS Instance Discovery

Secret Server can now scan for instance resources in AWS. You can add this ability in the scanner settings section or through the wizard.

1. Create an AWS discovery source. See "Enabling AWS Discovery" on the next page.
2. Search for **Discovery**, and select the **Sources** tab.

3. Click the **Create** dropdown list and select **AWS (Amazon Web Services)**. The Create discovery source page appears.
   - In the **Name** field, enter the name of the AWS discovery source.
   - In the **Site** field, select the related site from the dropdown.
   - In the Source type field, live **AWS (Amazon Web Services)** as is.
   - In the **Secret** section, use the Noe secret selected link to select a desired secret, or Create new secret link to add a new secret. These credentials will be used to scan for accounts in discovery and should be a Secret that is able to connect with appropriate permissions to scan machines or services.
4. When done, click **Save**. The **Add flow** wizard appears.
5. In the **Add flow** wizard, in the **Flow** field select **AWS**. If prompted, select the related options by checking the **AWS User Accounts**, **AWS Access Keys**, **AWS Windows Machines**, **AWS (Non-Windows) Machines** checkboxes. When done, click **Add**. The new Discovery source page appears, with the Scanners tab selected.
6. Click **Add scanner** to add an existing or create a new scanner:
   - To add an existing scanner, select the related scanner from the list and click **Add scanner**.
   - To create a new scanner, scroll down and click **Create scanner**. The New Scanner page appears. Fill in the following:
     - **Name** - enter the desired name.
     - **Description** - enter the related description.
     - **State** - check to enable scanner.
     - **Scanner type** - select **Host**, **Machines**, **Accounts**, **Dependency**.
     - **Base scanner** - select **AWS Discovery**.
     - **Input template** - select **AWS Discovery source**.
     - **Output template** - select **AWS Path** or **AWS Region**.

   When done, click **Save**.

Enabling AWS Discovery

AWS Identity and Access Management (IAM)

1. For Secret Server to communicate with AWS, users with sufficient privileges need to create an access key for their account in AWS Identity and Access Management (IAM). The account used to do this requires the following AWS IAM permissions to discover users and access keys:
   - iam:ListUsers
   - iam:GetLoginProfile
   - iam:ListAccessKeys

   These AWS IAM permissions are limited to the resources the user is allowed to access.

2. Once this access key is created, use the access key and secret key to create a secret in Secret Server using the Amazon IAM key template.
3. Create a new AWS discovery source and use the Amazon IAM key as the credentials secret for that discovery source.

> AWS only allows programmatic integration through access keys. This type of secret is required for discovery to work. Discovery must be enabled in Secret Server for this feature to work.

Amazon Elastic Compute Cloud (EC2)

Amazon Elastic Compute Cloud (EC2) is a part of AWS that allows users to rent virtual computers on which to run their own computer applications. The EC2 account used to do this requires the following AWS EC2 permissions to discover users and access keys:

- EC2:DescribeInstances
- EC2:DescribeAvailabilityZones

The configuration is very similar to IAM.

Password Management in AWS

Secret Server manages AWS key secrets through direct usage of the AWS IAM API. In order to do this, the following AWS permissions are required.

Amazon IAM Keys

Password changing, privileged password changing, and running heartbeats are available for Amazon IAM key secrets. When an Amazon IAM key has its password changed through Secret Server, the new secret key is generated automatically and is not set by user input.

During password changing, you can disable or remove old keys through settings available in the advanced configuration:

- `<add key="ShouldDeletePreviousKey" value="true" />`
- `<add key="ShouldInactivatePreviousKey" value="true" />`

> Altering advanced settings can significantly impact the performance and behavior of Secret Server, so there is no direct link anywhere in Secret Server to the Advanced Settings page. If you need to change any advanced setting (as mentioned in this guide), please contact Delinea Technical Support.

Amazon IAM Console Password

Password changing, and privileged password changing are available for Amazon IAM console password secrets. Due to AWS IAM's restrictions on programmatic integration, this secret type cannot use Secret Server heartbeat.

In addition, an Amazon IAM key secret must be associated with an Amazon IAM console password secret for password changing to occur. To associate the two:

1. Create the Amazon IAM console password secret, and an Amazon IAM Key secret for an account that has AWS permissions to change the console user's password. This can be the console account's own access keys, if the user has permission.
2. Navigate to the RPC tab of the Amazon IAM Console Password.
3. Under **Change Password Using Privileged Account** select **Edit** and choose the IAM key secret created in the previous step. RPC should now be possible on the console password secret.

AWS Permissions Required for Secret Key Changes

> These permissions are at the most granular level. You can implement broader methods through wildcard resource restrictions, permission policies, or groups.

Privileged Permissions: (those the AWS account needs to change another users' access keys):

- `iam:DeleteAccessKey` on resource `arn:aws:iam::<account>:user/<otherUserName>`
- `iam:UpdateAccessKey` on resource `arn:aws:iam::<account>:user/<otherUserName>`
- `iam:CreateAccessKey` on resource `arn:aws:iam::<account>:user/<otherUserName>`
- `iam:ListAccessKeys` on resource `arn:aws:iam::<account>:user/<otherUserName>`

Basic AWS Permissions (those the AWS account needs to change its own access keys):

- `iam:DeleteAccessKey` on resource `arn:aws:iam::<account>:user/${aws:username}`
- `iam:UpdateAccessKey` on resource `arn:aws:iam::<account>:user/${aws:username}`
- `iam:CreateAccessKey` on resource `arn:aws:iam::<account>:user/${aws:username}`
- `iam:ListAccessKeys` on resource `arn:aws:iam::<account>:user/${aws:username}`

AWS Permissions Required for Changing the Amazon IAM Console Password

> These AWS permissions are at the most granular level. You can implement broader methods through wildcard resource restrictions, permission policies, or groups.

The permissions are:

- Privileged Permission: `iam:UpdateLoginProfile` on `resource arn:aws:iam::account>:user/<otherUserName>`
- Basic Permission: `iam:ChangePassword` on resource `arn:aws:iam::<account>:user/${aws:username}`

Viewing AWS Discovery Source Scanners

To view these scanners:

1. Search for **Discovery**, and select the **Sources** tab.
2. Click the discovery source name link in the table. The Discovery Source page for it appears. Select the **Scanners** tab.
3. Click on a scanner. The scanner settings appears on the right. The following settings for that scanner appear:

- **View scanner definition**: Allows viewing basic scanner settings, and edit **API request page size** (The max results per request for the API. Larger size can limit calls for more results. (For Service Accounts, the max page size is 100), and **API call pause (milliseconds)** (Used to limit the speed that API calls are made to avoid API rate limits).
- **Edit scanner**: Allows viewing Scanner name, Mapping, Credentials, add secret, add secret search filter, edit **API request page size**, and **API call pause (milliseconds)**.
- **Remove scanner**: Click and confirm in the popup to remove current scanner.
- **Add child scanner**: Allows adding a new scanner (see AWS Instance Discovery for details).

Entra ID Discovery

Discovery must be enabled in Secret Server to discover Entra ID accounts.

A distributed engine is required to use Entra ID Discovery with Secret Server Cloud. Secret Server On-Premises customers can leverage both distributed engines and webnodes.

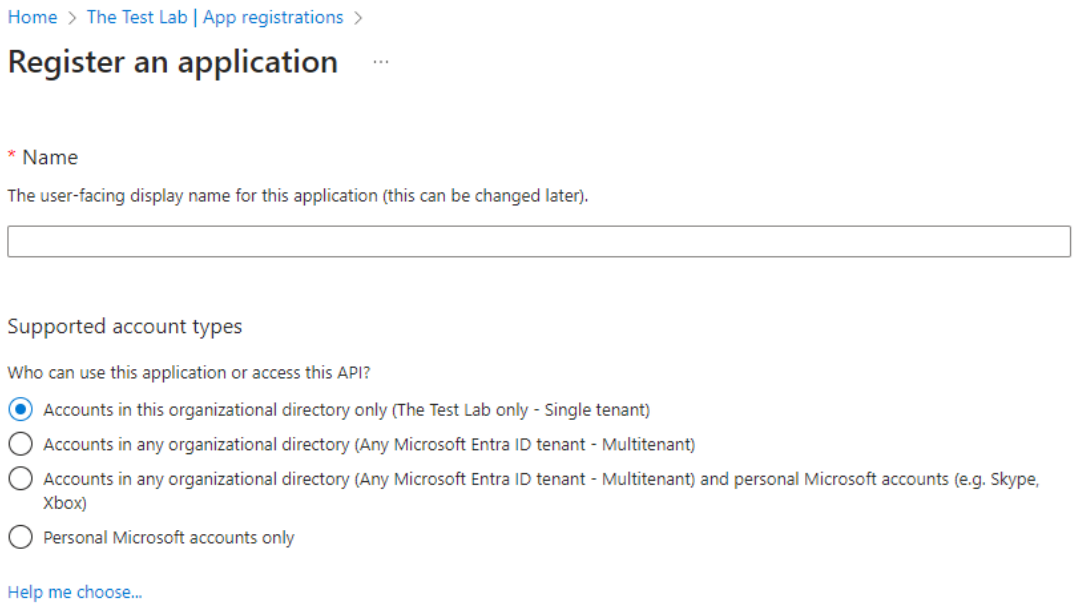
Overview

Secret Server can scan Microsoft Entra ID for Roles and Users. Users can be exported as secrets of the Entra ID User Account template.

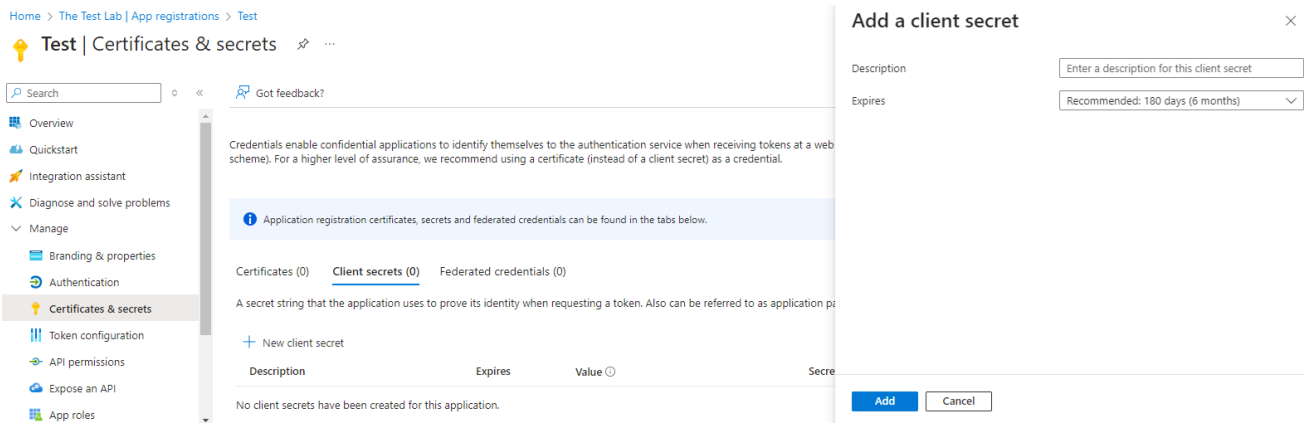
Configuration

Setting Entra ID permissions:

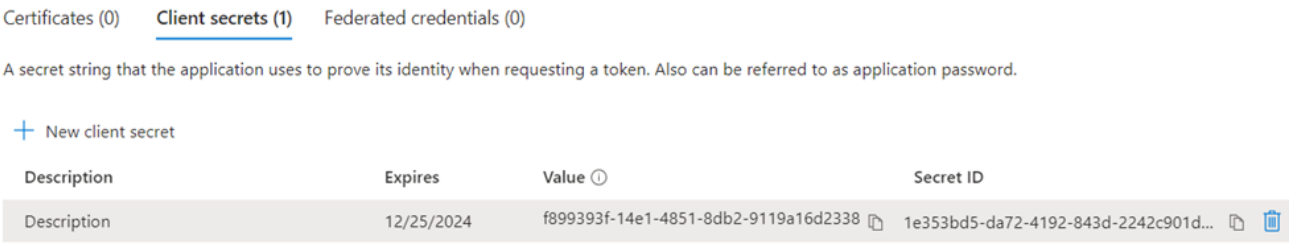
1. Create an App Registration in Entra ID:



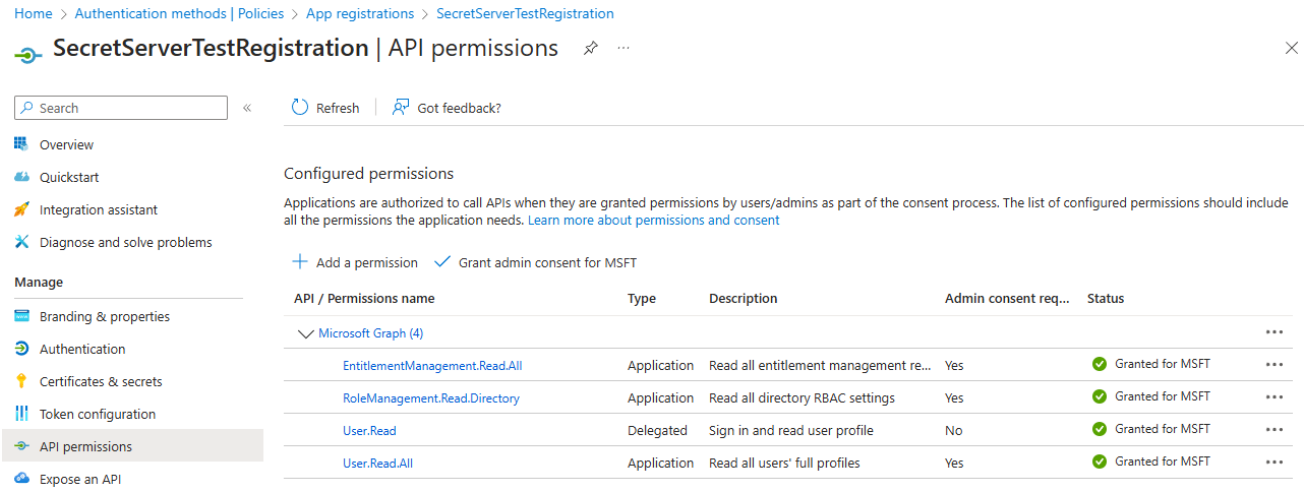
2. Add a client secret to the registration:



3. Once the client secret is created, the following data will appear. Copy the data in the **Value** column immediately–it will not be displayed again:



4. Grant API Permissions for the registration. Click **Add A Permission** to add each permission. The minimum required Microsoft Graph application permissions for discovery are:
   - EntitlementManagement.Read.All
   - RoleManagement.Read.Directory
   - User.Read.All

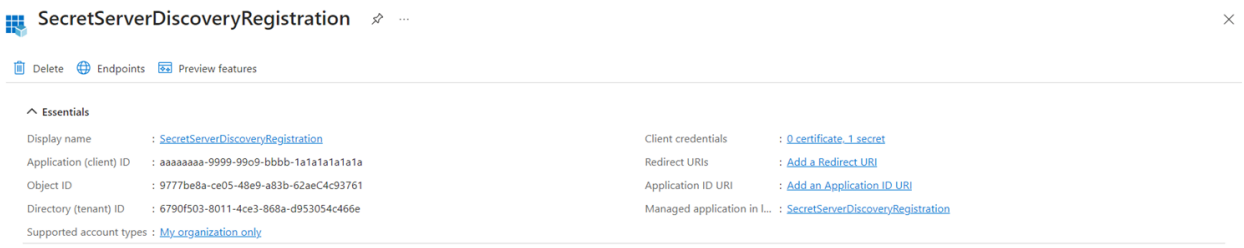


> These Microsoft Graph API permissions must be added as Application Permissions not Delegated Permissions.

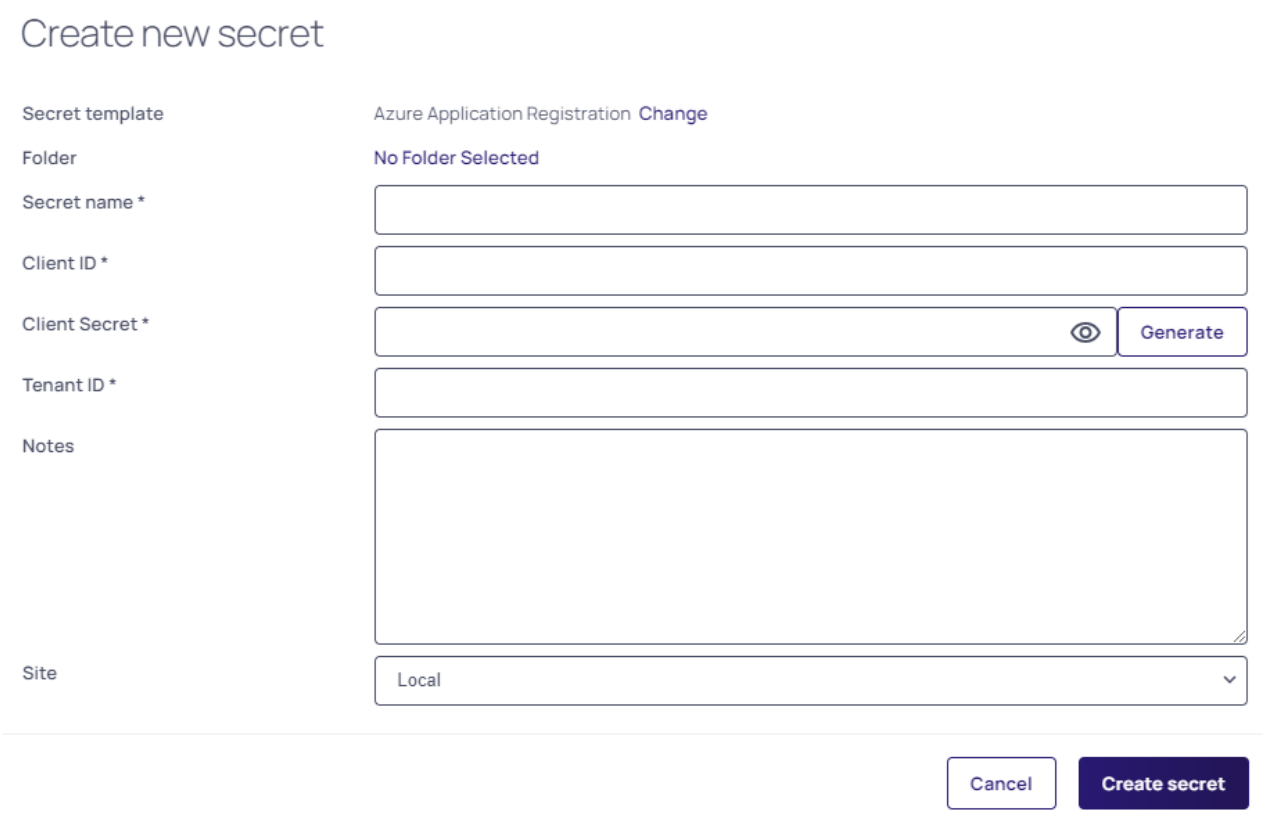
> The Application Registration may have permissions granted by default in addition to the ones listed above. These should have no impact on Discovery.

> If you want to use the same Application Registration for password changing you will also need the `User.ReadWrite.All` and the `UserAuthenticationMethod.ReadWrite.All` permissions. For administrator accounts, users need to have at least **Privileged Authentication Administrator** permissions as well. See "Minimum Permissions for Entra ID RPC" on page 1016 for details.

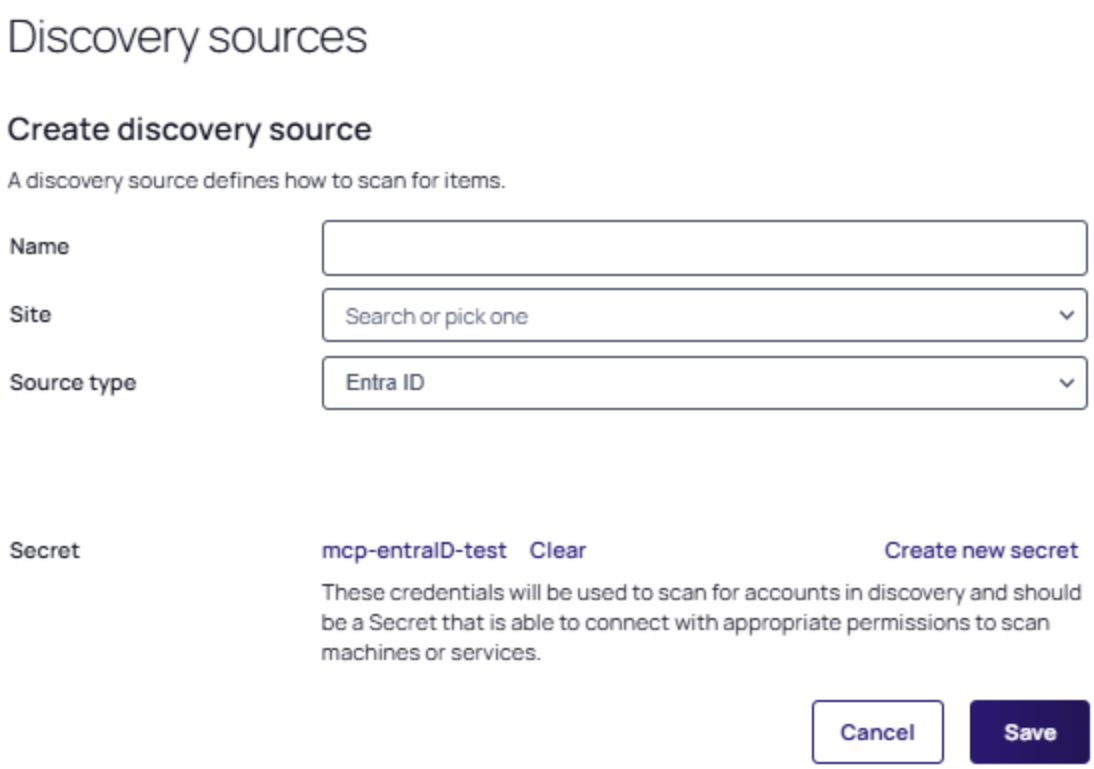
5. Map the appropriate fields to an Azure Application Registration secret in Secret Server:
   - Azure Portal:



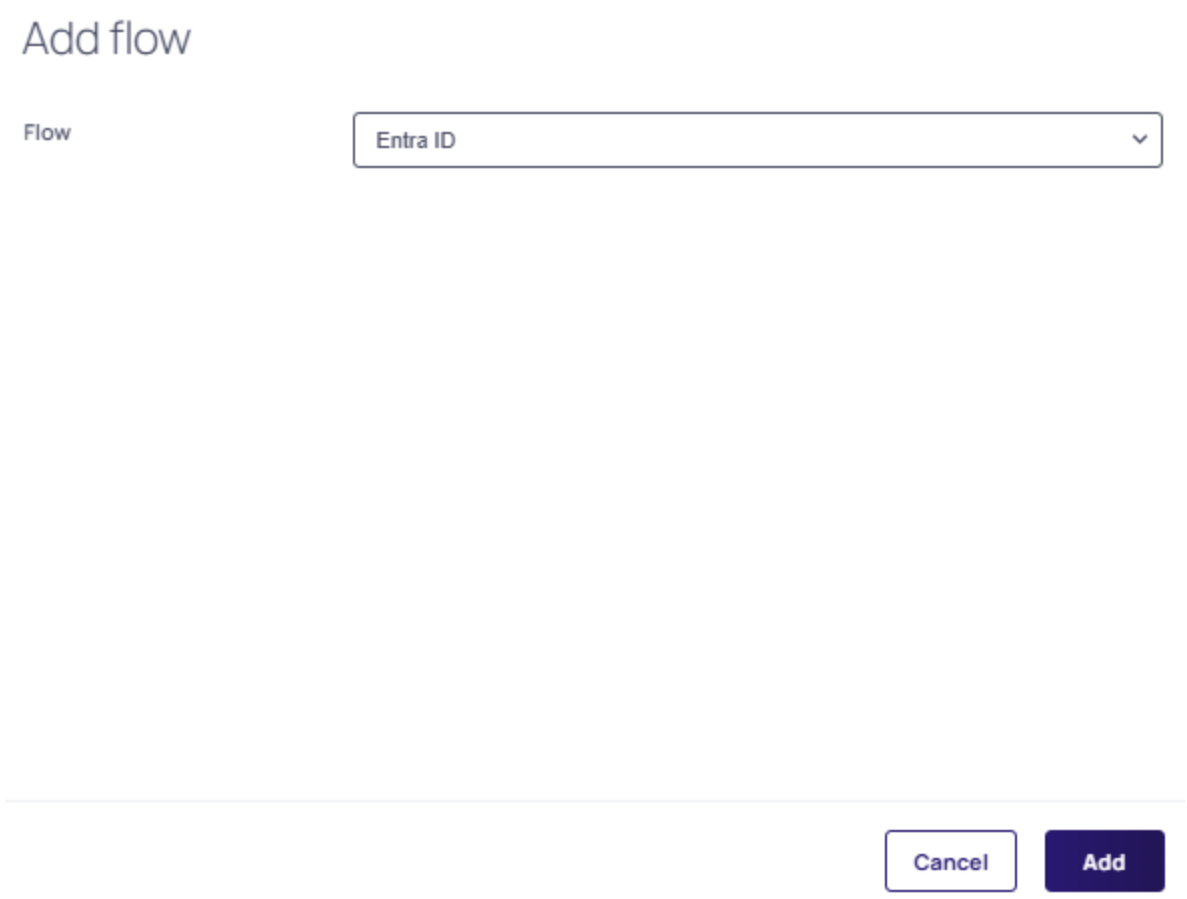
- Secret Server:



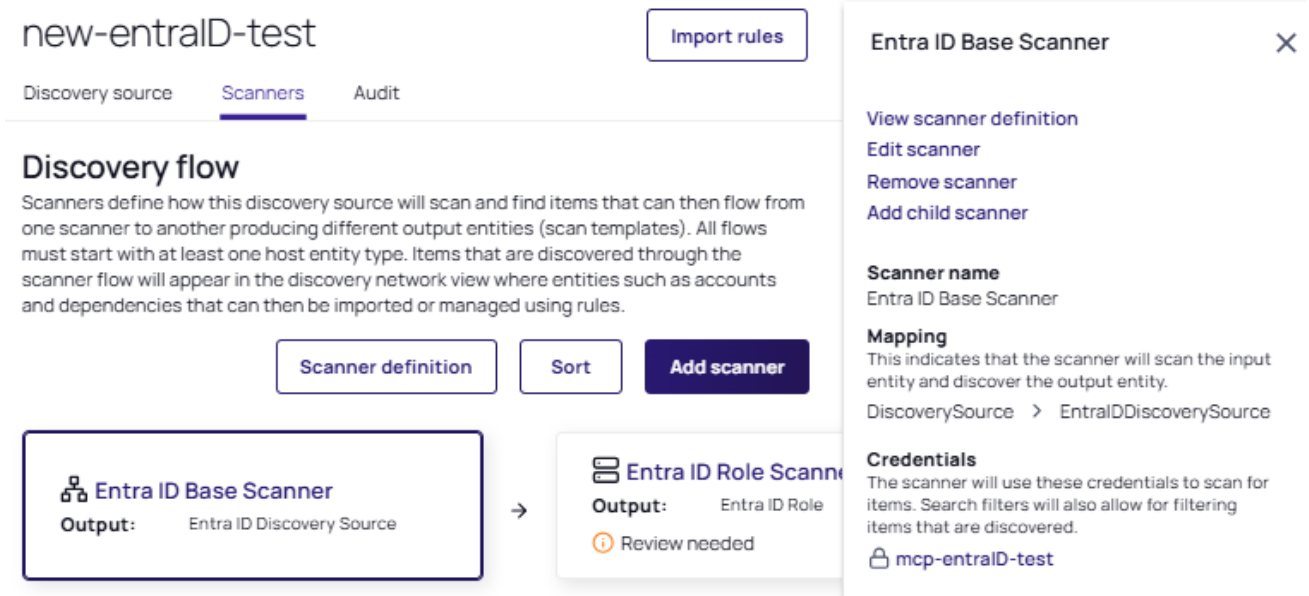
6. When mapping the fields from Entra ID to the new secret, note the following:
   - Application ID maps to Client ID.
   - Directory ID maps to Tenant ID.
   - The Client Secret is the value generated in Step 2.
7. In your Secret Server instance, create a new **Discovery Source** using the Azure Application Registration Secret:



8. By clicking **Save** you are automatically prompted to add the scanner flow for Entra ID to the Discovery Source:



9. For each scanner set the Azure Application Registration as the credential secret:



Scanning

Entra ID Roles can be obtained by running a Discovery Scan. To scan for Users, run a computer scan. Once scanning is complete you can view the role assignments for a user by clicking on their name in the **Discovery Network View** tab, or you can view user assignments for a role by clicking on the role name.

Notes

The following list of URLs should be used for network configuration when setting up Entra Heartbeat and RPC:

Heartbeat:

- https://graph.microsoft.com/.default
- https://login.microsoftonline.com/{Directory (tenant) ID of Application Registration}/oauth2/v2.0/token

RPC:

- https://graph.microsoft.com/.default

Local Account Discovery Methods

Remote Procedure Calls (RPC)

This is the method that is used for local account discovery for all versions of Secret Server prior to release 8.6.000000 and is the default for all upgrades and fresh installations. It uses the same technology as the Windows remote password changing in Secret Server and is the most dependable and proven of the options. It can, however, be slower in some environments when scanning computers over a WAN.

Windows Management Instrumentation (WMI)

This method uses the WMI technology to query the Windows computer. In some environments, this method can be faster than the Remote Procedure Call. It does, however, require having the proper Windows permissions and network configuration setup correctly for WMI to run.

Attempt WMI First, and Failover to RPC if Needed

This option attempts to use the WMI method first, and if that fails to work correctly, it attempts the RPC method for local account discovery. This option is potentially slower because it has the possibility of performing two separate scans for each computer.

Google Cloud Platform Discovery

Overview

Secret Server can manage Google Cloud Platform (GCP) service accounts and VM instances. This feature allows users to run discovery to pull and manage VM Instances, as well as import and manage GCP service accounts.

> Accounts with Owner Permissions within Google's Admin panel cannot be granted API permissions by Google Design. Please create a new user account within Google for Secret Server's access into Google.

Configuration

Task 1: Creating GCP Service Accounts

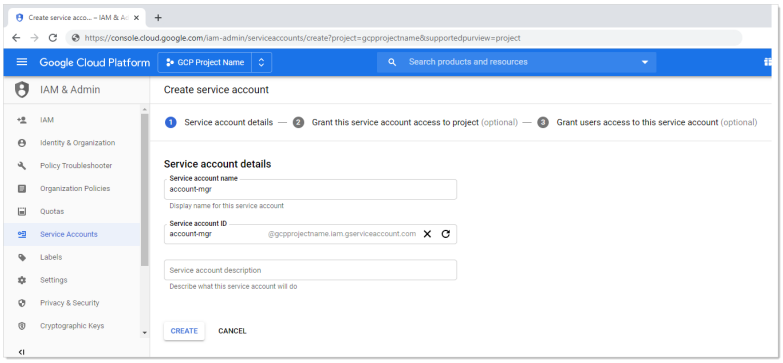
These are special accounts created in GCP to make authorized API calls for Compute Engine and other GCP applications.

> See GCP Service Accounts for more information.

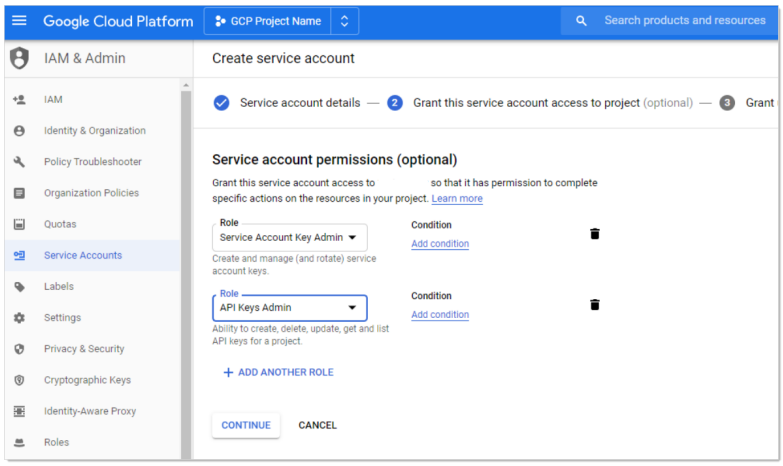
Secret Server uses the GCP service account to make authorized API calls to GCP to pull projects, zones, instances, service accounts and service account keys.

To create the service account:

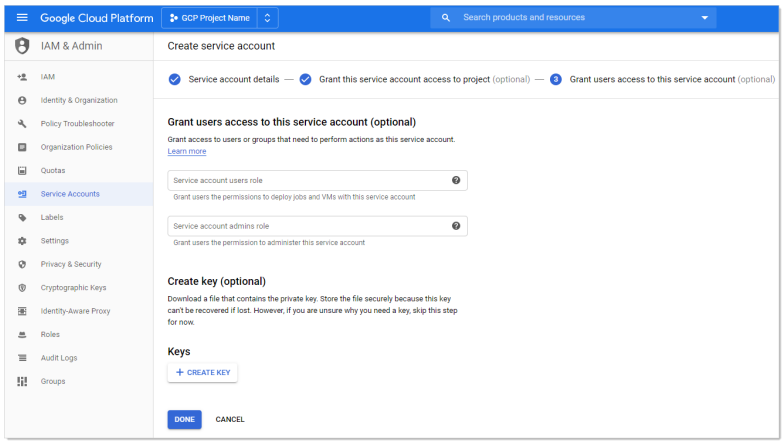
1. Click the **IAM & Admin** dropdown list in the left menu in GCP and select **Service Accounts**. A list of service accounts appears.
2. Click the **+ Create Service Account** button. The "Service account details" page of the Create Service Account wizard appears:



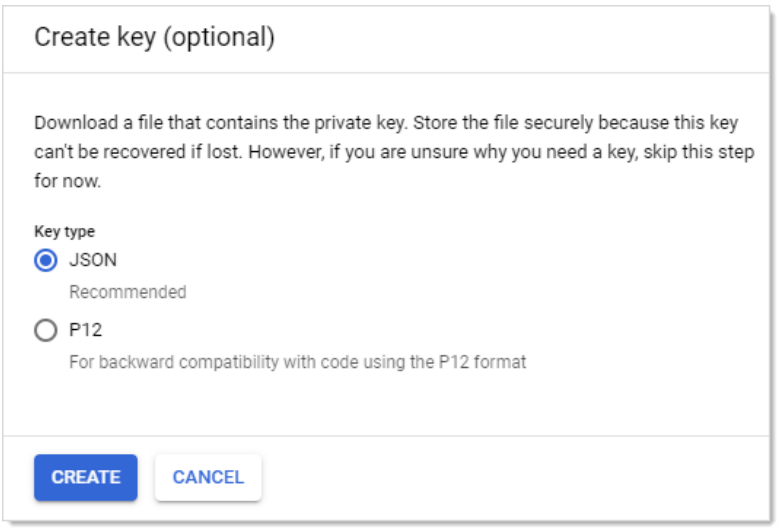
3. Type the service account name in the **Service Account Name** text box.
4. Start to type the service account ID name and select the service account in the **Service Account Name** text/list box.
5. Click the **Create** button. The "Grant this service account access to project (optional)" page appears:



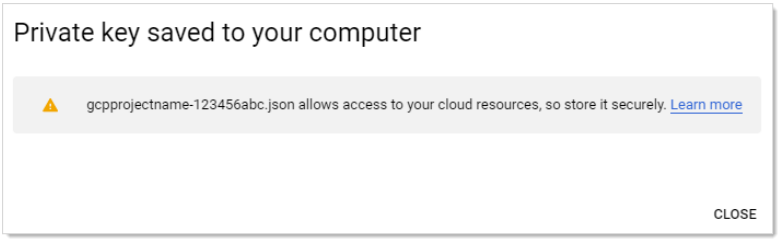
6. Click the **Role** list box and select **Service Account Key Admin**.
7. Click the **+ Add Role** button to add another role.
8. Click the new **Role** list box and select **API Keys Admin roles**.
9. Click the **Continue** button. The "Grant users access to this service account (optional)" page appears:



10. Click the **+ Create Key** button in the **Keys** section. The "Create key (optional)" popup appears:



11. Click to select the **JSON** selection button.
12. Click the **Create** button. This creates and downloads a JSON private key file. A confirmation popup appears:



13. Click the **Close** button in the bottom right. The service account is created, and its JSON private key is on your computer.

> Note where you downloaded the file. You will need it later in this instruction.

> For more information on this process, see Creating and managing service accounts on the GCP website.

Task 2: Setting GCP Permissions

GCP permissions are IAM permissions from the IAM & Admin section of GCP. Without the proper permissions, GCP discovery, RPC, and heartbeat may not function properly.

For the service accounts to have access to a project, you must add the service account IAM permissions in each Project. If you did not add the permissions when you created the service account, you need to add the IAM permissions in the project they were created in as well.

Discovery

To run discovery in Secret Server, the GCP service account needs the "project viewer" read only permission, which can list projects, zones, service accounts, and instances.

To add the permission In GCP:

1. Click the **IAM & Admin** dropdown list in the left menu in GCP and select **IAM**. The "Permissions for project..." page appears.
2. Click the **Add** button. The "Add member to..." page appears.
3. Type the service account email address in the **Members** text box.
4. Click the **Roles** dropdown list to select **Project > Viewer** (you can also type it).
5. Click the **Add** button. The new member appears in the table on the "Permissions for project..." page.

RPC/Heartbeat

To run RPC/Heartbeat in Secret Server, the service account needs the "service account key admin" permission, which can create, delete, and rotate service account keys.

To add the permission In GCP:

1. Click the **IAM & Admin** dropdown list in the left menu in GCP and select **IAM**. The "Permissions for project..." page appears.
2. Click the **Add** button. The "Add member to..." page appears.
3. Type the service account email address in the **Members** text box.
4. Click the **Roles** dropdown list to select **Service Account Key Admin** (you can also type it).
5. Click the **Add** button. The new member appears in the table on the "Permissions for project..." page.

Task 3: Creating a GCP IAM Service-Account Secret

Secret Server now has a build in GCP IAM Service Account Key template.

> To create a Secret using GCP IAM service account key template, you must have the service account's JSON private key file from GCP (created earlier).

Create a new secret (see "Creating Secrets" on page 1146 for details):

1. Search for **All secrets**, and click **Cretae secret**. The Create New Secret page appears.
2. Select **Google IAM Service Account Key** as the template. Another Create New Secret page, tailored to GCP, appears.
3. Click **No Folder Selected** to select a folder for the new secret.
4. Type the secret's name in the **Secret Name** text box.
5. Type the service account email address (use client_email from the JSON private key file) in the **Email** text box.
6. Type the private key ID (use private_key_id from the JSON private key file) in the **Private Key ID** text box.

7. Click the **Change** button to upload the JSON private key file you created earlier.
8. Click the **Create Secret** button.

Task 4: Creating an RPC/Heartbeat Password Changer

Secret Server can check if a service Account key is valid and can rotate the Service Account key. This should work the same as any other RPC or Heartbeat. RPC and Heartbeat must be enabled

RPC/Heartbeat can be tested from the Password Changers page

1. In Secret Server, Search for **Remote Password Changing.**
2. Click **Options** and select **Configure Password Changers** from the dropdown. The Password Changers Configuration page appears.
3. Click the **Google IAM Service Account Key** link. The Google IAM Service Account Key page appears.
4. Test the heartbeat: Click the **Test Action** button in the **Verify Password Changed Commands** section. The Test Action popup appears.
5. Ensure that the **JSONPRIVATEKEY** text box is populated. The others are optional.
6. Click **OK**. The popup goes away. If successful, the **Password Verify was Successfull** message appears on the previous page.
7. Test RPC: Click the **Test Action** button in the **Password Change Commands** section. The Test Action popup appears
8. Ensure that the **JSONPRIVATEKEY** and **Email** text boxes are populated. The others are optional.
9. Click the **OK** button. The popup goes away. If successful, the P**assword Successfully Changed** message appears on the previous page.
10. Test RPC with admin credentials: Click the **Test Action** button in the **Password Change By Admin Credentials Commands** section. The Test Action popup appears.
11. Ensure that all text boxes are populated except **JSONPRIVATEKEY**, **Admin Email**, and **Admin PRIVATEKEYID**, which are optional.
12. Click the **OK** button. The popup goes away. If successful, the **Password Successfully Changed using Admin Credentials** mesaage appears on the previous page.

Task 5: Creating a GCP Discovery Source

Secret Server now has a built-in GCP discovery source wizard that creates the scanners to pull the projects, zones, service accounts. To create a GCP discovery source:

1. In Secret Server, Search for **Discovery.**
2. Under the **Sources** tab, click **Create** and select **GCP (Google Cloud Platform)** from the dropdown. The GCP Discovery Source wizard Overview page appears.
3. Type the name of the GCP discovery source in the **Name** field.
4. Select the related site from the **Site** dropdown.
5. Leave GCP **(Google Cloud Platform)** as is in the **Source type** field.

6. Click **No secret selected** to select the related secret from the list, or **Create new secret** to create a new secret in the **Secret** section.
7. When done, click **Save**, and in the Add flow popup select **GCP** for the flow, and check the related options if prompted:
   - **GCP Service Accounts**: This is an account scanner that scans each project and pull all of the GCP Service accounts.
   - **GCP Windows Machines**: This is a machine scanner that scans each project and pulls all of the GCP Windows OS VM instances.
   - **GCP Non-Windows Machines**: This is a machine scanner that scans each project and pulls all of the GCP Non-Windows OS VM instances.

   When done, click **Add**.

Viewing Discovery Scanners for the GCP Discovery Source

To view these scanners:

1. In Secret Server, Search for **Discovery**.
2. Under the **Sources** tab, click the discovery source name link in the table. The Discovery Source page for it appears.
3. Select the **Scanners** tab, which lists the scanners.

Instance Custom Filter

This option is only available for the instance scanners. The Custom Filter Setting can be used to include or exclude instances using a filter expression on the name, label, or any other field allowed by GCP. The filter must:

- Be a string, number, or Boolean value
- Use these comparison operators: =, !=, >, or <
- Use parentheses ( ) around each filter
- Combine different filters using AND or OR (all caps). For example: `(name="instanceName") AND (labels.key="value")`

See Method: instances.aggregatedList for more on filtering instances.

Other useful filters:

Status:

`status="StatusValue"`

`StatusValue` can be `Running` or `Terminated`

Zone:

`zone=https://www.googleapis.com/compute/v1/projects/{ProjectName}/zones/{ZoneName}`

Unfortunately, at this time of this topic, Google has an open issue of the tag filter not working.

Importing Service Accounts

From the Discovery Network View, Secret Server can import Service Account keys and automatically take over the account. This import process will create a new Secret for the Service Account key, delete the associated key, create a new key, and save the json private key file with the Secret, so this can be easily managed by Secret Server.

To Import a Service Account

1. Search for **Discovery**.
2. Select the **Network View** tab.
3. In the **Item type** filter select **Service accounts** from the dropdown.
4. Click to select the related Service Account(s) to import, and click **Import**.
5. The **Import accounts and dependencies** wizard begins:
   a. **Scan Template**: Windows Service by default and can't be changed.
   b. **Site**: Select the related site from the dropdown.
   c. **Dependency Template**: Select Windows Service.
   d. **Dependency Privileged Account**: Click **No secret selected** to select the related secret.
   e. **Windows Services: Restart on Change**: Check to enable.
   f. When done, click **OK**.
6. When the **Bulk progress** pop up is completed, click **Close**.

GCP APIs

Overview

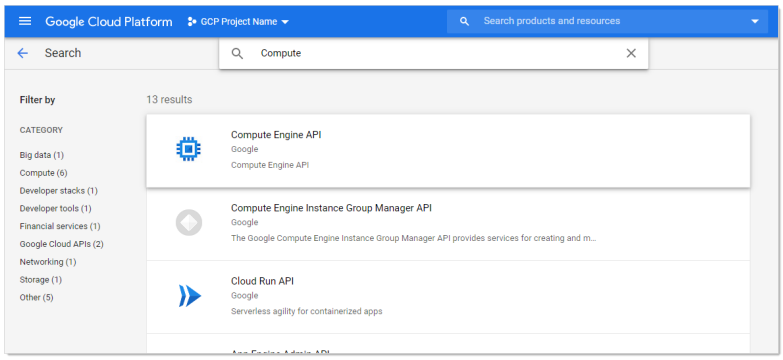
To make API calls to GCP, you need to enable the following APIs to use GCP discovery in Secret Server. More information can be found on the GCP Getting Started page. The APIs are:

- **Cloud Resource Manager API**: Used for managing GCP resource containers, such as Projects.
- **Compute Engine API**: Used for managing GCP instances (virtual machines).
- **Identity and Access Management (IAM) API**: Used for managing identity and access control for GCP resources, such as service accounts.

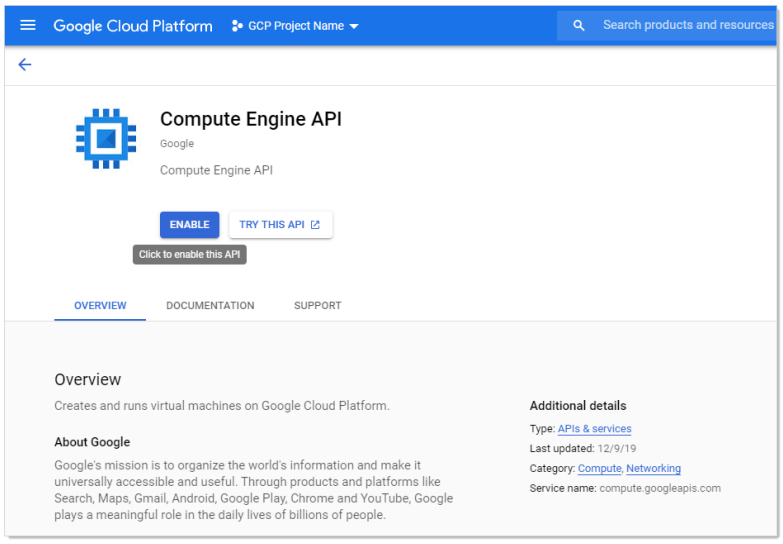
Enabling GCP APIs

In GCP:

1. In GCP, click the **APIs & Services** menu item and select **Library**. The Library page appears.
2. Type the name of the API in the Search text box and press **<Enter>**. Matching APIs appear:



3. Click the button for the desired API. That API's page appears:



4. Click the **Enable** button.

> If you're setting up a new instance and haven't used certain APIs before, you'll need to enable the Identify and Access Management (IAM) API. If you encounter a "Heartbeat Failure" message, just follow the link provided in the message to enable the IAM API. After that, give it a few minutes for the changes to take effect, then try enabling the Compute Engine API again.

Errors and Solutions

Create Keys Failed: Access Denied

Error

```
Create Keys Failed: AccessDenied, Google.Apis.Requests.RequestError Permission
iam.serviceAccountKeys.create is required to perform this operation on service account
projects/-/serviceAccounts/discovery-me@gcpprojectname.iam.gserviceaccount.com. [403] Errors
[ Message[Permission iam.serviceAccountKeys.create is required to perform this operation on
service account projects/-/serviceAccounts/discovery-
me@gcpprojectname.iam.gserviceaccount.com.] Location[ - ] Reason[forbidden] Domain[global] ]
```

Likely Cause

The service account used to rotate the key does not have necessary permission to perform this task.

Solution

1. Go to the GCP console.
2. Select **IAM > Permissions**.
3. Select the service account.
4. Add the **Service Account Key Admin** permission.
5. Once the service account has permission:
    a. In Secret Server, select the secret to rotate.
    b. Stop the current rotation.
    c. Try the operation again.

Create Keys Failed: Maximum Number of Keys on Account Reached

Error

```
Create Keys Failed: ArgumentError, Google.Apis.Requests.RequestError Maximum number of keys
on account reached. [429] Errors [ Message[Maximum number of keys on account reached.]
Location[ - ] Reason[rateLimitExceeded] Domain[global] ]
```

Likely Cause

The rotated service account has reached the maximum number of keys allowed. GCP maximum is 10 keys.

Solution

1. Go to the GCP console.
2. Select **IAM > Permissions**.
3. Remove the unused keys.
4. Once the service account has less than 10 keys, in Secret Server:
    a. In SS, select the secret to rotate.
    b. Stop the current rotation.
    c. Try the operation again.

Discovery Consumer: Syncing OUs Failed

Error

```
DiscoveryConsumer: Synchronizing Organizational Units failed for [Our Google Cloud]! Error:
An issue was encountered during the scan. Google.Apis.Requests.RequestError Access Not
Configured. Compute Engine API has not been used in project 123456 before or it is disabled.
Enable it by visiting
https://console.developers.google.com/apis/api/compute.googleapis.com/overview?project=123456
```

```
then retry. If you enabled this API recently, wait a few minutes for the action to propagate
to our systems and retry. [403] Errors [ Message[Access Not Configured. Compute Engine API
has not been used in project 123456 before or it is disabled. Enable it by visiting
https://console.developers.google.com/apis/api/compute.googleapis.com/overview?project=123456
then retry. If you enabled this API recently, wait a few minutes for the action to propagate
to our systems and retry.] Location[ - ] Reason[accessNotConfigured] Domain[usageLimits] ] ,
-2146233088
```

Likely Cause

The discovery service account used for has access to a GCP project that has not been set up or is disabled.

Solution

1. Go to GCP console.
2. Go to **Compute Engine > VM Instances**.
3. Set up the compute engine

This requires billing information.

Discovery Consumer: Syncing Machines Failed

Error

```
DiscoveryConsumer: Synchronizing Machines failed for [GCP Discovery Source]! Error: An issue
was encountered during the scan. Google.Apis.Requests.RequestError Invalid value for field
'filter': 'filtername="value"'. Invalid list filter expression. [400] Errors [ Message
[Invalid value for field 'filter': 'filtername="value"'. Invalid list filter expression.]
Location[ - ] Reason[invalid] Domain[global] ] , -2146233088 Exception Caught:
Google.Apis.Requests.RequestError Invalid value for field 'filter': 'filtername="value"'.
Invalid list filter expression. [400] Errors [ Message[Invalid value for field 'filter':
'filtername="value"'. Invalid list filter expression.] Location[ - ] Reason[invalid] Domain
[global] ] Attempting GCP scan for Instances Parameters are valid. Checking for permissions
to list Projects.. Has permissions to list Projects.. Starting scan..
```

Likely Cause

The instance scanner custom filter is not valid.

Solution

1. In Secret Server, go to the GCP discovery source.
2. Edit the instance scanner.
3. Update the "custom filter" setting.

See Method: instances.aggregatedList for more on filtering instances.

Discovery Consumer: Machine Scan Completed but Computers Failed Authentication

Error

```
DiscoveryConsumer: Synchronizing Machines failed for [GCP Discovery Source]! Error: An issue
was encountered during the scan. Google.Apis.Requests.RequestError Invalid value for field
'filter': 'filtername="value"'. Invalid list filter expression. [400] Errors [ Message
[Invalid value for field 'filter': 'filtername="value"'. Invalid list filter expression.]
Location[ - ] Reason[invalid] Domain[global] ] , -2146233088 Exception Caught:
Google.Apis.Requests.RequestError Invalid value for field 'filter': 'filtername="value"'.
Invalid list filter expression. [400] Errors [ Message[Invalid value for field 'filter':
'filtername="value"'. Invalid list filter expression.] Location[ - ] Reason[invalid] Domain
[global] ] Attempting GCP scan for Instances Parameters are valid. Checking for permissions
to list Projects.. Has permissions to list Projects.. Starting scan..
```

Likely Cause

The instance scanner custom filter is not valid.

Solution

1. In Secret Server, go to the GCP discovery source.
2. Edit the instance scanner.
3. Update the "custom filter" setting.

See Method: instances.aggregatedList for more on filtering instances.

Invalid Grant: Account Not Found

Error

```
An issue was encountered during the scan. Error:"invalid_grant", Description:"Invalid grant:
account not found", Uri:"", -2146233088
```

Likely Cause

The service account does not exist in GCP. There may be a typo or it was deleted.

Solution

1. Go to GCP console.
2. Create a service account to use. See Task 1: Creating GCP Service Accounts.

Request Error: Caller Does Not Have Permission

Error

```
An issue was encountered during the scan. Google.Apis.Requests.RequestError The caller does
not have permission [403] Errors [Message[The caller does not have permission] Location[ - ]
Reason[forbidden] Domain[global]], -2146233088
```

Likely Cause

The service account does not have permissions in IAM.

Solution

1. Go to GCP console.
2. Select IAM.
3. Click the **Service Account** menu item to create a service account with the desire permissions. See Task 1: Creating GCP Service Accounts and Task 2: Setting GCP Permissions.

Unix Account Discovery

Unix account discovery follows these steps:

1. During configuration, Secret Server is given a list of IP address ranges and ports on the network to scan for. See "Creating a Unix Discovery Source" below
2. Within that range, discovery searches for computers listening on the specified ports (default is 22). The ports and other parameters are configurable via the scanners belonging to the discover source. See "Introduction to Discovery Sources, Scanners, and Templates" on page 538
3. Secret Server then attempts to use DNS to resolve the found IPs to discover the associated computer name.
4. Secret Server saves all the collected information to its database.
5. Secret Server then attempts to connect to each computer using the provided credentials and query for a list of user accounts on the target system.

Creating a Unix Discovery Source

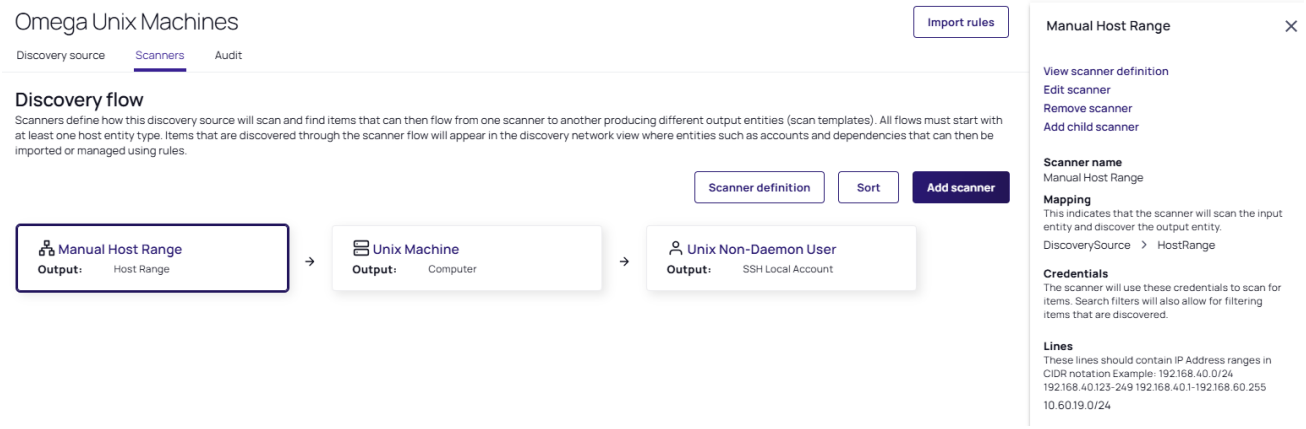
Discovery sources define a set of discovery operations. You must create a discovery source based on the built-in types prior to running discovery.

Creating the Discovery Source

See "Creating a Discovery Source" on page 546 for details.

Editing Unix Discovery Source Scanners

1. Select **Discovery > Sources**. The Sources tab of the Discovery page appears.
2. In the list of existing discovery sources, click the name of the one you want to edit.
3. Select the **Scanners** tab. The Discovery flow for that source and its scanners appear:



To add a dependency scanner, one needs to be available which has an input template matching an unused output scan template. The output template must be unique for each scanner, but the input template may be shared.

4. **Manual Host Range** is typically the first scanner of the discovery source, which is the input template. This means the initial data comes from information you enter into the discovery source when you create it. The output template is named Host Range.
5. Click the **Manual Host Range** scanner. The details pop-out appears to the right of the screen. Note the following:
   - You have four links at the top, View scanner definition, Edit scanner, Remove scanner, and Add child scanner.
   - The **Mapping** section indicates the scanner will look through the input entity and discover the output entity. For this scanner these are **DiscoverySource** and **HostRange**, respectively.
   - The **Credentials** section displays the secret credentials used to scan for items and allows for filtering.
   - The Unix discovery source finds all machines and local accounts on a set of manually defined host ranges for Unix machines accessible with SSH.
   - The **Lines** section lists multiple, distinct IP address ranges on the same discovery source.
6. The **Unix Machine** scanner is the consumer of the Computer output template, and has the following configurations available that differ from the previous scanner:
   - The **Mapping** section the input entity that is used and what the scan will discover as the output entity. For example: HostRange > Computer.
   - The **Ports** section displays the comma-separated list of port values (1-65535) used for the scanner.
   - The **Max TCP Connections** section determines how many concurrent TCP connections will be used during a scan.
   - The **Attempt Authentication** option allows the server to attempt to login and determine the operating system of any machines found. This requires a Credential Secret and a Command Set.

- The **Parse Format** option details the format in which the scanner will parse the operating system and hostname from a found machine after the commands are run, when using authenticated scanning.
- The **Identify computer by host name** option, if true, allows for computers to be considered unique by host name, not just their IP address. This is helpful if one machine is bound to multiple IP addresses. If you change this option after having run discovery any secrets previously linked will not automatically transfer to the new computer.

7. The **Unix Non-Daemon User** scanner has the following configurations available that differ from the previous scanners:
   - The **User Regex Format** text box contains a regular expression that finds the lines of text received during the scan that are valid for user parsing. The matched groups in the regular expression should correspond to the comma-separated items in the parse format.
   - The **Parse Format** text box defines the order of values retrieved during a scan. If the parse names match the fields defined in the imported secret, the values are populated from the data collected on the scan.
   - The **Newline Separator Character** dropdown defines the character that divides the lines in the output received during a scan.

> There are other discovery source-specific scanners available for use with different options to choose from. Each option is detailed when the scanner is selected.

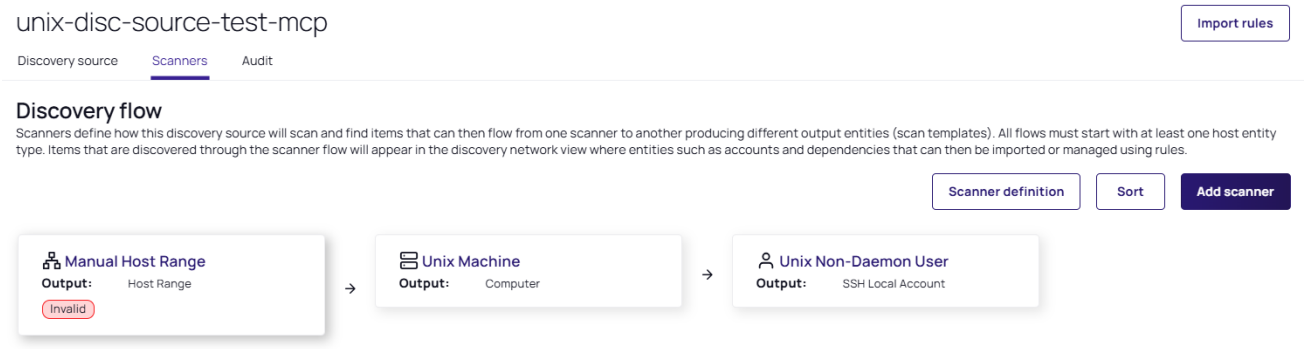
Discovering SSH Public Keys

Secret Server can scan for SSH public keys on Unix machines. You can add this ability in the scanner settings section of Unix Account Discovery.

> This document assumes you have already created a Unix account discovery source. See "Creating a Unix Discovery Source" on page 633.

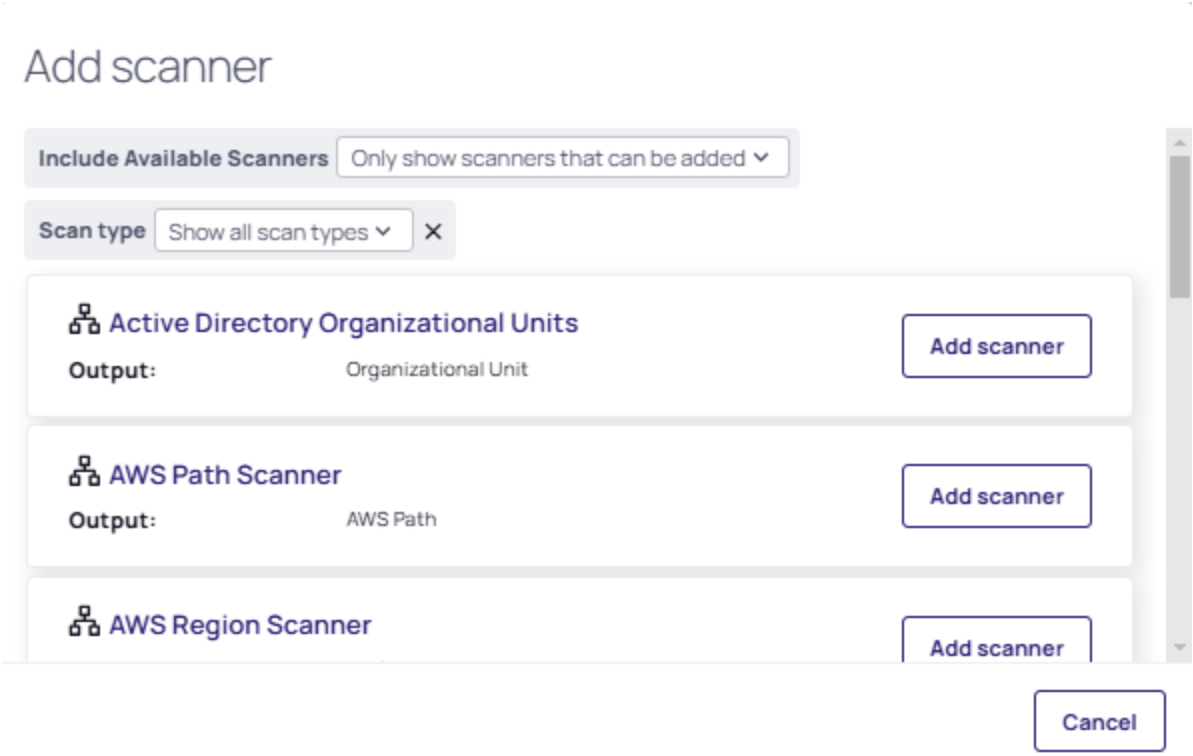
Task 1: Viewing Discovery Scanners for the Unix Discovery Source

1. Access **Discovery** from the side menu and select **Sources**.
2. Select the Unix discovery source that you created in the previous section. The **Discovery Source** tab for it appears.
3. Select the **Scanners** tab. The discovery source **Scanners** page appears:



Task 2: Adding the SSH Public Key Scanner

1. In the discovery source **Scanners** page, click **Add Scanner**. The Add Scanner popup appears:



2. Select the **SSH Public Key Scanner**.
3. Select the newly added **SSH Public Key Scanner**. The details open in a panel on the right side of the screen.
4. Click **Edit Scanner**. Various sections in the details panel are now editable.
5. Click the **Add Secret** link and choose one or more secrets that have Unix sudo or su permissions for the host range selected in the discovery source.

   These permissions are necessary to navigate each user's home directory on a machine in search of SSH public key entries in the user's `<user home directory>/.ssh/authorized_keys` file.
6. Click **Save**.

Task 3: Importing SSH Public Keys

From the **Discovery Network View**, Secret Server can import SSH public keys and potentially take over an account. The import process creates a new secret for the SSH public key in one of two ways:

- Including a provided matching SSH private key and passphrase.
- Taking over the key by creating a new key and saving the private key file and passphrase with the secret. This can be easily managed by Secret Server.

Prerequisites

Before proceeding with importing an SSH Public Key based account, ensure that an SSH key pair has been generated and that the public key is available for import.

If you do not already have an SSH key for your account user, follow these steps:

1. Generate one using the following command:

   ```
   ssh-keygen -t rsa -b 4096 -C "your-email@example.com"
   ```

   This creates a public key (`id_rsa.pub`) and a private key (`id_rsa`) in the `~/.ssh/ directory` (Linux/macOS) or `C:\Users\YourUser\.ssh\` (Windows).

   The public key (`id_rsa.pub`) is the file that will be imported.

2. If you already have an SSH key pair, verify that the public key exists by running:

   ```
   cat ~/.ssh/id_rsa.pub
   ```

   If no output appears, an SSH key may not have been created or may be stored under a different filename.

3. Before importing, verify whether the public key must be linked to an account in the system:

   - If an account must have a public key before import, manually add the key:

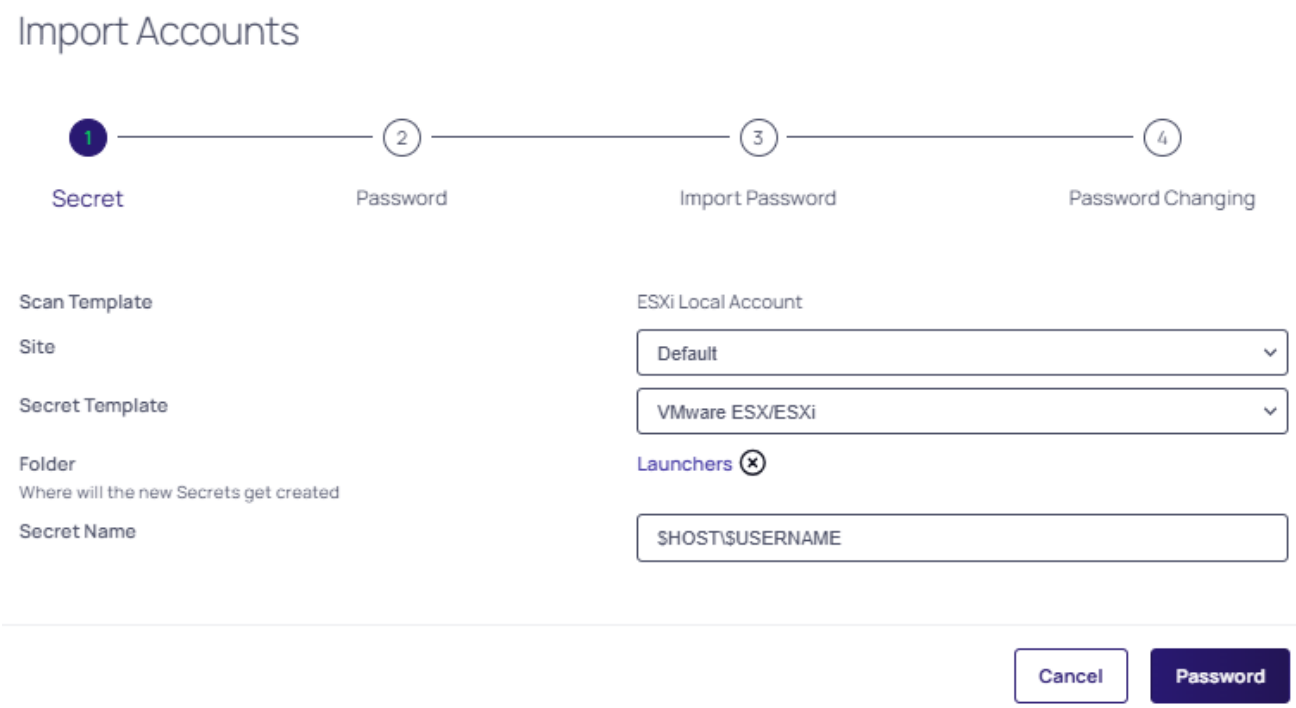
     ```
     ssh-copy-id username@remote-server
     ```

   - If the import process automatically associates the key, ensure the system can discover existing public keys.
   - If accessing a remote server, ensure the key is added to the `~/.ssh/authorized_keys` file on that server.

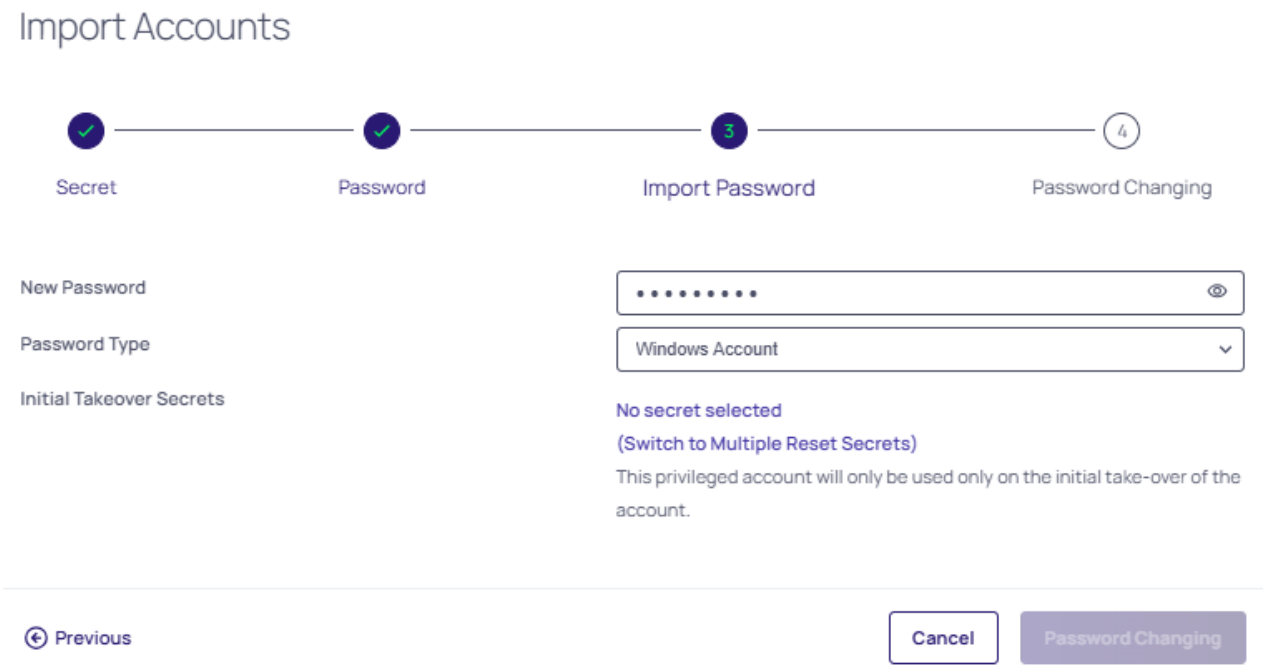
   Once the public key is available, proceed with the steps outlined in "To Import an SSH Public Key" below.

To Import an SSH Public Key

1. Access **Discovery > Network View**. The Discovery Network View page appears listing all discovered and managed items.
2. Set the **Item type** option to **Computer accounts**.
3. Select the account with your associated key from the list. The Computer account detail panel opens to the right.
4. Click the **Actions** dropdown list and choose **Import**. The import Accounts popup appears:

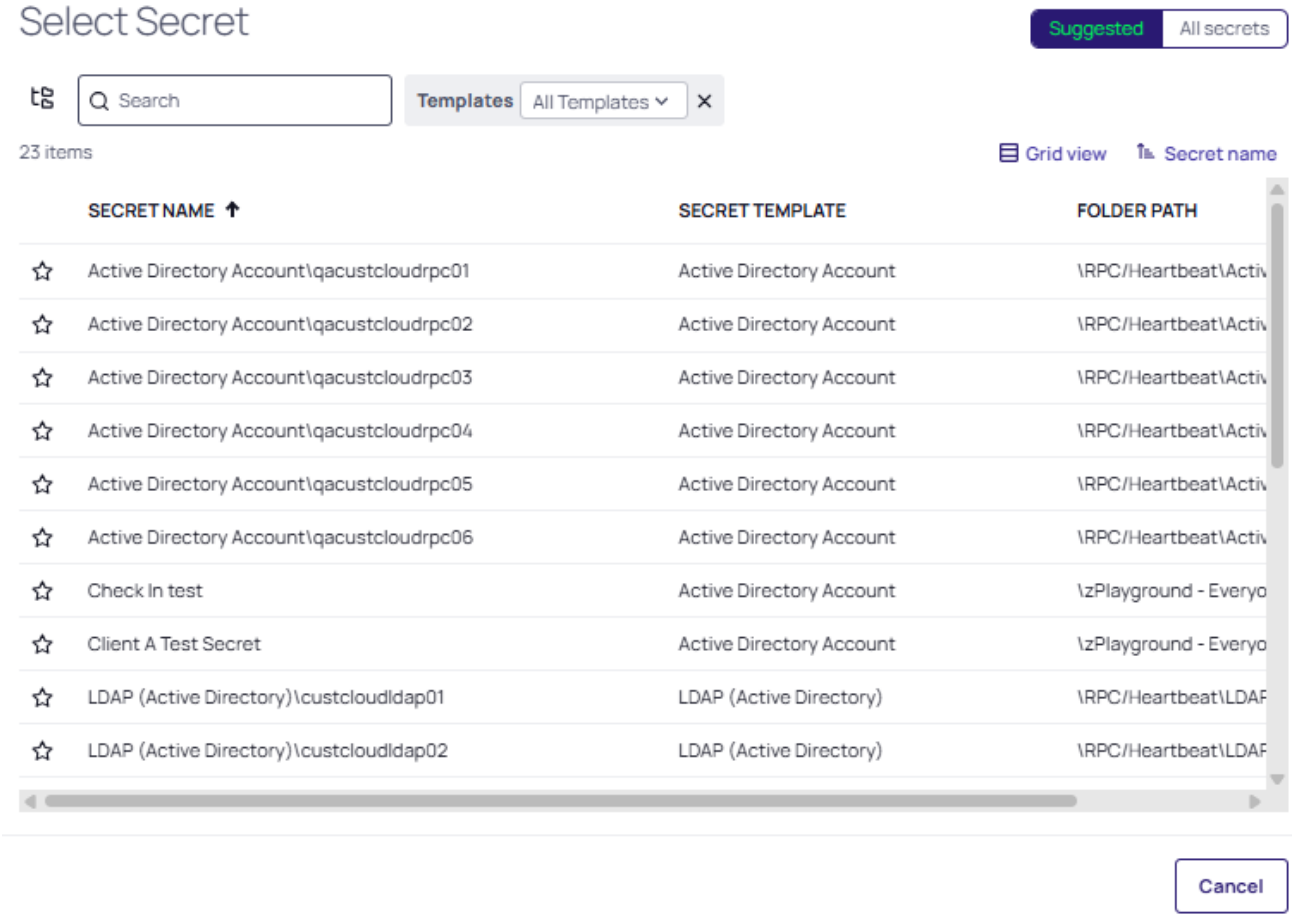


5. Click the **Site** dropdown list to select a site.
6. Click the **Secret Template** dropdown list to select a template. Usually only one is available.
7. Click the **Folder** link to select a folder. This is where will the new secrets will be created.
8. Type a name in the **Secret Name** text box. (It auto fills with `$MACHINE\$USERNAME`).
9. Click the **Password** button. The Password screen in the popup appears.
10. Select one of the three options:
    - **I know the current password and do not want to change it**
    - **Assign a new specific password to all accounts**
    - **Generate a random password for each account**
11. Click the **Import Password** button, the following will happen based on your choice:
    - If you chose "I know the current password and do not want to change it" you will be prompted to provide the current password. before being able to click **Password Changing**.
    - If you choose "Assign a new specific password to all accounts" you will be prompted to type in a new password, choose the password type, and choose the Initial Takeover Secrets from the available link:

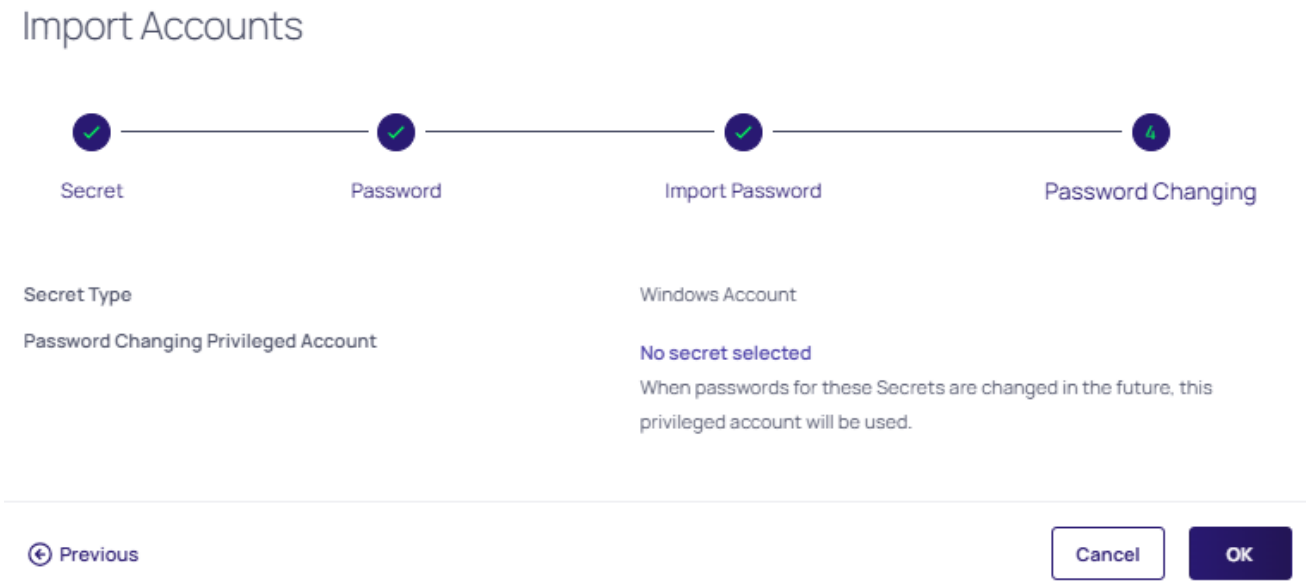


- If you chose "Generate a random password for each account" you will be prompted to choose the password type and the Initial Takeover Secrets from the available link.

12. For the two choices that require selecting Initial Takeover Secrets from the available link, choose a secret:



13. Click the **Password Changing** button, the Password Changing section appears:



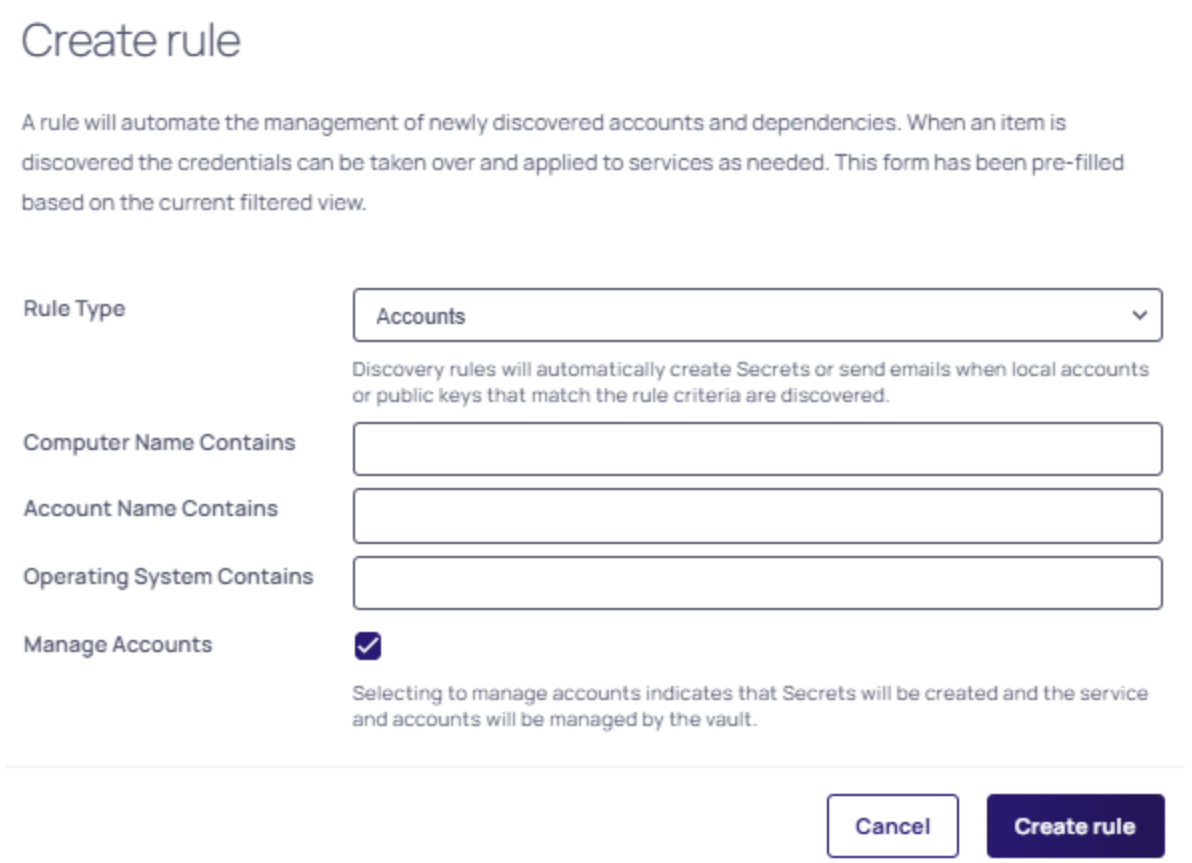
14. Click the **Add Secret** link to choose a Unix sudo or su secret for future key rotations.
15. Click the **OK** button to complete the dialog and import the selected secrets.
16. The **Bulk Progress** popup will appear as the process runs. If successful, you will see "Task complete: DiscoveryImport".
17. Click **Close** when done. The new secret will now appear in the folder you designated previously.

Task 4: Creating an Import Rule

Discovery rules automatically create secrets and send emails when local accounts or public keys match the rule.

To create a rule to import discovered SSH public keys:

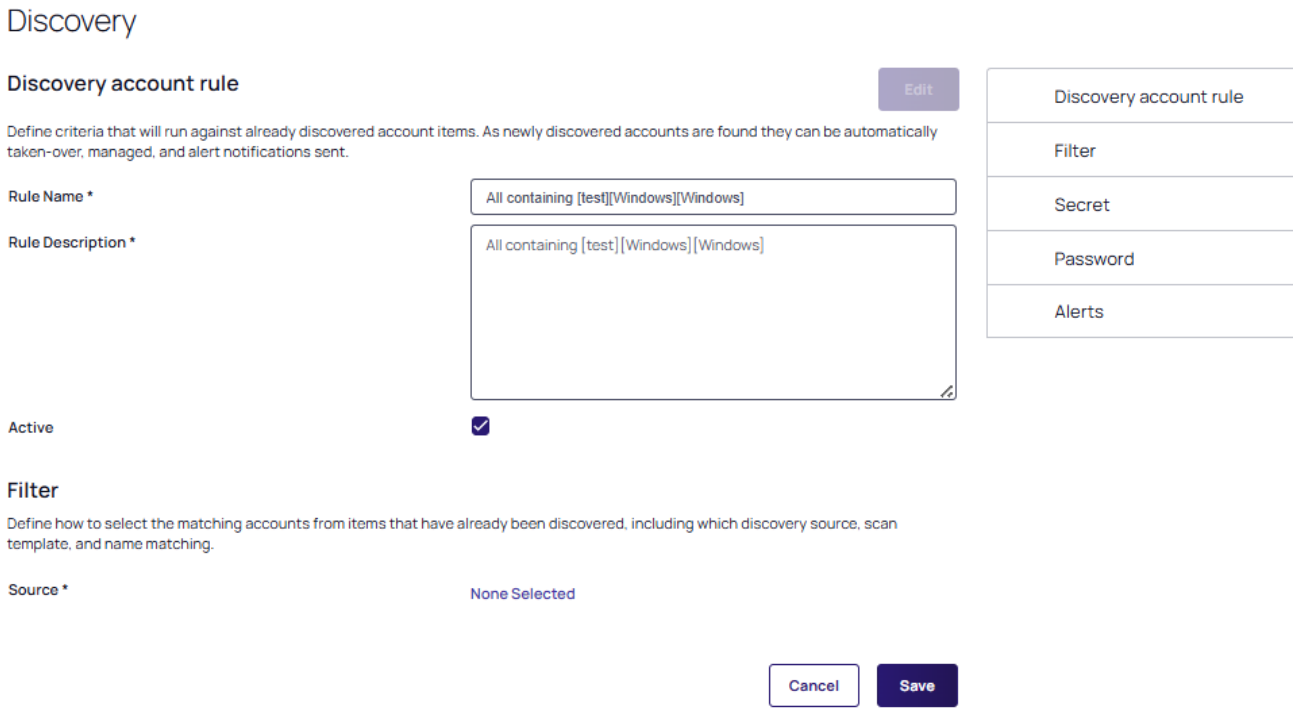
1. Access **Discovery > Network View**. The Discovery Network View page appears.
2. Click the **Create Rule** button. The Create Rule wizard appears:



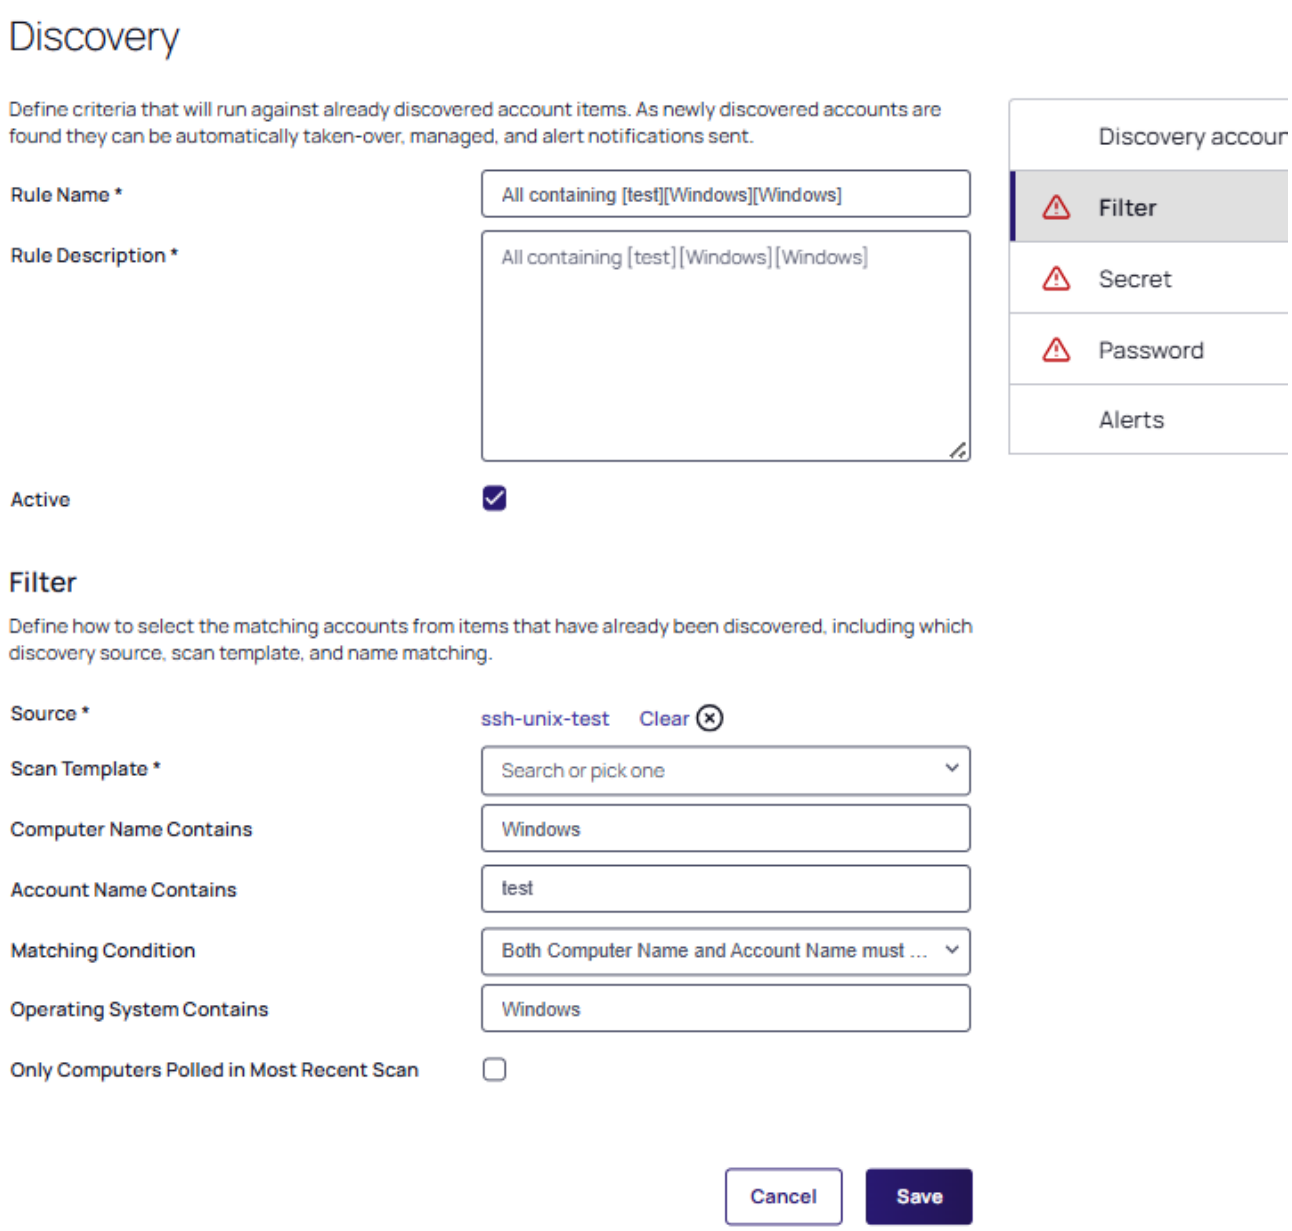
3. Select the **Rule Type**: Accounts or Dependencies.
4. Fill in the following fields if you chose Accounts:
   - Computer Name Contains
   - Account Name Contains
   - Operating System Contains

> Make sure the Manage Accounts checkbox is selected. Selecting to manage accounts indicates that secrets will be created and the service and accounts will be managed by the vault.

5. Click **Create Rule** to save your changes. The Discovery Account Rule page appears:



6. The **Rule Name** field contains the values of the three fields you completed in step 4. The Rule Description contains a duplicate of the rule name values. You can change both manually.
7. Make sure the **Active** checkbox is selected.
8. Under the **Filter** section, click on the **Source** link that displays as **None Selected**. The Pick OU popup appears.
9. Select the Unix source you created in step 1 from the list and the Filter section will automatically display fields like the following:



10. Most of the fields are completed automatically. Choose the **Scan Template** from the dropdown list, in this case **SSH public key**:

Filter

Define how to select the matching accounts from items that have already been discovered, including which discovery source, scan template, and name matching.

Source *: ssh-unix-test Clear

Scan Template *: SSH public key

Computer Name Contains: Windows

Account Name Contains: test

Matching Condition: Both Computer Name and Account Name must ...

Operating System Contains: Windows

Only Computers Polled in Most Recent Scan: ☐

Public key:

Secret

Define where, how, and what type of new Secret will be created

Create Secrets: ☑

Secret Template *: Search or pick one

Folder *: No Folder Selected

Secret Name *: $MACHINE$USERNAME

New Secret Permissions *: Copy permissions from folder

Site *: Search or pick one

Alerts

Send notifications of newly discovered accounts or threshhold limits

Accounts Found Notification: ☐ Send email alert for newly discovered accounts

Cancel Save

11. You can alter the **Marching Condition** and select or deselect the **Only Computers Polled in Most Recent Scan** checkbox.
12. Add in the Public Key for your account user (previously created or associated in the prerequisites).
13. In the **Secret** section under **Filter** define where, how, and what type of new secret will be created:
    a. Select the **Create Secrets** checkbox.
    b. From the **Secret Template** dropdown list, choose one of the two options: **Unix Account (SSH Key Rotation - No Password)** or **Unix Account (Privileged Account SSH Key Rotation - No Password)**.
14. Click the **Folder** link to select a folder in which the secret will be created.
15. Type a name in the **Secret Name** text box (It auto fills `$MACHINE\$USERNAME Key`).
16. Click the **New Secret Permissions** dropdown list to choose how permissions are propagated for the new secret, either copied or inherited from the folder.
17. Click the **Site** dropdown list to select a site. The **Password** section appears.
18. In the **Password** section, select one of the following options:
    a. **I have the matching private key** - This choice causes the following to appear:
        i. **Current Private Key field**: copy and paste the account's current private key in this field.
        ii. **Current Passphrase**: copy and paste the account's current passphrase in this field.
        iii. **Password Changing Privileged Account**: click the link to select a secret.

        > When passwords for the secret added here are changed in the future, this privileged account will be used.

    b. **I want to change the public SSH key on the Account** - This choice causes the following to appear:
        i. **Take-over threshhold**: this field displays 1000 by default and can be changed to another value.

        > If the number of accounts that will be taken over exceeds the max threshold, the import is canceled and the subscribed users below are notified by email.

        ii. **Initial Takeover Secrets**: this button allows you to add multiple secrets to modify.

        This privileged account will only be used on the initial takeover of the account.

        iii. **Password Changing Privileged Account**: this button allows you to add multiple secrets to modify.

        When passwords for these secrets are changed in the future, this privileged account will be used.
19. In the **Alerts** section, you have the option of selecting to send an email alert for newly discovered accounts.

    Example:

Secret

Define where, how, and what type of new Secret will be created

Create Secrets ☑

Secret Template * Unix Account (Privileged Account SSH Key Rot...

Folder * Miruna Paun ⊗

Secret Name * $MACHINE\$USERNAME Key

New Secret Permissions * Copy permissions from folder

Site * GAMMA

Password

Specify how to gain access to this account and whether or not it should be managed

Password *
- ○ I have the matching private key.
- ◉ I want to change the public SSH key on the Account.

Take-over threshhold * 1000

If the number of accounts that will be taken over exceeds the max threshold, the import is cancelled and the subscribed users below are notified by email.

Initial Takeover Secrets * Add Secret

- Check In test Remove

This privileged account will only be used only on the initial take-over of the account.

Password Changing Privileged Account Add Secret

- ad-disc-test-mcp Remove

When passwords for these Secrets are changed in the future, this privileged account will be used.

Alerts

Send notifications of newly discovered accounts or threshhold limits

Accounts Found Notification ☐ Send email alert for newly discovered accounts

Cancel Save

20. Click **Save** when all your settings are complete.
21. Return to the **Discovery Network View** page.
22. Click **View Rules** and select the **Account** or the **Dependency** tab depending on your rule type, to see a list of rules including the one you just created.

Troubleshooting SSH Key Import Issues

If the import fails, consider the following:

- **Public key not found**: Ensure the key exists in `~/.ssh/` and is readable.
- **Authentication failures**: Check that the public key is correctly associated with the target account.
- **Debugging SSH authentication**: Increase logging verbosity with by using the `ssh -vvv username@remote-server` command.
- **Scanning for public keys**: If the system supports key discovery, verify that the process is correctly configured.

VMware ESX/ESXi Account Discovery

During configuration, Secret Server is given a list of IP addresses or computer names that correspond to ESX or ESXi servers. Secret Server then connects to each server using the provided credentials to query for a list of user accounts on the target system.

VMware ESX/ESXi Account Discovery and RPC Configuration

Please see Discovery General Topics for a comprehensive guide to configuring and using discovery.

Download Locations

- Run the following PowerShell command:

  ```
  Install-Module -Name VMware.PowerCLI -Force
  ```

- If the server does not have internet access, download supported versions of PowerCLI from VMware using the following link: VMware PowerCLI

You should use this link only if the server does not have internet access. The preferred installation method is using the PowerShell command above.

Overview

The ESX/ESXi (API) password changer verifies (using heartbeat) and changes VMware ESX/ESXi passwords via the vSphere API. Password changing and discovery requires PowerCLI 6.5.1 or higher.

Either PowerCLI 6.5.1 or higher must be installed on the servers running discovery or your local Secret Server machine or machines running distributed engine. Earlier versions of the password changer are now deprecated.

If you get an error about not being able to load file or assembly VMware.Binding.Wcf.dll or VMware.Binding.WsTrust.dll, you can copy either file from location: *C:\Program Files\WindowsPowerShell\Modules\VMware.VimAutomation.Common\X.X.X.X\net45* - where *X.X.X.X* is the number of version installed on your system, and paste it to the location: *C:\Program Files\WindowsPowerShell\Modules\VMware.Vim\X.X.X.X\net45* - where *X.X.X.X* is the number of version installed on your system.

Starting with version 13.1.0 the VMware PowerCLI installation files no longer have *net45* folders. For versions 13.1.0 and greater use the *net472* folders instead.

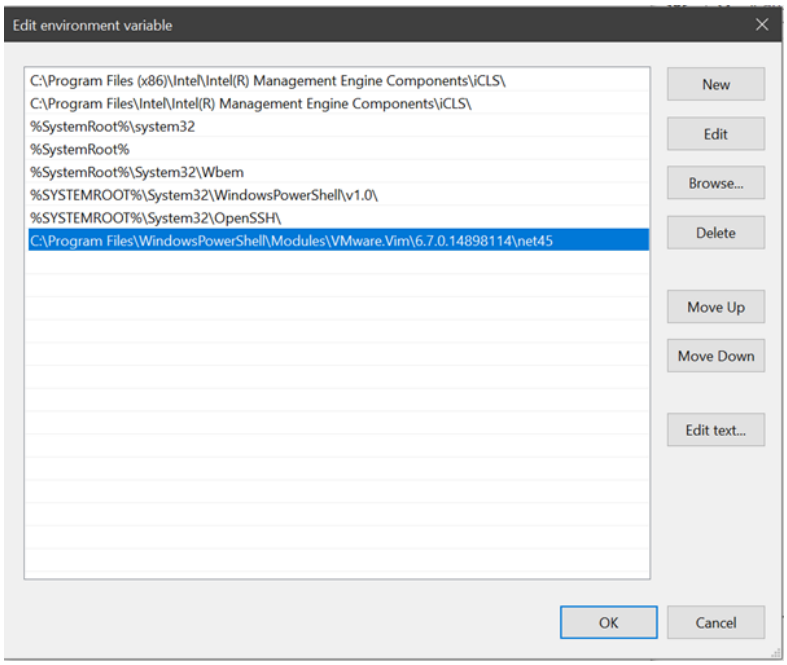
Details

Secret Server searches the machine's Windows PATH environment variable for the VMware SDK, therefore installing the correct version of it is all that is needed. On the machine you install VMware PowerCLI, update the Windows PATH environment variable to include the folder where the file `VMware.Vim.dll` is located.

After installing the VMware PowerCLI, the default installation path is: `C:\Program Files\WindowsPowerShell\Modules\VMware.Vim\[version]\net45`. The PowerCLI installation path **must be** in the system PATH variable.

To edit your PATH:

1. Add `C:\Program Files\WindowsPowerShell\Modules\VMware.Vim\[version]\net45` to the PATH using the system panel (sysdm.cpl).
2. From the **System Properties** dialog, select **Advanced** tab
3. Click **Environment Variables...**
4. Under the **System Variables** section, highlight **Path** then **Edit**. The Edit Environment Variable dialog box appears:



5. Click**New**.
6. Type `C:\Program Files\WindowsPowerShell\Modules\VMware.Vim\[version]\net45`, similar to the example above.
7. Click**OK**when done.

> Note that starting with version 13.1.0 the VMware PowerCLI installation files no longer have *net45* folders. For versions 13.1.0 and greater use the *net472* folders instead.

Setting Up and Troubleshooting VMWare ESXi with Secret Server

The following script can be used to setup the PowerCLI components on a Secret Server Distributed Engine automatically. The script can also be used to test a heartbeat and Discovery scan of an ESXi machine.

Run the following script as an Administrator:

```
#region Helper Functions

function Ensure-NuGetProvider {
    if (-not (Get-PackageProvider -Name NuGet -ErrorAction SilentlyContinue)) {
        Write-Host "NuGet provider is not installed. Installing..."
        Install-PackageProvider -Name NuGet -MinimumVersion "2.8.5.201" -Force -Scope
CurrentUser
    }
}

function Get-ModuleFolderPath {
    param (
```

```
        [Parameter(Mandatory)]
        [string]$ModuleName
    )
    $mod = Get-Module -ListAvailable -Name $ModuleName | Sort-Object Version -Descending |
Select-Object -First 1
    if ($mod) { return $mod.ModuleBase } else { return $null }

Troubleshooting and Issues

- The error "The VMware VIM API is not installed or is the wrong version" indicates that PowerCLI needs to be installed.
- We recommend not using an outdated SDK with an updated version of VMware.
- Secret Server's VMware password changer rejects self-signed SSL certificates. Make sure your VMware servers have valid SSL certificates (see below for settings).

- The error "Exception: The remote certificate is invalid according to the validation procedure" indicates that vCenter server root certificates needs to be installed. For more information, see Download and install vCenter Server root certificates to avoid web browser certificate warnings.
- For Secret Server installed editions, you may need to restart the Secret Server website after installing PowerCLI. Do this by recycling the Secret Server application pool or performing an IIS reset.
- For distributed engines, the distributed engine service may need to be restarted after PowerCLI is installed.

ESXi Certificate Settings

> VMware recommends not including a CRL/CDP in certificate templates. To that end, we recommend adding the `X509RevocationMode.NoCheck` option to the `ESXi.CertificateChainPolicyOptions` setting.

Delinea added a configuration option for Secret Server to allow ESXi TLS connections to ignore self-signed certificates, allow certificates from specific issuers (even if issuer is not in trusted certificate lists), or completely skip certificate validation when using ESXi password changer, heartbeat, or discovery.

> For security reasons, we do **not** encourage customers to use self-signed certificates. Therefore, the new configuration settings listed below are not accessible through the UI. If you need to alter the default ESXi certificate validation settings, **submit a case through Delinea's Support Portal** for assistance.

New advanced configuration settings include:

- ESXi: Enable TLS Debugging and Connection Tracking: Identical to TLS Audit option, but specifically for ESXi. If set to true and Secret Server (or DE) auditing is set to DEBUG, detailed debug messages about the certificate chain will be written to the log file.
- ESXi: Certificate Chain Policy Options: Identical to TLS Audit option, but specifically for ESXi. Allows setting X509 options to be applied to certificate validation. This is a comma-delimited list of options. See TLS Auditing or the Details section for more information.
- ESXi: Allow Certificates Issued By: Semi-colon delimited list of issuer names (in format shown on certificate---such as "O=Issuer Name"). Ignores partial chain errors due to certificate being issued by any issuer in this list when that issuer is not in the trusted root or intermediate CAs lists on the server.
- ESXi: Client Certificate Thumbprints: Identical to TLS Audit option, but specifically for ESXi. If ESXi host requires the client to present a valid certificate, this is a semi-colon delimited list of client certificates on the server to try to present.
- ESXi: Ignore All Certificate Errors: If true, certificate validation will not be performed. All certificate errors will be ignored.
- ESXi: Allow Default Host Certificates: Sets all the TLS configuration options necessary to not fail due to a default ESXi host certificate and its issuer not being in the trusted certificates lists. This is a combination of setting the issuer to ignore and not performing a revocation check. Setting this to false should be the first change to make when attempting to resolve heartbeat, RPC, or discovery issues to ESXi hosts when using PowerCLI versions later than 5.5.

- ESXi: Ignore Self-Signed Certs: If true, ignores any self-signed certs (subject = issuer) from ESXi hosts during heartbeat, RPC, and discovery.

> Issues with self-signed certificates previously implemented by customers were caused by a security update to the VMware vSphere PowerCLI in versions after 5.5 that no longer permits the use of self-signed certificates.

Overview of Secret Launchers and Protocol Handlers

The relationship between Secret Server launchers and protocol handlers is integral to the functionality of Secret Server in automating and securing access to various applications and systems.

Secret Launchers

Secret launchers are tools within Secret Server that allow users to launch applications and automatically log in using credentials stored in Secret Server. There are several types of launchers, including:

- RDP (Remote Desktop Protocol)
- SSH (Secure Shell)
- Custom Launchers

These launchers provide a convenient method to open connections without requiring users to know or manually enter their passwords. For example, a web launcher can automatically log into websites using the client's browser.

Protocol Handlers

A protocol handler is an application installed on an end-user's machine that facilitates communication between Secret Server and the client machine. It also provides the necessary files for the launchers to function. When a user initiates a launcher, the protocol handler:

1. Bootstraps the client-side application.
2. Communicates with Secret Server over HTTP(S) to ensure it is the latest version and initiates an upgrade if necessary.
3. Bootstraps the target launcher type and begins the process of securely logging in the user.

The protocol handler ensures that credentials are retrieved securely from Secret Server using signed AES-256-encrypted messages, adding an extra layer of security.

Managing Multiple Instances

In environments with multiple instances of Secret Server, users might need to manage different versions of the protocol handler. To address this, the protocol handler auto-update function can be disabled, allowing users to manually update their protocol handlers as necessary.

Custom Launchers

Custom launchers extend the functionality of Secret Server by allowing integration with any application that can be started via the command line. They pass values from the secret text fields to the command-line of the application being launched, enabling users to initiate processes or connect to services directly from the Secret Server interface without manually entering credentials.

Launchers

Launchers are tools within Secret Server that enable users to securely and conveniently access remote systems and applications using stored credentials without manually entering passwords. These launchers come in various types, including Remote Desktop Protocol (RDP) for Windows sessions, SSH for Unix systems, and web launchers for automatic website logins. The launchers work in conjunction with protocol handlers, which are applications installed on the user's machine to facilitate secure communication between Secret Server and the client machine. This setup ensures that credentials are retrieved securely using encrypted messages, adding an extra layer of security. Additionally, custom launchers can be created to integrate with any application that can be started via the command line, further extending the functionality of Secret Server.

Built-In Launcher Types

Secret Server launchers, supported by protocol handlers, come in three primary types:

- **Remote Desktop:** Launches a Windows Remote Desktop session and automatically authenticates the user to the machine.
- **PuTTY:** Opens a PuTTY session and authenticates the user to a Unix system.
- **Web Password Filler:** Uses a Chrome extension to automatically log the user into a website with secret credentials.
- **Web Launcher:** An alternative method to automatically log on websites. See "Web Launchers" on page 707.

Launcher Settings

Overview

Launcher settings control the global behavior of all launchers in Secret Server. These settings apply to protocol handlers and launchers after they're installed on user machines.

Search for **Launcher Settings** to enable or disable the related settings.

The settings in this section apply only to launchers that connect to this server. To change global settings for new installations of the Protocol Handler from this server, see the 'Protocol Handler Installer' section.

- **Enable Launcher**: Controls whether the launcher feature is enabled for this Secret Server instance.
- **Enable Protocol Handler Auto-Update**: Controls whether protocol handlers automatically update when Secret Server is upgraded. Disable this in environments with multiple Secret Server instances to prevent version conflicts.
- **Send Secret URL to Launcher**: Allows sending Secret URL to the launcher.

- **Allow the Server to Retrieve Website Content**: Allows the server to retrieve and parse the mapped website when using the web launcher.
- **Allow Web Launcher Mappings to be Downloaded**: Allows the user to download existing and tested mappings from Delinea.com.
- **Allow Web Launcher Mappings to be Uploaded Off-Site**: Allows the user to upload successful mappings to Delinea.com in order to be shared with other users.
- **Check in Secret on Launcher Close**: Forces Check In of Secret when user closes their only active launcher.
- **Close Launcher on Check In Secret**: When Secret is Checked In, all active launchers associated with it will close.

Launcher Procedures

This section contains procedures for configuring Secret Server launchers.

Adding a Program Folder to the Windows PATH

If a launcher does not automatically add the program's folder to the Windows PATH:

1. Right click on **Computer** and go to **Properties**.
2. In the Properties window, click Advanced System Settings.
3. On the **Advanced** tab, click the **Environment Variables** button.
4. In the **System Variables** section scroll to **Path**.
5. Click **Edit** then at the very end of the text box, paste the full path to the folder where the program file is located, but make sure not to replace any existing entries. The list is semi-colon separated.
6. Click **OK** to close the dialogs.

Automatic Sudo or Su Privilege Elevation

Secret Server has a convenience feature that eliminates the need to manually enter a su or sudo command's password when using a proxied SSH session to a Unix or Linux server. When a user manually types a su or sudo command with a valid secret ID, the SSH proxy automatically provides the username and password to use. The user does not need to know either.

For su, the connection procedure is as follows:

1. Secret A is created to contain the username and password for the su privilege elevation. Any potentially elevated users must have access to this secret.
2. Using secret B, a user (with access to secret A) starts a Secret Server proxied SSH session.
3. When the user types su at the command prompt, the SSH proxy detects it, determines the user has access to secret A, and augments the command with the secret ID for secret A via a command line argument. Any other arguments the user may have typed are left as is.
4. The user runs the su command, and the secret ID is replaced with the user and credential from secret A.

5. With the elevated permissions (temporarily as another user) from secret A, the user completes the desired tasks.
6. When finished, the user uses an exit command to return to their non-elevated status based on secret B.

> The added argument appears as `--secret-id <secret ID>` or `-id <secret ID>`, such as `su --secret-id 15`, which is replaced by a username and password from secret ID 15 when the command runs.

> Sudo does not take either secret argument and automatically types the current user's password.

Common Launcher Errors

Two of the most common launcher errors:

- **The process (process name) was not found:** The application has not been installed on the machine. If the application was installed, the program folder needs to be added to the path.
- **The stub received bad data (1783):** The process is set to launch as the credentials of the secret but the username or domain is not correct on the secret or the client machine cannot find the user or domain credentials specified.

Configuring Launchers on the Secret

Custom and SSH launchers provide additional settings on the Launcher tab of the secret for customizing authentication to the target.

- **Run Launcher using SSH Key:** If there is an SSH key set on the secret, it is used by default for authenticating to the target. Alternatively, you can specify a key from a different secret.
- **Connect As**: When an SSH secret is proxied, you can choose to connect as another user and then do an **su** to the current secret's user. This is a common practice for connecting with a lower privileged account and then switching to the root user.

Configure RDP Launcher Domain for Windows Account Template

Problem

When a Remote Desktop Launcher fails to log into a machine, it is sometimes because the machine is configured to have a default domain name (other than the local machine name). To determine whether the machine is configured to have such a default domain name, check one of the following:

Registry Setting: HKLM\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\DefaultDomainName

Group Policy (Windows 2008 and higher): "Assign a default domain for logon" under Computer Configuration\Administrative Templates\System\Logon

Solution

Add a key to `web-appSettings.config` that will cause the RDP launcher to use the machine name as the domain name when authenticating using a local Windows account.

1. Run a text editor as an administrator on the server running Secret Server.
2. Open the `web-appSettings.config` file located in the Secret Server application directory (typically `C:\inetpub\wwwroot\secretserver`).
3. Add the following key within `<AppSettings>`

   ```
   <add key="RDPUseComputerForDomain" value="true" />
   ```
4. Perform an IIS reset
5. Test the launcher.

Configuring SSH Proxies for Launchers

Launchers using an SSH connection can alternatively use Secret Server as a proxy rather than the launcher connecting directly to the target system from the machine it is being launched from.

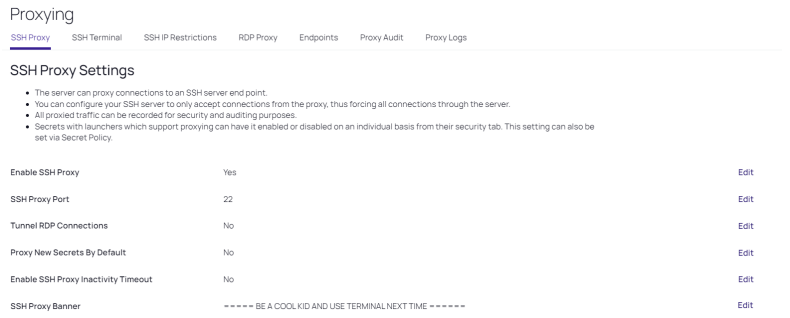
> Remote Desktop Services (RDS) is a special version of Secret Server Protocol Handler (SSPH) that can record keystrokes on its own, if configured in Secret Server. See "Secret Server Session Connector" on page 688 for details.

When proxying is enabled, all RDS sessions are routed through Secret Server. You can configure your SSH server to only accept connections from the proxy, thus forcing all connections through Secret Server. All proxied traffic can be recorded for security and auditing. You can enable or disable proxying for individual launchers. You can also do this using a secret policy.

In Secret Server Cloud, the distributed engine service also supports acting as a proxy for session launchers for greater network flexibility and offloading connections from the Secret Server instance.

To configure this:

1. Select **Admin > Proxying**. The SSH Proxy tab of the Proxying page appears:



2. Scroll down and click the desired **Edit** links to enter your SSH proxy configuration settings.

   The **SSH Proxy Settings** are:

   - **Enable SSH Proxy:** Enable or disable SSH proxying.
   - **SSH Proxy Port:** The port to proxy through. Changing this setting closes all active SSH proxy connections.

- **Tunnel RDP Connections:** SSH Tunneling allows Remote Desktop Sessions to be proxied using the same proxy configuration settings. If enabled, RDP launchers will tunnel through a SSH Proxy if possible. This option predates the RDP Proxy which is now recommended instead.
- **Proxy New Secrets by Default:** Enable proxying for applicable secrets when you create them.
- **Enable SSH Proxy Inactivity Timeout:** Enable the SSH connection timeout - the period of inactivity after which the SSH will terminate the connection (15 minutes by default).
- **SSH Proxy Banner:** Users connecting through SSH proxy see this text banner. This is not the same as the SSH Terminal Banner.
- **Hide Passwords from SSH Keystroke Capture:** By default proxying records keystrokes. This disables that.
- **Regular Expression to Find Password Prompts:** Specify regular Expression to find password prompts here. Note that modifying this field can slow down SSH Proxy output if regular expression is improperly formatted.
- **Send Window Title Change Command on Startup:** Enable to change client window title to $USERNAME@$HOST.
- **SSH Proxy Host Fingerprint**: The Secret Server SSH private key. Select **ECDSA** or **RSA** to generate the related SSH Proxy Host Key.
- **Days to Keep Operational Logs**: Number of days to store operational audit logs.

The **SSH Block List Settings:** SSH Proxy can block incoming clients that connect and fail to authenticate. Enable to select the following settings:

- **Enable Block Listing:** Block incoming SSH proxy clients that connect and fail to authenticate.
- **Auto Block Max Attempts:** How many times authentication can fail before the connection is blocked.
- **Auto Block Max History:** How many times overall authentication can fail before the connection is blocked.
- **Auto Block Time Frame (minutes):** If you hit the maximum attempts within the time frame specified here, they are added to the block list. For example, if I have these settings set to five attempts and 30 minutes, if I fail to authenticate five times within 30 minutes I will be added to the list, but if I fail five times over five hours I would not be added to the list.

Once the period has passed, the address must still be manually removed from the blocked list.

Client Override IP Address Ranges: IP address ranges that you can configure to always allow or always block the incoming connection. Click the **Add** link to add one.

- **Range:** Enter the IP address range, for example: 192.168.3.12, 192.168.42.147-192.168.42.194, 192.168.3.52/22.
- **Client Type:** Select Allow List or Block List.

Launcher Configuration and Support

Launcher configuration and support in Secret Server enable users to automate and secure access to various applications and systems by launching sessions directly from the Secret Server interface. Launchers can be

configured for different types of connections, including Remote Desktop Protocol (RDP), SSH, and custom applications. The configuration process involves setting up the launcher type, mapping secret fields to the appropriate login fields, and enabling the launcher on the secret template. Secret Server supports both ClickOnce and MSI installer deployment methods for the protocol handler, ensuring compatibility with different environments. Additionally, advanced settings such as SSH proxy and "Connect As" commands can be configured to enhance security and flexibility. This robust launcher support streamlines the process of accessing remote systems while maintaining strict security controls.

Custom Launchers

In addition to the built in PuTTY and Remote Desktop launchers, Secret Server supports custom launchers. A Secret Server custom launcher is a feature that allows you to integrate Secret Server with any application that can be started via the command line. Custom launchers are designed to pass values from the secret text fields to the command-line of the application being launched. This enables users to initiate processes or connect to services directly from the Secret Server interface without having to manually enter credentials or other required information.

For more information on launcher arguments see "Custom Launcher Process Arguments" on page 675.

Like the built in launchers, custom launchers run on the users machine not on the web server. Launcher Processes can be set to run either using the credentials of the logged in user or the credentials of the secret. The "Run Process as Secret Credentials" check box is used to switch between theses two options.

Custom launchers are needed for several reasons:

- Integration with Various Applications: They allow Secret Server to work with a wide range of applications beyond the built-in launchers like PuTTY and Remote Desktop.
- Automation: They automate the process of logging into applications, saving time and reducing the risk of errors from manual entry.
- Security: They help maintain security by not exposing sensitive credentials, as the credentials are passed directly to the application without user interaction.
- Flexibility: They provide flexibility to tailor the launcher to specific organizational needs or to work with custom applications.
- Convenience: They offer a convenient way for users to access remote systems or applications with a single click from the Secret Server interface.

There are four types of custom launchers to choose from:

- **Process**: Launches a process on the user's machine and replaces parameters with values from the Secret.
- **Proxied SSH Process**: Launches an SSH client on the user's machine, connecting through Secret Server's proxy.
- **Batch File**: Launches a batch file on the user's machine using information from Secret Server.
- **Session Connector Launcher**: Allows for downloading and running an RDP file to launch into a Remote Desktop Server with a protocol handler installed.

Having four different custom launchers in Secret Server is necessary to provide flexibility and cater to a variety of use cases and applications that organizations might need to integrate with. Each type of custom launcher serves a specific purpose and addresses different requirements:

- **Process Launcher**: This is the most general type of custom launcher. It is used to launch any application that can be started from the command line on the user's machine. It is highly customizable and can pass parameters from the Secret directly to the application. This type of launcher is useful for a wide range of applications that do not require special handling or proxying.
- **Proxied SSH Process Launcher**: This launcher is specifically designed for SSH clients other than the built-in PuTTY launcher. It provides an additional security layer by proxying the connection through Secret Server, which prevents credentials from being exposed on the client's machine. This is particularly important for secure environments where SSH credentials need to be protected.
- **Batch File Launcher**: This launcher allows for the execution of batch files, which can contain a series of commands and can launch multiple processes. This is useful when a sequence of actions needs to be performed, or when integrating with complex systems that require more than a single command-line instruction.
- **Session Connector Launcher**: This launcher is used for more advanced scenarios where an RDP file needs to be downloaded and run to establish a Remote Desktop connection. It is particularly useful when client machines do not have certain applications installed, as it does not require any installation on the end-user's part.

The variety of custom launchers ensures that Secret Server can be adapted to the unique operational needs of different organizations. It allows for seamless integration with a diverse set of applications and services, enhancing both the user experience and security posture by automating access and protecting sensitive credentials.

See also "Configuring SSH Proxies for Launchers" on page 661.

Configuring WinSCP As a Custom Launcher

This topic is configuration only–see "General Settings" on page 670 for instructions.

Custom Process Launcher

General Settings

- Wrap custom parameters with quotation marks: No
- Record Multiple Windows: Yes
- Record Additional Processes: < None >
- Use SSH Tunneling with SSH Proxy: No

Windows Settings

- Process Name: winscp.exe
- Process Argument: `scp://$username:$password@$machine:$port`
- Process Argument: `sftp://$username:$password@$machine:$port`

- Run Process As Secret Credentials: No
- Load User Profile: No
- Use Operating System Shell: No

> Process Arguments:
>
> - WinSCP provides different protocols. The settings above show SCP or SFTP.
> - `$machine` is used because it is a direct connection.

Custom Process Tunneled Launcher

General Settings

- Wrap custom parameters with quotation marks: No
- Record Multiple Windows: Yes
- Record Additional Processes: < None >
- Use SSH Tunneling with SSH Proxy: Yes

Windows Settings

- Process Name: winscp.exe
- Process Argument: `scp://$username:$password@$host:$port`
- Process Argument: `sftp://$username:$password@$host:$port`
- Run Process As Secret Credentials: No
- Load User Profile: No
- Use Operating System Shell: No

> Process Arguments:
>
> - WinSCP provides different protocols. The settings above show SCP or SFTP.
> - `$host` is used because it is a tunneled connection.

Custom Process Proxied Launcher

General Settings

- Wrap custom parameters with quotation marks: No
- Record Multiple Windows: Yes
- Record Additional Processes: < None >
- Use SSH Tunneling with SSH Proxy: Yes

Windows Settings

- Process Name: winscp.exe
- Process Argument: `scp://$username:$password@$host:$port /rawsettings Shell=/bin/bash`
- Process Argument: `sftp://$username:$password@$host:$port /rawsettings SftpServer=/usr/libexec/openssh/sftp-server`
- Run Process As Secret Credentials: No
- Use Operating System Shell: No

> Process Arguments:
>
> - WinSCP provides different protocols. The settings above show SCP or SFTP.
> - `$host` is used because it is a proxied connection.

SCP

`/rawsettings Shell=/bin/bash` must be specified to state the Unix shell used.

The value will be different depending on each account, `/bin/bash` is common but the exact value is obtained from executing the following command

```
[jeff@box ~]$ echo $SHELL
/bin/bash
```

SFTP

`/rawsettings SftpServer=/usr/libexec/openssh/sftp-server` must be specified to instruct how to launch the FTP server. The value could be different depending on what is installed on the Unix server–best to run one of the following commands to determine the answer:

```
[root@box jeff]# ps -ef --forest
```

```
root      7335  6171  1 11:26 ?        00:00:00  \_ sshd: jeff [priv]
jeff      7339  7335  0 11:26 ?        00:00:00      \_ sshd: jeff@notty
jeff      7340  7339  0 11:26 ?        00:00:00          \_ /usr/libexec/openssh/sftp-server
```

```
[root@box jeff]# ps -ef | grep ftp
```

```
root      3508     1  0 Jul18 ?        00:00:00 /usr/sbin/vsftpd /etc/vsftpd/vsftpd.conf
jeff      7340  7339  0 11:26 ?        00:00:00 /usr/libexec/openssh/sftp-server
root      7356  7250  0 11:29 pts/0    00:00:00 grep --color=auto ftp
```

Using SSH Keys for Authentication

Users can authenticate via SSH using public keys generated within Secret Server, eliminating the need for passwords. This method enhances security by leveraging SSH key pair authentication through the SSH Terminal server when the SSH Proxy is enabled.

Configuration Steps

1. Enable SSH Proxy and SSH Terminal:
   - Search for **SSH Proxy**, click **Edit** next to **Enable SSH proxy**, and click **OK** in the popup.
   - Search for **SSH Terminal**, click **Edit** next to **Enable SSH terminal**, and click **OK** in the popup.
2. Activate SSH Key Integration:
   - Search for **SSH key integration**, click **Edit**, and check to enable **SSH key integration (for SSH terminal)** (if not enabled).
   - Set the **Unix Authentication Method** to **Public Key only**. When done, click **Save**.
3. Generate SSH Key Pairs:
   - Click on your username at the top right corner of the Secret Server interface to open the dropdown menu, and select **User Preferences**.
   - Under the General tab, click on the **Public SSH keys**.
   - Click **Create SSH Key** and complete the required details to generate a key pair:
     - **SSH Key Name**: enter the related key name.
     - **Format**: select the key format - OpenSSH, PuTTY, or PuTTY3.
     - **Algorithm**: Select algorithm - RSA 4096, or ECDSA P-256.
     - **Passphrase**: Enter the passphrase.
     - **Key Expiration**: Set by admin.
     - Check the box for **I acknowledge that this will download the only copy of the private SSH key**.
     - When done, click **Create SSH Key**.
   - Click on the key that now appears in the Public SSH keys list, its detail will expand to the right. Save the private key and store it securely, as it can only be downloaded once. The public key is stored in the user's settings.

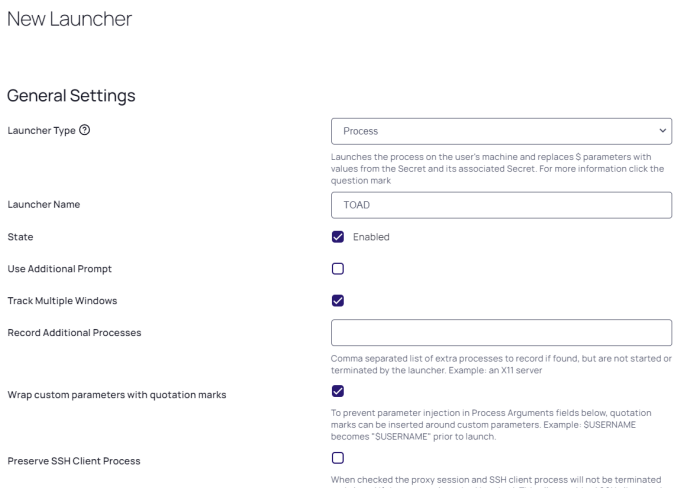
Authentication Process

- During terminal login, Secret Server validates the provided private key against the user's saved public keys. If a match is found, authentication succeeds.
- In SSH clients like PuTTY, users can add the private key file saved from Secret Server to authenticate without a password.
- When accessing the SSH Terminal, the user is prompted for their Secret Server Username that matches the key and enters the key passphrase; the user password is not required.

Creating a Custom TOAD Launcher

You can create a custom launcher for TOAD by entering custom command line parameters in the "Process Arguments" field.

1. Search for **Secret Templates**,
2. Select the**Launchers** tab, and click **Create**.
3. On the New Launcher page, select a Launcher Type:
   - Use **Process** if you would like to use Secret credentials to connect directly to the remote host.
   - Use **Proxied SSH Process** if you have SSH Proxy enabled, to prevent passing Secret credentials to the client by connecting to Secret Server's proxy to interact with the remote host.



4. Enter a **Launcher Name** of your choice.
5. For **Process Name**, enter the location and the Toad executable. The location must exist on the client machine that will run the Toad launcher.
6. For **Process Arguments**, enter your own custom command line parameters, or the following:

   ```
   -C $USERNAME/$PASSWORD@$SERVER:$PORT/$DATABASE
   ```

7. When finished, click **Save**.

Creating and Implementing an Ultra VNC Custom Connection Launcher

Follow the steps below to create an Ultra Virtual Network Computing (VNC) custom connection launcher using Secret Server on a Windows machine.

Create an Ultra VNC Custom Connection Launcher

1. Search for **Secret Templates**. The Secret Template page appears.
2. Click the**Launchers** tab.
3. Click the **Create** button. The New Launcher page appears.

4. Click the **Launcher** type dropdown list and select **Process**.
5. Type a launcher name in the **Launcher Name** text box.
6. Go to the **Windows Settings** section.
7. Type `C:\Program Files (x86)\UltraVNC\vncviewer.exe` in the **Process Name** text box.
8. Type `$USERNAME $PASSWORD $HOST` in the **Process Arguments** text box.

> You may need to change the Process Arguments if the names of these fields in your Secret Template are something other than "Username" "Password" and "Machine"

9. Click the **Save** button at the bottom of the page.

Assign the Launcher to a Template

Assign the new launcher to an appropriate existing template. To build a new template specifically for VNC connections, see "Creating or Editing Secret Templates" on page 1194)

1. Search for **Secret Templates**.
2. Click the link for the desired template. The template's page appears.
3. Click the **Mapping** tab,
4. Click the **Add Mapping** button. The Add Mapping dialog box appears.
5. Click the **Mapping Type** dropdown list and select the launcher you created. New controls appear.
6. Click the **Domain** dropdown list to select the domain.
7. Type the password in the **Password** text box.
8. Type the username in the **Username** text box.
9. Click the **Save** button.

Creating Custom Launchers

This guide walks you through the process of creating a custom launcher, including defining launcher settings, and specifying command-line parameters. Follow the steps below to build a launcher that fits your organization's unique needs.

Procedure

> See "Custom Launcher Errors" on page 673 if errors arise.

To create a new custom launcher:

1. Search for and select **Secret Templates**. The Secret Templates page appears. Select the **Launchers** tab. Alternatively, Search for **Launchers**.
2. Click **Create**. The New Launcher page appears.

3. Configure the page as needed, see "Settings" below below for details.
4. Click the **Save** button.

> See the following section for details on General, Windows and Mac settings.

Settings

> Not all of the following settings are available for all types of launchers.

General Settings

The following settings are available in the General Settings section:

- **Launcher Type**: You can select either Process, Batch file, Proxied SSH process, or the Session connector launcher.
  - **Process**: Launches the process on the user's machine and replaces $ parameters with values from the Secret and its associated Secret.
  - **Batch file**: Launches the indicated batch file on the user's machine. Allows multiple processes to be kicked off by the script using information from the server. Recommended only for advanced users.
  - **Proxied SSH pocess**: Launches the specified SSH client on the user's machine. When the SSH Proxy Server is running, launched SSH sessions are proxied through the server.
  - **Session Connector Launcher**: Allows for downloading and running an RDP file to launch into a Remote Desktop Server with a protocol handler installed.
- **Launcher Name**: Name of the launcher that is displayed to the user.
- **State**: Whether the launcher is active for use.
- **Use Additional Prompt**: If selected, the user is prompted for additional information when using the launcher. When selected, the **Additional Prompt Field Name** text box appears.

  > This option is mutually exclusive with **Use SSH Tunneling with SSH Proxy**.

- **Additional Prompt Field Name**: Name of the text field providing the prompt when the user activates the launcher. This value can be referenced in the process arguments with a `$` prefix.

After selecting a launcher type, a combination of the following additional fields appears:

- **Track Multiple Windows**: When this checkbox is selected, all visible windows of the primary process, not just the primary window of the primary process, are tracked. This helps record applications with multiple windows or dialog boxes. In addition, if the primary process (or one of its children) spawns child processes, any visible windows are recorded too.

  For example, if you run `cmd.exe` and then the `notepad.exe` application from the command prompt, notepad is recorded along with the command prompt. This checkbox is enabled by default. Enabling this setting is a prerequisite for **Record Additional Processes**.

- **Record Additional Processes**: Add a comma-separated list of additional process names to record if they are running. When a launcher is in progress and recording, any visible windows from the listed processes are also recorded. This only applies to processes running in your session—other users running the same process are not recorded. The processes themselves are not affected—they remain running after the launch is finished. This setting is only active if **Record Multiple Windows** is enabled too.
- **Wrap Custom Parameters with Quotation Marks**: This setting wraps the variables in the process argument fields with quotation marks. This is a security and disambiguation feature.

  For example, given these process arguments:

  ```
  --host=$HOST --port=$PORT --username=$USERNAME --password=$PASSWORD
  ```

  With no quotation mark wrap, the problematic process arguments for a launcher mapped to a secret might look like this:

  ```
  --host=xyz --port=123 --username=user --password=x x x
  ```

  The final parameter would be ambiguous, causing the last three characters to be misinterpreted, with the process thinking a single "x" is the password. Text could be injected, causing the value to be interpreted as another parameter, resulting in a security issue. Wrapping the parameter values fixes these potential problems:

  ```
  --host="xyz" --port="123" --username="user" --password="x x x"
  ```

  This checkbox is selected by default.
- **Preserve SSH Client Process**: When enabled, the proxy session and SSH client process will not be terminated and closed if the process launched is exited. This allows tabbed SSH clients to be used.
- **Use SSH Tunneling with SSH Proxy**: When enabled and the launcher is mapped to a secret template, the user can select host and port fields. You can provide a default port, which can be referenced using `$HOST` and `$PORT` in the process arguments. If the launching secret has proxying enabled and a Secret Server SSH proxy is available, those process arguments are replaced with SSH tunnel values (localhost [127.0.0.1] and a random port).

  This causes the launched process to connect to the local tunnel, and traffic then flows from the client to the Secret Server SSH proxy, which connects to the real endpoint. This is useful when users are not allowed to directly connect to the endpoint but Secret Server or distributed engines can.

  The checkbox is disabled by default. This option is mutually exclusive with **Use Additional Prompt**.

  > To use this feature, you must first map the host and port fields when you map the launcher to a template. To do so, edit the secret template and click **Configure Launcher**.

- **Use SFTP Tunneling with SSH Proxy**: Enable this setting when using SFTP to allow multiple data connections through the SSH Proxy. Many SFTP clients will not function correctly without this being enabled.
- **Recording Options**: Select to record video only or record video and keystrokes.
- **Child launcher type**: Select the child launcher type if prompted.
- **RDS server hostname**: Enter the related RDS server host name.
- **RDS server port**: Enter the related RDS server port.

- **RDS server credentials**: Use the **No secret selected** link to select an existing sectret, or **Create new secret** to add a new secret.

Windows Settings

The following settings are available in the Windows Settings section:

- **Process Name**: Name of the process that is launched. Example: `PowerShell`.
- **Process Arguments**: Process arguments depend on the process that is being launched. View the built-in SQL Server launcher for examples on how the text-entry fields are substituted. For greater flexibility, other secrets can be linked in the Launcher tab onto the secret. The text-entry field values from those secrets can also be used in the process arguments using the same prefix `$[1][FieldName]` syntax as the SSH custom commands.

  There is a launcher-specific token `$SESSIONKEY` that can be passed to the command line. This passes an identifier to the customer launcher that can be used to anonymously check-in the secret using the `CheckInSecretByKey` Web service method.

  Example: `-user $USERNAME -pwd $PASSWORD -f`. See "Custom Launcher Process Arguments" on page 675 for details.
- **Run Process as Secret Credentials**: This option allows the process to authenticate with the secret credentials (username, domain, and password) instead of the client user that is using the launcher. This can be overridden at the secret level to use a privileged account to run the process.
- **Use Operating System Shell**: this option allows for the use of the OS shell for the launcher. Useful for processes requiring UAC Confirmation.
- **Escape Character**: Enter the character to use as an escape character in passwords. Escape characters are required to allow the use of characters that are otherwise not allowed in passwords because they have special meaning to the launcher's target application.
- **Characters to Escape**: Enter the characters that require escaping for the target application.
- **Batch file**: Upload the batch file needed when the launcher is initiated.

Mac Settings

The following settings are available in the Mac Settings section:

- **Process Name**: Name of the process that is launched. Example: `/Applications/TextEdit.app/Contents/MacOS/TextEdit`.
- **Process Arguments**: Process arguments depend on the process that is being launched. View the built-in SQL Server launcher for examples on how the text-entry fields are substituted. For greater flexibility, other secrets can be linked in the Launcher tab onto the secret. The text-entry field values from those secrets can also be used in the process arguments using the same prefix `$[1][FieldName]` syntax as the SSH custom commands.

  There is a launcher-specific token `$SESSIONKEY` that can be passed to the command line. This passes an identifier to the customer launcher that can be used to anonymously check-in the secret using the `CheckInSecretByKey` Web service method.

  Example: `-user $USERNAME -pwd $PASSWORD -f`. See "Custom Launcher Process Arguments" on page 675 for details.

Custom Launcher Errors

Common errors when creating custom launchers:

The process (process name) was not found

The application has not been installed on the machine. If the application was installed, the program folder will need to be added to the path.

The stub received bad data (1783)

The process is set to launch as the credentials of the secret but the username or domain is not correct on the secret or the client machine cannot find the user or domain credentials specified.

Error(740): The requested operation requires elevation

When using "Run process as Secret credentials," even though the credentials have admin privileges, the process cannot be run with elevated privileges from the command prompt using runas. Instead, configure the process launcher as follows (substituting your .exe for program.exe):

- Process Name: cmd.exe
- Process Arguments: `/C start /B program.exe /wait`

Custom Launcher for SecureCRT (SSH)

The following instructions describe how to set up a custom launcher using SecureCRT:

Step 1: Creating the Custom Launcher

1. Log into Secret Server.
2. Search for **Secret Templates**.
3. Click the **Launchers** tab.
4. Click the **Create** button. The New Launcher page appears.
5. Click the **Launcher Type** dropdown list and select one of the following:
   - **Process**: use this type if you want to use secret credentials to connect directly to the remote host. This choice launches the process on the user's machine and replaces $ parameters with values from the secret and its associated secret.
   - **Batch File**: Not used for this task. Launches the indicated batch file on the user's machine. Allows the script to launch multiple processes using information from the server. Recommended only for advanced users.
   - **Proxied SSH Process**: If you have SSH proxy enabled, this type launches the specified SSH client on the user's machine. This prevents secret credentials from being passed to the client, by connecting to the Secret Server proxy to interact with the remote host. When the SSH proxy server is running, launched SSH sessions are proxied through the server.
   - **Session Connector Launcher**: Not used for this task. Allows for downloading and running an RDP file. This file is used to launch a Remote Desktop Server with protocol handler installed, making it unnecessary for end-user client machines to install anything. Recommended only for advanced users.

> Depending on what launcher type you chose, all the steps below may not apply. The steps are in the order they appear in the UI, so if you do not see the item mentioned in the interface, you can ignore it.

6. For the sake of this example, choose the **Proxied SSH process** type.
7. In the **Launcher Name** text box, type the name *Secure CRT Proxied Process*.
8. Select the **State** checkbox to enable the launcher.
9. Select the **Use Additional Prompt** checkbox to add another field to the prompt. A text box appears to type the name of the field. You can reference the value in the arguments with the $ prefix.
10. Select the **Track Multiple Windows** checkbox to track child windows of the initial window.
11. Type a comma-delimited list of the names of other processes that are not started or terminated by the launcher, that you want tracked, in the **Record Additional Processes** text box. For example, an X11 server.
12. Select the **Wrap custom parameters with quotation marks** checkbox to prevent parameter injection in process argument fields. This means quotation marks are inserted around custom parameters prior to launch. For example: `$USERNAME` becomes `"$USERNAME"`.
13. Select the **Preserve SSH Client Process** checkbox to keep SSH client processes running after the launched process terminates. This is to support tabbed SSH clients and only applies to proxied SSH processes.
14. Select the **Use SFTP Tunneling with SSH Proxy** checkbox to enable using multiple SFTP data connections. Many SFTP clients require this setting to be enabled.
15. In the **Windows Settings** section, type the location and filename of the executable (`C:\program files\acme software\clients\securecrt.exe`) in the **Process Name** text box. The location must be on the client machine, i.e. the machine that will run the launcher.

    > This step is a requirement for the SecureCRT launcher to work.

16. Type the following custom command-line parameters in the **Process Arguments** text box:

    ```
    /ssh2 /AUTH keyboard-interactive /PASSWORD $PASSWORD /P $PORT /L $USERNAME $HOST
    ```

    > See "Custom Launcher Process Arguments" on the next page for details.

17. Click the **Save** button. The new launcher appears.

Step 2: Creating a Custom Secret Template (optional)

See "Creating or Editing Secret Templates" on page 1194 for details on creating a custom secret template.

Step 3: Associating the Launcher with a Secret Template

1. Log into Secret Server.
2. Search for **Secret Templates**. The Secret Templates page loads.
3. Click the link for the desired template. That template's page appears.

4. Click the **Mapping** tab.
5. Click the **Add Mapping** button. A popup appears.
6. In the **Mapping Type** dropdown list, select your custom launcher. The Host, Password, Port, and Username fields appear. For each field dropdown list, select the following:
   - **Host**: <user input>
   - **Password**: <blank>
   - **Port**: <use default>. The **Default value** field appears.
   - **Default value**: user's choice, pick an integer.
   - **Username**: select an available item.
7. Click the **Save** button.

You can now launch SecureCRT whenever you use the launcher for secrets based off of this template.

Custom Launcher Process Arguments

Custom launcher process arguments can use a combination of parameters from:

- A field value from the secret.
- A field value from a linked secret.
- User input obtained from a prompt prior to launching.
- `$Host` and `$Port` (for use with a proxied SSH process or SSH tunneling)

For more information, see the "Dependency Token List" on page 1512.

Syntax

Parameters are prefixed with a dollar sign `$`. To obtain a value from the secret being launched, use `$FieldName`. To obtain a value from a prompt, use `$PromptName`. To obtain a value from a linked secret being launched, use `$[n]$FieldName` (where n represents the nth linked secret).

Examples

```
-user $UserName -color $[1]$Color -Location $LocationPrompt
-ssh $UserName@$Host -pw $Password -P $Port
```

For more information on custom launcher process arguments, refer to the Connection Manager documentation.

Default Launcher Requirements

- **IBM iSeries Launcher:** For Secret Server itself, nothing is required. For distributed engines, the `ws3270.exe` file, found in the Secret Server directory, must be copied to the distributed engine folder on the engine, which is typically found at `C:\Program Files\Thycotic Software Ltd\Distributed Engine`. The `ws3270.exe` file itself can be downloaded on the ws3270 Downloads page.

- **PowerShell Launcher:** Requires PowerShell to be installed. When installed, the program is automatically added to the PATH.
- **SQL Server Launcher:** Requires SQL Server Management Studio to be installed. When installed, the program is automatically added to the PATH.
- **Sybase iSQL Launcher:** Requires that `isql.exe` is installed.
- **z/OS Launcher:** For Secret Server itself, nothing is required. For distributed engines, the `ws3270.exe` file, found in the Secret Server directory, must be copied to the distributed engine folder on the engine, which is typically found at `C:\Program Files\Thycotic Software Ltd\Distributed Engine`. The `ws3270.exe` file itself can be downloaded on the ws3270 Downloads page.

Enabling CAC/PIV Smart Cards for Secret Launchers

Overview

A Common Access Card (CAC) or Personal Identity Verification (PIV) smart card is a physical card with an embedded electronic chip that uses a certificate-key pair to authenticate users. The certificate is issued by an authorized organization. The user has a PIN that should be known only to that user, which serves a second factor for two-factor authentication–access requires physical possession of the card, as well as the PIN. The user inserts the card into a card reader, which prompts for the PIN.

Secret Server launchers can pass smart card credentials through Remote Desktop Protocol (RDP) sessions. This is useful when a user needs to authenticate through an RDP session to a resource that requires smart card authentication, for example, a secured network drive that the user attempts to open while using the RDP session.

Currently, you can enable this either globally, via user settings, or per secret:

Enabling Globally with User Settings

1. In Secret Server, click the user icon and select **User Preferences**. The User Preferences page appears.
2. Click the **Settings** tab.
3. In the **Launcher Settings** section, click to enable the **Allow Access to Smart Cards** toggle. The change is automatically saved.

Enabling on a Specific Secret

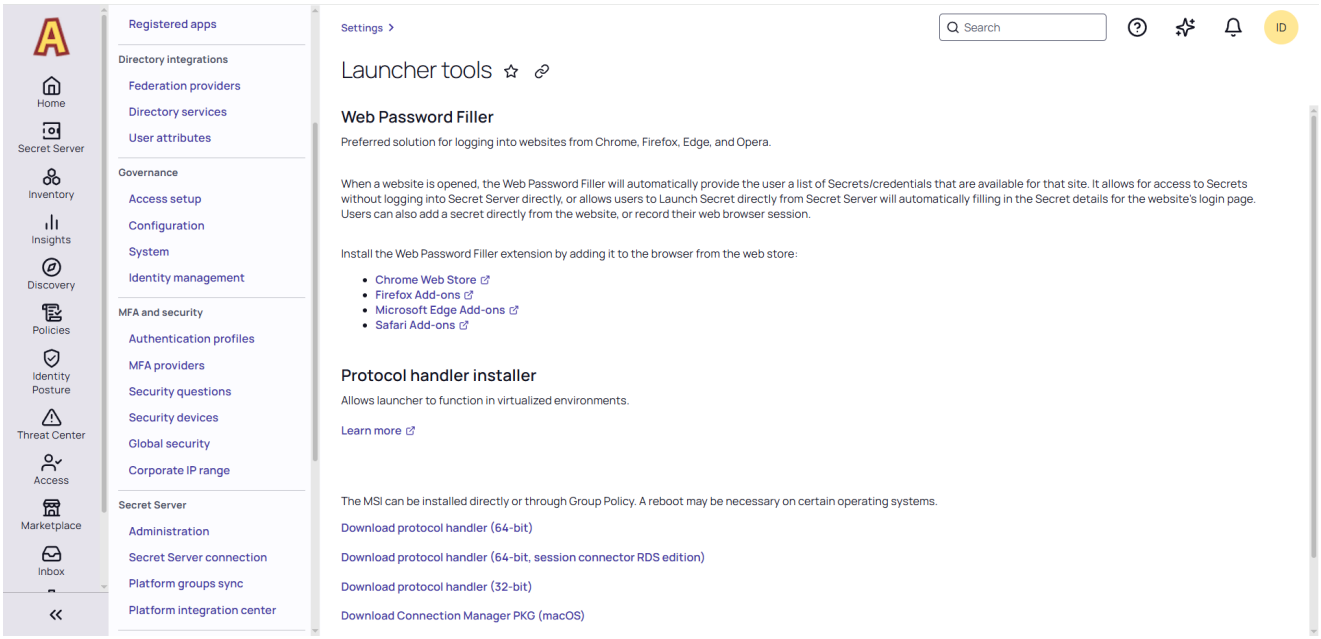
1. On a Secret with an RDP launcher, click the **Settings** tab.
2. Click the **Edit** link on the **Under RDP Launcher – Personalized User Settings** title bar. The page changes to edit mode.
3. Click to select the **Allow Access to Smart Cards** check box.
4. Click the **Save** button.

Enabling Launchers

Introduction

By default, the launcher is enabled by the **Enable Launcher** setting under **Admin > Configuration**.

The launcher (protocol handler) can be deployed in two ways—with the ClickOnce (the default) or MSI-installable applications. This can also be set in the configuration settings. The latter method allows the launcher to be used in virtualized environments or any environment in which the user does not have access to a Windows Temp directory. The Protocol Handler can be downloaded by clicking one of the links under the Protocol Handler section:



A ClickOnce application is any Windows Presentation Foundation (.xbap), Windows Forms (.exe), console application (.exe), or Office solution (.dll) installed with ClickOnce technology in one of three ways: from a Web page, from a network file share, or from media. See ClickOnce Security and Deployment for details.

MSI Installer

To use the MSI installer (protocol handler installer) following steps below:

1. Select **Settings**.
2. In the **Tools and Integrations** section, click **Launcher Tools**.
3. In the section labeled **Protocol Handler Installer**, select the **Download Protocol Handler MSI** link for the operating system you want to install on.
4. Run the MSI file with admin privileges.

The session is kept in check for security reasons with the session process pinging back to Secret Server to ensure it is still valid. This checks secret settings, such as checkout and secret access. If that check fails or the callback times out, Secret Server errs on the side of security and kills the sessions, ensuring access is not allowed.

Installing by Group Policy

The Protocol Handler application runs without requiring any input from the user. The installation may be pushed to your network without any special configuration. For details, see "Installing Protocol Handler Through Group Policy" on page 709.

Launching Sessions

On the Secret View page, clicking the Launcher icon launches the Remote Desktop, PuTTY, or custom session directly from the browser or log into the website. The mapped text fields are passed to the launcher for automatic authentication.

If the machine is set for Remote Desktop, the console launches and allows the machine to be specified from the RDP dialog.

If the Host is set to `<user>`, a prompt asks for the specific machine before launching the PuTTY session.

For some browser security levels, you might need to click **Allow** for the launcher application to open.

> The View Launcher Password permission can be removed to prevent users from viewing the credentials but can still use the authentication session to access the computer.

The settings under the Launcher tab are used for secrets that are enabled for SSH and custom launchers.

Limiting Launcher Domains

> This capability applies to Secret Server 10.9 or later. That is Secret Server Protocol Handler 6.0.0.28 or later.

You can limit the domains that a launcher connects to. If this is not set, then nothing changes–the launcher can connect to any domain. If it is set, however, Secret Server refuses to connect to any domains that are not explicitly allowed.

This setting is done via a Windows Group Policy Object (GPO) administrative template XML file (.admx). The file specifies the registry key that are changed when the GPO is edited. Download that file here: LimitLauncherDomainPolicyDefinitions.zip.

For details on using these files, see How to create and manage the Central Store for Group Policy Administrative Templates in Windows on the Microsoft site. The settings are present in both user and machine configurations in the group policy editor. If both are specified, then only the machine configuration is used (the user configuration is completely ignored). This is because the user configuration is stored in part of the registry that does not require administrator access to edit, so the machine configuration should be used in most cases.

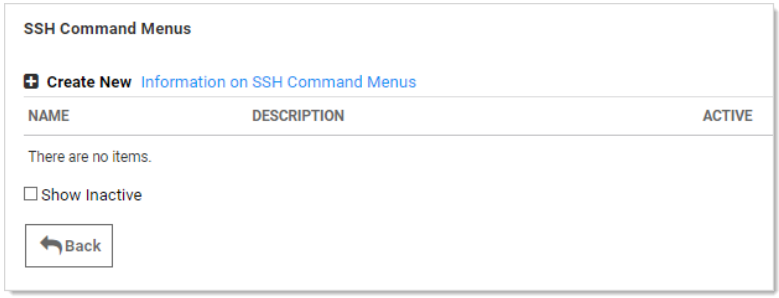
The Group Policy valid values are just domain names, like `example.com`, or IP addresses, like `192.168.1.2`. No port should be specified, and no scheme. A value like `https://example.com` is not valid, because it has `https://` in the front. Ports are also invalid, so `example.com:885` will not match. The correct value would simply be `example.com`. Wildcards are not supported, but subdomains matter, so a value of `example.com` will not match `something.example.com`.

Managing Superuser Privilege

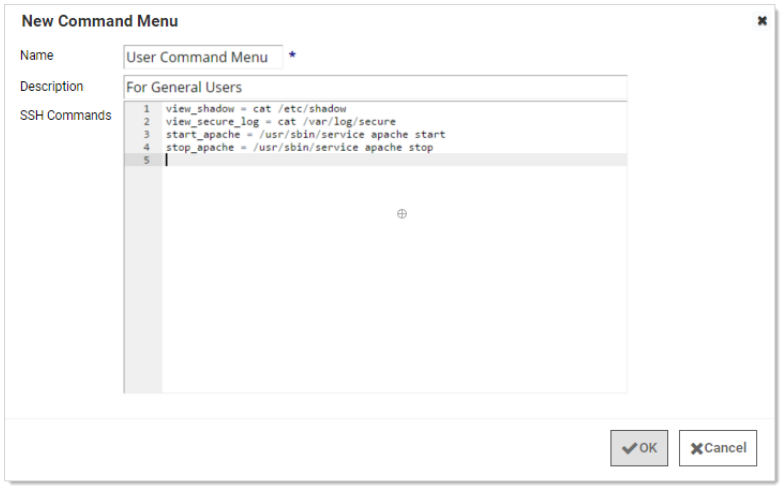
Administrators can create command menus for use with a proxied SSH connection to restrict what commands can be run by users or groups on the connected server. This feature requires an additional license. To add a command menu:

For details, see "SSH Command Menus" on page 856.

1. Search for **All**.
2. Click the **SSH Command Menus** button.



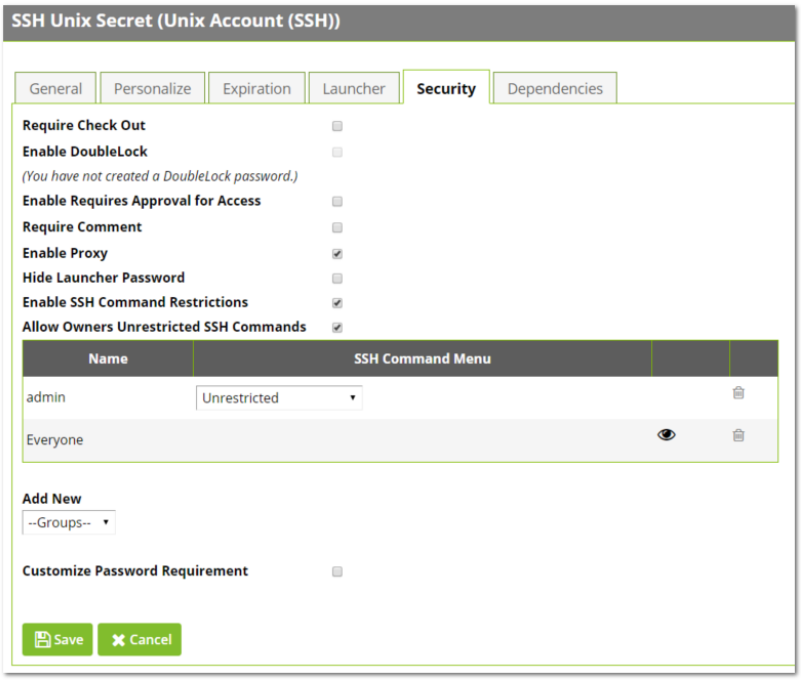
3. Click the **Create New** button.
4. Type a name, description and the SSH commands:



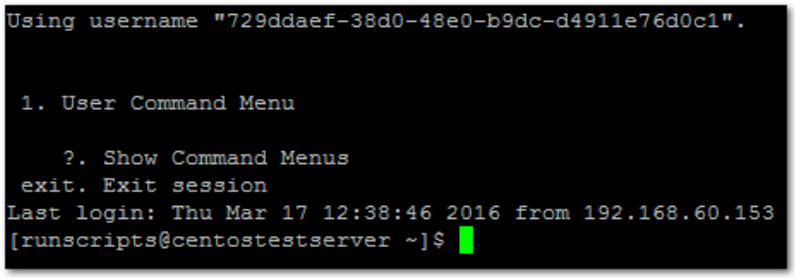
Once one or more command menus have been created, access can be controlled to individual Unix SSH secrets.

On the **Security** tab of a secret that can use a proxied PuTTY session, proxy must be enabled as well as command menu restrictions. If **Allow Owners Unrestricted SSH Commands** is enabled, any user who is an owner of the secret has unrestricted use of the PuTTY session, that is, that user is able to type in commands as in a normal session. Additionally, other groups can be assigned the Unrestricted role as well.

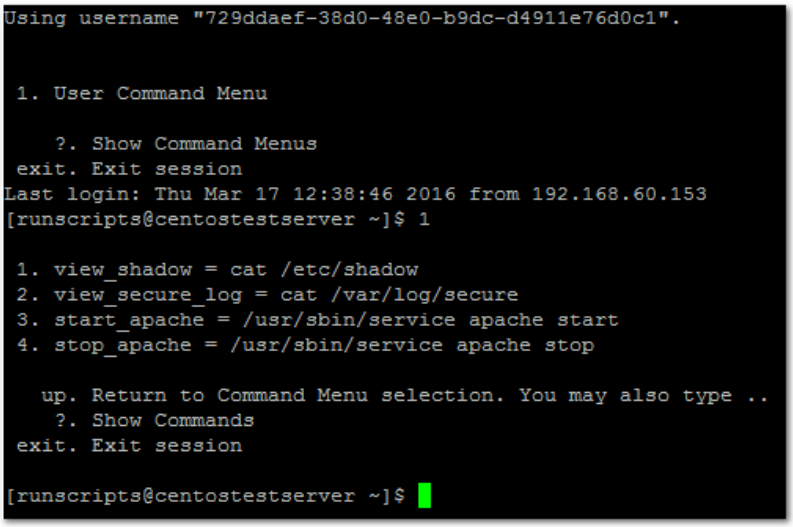
In the following example, the "admin" group is unrestricted, while everyone who is not in the admin group is restricted to only being able to run the commands that are enumerated in the user command menu, created above.



A user who is subject to SSH Command Restrictions are presented with a screen similar to the following when connecting to an SSH session:



The user simply enters the number of the command menu to see available commands, or types "?" to display the options again.



Only the commands listed can be run by this user. The user can either enter the number of the command to be run, or the name of the command, which is the word to the left of the equal (=) sign. Other options are available (as shown) to navigate through the available command menus, display help, or exit the session.

Remote Desktop Launchers

Secret Server remote desktop launchers provide a secure and convenient way to initiate Remote Desktop Protocol (RDP) sessions directly from the Secret Server interface using stored credentials. These launchers allow users to access remote Windows machines without needing to manually enter or even know the passwords, as the credentials are automatically retrieved and used from Secret Server. This not only streamlines the login process but also enhances security by minimizing the exposure of sensitive credentials. The launchers work in conjunction with protocol handlers, which facilitate secure communication between Secret Server and the client machine, ensuring that all credential exchanges are encrypted and secure.

Adding Remote Desktop Launchers

1. On the related template page select the Mapping tab, and click **Add Mapping** to add a launcher to the template.
2. On the following page, select mapping type and add Domain, Password, and Username. The text-entry fields below reflect the text-entry fields necessary to map to the launcher. In the case of a custom launcher, these text-entry fields are used to run the launcher process if the launcher is configured to run as secret credentials.
3. Choose a secret text-entry field in the drop-down menu on the right to map to each launcher value on the left. See the following section for further details on editing launcher configuration.
4. Click the **Save** button to add the launcher to the template.

Browser Configuration

Remote Desktop (RD) launchers require the following:

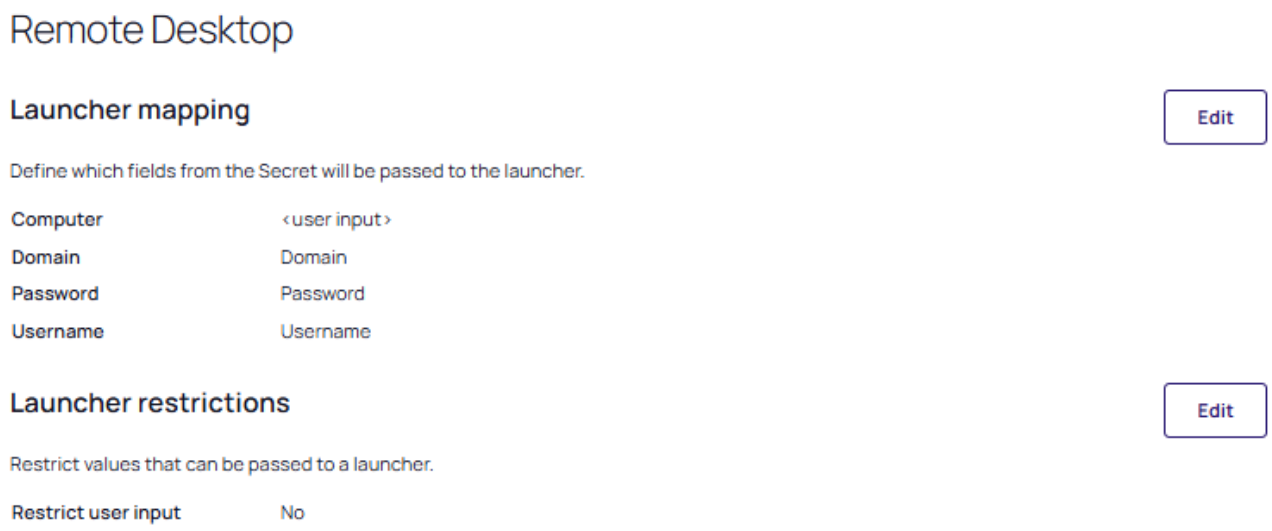
- **Firefox Configuration:** Firefox requires a helper add-on application to run the RD and PuTTY launchers. The Microsoft .Net Framework Assistant add-on and .NET framework version .NET 4.8+ needs to be installed.

- **Chrome Configuration:** If using ClickOnce, Chrome requires a Helper Add-on application to run the RDP and PuTTY Launcher. The ClickOnce add-on for Google Chrome Add-on needs to be installed. The launcher requires .NET framework version .NET 4.8+ as well.
- **SSL Certificates:** SSL must be set up properly for the RD launcher to work correctly. If Secret Server is using SSL certificates, they must be trusted at the user's computer. This is only an issue with self-created certificates.

Editing RD Launchers

To edit a Remote Desktop Launcher:

1. Search for **Secret Templates**.
2. Access a secret template page.
3. Under the **Mapping** tab, scroll to the **Launchers** section.
4. For the Remote Desktop launcher, select **Edit**. This allows you to modify the settings for a launcher that has already been added to the template.
5. In the **Launcher mapping** section, select **Edit**:



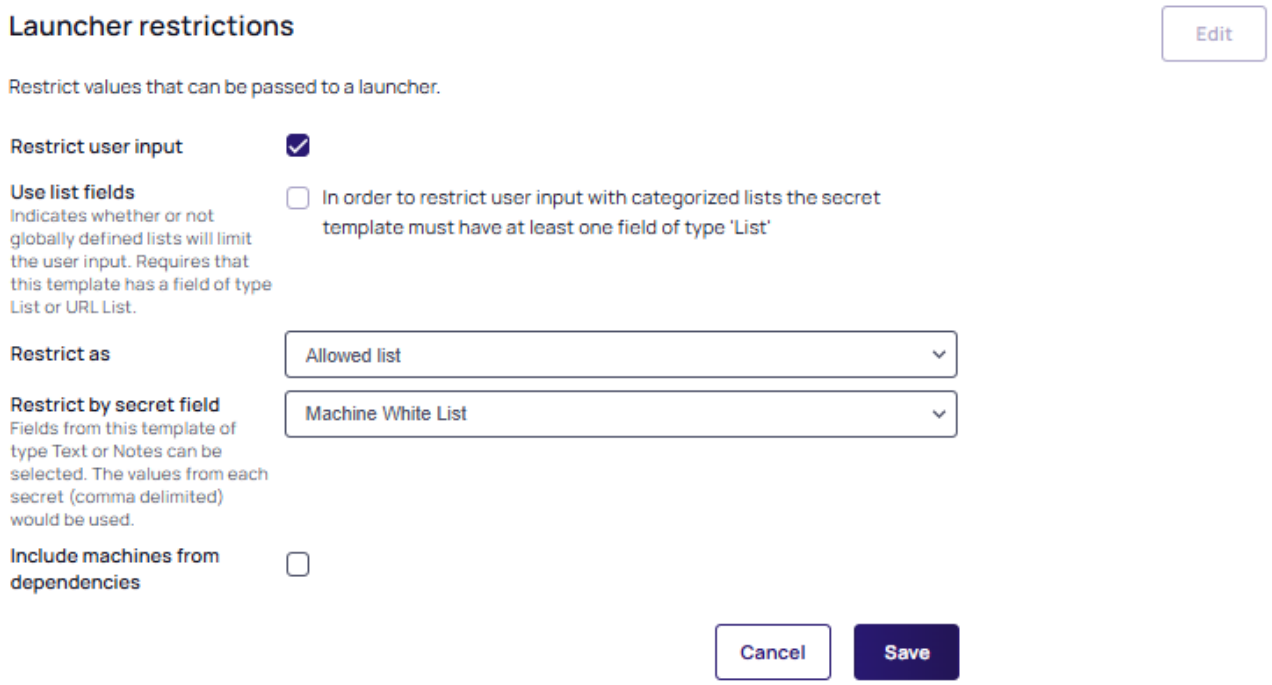
6. Define which fields from the secret will be passed to the launcher:
   - Computer
   - Domain
   - Password
   - Username

   For a launcher to work properly, Secret Server requires credentials to be taken from secret text-entry fields. These fields must be assigned their corresponding credentials from the list.

   In addition, the domain can be mapped to `<blank>`, which passes an empty string to be used with local accounts. The machine or host can be mapped to `<user input>`, which prompts the user for a specific machine to be used with domain accounts.

7. In the **Launcher restrictions** section, click **Edit**:

> This section allows you to restrict the values that can be passed to a launcher. The types of restrictions available for editing vary per secret template.



- **Restrict User Input**: Select this checkbox to enable restriction. In cases where there are multiple endpoints to connect to (such as with a domain account), the machines can be restricted to a set list. You may specify a field of comma-separated hosts or IP addresses that the user will be restricted to. Example: `192.168.1.2, MACHINE.EXAMPLE.COM, 192.168.1.60`.

  Choosing the **Allowed list** will allow only the option chosen in the **Restrict by secret field** dropdown list to be used. Choosing the **Blocked list** will allow all values except the option chosen from **Restrict by secret field** dropdown list.
- **Use list fields**: Indicates whether or not globally defined lists will limit user input. This option requires that this template has a field of type **List** or **URL List**.
- **Allowed list**: A user can select from values in this list.
- **Blocked list**: A user cannot enter these values. If used with an Allowed List, the Blocked List will take precedence.
- **Include machines from dependencies**: Selecting this checkbox adds the list of machine names from the secret dependencies to either the **Allowed list** or the **Blocked list**.

RDP Launcher Settings

To enable or disable the specific RDP Launcher Settings, on a related Secret with configured RDP Launcher, under the Settings tab, click Edit in the RDP Launcher section. Here you can enable or disable the following settings:

- Connect to console - enable to allow connecting to console.
- Allow access to printers - enable to allow access to printers.
- Allow access to drives - enable to allow access to local drives.
- Allow access to clipboard - enable to allow copy to clipboard.
- Allow access to smart cards - enable to allow access to smart cards. See Smart Card Integration with Secret Server for more details.
- Use Custom Window Size - enable to set window height and width.

Setting Up Secret Templates for RD Launchers

Launchers can be accessed from any secret created using a properly configured template.

By default, the Windows Account, Active Directory Account, Cisco Account (SSH), Unix Account (SSH), Web Password, Sybase Account, z/OS Mainframe, and SQL Server Account secret templates have one or more launchers automatically configured.

Secrets can be configured for launchers from the Secret Template Designer page. Clicking **Configure Launcher** displays the available options.

For more details on how to create and edit secret templates, see "Creating or Editing Secret Templates" on page 1194.

Removing the Mac Launcher

To upgrade or apply a fix to the Secret Server Mac Launcher, you must remove the version that is already installed. But first you must prevent the launcher from restarting, and terminate all processes related to the Delinea Launcher.

1. Open **Terminal** and type `launchctl remove com.thycotic.thycoticD`

   This step should remove the ThycoticDaemon and prevent the launcher from restarting, but you might need to perform the step more than once.
2. Open **Activity Monitor**.
3. Force Quit the **ThycoticLauncher** process and all related processes. See Quit an app or process in Activity Monitor on Mac.
4. Open **Finder**.
5. Navigate to **Application > Delinea**.
6. Right-click **ThycoticLauncher** and select **Move to Trash**.
7. Empty your trash.

Session Recording and Launchers

Session recording provides an additional level of security by recording a user's actions after a launcher is used. Session recording works for any launcher, including PuTTY and SSH, Windows Remote Desktop, Microsoft SQL Management Studio, and custom executables. The resulting movie is viewable from the secret audit. Session recording can be toggled on or off globally on the Configuration page and set for individual secrets on the Security

tab. Detailed information on supported codecs can be found in "Session Recording Overview" on page 1256. When a user launches a session with session recording enabled, a brief message is displayed to inform the user that their actions are recorded.

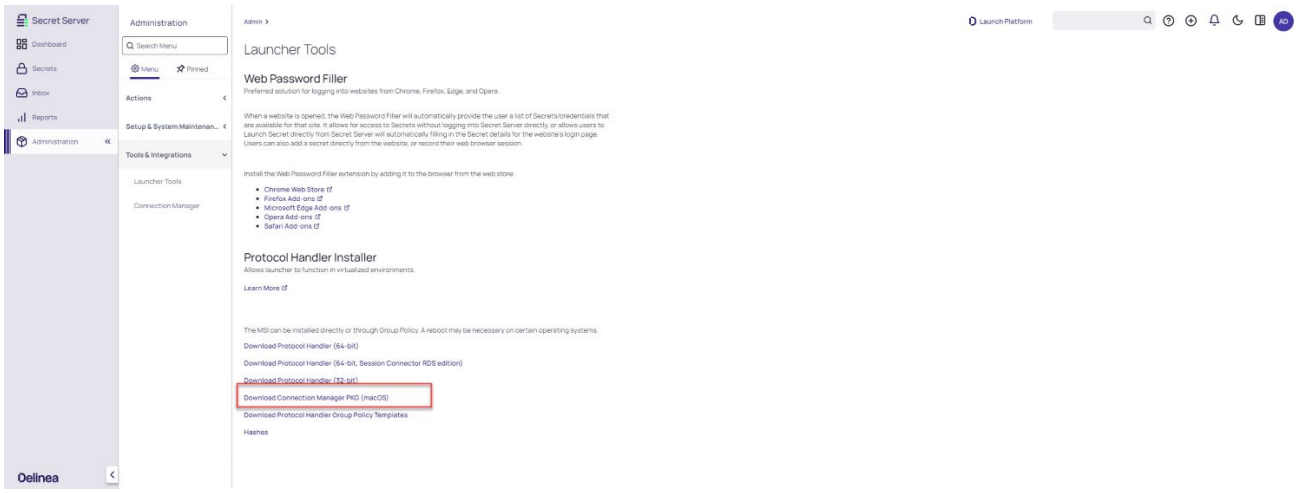
When multiple Launchers are enabled for a secret template, enabling session recording for a secret applies the setting to all launchers for that secret.

Protocol Handler cannot record processes when running as Secret Credentials without Administrator Elevation.

Setting Up the Mac Launcher

To set up the Mac launcher, simply follow these steps:

1. Inside Secret Server, navigate to Admin | Launcher Tools.
2. Select the Protocol Handler Installer for macOS



3. Navigate to your downloads directory and install the pkg on your Mac.

Removing the Mac Launcher

To upgrade or apply a fix to the Secret Server Mac Launcher, you must remove the version that is already installed. But first you must prevent the launcher from restarting, and terminate all processes related to the Delinea Launcher.

1. Open **Terminal** and type `launchctl remove com.thycotic.thycoticD`

   This step should remove the ThycoticDaemon and prevent the launcher from restarting, but you might need to perform the step more than once.
2. Open **Activity Monitor**.
3. Force Quit the **ThycoticLauncher** process and all related processes. See Quit an app or process in Activity Monitor on Mac.

4. Open **Finder**.
5. Navigate to **Application > Delinea**.
6. Right-click **ThycoticLauncher** and select **Move to Trash**.
7. Empty your trash.

Special Argument Handling

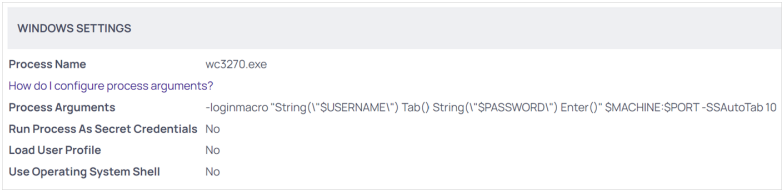
IBM iSeries Launcher

Usernames and passwords can run into length issues during the automated login process initiated by a launcher. The issue stems from the behavior in the client–when a user logs in and enters a username of 10 characters, the client automatically tabs to the next field (the password field). The launcher's automated login process automatically inserts a tab, which can cause improper behavior in the headless client.

If this behavior is observed, we added a parameter to the launcher's configuration to resolve it:

If you client adds a different number of tabs, replace 10 with that number.

1. Search for **IBM iSeries Launcher**.
2. Edit the value "Process Arguments," adding the `-SSAutoTab 10` parameter: For example:



Using Connect As Command and SSH Proxy with a PuTTY Launcher

Overview

Connect As Command is an advanced setting for the PuTTY launcher type where SSH proxy automatically runs the su command for a Unix root account secret after the user launches a PuTTY session. This provides a user elevated privileges without allowing a remote root connection or giving the user direct access to the credentials.

The connection procedure is as follows:

1. An admin uses this instruction to set up secret A (a Unix root account secret) to use secret B (a regular Unix account secret) as its "connect as" secret.
2. A user launches secret A.
3. SSH proxy connects using secret B's credentials.
4. SSH proxy issues the su command to switch the user back to secret A.

The procedure is performed once at the beginning of the session.

As noted, to implement this feature, you typically use a Unix *root* account secret and a Unix *regular* account secret. The session usually launches as the Unix *regular* account secret that is specified in the **Secret To Use** field on a Unix *root* account secret's **Settings** page.

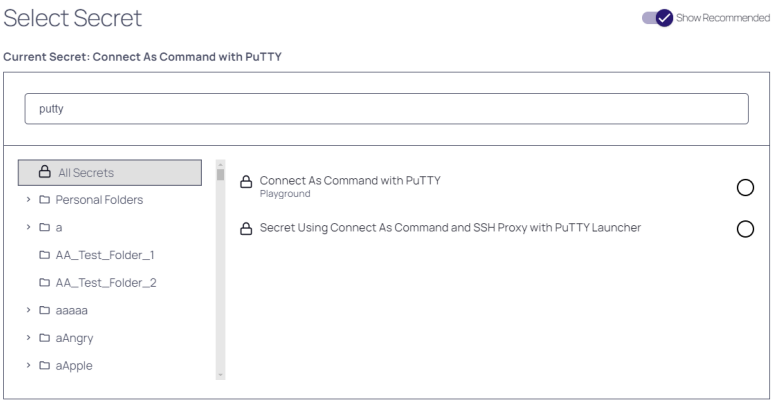
Setting up SSH Proxy to Use the Connect As Feature

This procedure explains how to set a "connect as" secret when using SSH Proxy to allow connecting with a less privileged account and then using sudo or su to elevate privileges.

1. Make sure SSH proxy is enabled in Secret Server's global configuration settings.
2. Open a secret based on a template with SSH proxy enabled that specifies PuTTY as the launcher type to use.

   For this feature, we recommend building a custom secret based on a copy of the built-in **Unix Root Account (SSH)** template, and associating the PuTTY launcher with it.

3. Click the secret's **Settings** tab.
4. Click **Edit** in the **SSH Launcher** section. Next to **Connect Using**, select **SSH Key on another Secret**.
5. Next to **Secret to Use**, click **No Selected Secret**.



Selecting a secret requires that the selected secret be either the same template type, or both template types use the same launcher type, or the template of the connect as secret has to have the Username and Password extended user mapping. If one of those isn't satisfied an error banner appears on the page.

6. Select the related secret from the Select Secret list and click **Save**.
7. Search for **Secret Templates**.
8. Select the related template.
9. Under the Mapping tab, scroll down to the Launchers and click **Edit** next to the PuTTY launcher.
10. Verify that the commands in the **Connect As Command** field are correct.

11. Click **Edit** if you need to make changes.

Secret Server Session Connector

Overview

Introduction

Normally, Secret Server requires installing additional software such as Connection Manager or Secret Server Protocol Handler (SSPH) on the end-user computers to launch secrets, such as RDP, SSH, or custom, and optionally record the session.

With Secret Server Session Connector (SSSC) installed on a Remote Desktop Services (RDS) server, anyone who can download and launch a standard Remote Desktop Protocol (RDP) shortcut file can have the same experience. The RDS server itself runs a special SSPH for RDS–SSPH (RDS) as a remote app to record the sessions, so end-users do not need to install any additional software.

The SSSC feature is largely scalable and can be set up using a single RDS server, a load-balanced cluster of RDS servers, or multiple load-balanced clusters of RDS servers. Before you set up the SSSC feature, there are some baseline requirements for those RDS servers and on your domain.

> SSPH (RDS) is sometimes referred to as RDPWin in this topic. RDPWin is the main executable that SSPH runs to launch and record sessions.

Table: Terms and Definitions

Term	Definition
RDP	*Remote Desktop Protocol*. A Microsoft protocol for remote control of computers.
RDPWin	The primary executable for SSPH.
RDS	*Remote Desktop Services*. Remote control services (using RDP) provided by a dedicated server or servers.
SSPH	*Secret Server Protocol Handler*. SSPH is an application on an end-user's machine. It enables communication between Secret Server and that client machine. It also provides the files needed by secret launchers.
SSPH (RDS)	*Secret Server Protocol Handler, RDS Version*. A special SSPH for use with SSSC that enables optional keystroke recording.
SSSC	*Secret Server Session Connector*. SSSC is the subject of this topic.

Session Connector Downloads

Two components must be installed on the RDS server to support Session Connector: the Session Connector MSI and the RDS version of the Protocol Handler.

- Session Connector MSI Version 1.0.4.0
- For the Protocol Handler, RDS version, Search for **Launcher Tools**, and click **Download Protocol Handler (64-bit, Session Connector RDS edition)** MSI' link.

Security Note – Protocol Handler Update

A previously identified security issue in older releases of the Secret Server Protocol Handler (including the RDS edition used by Session Connector) has been addressed in recent product updates.

The issue involved unsafe URI validation inside the protocol handler, which could allow unintended execution if a user opened a specially crafted link or document. Delinea has corrected this behavior in updated versions of Secret Server and the Protocol Handler.

Action Recommended:

- Verify that your environment is running a current, fixed version of Secret Server and the Protocol Handler before deploying Session Connector.
- Administrators running older on-premises versions (prior to 11.9.x) should review Delinea's official security advisories (trust.delinea.com) and upgrade accordingly.
- Always ensure that endpoints using Session Connector or protocol-handler-based launchers receive the latest approved build.

Connection Sequences

Figure: Session Connector Connection Sequences for an RDS Server.

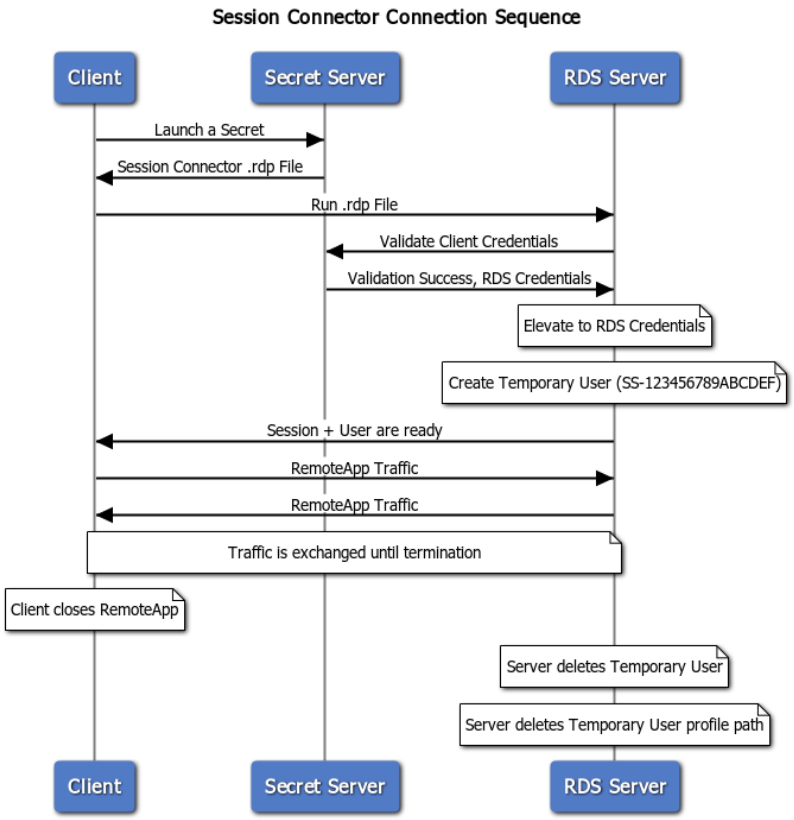


Figure: Session Connector Connection Sequences for Clustered RDS Servers.

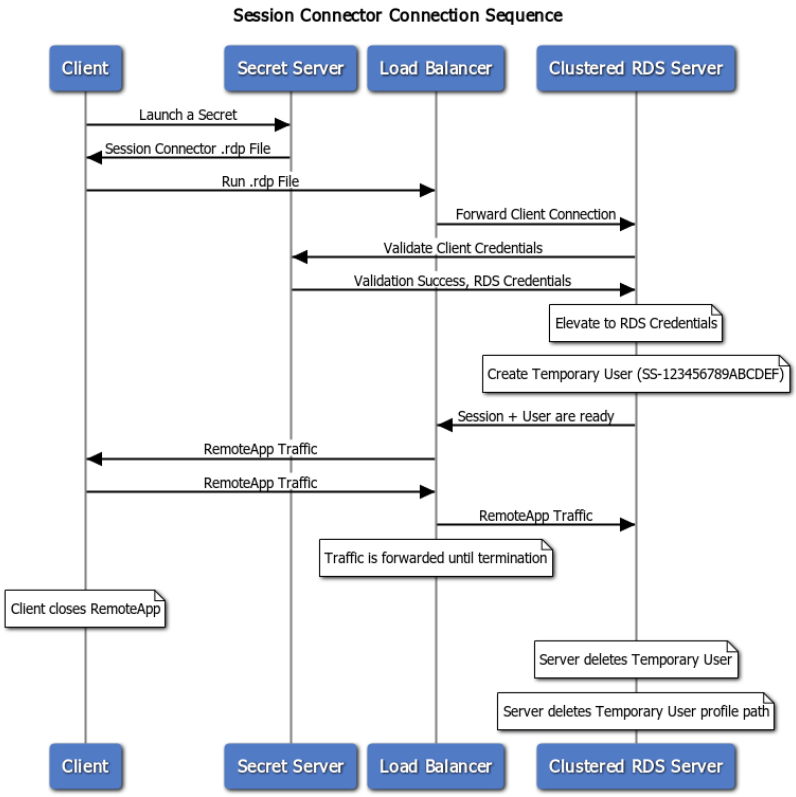


Session Connector is downloaded separately from Secret Server. Search for **Launcher Tools** to download the launcher application. Click the **'Download Protocol Handler (64-bit, Session Connector RDS edition) MSI'** link.

Configuration

> To comply with Microsoft licensing requirements, there is an additional constraint on which Microsoft Windows Server version you can use as the RDS server for session connector.

If you use Microsoft User or Device CALs, they must be the same version or newer than the Windows Server version they are accessing. For example, to access Windows Server 2019, you must have 2019 CALs (or newer). Older 2016 CALs will not work for a 2019 server, but newer 2022 or 2025 CALs are backward-compatible and can be used with any older supported version.

When configuring a session connector, it is essential to obtain Client Access Licenses (CALs) for Remote Desktop Services (RDS). These licenses may be required for the total number of users who will utilize the session connector. Delinea recommends consulting with your Microsoft representative for detailed guidance.

Security Hardening Recommendation

Once basic Session Connector installation is complete, Delinea recommends hardening the RDS hosts used for Session Connector.

See Hardening RDS Hosts for Session Connector for operating system, network, GPO, and AppLocker guidance specifically designed for this deployment scenario.

Task 1: Reviewing RDS Server Prerequisites

> Please ensure you turn on file and printer sharing on the Windows network configuration of the session connector machine before RDS installation and configuration. This can be done in the advanced sharing settings in the Network and Sharing Center. This is because when creating the collection, if such sharing is not on, the RDS service cannot recognize the session host by its name.

- Each RDS server should be a 64-bit installation of Windows Server 2016 or 2022.
- You **MUST** have access to the console session (non-RDP) to install the SSSC integration. This is in case of any errors during installation, which may disable RDP access to the server.
- Each RDS server must be domain-joined. Configuration of the RDS feature requires being logged in as a domain user.
- Each RDS server needs to have a recent version of the C++ redistributable installed (v14.44.35211.0):
  - Download: https://aka.ms/vs/17/release/vc_redist.x64.exe
  - More info: The latest supported Visual C++ downloads
- Each RDS server needs to have a credential available to manage temporary users. This credential should be able to create and delete local users and add users to the Remote Desktop Users group. If you plan to use one or more load-balanced clusters of RDS servers, this credential should be a domain user and will be used for all servers inside of a cluster. We recommend one domain user per cluster. This credential will be referred to as the **RDS Credential**. The RDS Credential account needs to be added to the **Log on as Batch job** GPO on the RDS servers.
- Each RDS server needs to have the RDS Session Host Windows feature installed. See the next section for details.
- The Default Domain Policy should be set to Log on as a batch job. The SSSC `.dll` requires this permission when it creates a disposable local account for the inbound session running the protocol handler. It calls the `Win32 API LoginUserW` passing in `LOGON32_LOGON_BATCH` as an input argument. Learn more about LogonUserW function here.

Task 2: Setting up RDS Services

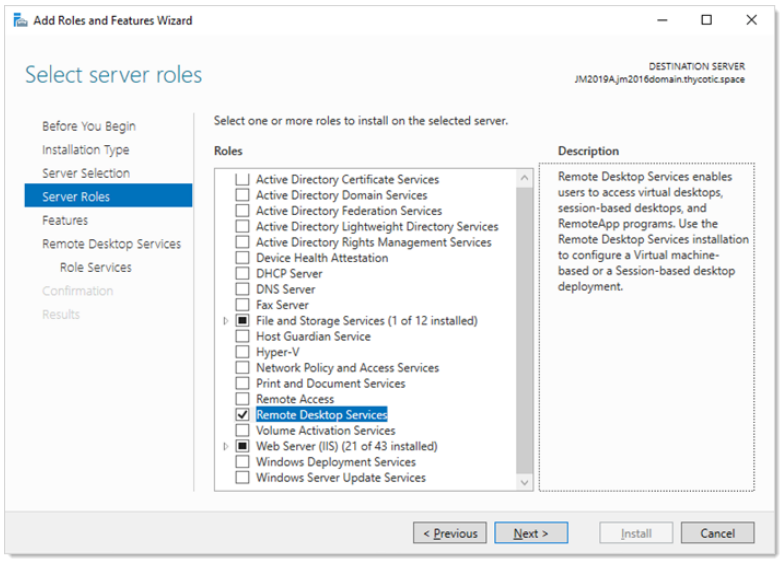
Step 2.1: Installing Remote Desktop Services–Remote Desktop Session Host

> SSSC cannot function without this feature and will refuse to install if it is not present. **RDS requires additional remote desktop licensing from Microsoft.** This may also require installing the remote desktop licensing feature if you do not already have a licensing server available in your environment. See Activate the Remote Desktop Services license server for details.

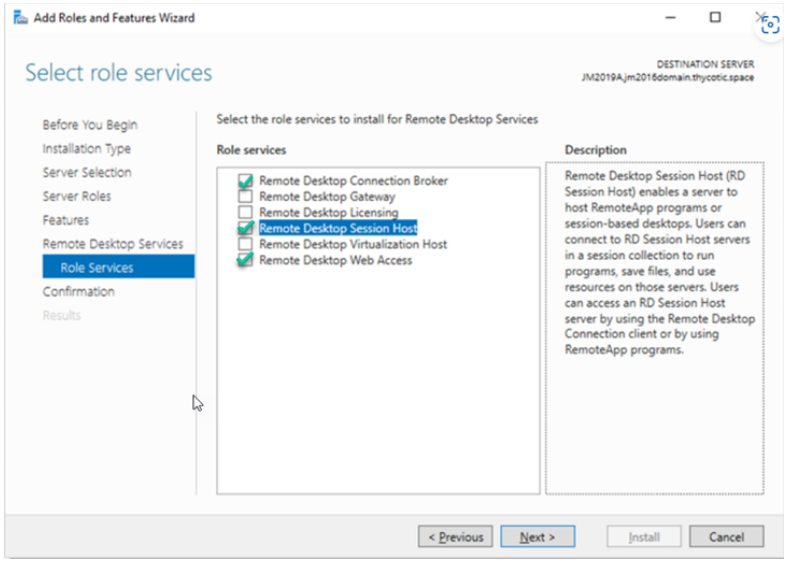
> The steps below have been tested on Windows Server 2016. The steps in newer versions may vary.

1. In Server Manager, click **Add roles and Features**. The Add Role and Features wizard appears.
2. Click the **Next >** button. The Installation Type page appears.

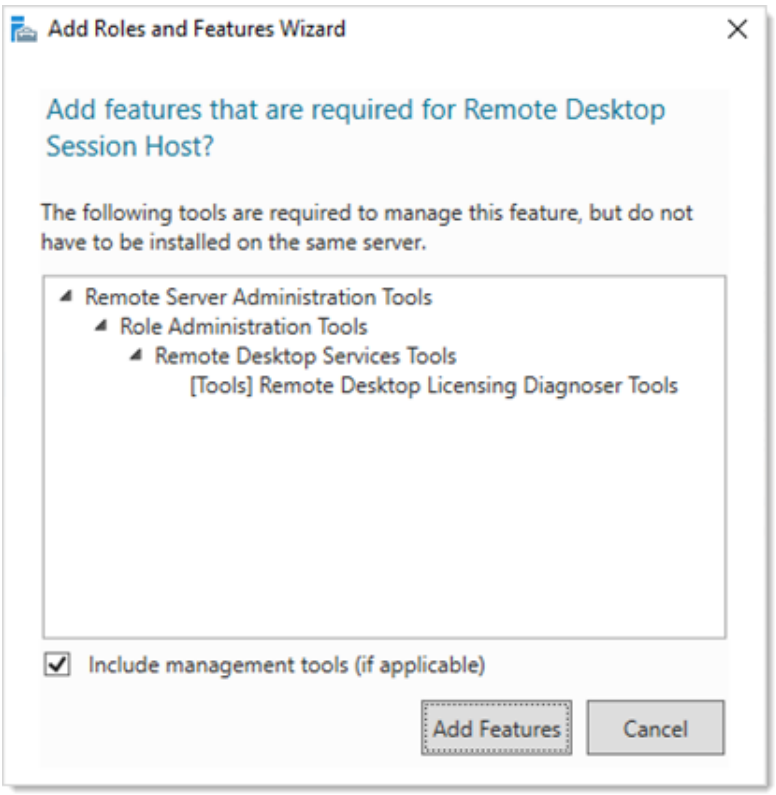
3. Select **Role-based or feature-based installation**.
4. Click the **Server Roles** menu item (or press **Next >** twice). The Select server roles page appears:



5. Click to select the checkboxes for **Remote Desktop Services**, **Remote Desktop Connection Broker** and **Remote Desktop Web Access** roles.
6. Click the **Next >** button. The Select role services page appears:



7. Click to select the **Remote Desktop Session Host** checkbox.
8. Click the **Next >** button. The Add features... page appears:



9. Click the **Add Features** button. A "Confirm installation selections" page appears.
10. Click the **Install** button.

Step 2.2: Configuring Session Connector Settings

The RDS session connector feature functions in the same manner without a certificate being set, but specifying a proper, password-protected certificate secret solves the trust issue between the publisher of the executed RDP file on the client server, and the RDS server. By doing this, you can avoid a warning indicating the **RemoteApp program can't be identified** when beginning the session.

The following applies to Session Connector Launchers with Keystroke Recording enabled: To enhance RDP security and ensure keystroke recording for all Secret Server Session Connector (RDS) sessions, we strongly recommend using certificate-signed RDP files (see Step 7 below) and deploying a Group Policy rule that disables the **Allow .rdp files from unknown publishers** default policy.

Enable Secret Server session connector:

1. Before continuing, note the following:
   - To create the certificate for this setting in Secret Server, create a new "Certificate with Private Key" secret.
   - The certificate file used by the secret must be of type `.pfx` or `.p12 (PKCS#12)`.

- The certificate file must be password-protected.
- The certificate file password must be specified in the secret itself.

2. Go to one of the following:
   - Secret Server Instance: `https://app/#/admin/configuration/session-connector-settings`
   - Secret Server on Delinea Platform: https://view/vault/admin/configuration/session-connector-settings
3. Click the **Edit** button on the right side of the page.

> Do not change any other settings on this page without consulting Delinea Support. Your Secret Server installation could malfunction.

4. Click to enable the **Session Connector Enabled** checkbox.
5. (Optional) If you do not want to use the 900-second (15-minute) default, type your desired number of seconds in the **Session timeout** text box. Session connector .RDP files are valid for this many seconds (only for a single use). If set to 0 or below, the default is used..
6. (Optional) Click to enable the **Session Connector Allow Connection Sharing** checkbox. This changes the value of "disableconnectionsharing" in the output session connector RDP files. If true, this speeds up concurrent launches into the same RDS server quite a bit by re-using the existing Windows sessions at the risk of causing errors if launching a new session while an old session is in the middle of closing. The default is disabled.
7. (Optional) Select the **No secret selected** button to set a certificate secret. Setting this secret to a secret of type “Certificate with Private Key” enacts the process of signing the RDP file with a certificate for the Subject Alternative Name (SAN)(not applicable for Secret Server On-Premises).
8. Click the **Save** button.

> When uploading a .pfx certificate, the file must contain exactly one private key. .pfx files with no private key or more than one private key are not supported. Certificate chains are supported only if the .pfx contains a single private key.

Step 2.3: Setting up RDS in Secret Server

1. Enable the **Session Connector** advanced configuration setting. For more instructions on this please follow the steps under **Configuring Session Connector Settings** below.
2. Search for **Application**. Ensure the **Custom URL** is set to a valid URL for your Secret Server. This URL is given out to SSPH launches (including SSSC and RDS SSPH) to ensure it knows how to connect back to Secret Server. Use HTTPS for maximum security. In fact, as of Secret Server version 10.9, SSPH and SSSC both refuse to connect to HTTP. This step applies to on-premise deployments only. Secret Server Cloud customers can skip this.
3. Create a Secret for the **RDS Credentials** mentioned above. If the credential is a local account, use a Windows Local Account secret, and if it is a domain user, use an Active Directory secret.
4. Create application users in Secret Server, one for each of the RDS server machines. See Creating RDS Application Accounts for details.

5. Share the secret created for the RDS credential mentioned above with the RDS application accounts that will be used by the RDS server(s). See Application Account RDS Credential Sharing.
6. Create SSSC custom launchers. For example, if you wanted to run an RDP session on the RDS server, you should configure a custom SSSC launcher that uses the built-in RDP launcher as its child launcher. See Configure Session Connector Custom Launchers.
7. Assign your SSSC custom launchers to the secret templates you want to launch from. See Assign Session Connector Custom Launchers to Secret Templates.
8. Configuration and setup is finished for Secret Server, but there are still some things you need to do inside of the RDS servers before setup is complete.

Task 3: Setting up RDS

Step 3.1 Install Session Connector MSI

1. Download the Session Connector ZIP from the updated link above and unzip to extract the MSI.
2. Open `cmd.exe` as **Administrator** (this is required due to the Windows Installer version used).
3. Run the installer: `msiexec /i SSSessionConnector.MSI`

Step 3.2: Installing the Secret Server RDS Protocol Handler

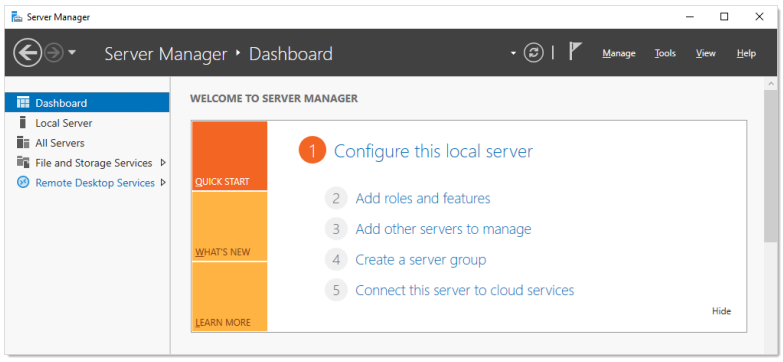
1. Go to **Tools > Launcher Tools** to download the launcher application.
2. Click the **Download Protocol Handler (64-bit, Session Connector RDS edition) MSI** link.
3. (Optional) Ensure the listed hash value matches that of the file.
4. Install the protocol handler on the RDS host

> SSPH (RDS) is a special version of SSPH that can record keystrokes on its own, if configured in Secret Server. Due to this optional keystroke recording, you may need to allowlist the `RDPWin.exe` file (the primary executable for SSPH) in any antivirus software running on the server. This is not currently necessary with Windows Defender.

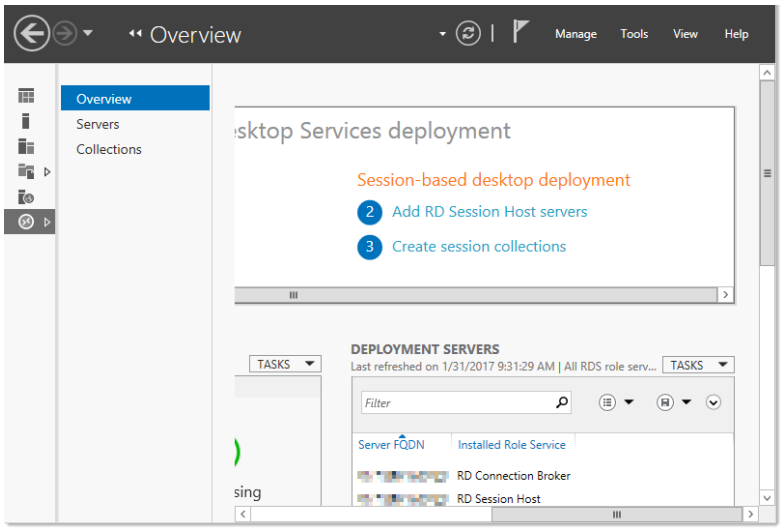
> SSPH (RDS) does not auto-update itself, unlike SSPH, because this could cause problems with multiple users running it at once on a single RDS server. Older SSPH (RDS) versions will continue to work with new Secret Server releases until updated, but a manual update is required on the RDS server(s) to take advantage of any future SSPH (RDS) features.

Step 3.3: Adding the Remote Desktop Collection and Application

1. While logged in as a domain user, go to Server Manager:

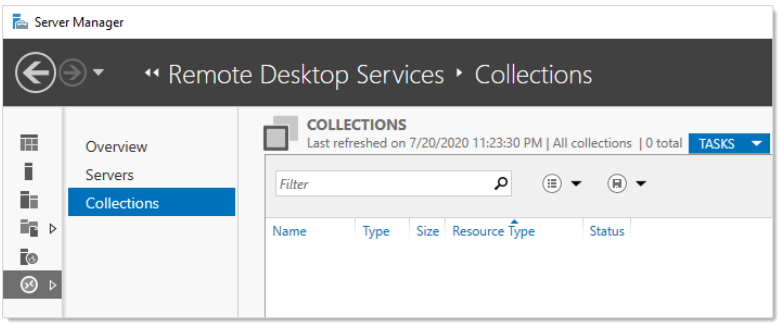


2. Click the **Remote Desktop Services** menu item on the left. The Overview page appears:

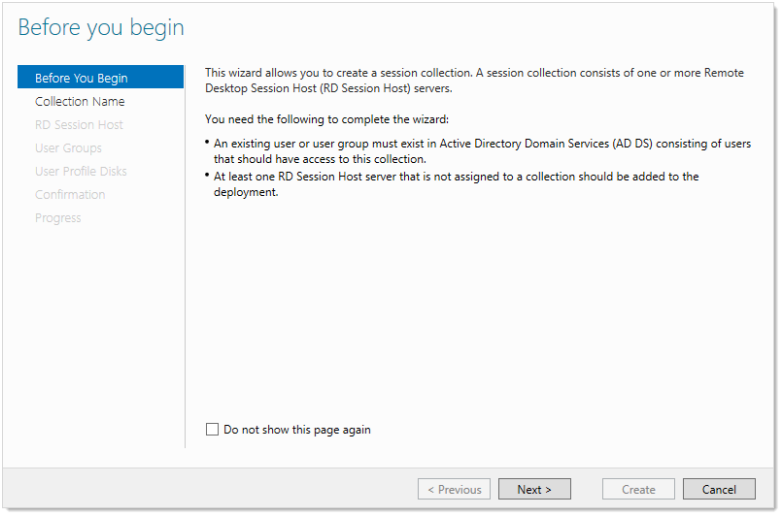


If you logged on as a local user, you will see this error and be unable to configure RDS. You must be logged on as a domain user.

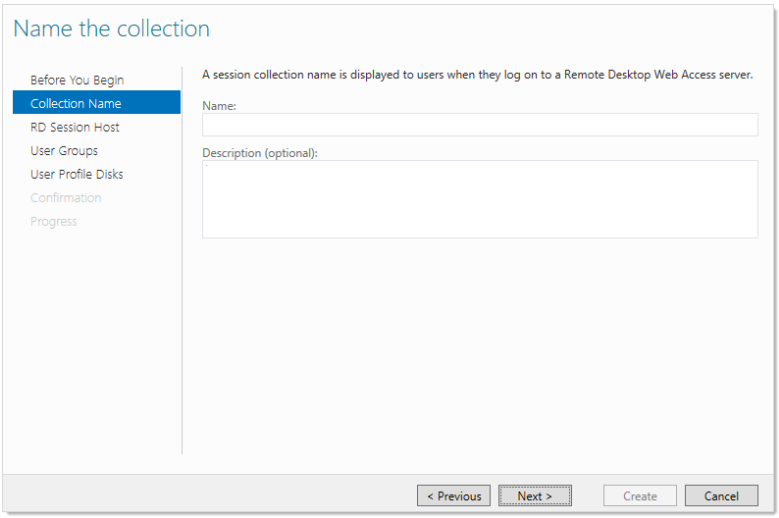
3. Click the Collections menu item. The Collections page appears:



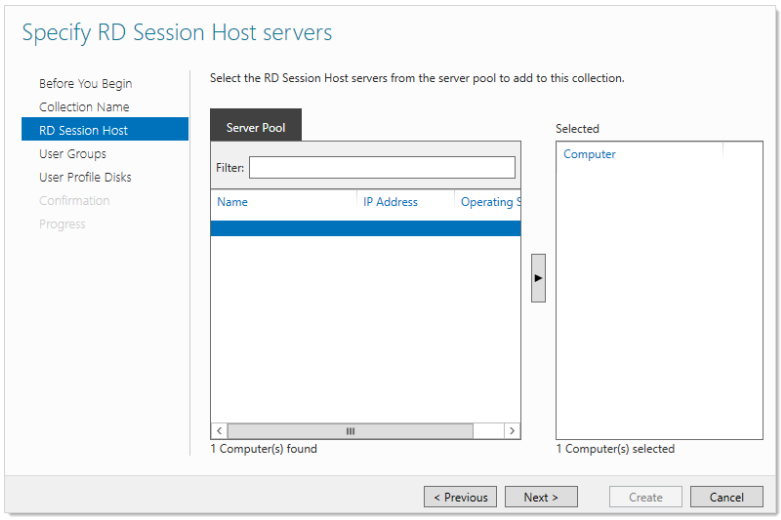
4. Click the **Tasks** dropdown list and select **Create Session Collection**. The **Create Collection** wizard appears on the Before You Begin page:



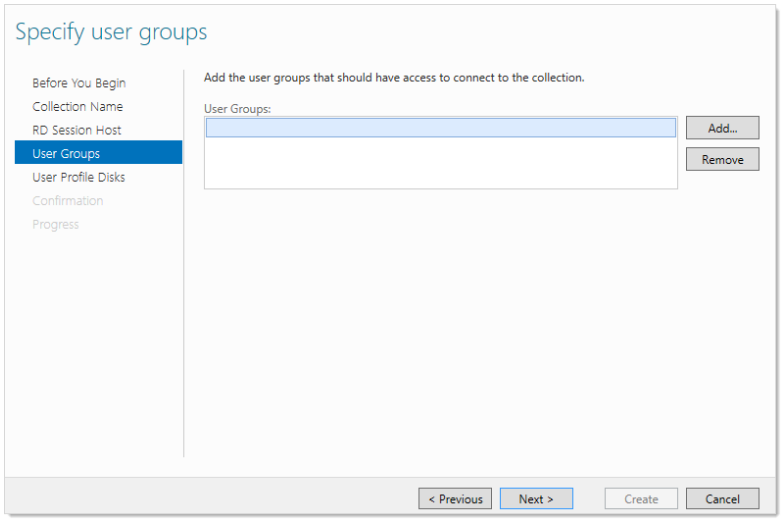
5. Click the **Next >** button to arrive at the Collection Name page:



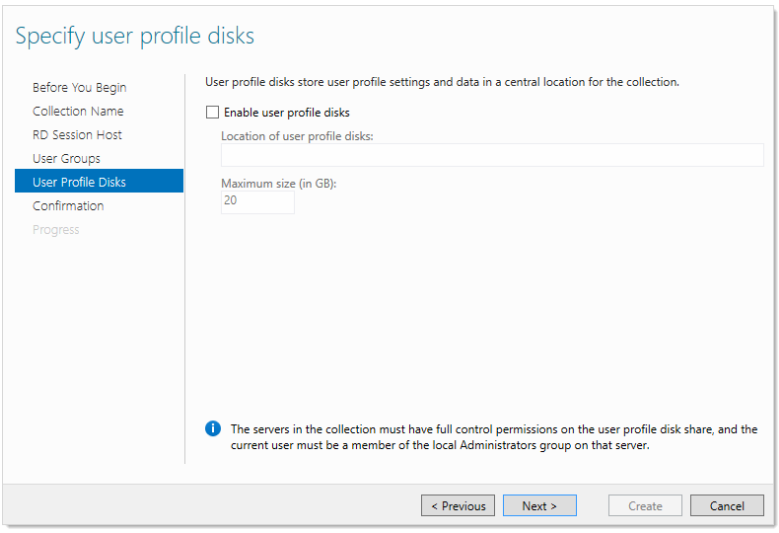
6. Type `Session Connector` in the **Name** text box.
7. Click the **Next >** button. The Specify RD Session Host Servers page appears:



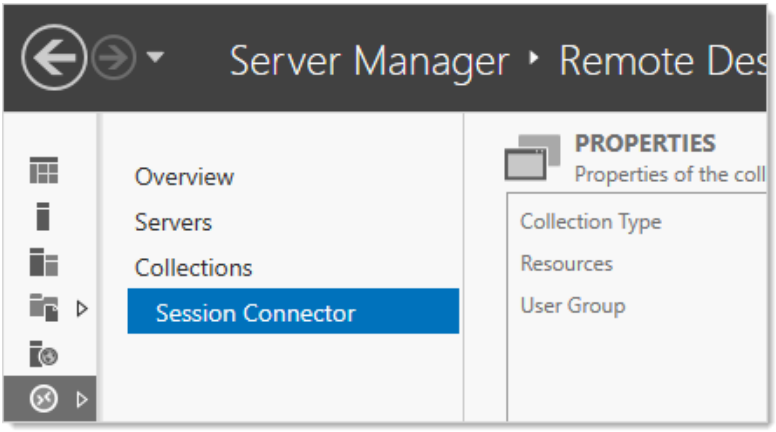
8. Add the local server from the left side (**Server Pool**) to the right side (**Selected**).
9. Click the **Next >** button. The User Groups page appears:



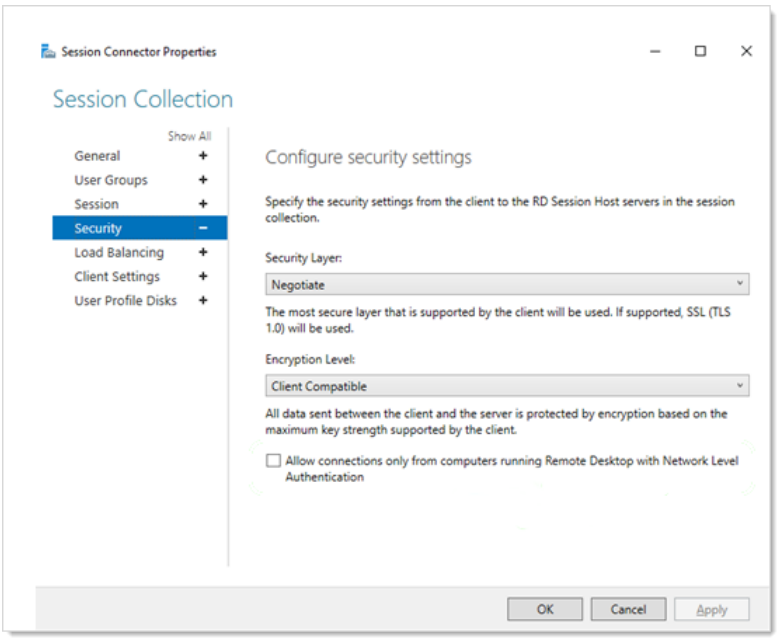
10. Create an empty group in Active Directory and reference it in the Collection configuration
11. Click the **Next >** button. The User Profiles page appears.



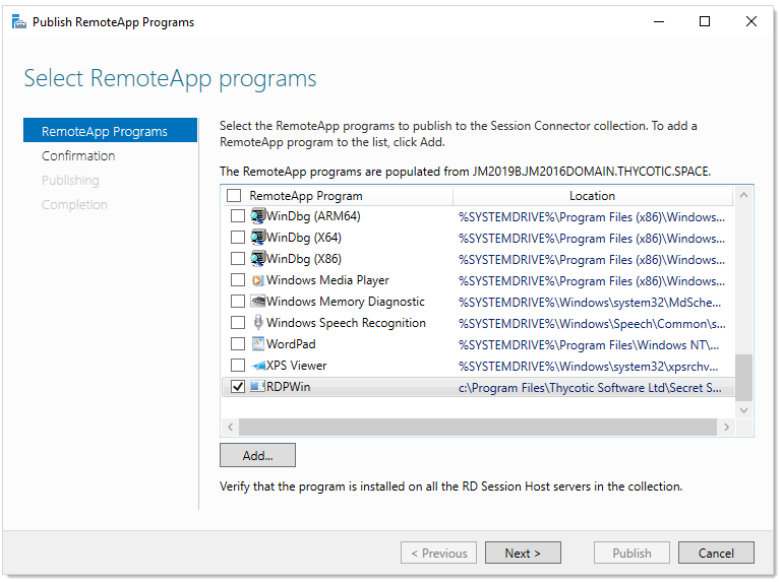
12. Click to select the **Enable user profile disks** check box to enable the **Create** button.
13. Click the **Create** button. The collection is created, and the wizard disappears. The session connector is now listed under Collections:



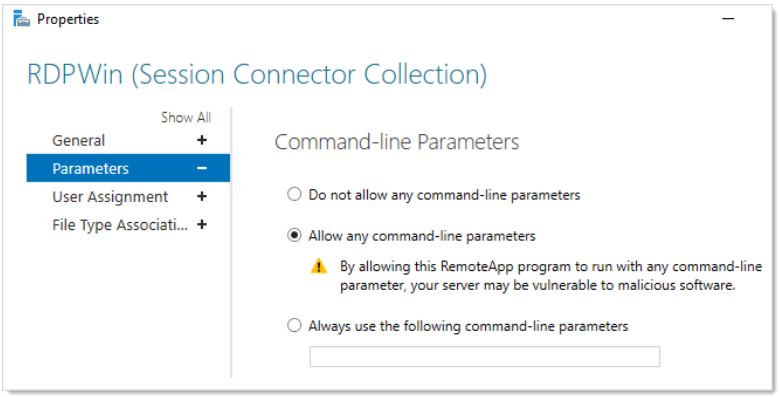
14. Click the **Tasks** dropdown list in the **Properties** section and select **Edit Properties**. The Properties popup appears.
15. In the left menu, click **Security**:



16. Click to deselect the **Allow connections only from computers…** check box. This is necessary because SSSC uses temporary one-time use local users that do not exist until a connection is authenticated with Secret Server, making them incompatible with network-level authentication.
17. (Optional) If you want to restrict what can be mapped at the server level, such as drives, you can do so on the **Client Settings** tab. This is also configurable in Secret Server on each secret.
18. Click the **OK** button. The popup disappears.
19. Click the collection name in the menu on the left.
20. In the **RemoteApp Programs** section, click the **Tasks** dropdown and select **Publish RemoteApp Programs**.
21. Click the **Add…** button to add the RemoteApp for RDS protocol handler. A dialog box appears.
22. Navigate to `C:\Program Files\Delinea Software Ltd\Secret Server Protocol Handler`.
23. Select `RDPWin.exe`.
24. Click the **Open** button. The dialog closes, and RDPWin (SSSH (RDP)) is now selected in the list:



25. Click the **Next >** button. The Confirmation page appears.
26. Click the **Publish** button to save.
27. Click the **Close** button.
28. On the RemoteApp Programs page, right click **RDPWin RemoteApp** and select **Edit Properties**. A property panel appears.
29. Click the Parameters menu item on the left:



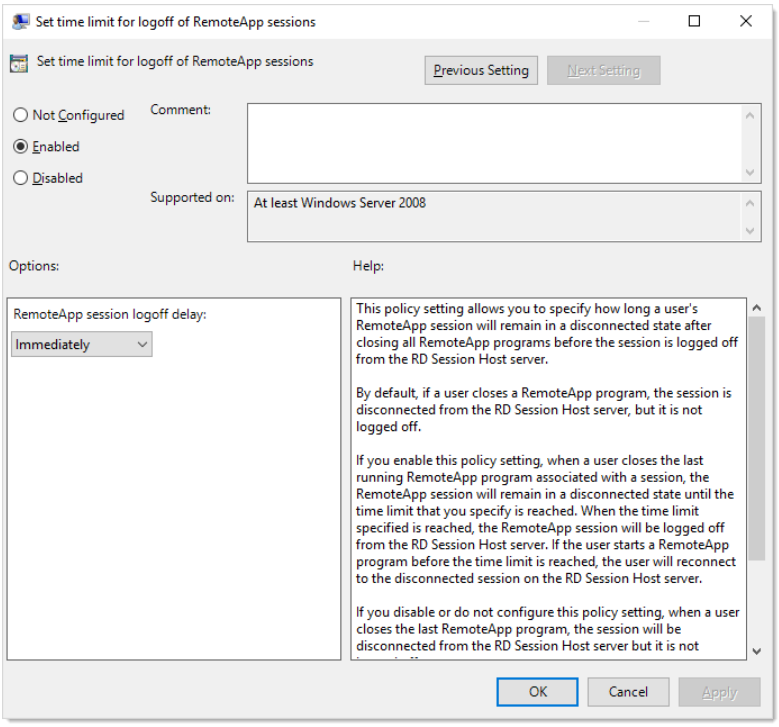
30. Click to select the **Allow any command-line parameters** selection button.
31. Click the **OK** button.

Step 3.4: Configuring RDS-related Group Policy Settings

To configure on a single server:

Set Time Limit for *Logoff of RemoteApp Sessions*:

1. Run the Group Policy Editor (gpedit.msc).
2. Go to **Computer Configuration > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Session Time Limits**.
3. Click **Set time limit for logoff of RemoteApp sessions** to edit it. Its properties appear:



4. Click the selection buttons to select **Enabled**.
5. Click the **RemoteApp session logoff delay** dropdown list and select **Immediately**.

Disable the *Always Prompt for Password Upon Connection* GPO Setting:

1. Navigate to **Computer Configuration > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Security**.
2. Locate the policy **Always prompt for password upon connection**.
3. Set this policy to Disabled. This ensures that passwords are automatically filled when launching an .rdp file, which is necessary for the seamless operation of the Session Connector.
4. Click **OK** to save.

Task 4: Updating API Credentials

The credentials for the SA application account are saved encrypted in the registry. The credentials are restricted to the NETWORK SERVICE account, which Remote Desktop runs under using DPAPI-NG.

If those application account credentials change in the future, follow these steps to update them:

1. Run the Windows Registry Editor, `Regedit.exe`.
2. Navigate to `HKLM\SOFTWARE\Thycotic\SessionConnector`.
3. Set **CredentialsEncrypted** to 0.
4. Set **SecretServerUsername** to the plain text new username.
5. Set **SecretServerPassword** to the plain text new password.

These credentials are encrypted upon their first use, either the next time someone launches a SSSC session that hits this server, or if you reboot the entire server. Once this happens, returning to the Registry Editor, CredentialsEncrypted will be set back to "1," and an encrypted version of the username and password will be visible.

Task 5: Launching Session Connector Sessions

Now that it has been configured and installed, you should be able to launch SSSC sessions.

Once configured, the SSSC custom launchers appear just like any other launcher on the associated secret template types. When clicked, a Remote Desktop shortcut (.RDP) file is downloaded. This .RDP file can then be opened by standard Remote Desktop clients, such as mstsc.exe in Windows or RoyalTS in OSX.

When launched, the end-user will connect to the RDS host configured on the SSSC custom launcher. The RDS host then launches the RDS protocol handler and connects to the actual destination machine.

Subprocedures

Creating RDS Application Accounts

1. Search for **Users**.
2. Click the **Create user** button. The Add User page appears.
3. Type in or set the account details.
4. Ensure that the **Enabled** check box is selected.

   Leave the Multifactor authentication set to default None, because this account is for SSSC and not a human being, so Multifactor authentication is not appropriate.

5. Click to select the **Application Account** check box. As an application account, the user can only log on through the application account API and does not require a separate user license.

   We recommend application account users because only API access is required by SSSC, and they do not consume regular user licenses. You may want to name the users to make it obvious which server they belong to. We recommend one user per RDS server for auditing purposes and to avoid one server with invalid credentials locking out the user, impacting all the other servers. See "REST API Reference Download" on page 1522 for more about the API.

6. Click the **Save** button.
7. Repeat this process for each RDS server if you are clustering more than one.

Enabling Application Account RDS Credential Sharing

Each RDS application account must have view access to the RDS Credential that the RDS server(s) use to manage the temporary Windows local accounts:

1. Go to the RDS credential secret you created earlier.
2. Click the **Sharing** tab.
3. Grant view access to the applicable application account users. That is usually one Secret Server user account per RDS server. If you are using a cluster, this secret would be an Active Directory secret for a domain credential that all the RDS servers can use, and you would share it with each of the RDS application accounts for each RDS Server in the cluster using in their SSSC configuration.

Configuring Session Connector Custom Launchers

You must create a custom launcher for each combination of RDS server cluster and custom launcher type:

1. Search for **Secret templates**.
2. Under the **Launchers** tab, click **Create**. The New Launcher page appears.
3. Type or set the parameters as follows:
   - **Launcher Type:** Session Connector Launcher. This launcher type will not be visible until the Configuration Advanced Setting is enabled.
   - **Launcher name:** Enter the related name for the Launcher.
   - **State:** Ensure this is enabled.
   - **Recording Options:** Select to Record video and keystrokes on related secrets with session monitoring enabled.
   - **Child launcher type:** Click to select the launcher type, such as Remote Desktop or PuTTY. This is the real launcher type that runs on the RDS server to connect to the secret.
   - **RDS server hostname:** IP or hostname for the RDS server or cluster.
   - **RDS server port:** Type the port. The default RDP port is TCP 3389.
   - **RDS server credentials:** Click the **Ne secret selected** link to pick the Secret configured above for credentials that can create and delete local users. If RDS Server Hostname points to a cluster, all servers must be able to use these credentials.
4. Click the **Save** button.

Assigning Session Connector Custom Launchers to Secret Templates

1. Search for **Secret templates**. The Secret Templates page appears.
2. Select a secret template that you want to allow SSSC to launch from.
3. Under the **Mapping** tab, click **Add mapping**.
4. In the **Add mapping** popoup select the related **Name**, **Domain**, **Username** and **Password**.

5. When done, click **Save**. The launcher is now displayed in the **Launchers** section. All secrets using this template are now ready to run SSSC launches.

Troubleshooting Session Connector

Launch Failures and Log Locations

When launching a downloaded .RDP file, if SSSC rejects the session due to any issues (including being expired based on the "Session Connector Session Timeout" setting), the user's Remote Desktop client will receive a generic error about the RemoteApp being invalid.

In the `SS.log` file, you can search for "SessionConnector" to find details about why sessions may have been rejected.

Session Connector will also log to the file `C:\Program Files\Delinea Software Ltd\Secret Server Session Connector\log\SS-SC.log` on each RDS server. If the RDS server encounters issues using the supplied RDS credentials—such as failing to create a local user—details of these errors will be recorded in this log file.

SSSC API Testing Tool

A dedicated API testing tool is available to help validate connectivity and troubleshoot issues with the Secret Server Session Connector (SSSC).

This tool allows you to test API connectivity between your RDS server and Secret Server, verify credentials, and check for common configuration issues.

Use this tool if you suspect connectivity problems, authentication failures, or configuration errors with the Session Connector. It is especially useful before deploying or when troubleshooting failed session launches.

When entering passwords in command line environments such as Command Prompt or PowerShell, avoid using special characters that are interpreted as escape characters by the shell. For example: ^, `, $, |, &

Basic usage:

1. Download and extract the zip file from GitHub - SessionConnectorAPITest.zip on GitHub.
2. Run the tool on the RDS server where Session Connector is installed.
3. Follow the prompts to enter your Secret Server URL and API credentials.
4. Review the output for connectivity status and error details.

For more detailed troubleshooting steps, see the Secret Server Session Connector API testing tool article on Delinea Support.

Uninstalling Session Connector

Secret Server Session Connector can be removed from "Add/Remove Programs" or "Apps & Features." Once uninstalled, a reboot is required to restore the default Remote Desktop behavior.

Any related SSSC custom launchers need to be un-associated with any secret templates they were previously tied to.

It is not currently possible to delete a custom launcher in Secret Server, but if it is unassociated with all secret templates, it will not appear on any secrets.

Notes

Many 3rd party applications have built-in functionality to create a new connection.

When a 3rd party application is used in conjunction with Secret Server Session Connector, if the remote app has the capability to create new connections the remote app could allow a user to bypass network segmentation controls that would otherwise limit access to controlled resources, with a potential to avoid session auditing in the event that the remote app creates a new system process along with the new connection upon creation.

They can also bypass access control lists configured on secrets designed to restrict which machines a secret can connect to.

Delinea recommends:

- Understanding whether configuring remote apps can cause users to be able to bypass any configured network segmentation or firewall designs by allowing the remote apps to connect from the RDS machine.
- Using Advanced Session Recording Agent (ASRA) to capture wider auditing.
- Determine whether Privileged Remote Access (PRA) or Privileged Manager fit your use case.

Using the Advanced Session Recording Agent on your RDS Servers where Session Connector is installed, you can ensure all remote activity is recorded.

Please see "Installing the Advanced Session-Recording Agent" on page 1271 for more details around installing and configuring ASRA.

Web Launchers

Web launchers are a separate login method from the Web password filler and provide a convenient click to automatically log on simpler websites. Web launchers do not work on complex login pages that rely on JavaScript. For those login pages, use the browser extension for the Web password filler. By default, Web launchers are enabled on the Web Password Secret template, but they can be enabled on custom templates as well, as described in "Enabling Launchers" on page 676.

Launching to a Website

The Web launcher can be used by clicking the Launcher icon on the Secret View page. The Web launcher opens a new tab in the browser, which attempts to login to the site using the credentials on the secret.

Installing Browser Extensions

Delinea Credential Manager

The Delinea Credential Manager (DCM) extension is the preferred launcher, and we recommend it for use instead of Web Password Filler (WPF). To use DCM, install one of the supported browser extensions as described below:

- Chrome: Download from the Google Chrome Web Store.
- Chrome Beta: Download from the Google Chrome Web Store.
- Other Chromium browsers, such as Vivaldi or Brave: Download from the Google Chrome Web Store.

  Rarely, certain Chrome extensions that rely on specific Google services or companion software may not work correctly in other Chromium browsers.

- Edge: Download from Microsoft Edge add-ons.

  Alternatively, you can install extensions from the Google Chrome Web Store in Edge by enabling the Allow extensions from other stores option in the Edge extensions settings, as Microsoft Edge supports Chrome extensions because it is a Chromium-based browser.

  Once enabled, you can add Chrome extensions to Edge almost exactly as you would in Chrome. Certain Chrome extensions that rely on specific Google services or companion software may not work correctly in Edge in rare cases.
- Firefox: Download from Firefox Browser add-ons.
- Safari and Opera **are not supported**.

DCM Beta provides early access to the latest version of the extension. We typically release the latest version a few days before the public launch. As a beta release, it may contain bugs and is intended for customer testing ahead of the official release. It is not recommended for production deployments.

Web Password Filler

WPF has been replaced by DCM. We recommend using that extension instead.

To use the WPF, install one of the supported browser extensions as described below:

- Chrome and other Chromium browsers: Install the extension by clicking the Web launcher icon in a Web Password secret, or by downloading it from the Google Chrome Web Store.

  See Managing Extensions in Your Enterprise for details on securely managing Chrome extensions at scale.
- Edge: Install the extension by downloading it from the Microsoft Edge add-ons site.
- Firefox: Install the extension by clicking the Web launcher icon in a web password secret, or by downloading it from the Firefox add-ons site.
- Safari: Install the extension by downloading it from Apple App Store. Please note the following installation specifics:
  - WPF supports Safari running on macOS Monterey and Big Sur 11.1.0, 11.2.1 and later.
  - WPF does not support the Native Messaging Host configuration in Safari browsers.
  - The Safari browser extension does not support Windows Admin Center.
  - Session recording is not supported on Safari 15 and above.
- Opera **is not supported**.

For information on enabling TOTP, see "Enabling TOTP for Secret Server Users" on page 461.

URL Lists

DCM supports URL lists. Users can map a list to the URL field in web launcher mappings. This can be useful in predefining various list categories of URLs. These can then be used as a field in a secret to allow that secret to be tied to various sites. This is especially convenient for dynamic secrets, such as Active Directory.

For more information on creating URL lists and launching comma-separated URLs, please refer to the Launching Comma-Separated URLs documentation.

Protocol Handlers

A *protocol handler* is an application on an end-user's machine. It enables communication between Secret Server and that client machine. It also provides the files needed by launchers.

When a Secret Server user starts a launcher, the protocol handler:

1. Bootstraps the client-side application.
2. Communicates with Secret Server over HTTP(S) to ensure that it is the latest version. If not, it begins an upgrade process.
3. Bootstraps the target launcher type and begins the process of securely logging in the user. Beyond HTTP(S) transport protection, credentials are retrieved securely from Secret Server using signed AES-256-encrypted messages.

Installing Protocol Handler Through Group Policy

Group policy allows you to install Secret Server Protocol Handler on specific computers and groups of computers in your domain. Installing through group policy does not require changes to your firewall.

Step 1: Prerequisites

The Secret Server Protocol Handler Installer requires that .NET Framework 4.8 or greater be installed on the client machine. Most machines should already have this installed.

Step 2: Downloading the MSI From Secret Server

1. Log in to Secret Server
2. Go to **Tools > Launcher Tools** and click **Download Protocol Handler** to download the MSI.

Step 3: Setting up a Network Share

1. Place the downloaded MSI file into a Network Share on your domain controller.
2. Give domain users read access to the share.

Step 4: Creating a Group Policy That Allows for the Installation of the MSI

1. Open up the group policy management console (**Start** >**AdministrativeTools** >**Group Policy Management**)
2. Expand the Forest and Domain nodes until you locate the domain on which you are installing Secret Server Protocol Handler
3. Right click on Group Policy Objects and click **New**
4. Enter a descriptive name for your GPO (such as Secret Server Protocol Handler Installation) and click “OK”
5. Right click on the newly created GPO node and click **Edit**.
6. Select **Computer Configuration** > **Policies** > **Software Settings** > **Software Installation**
7. Right click on the “Software Installation” node and select “New > Package”
8. Browse to the MSI on your network share (that is, `\\ServerMachineName\Shared` is a valid network share, while `C:\Shared` is not) and click **Open**.
9. Select the **Advanced** radio button and click **OK**.

   > If you wish to have Secret Server Protocol Handler uninstalled when it falls out of the scope of management, then click on the “Deployment” tab and check the “Uninstall this application when it falls out of the scope of management”

10. Click **OK**
11. In the group policy management object editor, expand **Computer Configuration > Administrative Templates > System** and click on the Logon node
12. Right click on the “Always wait for the network at computer start-up and logon”, select **Edit**, click **Enabled**, and click **OK**.

Step 5: Linking Your Group Policy Object to an OU

> If you want to install Secret Server Protocol Handler for specific computers and not for an entire OU, then the MSI allows for manual installation directly

1. Open up the group policy management console (**Start > Administrative Tools > Group Policy Management**)
2. Expand the Forest and Domain nodes until you locate the domain on which you are installing Secret Server Protocol Handler
3. To link the GPO to an entire OU:
   - Right-click the Organizational Unit for which you want Secret Server Protocol Handler to be installed and select **Link an Existing GPO**.
   - Select the GPO you created in "Step 4: Creating a Group Policy That Allows for the Installation of the MSI" above above.
   - Click **OK**

The OU is now linked to the GPO. To immediately force the group policy change and install the software on a client machine, open a command console on the client machine (start > run > cmd), type `gpupdate /force`, and restart the client machine. You can also wait for the group policy to go into effect, which usually takes one to two hours.

Step 6: Verifying the Configuration

1. **Start** > **Administrative Tools** > **Active Directory Users and Computers**
2. Right-click the Organizational Unit for which Secret Server Protocol Handler is now configured and select **All Tasks > Resultant Set of Policy**.
3. Check the box next to **Skip to the final page of this wizard without collecting additional information** , then click **Next** and **Next** again.
4. Click **Finish.**
5. In the new “Resultant Set of Policy” window, expand **Software Settings** under **Computer Configuration** and select **Software installation**.
6. “Secret Server Protocol Handler” should be visible under the **Installed Applications** column.

Managing Multiple Secret Server Instances with Protocol Handlers and Launchers

In an organization running multiple instances of Secret Server, some users might find themselves having to repeatedly uninstall and reinstall different versions of the protocol handler to match the different instances of Secret Server.

To enable Secret Server to simultaneously support multiple versions of the protocol handler, you just need to disable the protocol handler auto-update function using the procedure below.

Disabling auto-update for forward and backward compatibility is supported on the protocol handler only. The ClickOnce launcher and the Mac protocol handler do not support disabling auto-update.

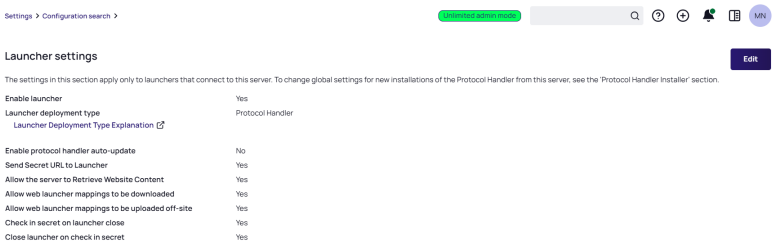
Prerequisites

- Secret Server Cloud 10.8+
- Secret Server On-Premises 10.8+
- Protocol Handler 6.0.0.23 or higher on your PC

Setup Steps and Configuration

1. In Secret Server, Search for **Launcher Settings**, and click **Edit**.
2. Uncheck the box next to **Enable Protocol Handler Auto-Update**, and click **Save**.

3. Ensure that the **Enable Protocol Handler Auto-Update** function is now labeled, **No**.



You can re-enable protocol handler auto-update at any time by following the steps above and re-checking the box next to **Enable Protocol Handler Auto-Update**. When you re-enable auto-update, users will be required to install the latest instance.

> While protocol handler auto-update is disabled, each user must manually update their installed protocol handler as necessary on a machine-by-machine basis. The MSI can be installed directly or through Group Policy. A reboot may be necessary on certain operating systems.

Manually Updating Protocol Handler

1. In Secret Server, Search for **Launcher Tools**.
2. On the **Launcher Tools** page, in the **Protocol handler installer** section, click **Download Protocol Handler (64-bit)** to download the file.
3. Follow the steps in the installation wizard.

Protocol Handler Administrative Settings

The Secret Server protocol handler has several administrative settings that you can configure through Microsoft's Group Policy Objects (GPOs) or through Secret Server itself.

> We **strongly** recommend using GPOs instead of Secret Server.

Available Settings

Allowed Secret Server Domains

This setting controls which domains or IP addresses the protocol handler installation may connect to.

Behavior prior to Protocol Handler 6.0.3.48: If the setting is not set or disabled, the protocol handler can connect to any domain. If one or more comma-separated values are provided, then the protocol handler is blocked from accessing any domains or IP addresses not included in the list.

Behavior in Protocol Handler 6.0.3.48 and later: When Group Policy (GPO) settings for Allowed Secret Server Domains are present, only those domains are allowed. When GPO settings are not present, the first Secret Server domain the protocol handler successfully contacts is automatically added to the local allow list. Subsequent attempts to contact other domains are rejected.

> To support multiple different Secret Server instances, configure Allowed Secret Server Domains via GPO.

It is important to note that the protocol handler performs a string match against the URL it receives. It does not attempt to resolve domain names to IP addresses. Values in the allow list should match only the domain or IP address portion of the actual URL used to access Secret Server.

For example, if users access your installation via `https://example.com/SecretServer`, then `example.com` should be added to the list. If `example.com` resolves to the IP address `192.168.1.5`, then adding that IP address *will not* allow access to the domain if users actually access it via `example.com`.

Wildcards are not supported, but subdomains do matter. Continuing with the example used above, the entry for `example.com` would not allow `www.example.com`. The two may need to be added separately depending on your configuration.

Ports and protocols are also unnecessary—only the domain portion is checked. For example, do not include an entry in the list like `https://example.com` or `example.com:885` as both are invalid. Simply using `example.com` covers these scenarios.

Disable Auto-Update

This setting ensures the protocol handler will never auto-update itself, even if told to by the Secret Server installation that it connects to.

> When this setting is enabled, protocol handler installations need to be updated either manually or as part of your organization's regular program-update process.

Configuration Methods

> If your domain is configured to use GPOs, we **strongly recommend** using that to configure the protocol handler.

Choosing a Configuration Method

Why use GPOs instead of Secret Server?

- GPOs are more resilient, as Windows reapplies settings if they are deleted from the registry. Settings applied through Secret Server have no such resilience.
- GPOs are centrally managed along with other settings for machines in your domain.
- For security reasons, Secret Server's configuration can only be applied during the initial installation of Secret Server. If you change these settings within Secret Server, users must reinstall the program before they will be applied. GPOs do not have this restriction.

Configuring through GPOs

You can download GPO definitions for your version of Secret Server by searching for **Launcher Tools** in the UI. For details about using these policy definition files, see How to create and manage the Central Store for Group Policy Administrative Templates in Windows.

Settings are available in the group policy editor under **(Computer/User) Configuration > Administrative Templates > Secret Server Protocol Handler**.

> Both machine and user configurations are supported. Machine configurations, however, override user configurations. If a machine configuration exists, the user configuration is ignored.

Configuring Settings During Secret Server Installation

If you do determine that using Secret Server's settings is necessary, you can configure them by accessing **Settings > All Settings > Configuration > Launcher Settings > Protocol handler installer**. The **Protocol Handler Settings (Install-Time)** page will load where you can edit and enable the **Enable install-time settings** option.

Enabling these settings causes downloads to generate a zip file rather than an MSI file. The zip file contains a batch file that configures the install-time settings. These settings only update when the protocol handler is manually reinstalled or updated—changing them later on through Secret Server has no effect on protocol handlers that are already installed on user machines.

Timeouts and Launch Behavior Issues

When launching a secret, you may see the alert **Protocol Handler Failed to Launch. The launcher application may not be installed**. This message is a false positive—the launcher still starts successfully after a short delay (3-5 seconds).

The timeout that triggers this alert is set to 15 seconds, which is the amount of time Secret Server waits for the Protocol Handler to launch. If it fails to launch within this time, the user will be prompted to download the Protocol Handler.

> This timeout is hardcoded within the application and cannot be adjusted through the user interface or configuration settings.

Secret Server Mobile Apps Overview

> Note: Credential Manager Mobile is transitioning to Credential Manager. Future updates and support will focus on Credential Manager as the primary mobile application.

Both Secret Server Mobile and Credential Manager Mobile provide secure access to secrets and support multi-factor authentication (MFA). However, they have distinct features and functions tailored to different use cases. Below is a comparison of the two mobile applications:

Secret Server Mobile

Primary Functionality

- Connects to a Secret Server instance to view, manage, and use secrets.
- Supports multi-factor authentication, biometric unlock, autofill, online and offline caching, and advanced secret workflows.

Key Features

- **Multi-Factor Authentication**: Supports DUO Push, DUO Phone call, Pin Code, and TOTP authenticators.
- **Biometric Authentication**: Supports fingerprint (Android and iOS) and facial recognition (iOS only).
- **Autofill**: Automatically populates username and password fields on specified websites or other mobile applications.
- **Online and Offline Caching**: Secure storage for secrets, with options for offline access.
- **Advanced Secret Workflows**: Includes checking in or out secrets, submitting access requests, and handling approvals and denials.

User Interface

- Similar to the Secret Server desktop interface, making it easy for users to navigate and find secrets.
- Home screen with options to view secrets in different ways (All, Favorites, Recent, Shared).
- Side navigation panel for quick access to Inbox, Folders, Cached items, Change Password, Settings, Feedback, and Logout.

Credential Manager Mobile

Primary Functionality

- Provides MFA verification for the Delinea Platform and portable access to secrets managed in Secret Server.
- Supports multiple Secret Server tenants for users needing access to multiple instances.

Key Features

- **Multi-Factor Authentication**: Supports Credential Manager Mobile Authenticator and biometric unlock.
- **Biometric Authentication**: Supports fingerprint (Android and iOS) and facial recognition (iOS only).
- **Autofill**: Automatically populates username and password fields on specified websites or other mobile applications.
- **Offline Access to Secrets**: Allows users to download secrets and access them without network connectivity.
- **TOTP Capabilities**: Provides time-based one-time password (TOTP) capabilities for sites and web applications that support TOTP-based authentication.

User Interface

- Designed to provide a seamless user experience with easy navigation and access to secrets.
- Supports viewing, creating, and organizing secrets into folders.
- Includes features for setting up and managing MFA, viewing notifications, and handling offline access.

For more details, refer to the Credential Manager Mobile Overview.

Summary

- **Secret Server Mobile** is primarily focused on providing comprehensive access and management of secrets within the Secret Server environment, with robust support for secret workflows and offline caching.
- **Credential Manager Mobile** extends its functionality to include MFA verification for the Delinea Platform, supports multiple Secret Server tenants, and offers additional features like TOTP capabilities and offline access to secrets.

Both applications enhance security and productivity by enabling secure access to secrets and supporting various authentication methods, but they cater to slightly different use cases and user needs.

Setting Maximum Time for Credential Manager Mobile Offline Caching

Overview

The **Maximum Time for Offline Access on Mobile Devices** setting in Secret Server determines how long to cache secret data on the mobile device. Once the device is not in contact with the server for longer than the specified amount of time, the device removes its cache of the stored secrets. The only way to view secrets on the device once the cache is cleared is to connect to Secret Server again so that the secrets can be re-downloaded and cached.

Procedure

To set the maximum time:

1. In Secret Server dashboard, Search for **Application**, and click **Edit**.
2. Click to select the **Enable Webservices** check box.
3. Type your preferred interval in the **Days** and **Hours** text boxes in the **Maximum Time for Offline Access on Mobile Devices** section. The Maximum Time for Offline Access on Mobile Devices setting in the server determines how long to cache secret data on the mobile device. Once the device is not in contact with the server for longer than the specified amount of time, the device removes its cache of the stored secrets. The only way to view secrets on the device once the cache is cleared is to connect to SS again so that the secrets can be re-downloaded and

Setting the Maximum Time Offline to less then an hour prevents the device from caching as the cache window is too small.

> Because caching all secrets creates an audit record in the database for each secret, we recommend not setting the window too short so that users constantly need to cache all secrets.

4. Click the **Save** button at the bottom of the page.

> Ensure configurations are compatible with Credential Manager. Future updates will focus on enhancing Credential Manager's offline capabilities.

Example

An example of a cache window:

If Maximum Offline Time is set to 7 days, an iPhone user can cache secrets. If the iPhone has connectivity every hour the iPhone is used, it will check in with the server. Each time the iPhone checks in the 7 days, the cache window is extended. Thus, if the user uses the app once every 7 days, the app cache will remain. If the user does not have connectivity (such as in Airplane Mode) or does not turn on the app for longer than 7 days, then the next time the app is used the cache will be cleared because the maximum allowed time offline has been surpassed.

Secret Server Networking Overview

Secret Server offers a comprehensive suite of networking features designed to secure and manage privileged access. Below is an overview of key components including messaging, distributed engines, RDP proxy, HTTP, and SSH.

Messaging

Secret Server uses RabbitMQ as its message bus or broker to facilitate message traffic between various components. This asynchronous message-based system ensures that operational instructions and data are passed back and forth efficiently. All messages are encrypted during transit, and any accumulation of messages in a queue is considered abnormal, indicating a potential application problem.

Distributed Engines

Distributed engines in Secret Server provide scalability and rapid results for large networks. They use secure network communication, queueing, and parallel processing to manage tasks such as password changes and discovery. A distributed engine consists of site connectors, sites, and engines, which work together to distribute and process work items efficiently.

RDP Proxy

Secret Server uses an SSH Proxy to secure RDP connections within a Privileged Access Management (PAM) solution. This approach mitigates the risks associated with direct RDP access by routing all RDP and SSH connections through the Secret Server host or a Distributed Engine. This setup ensures that only authorized sessions can access target hosts, and it prevents malware from spreading laterally between machines.

HTTPS

You can configure Secret Server to run with multiple front-end web servers, offering clustering for redundancy and load balancing. This setup ensures better performance and limits potential downtime from a single point of failure. The backbone bus, typically RabbitMQ, handles all internal communication between roles in a clustered environment.

SSH

Secret Server's SSH Proxy routes SSH sessions to protect endpoint credentials. It can be configured to proxy through the Secret Server web application or a distributed engine. This setup allows for secure and monitored SSH access, ensuring that all connections are authorized and audited.

These components work together to provide a secure, scalable, and efficient networking environment for managing privileged access in Secret Server.

Secret Server Architecture

To view the architecture diagrams for Secret Server, see Platform Architecture.

Distributed Engine Overview

> Distributed engine configurations for Secret Server On-Premises and Secret Server Cloud are not 100% equivalent. To view the differences, please refer to our reference architectures for Secret Server. They are, at minimum, refreshed every year and are created by our Professional Services Solutions Architect team.

> Distributed engine upgrades are no longer mandatory for every release. The Distributed Engine Configuration page can set the minimum required engine version. Modifying this triggers an automatic update for any engine below this version.

In the action menu for an engine on the Sites page, you can start a manual upgrade for individual engines below the latest version, which prompts the engine to update when it next calls in.

When changes are made needing an upgrade, the minimum required version is updated during the update process, and all engines update immediately.

Overview

Out of the box, Secret Server performs all functions from the Web server it is installed on; however, specific features can be routed through a distributed engine for enhanced performance. For example, synchronize and authenticate AD users can be done in Secret Server via your local site or from a distributed engine (DE).

You can install a DE in a remote site and allow it to operate many functions. Communication with Secret Server Cloud also requires the distributed engine to be installed. Note that you should not install a DE on the same machine running Secret Server.

Architecture and Workflow

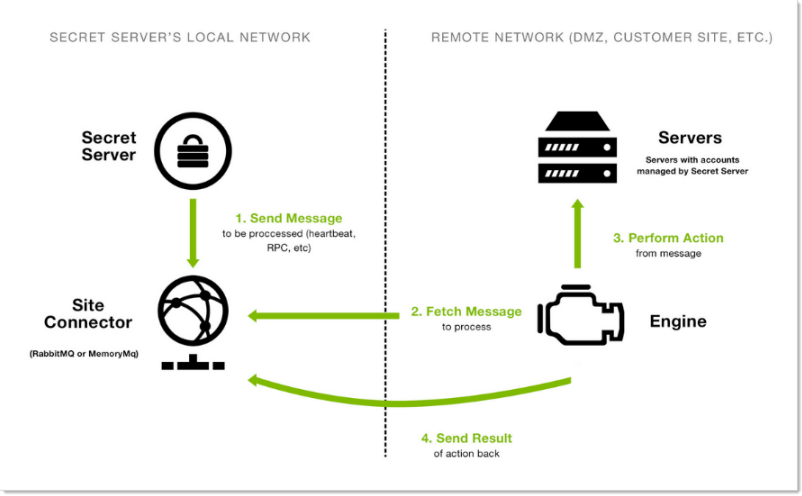
Main Components

DEs support heartbeat, Remote Password Changing (RPC), and discovery. A DE is composed of site connectors, sites, and engines:

- A **distributedengine** is a Windows service that does the actual work, such as password changing, heartbeat, discovery, and more. Each engine belongs to a site.
- A **site** can be thought of as a bucket of work items for a particular network area. Each engine is assigned to a single site, but each site can include multiple engines, significantly increasing throughput.
- A **site connector** is a Windows service that holds the work items for a number of sites. The site connector can be either RabbitMQ or MemoryMQ (a built-in service developed by Delinea). Each site can only be assigned to a single site connector, but you can have multiple site connectors running on separate machines, each storing work items for multiple sites. Those sites, in turn, distribute the work items among multiple engines. The ability to add new Site Connectors, Sites, and Engines as needed makes Distributed Engine a highly-scalable solution.

> For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.

Figure: Distributed Engine Components



> The above diagram is a simplified, conceptual one, not a network diagram. It does not show a callback port from the DE to Secret Server. DEs require either an HTTPS or TCP port to communicate with Secret Server for initial activation, updates, and continuous periodic check of site and site connector settings.

Ports

DEs have two configurable ports: one for connecting to the site connector, and one for the engine to retrieve configuration information from Secret Server at regular intervals. The callback port from an engine to Secret Server can be configured to contact the website directly over HTTP, HTTPS, or TCP. HTTP and HTTPS connections use the existing IIS port bindings. All connections are outbound—no inbound connections are made from Secret Server or the site connectors to the remote networks.

Default ports:

- RabbitMQ: 5672 (non-SSL), 5671 (SSL)
- MemoryMQ: 8672 (non-SSL), 8671 (SSL)
- Secret Server: existing IP address bindings or custom port over TCP. We reserve one port for legacy upgrades, usually port 9999.
- Secret Server Cloud: Either 443 (Web sockets—the default) or 5671 and 5672 (AMQP).

> These ports are used for outbound traffic for engines to communicate with Secret Server Cloud instances. They are set by the "Azure ServiceBus Transport Type" global engine setting.

Security

Distributed engines have multiple security layers:

- Engines must be approved within Secret Server before they will be given access to a site.
- Work items are encrypted with a site-specific symmetric key prior to sending them to the site connector.
- Communication to the site connector supports SSL and TLS.
- Direct communication from engine to Secret Server uses a public-private key exchange.
- The engine configuration file is DPAPI encrypted.

For more information about DE security, see the "Distributed Engine Hardening" on page 1388.

Engine Workflow

> This workflow applies to Secret Server On-Premises.

When an engine Windows service starts, the following steps occur:

1. The service contacts Secret Server directly using the engine callback port.
2. The service receives configuration information for the site connector to connect to and what site to process work items for.
3. The service connects to the site connector and registers with the site for work item processing.
4. The service fetches a work item from the site.
5. The service processes the work item.

6. The service gives the site the result of the processing, such as heartbeat success or discovery results.
7. The service fetches another work item, and the process continues.

Configuring Distributed Engines

> When DEs auto update, they remove the MySQL, Oracle, and other DLLs that were manually placed there. To forestall this, we recommend creating an ignore file for DE upgrades. Please see How to create an ignore file for Distributed Engine upgrades for details.

Configuration

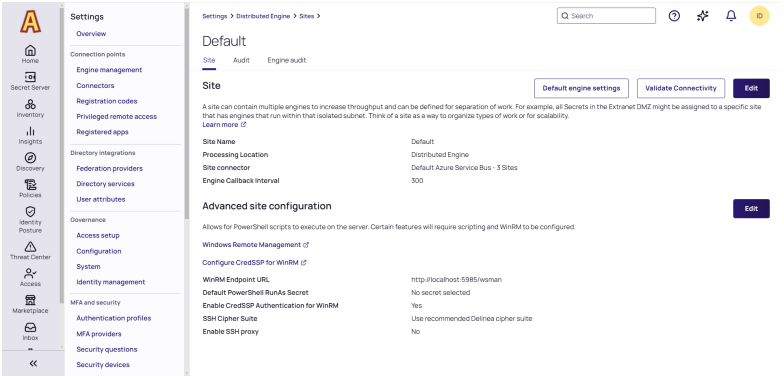
Below is a summary of the steps required to configure DEs:

1. Enable the DE and specify the engine callback settings.
2. Configure and Install the site connector.
   - If you plan to use RabbitMQ (recommended), please see "Installing RabbitMQ" on page 104. You can find general information on using RabbitMQ Helper to install RabbitMQ can be found in Installing Rabbit MQ.
   - If you plan to use MemoryMQ, create the site connector record within Secret Server then click the **Download Site Connector Installer** button to get the MSI. Run the MSI on the desired host.
3. Setup sites.
4. Configure default DE settings. See "Engine Settings" below.
5. Install engines.
6. Assign secrets to sites. Secrets can be assigned to a site through their Remote Password Changing tab or via a bulk operation on the Secret Server dashboard. Once assigned to a site, all heartbeat or password changing operations take place through that site.
7. Assign discovery sources to sites. To run discovery through a site, edit the discovery source and assign the site. Once assigned, all discovery operations for that discovery source take place through that site.

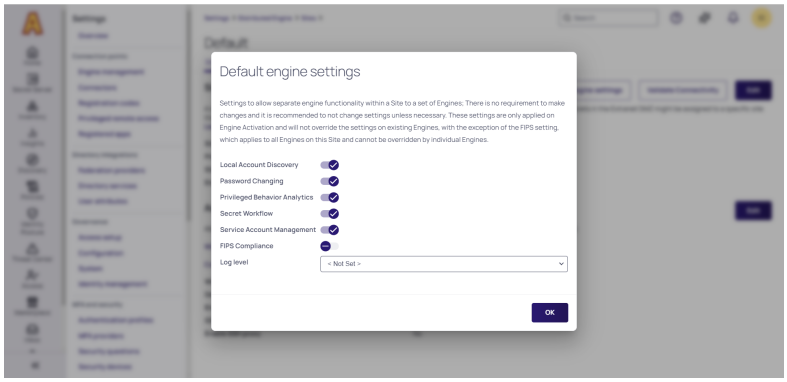
> Discovery should (a) have a dedicated DE and/or (b) a dedicated Site.

Engine Settings

1. If you click a site name, there is a **Default Engine Settings** button that allows you to pick which features of apply to new DEs connected to this Site:



2. Click the **Default Engine Settings** button.



3. When a new DE is installed, it inherits these settings from the site it is attached to. You can further customize engines by going to **Show Settings** in the Kebab menu for the engine.
4. FIPS Compliance is the only setting only available at the site level, and all DEs on the site use the same value. You cannot have a mix FIPS and non-FIPS engines on a single site. If you toggle the FIPS Compliance setting, Windows OS FIPS setting needs to be set to match it, and the engine server should be rebooted. The next time an engine checks in, if the engine's settings have been changed from those set on the site, the engine reloads itself and starts only performing the site's selected duties.

FAQ

What happens if Secret Server sends work items to the site connector, but no engines are running to consume them?

Work items continue to build up in the site connector until a limit is reached. Heartbeat work items have a Time To Live (TTL) of 5 minutes, Password Changing work items have a TTL of 20 minutes. Expired work items are thrown away and will not be processed. Once a heartbeat or password changing work item is sent to the site connector, Secret Server will not send the same work item to the queue until 5 minutes after the TTL is up (10 and 25 minutes for heartbeat and password changing, respectively). This prevents multiple pending heartbeat or password changing work items for the same secret at the same time.

How many Sites can a Site Connector hold?

MemoryMQ supports up to 100. RabbitMQ supports up to 200.

Can I cluster Site Connectors?

RabbitMQ supports clustering, MemoryMQ does not.

Can I use both RabbitMQ and MemoryMQ?

Yes. You can have as many site connectors, of either type, installed as needed. Note that while you can have both RabbitMQ and MemoryMQ installed on a single machine, you cannot have two RabbitMQ instances or two MemoryMQ instances on the same machine.

Can I convert a site connector from MemoryMQ to RabbitMQ or vice versa?

Yes. You can install the new site connector, swap the sites over to the new service, and then decommission the old site connector.

I've reinstalled my Distributed engine, but why is it not showing in the console?

If you have distributed engines installed and encounter an error or decide to reinstall distributed engine on a machine that had it previously, please be aware that the Add/Remove Programs option does not clear out the installation folder of the Distributed Engine (C:\Program Files\Delinea Software Ltd\Distributed Engine\)

This leaves behind some configuration files. If these are left behind during an uninstall, then during a reinstall it may cause issues where the distributed engine will not appear in the console for activation or assignment to a site.

Does the Windows control panel reflect the current version of the distributed engine installed?

No, the distributed engine version does not increment in the Windows control panel. To view the version of the distributed engine you have installed, click on Distributed Engine on the Settings page.

Distributed Engine Hardening

Introduction

This topic discusses best practices for hardening Secret Server distributed engine servers.

If attackers compromise one of the DE servers, they would have access to all critical DBs, applications, and network devices at the network level. DEs do not store any passwords, PII, or user data in any configuration files.

Due to their intrinsic nature, some PowerShell script run by DEs may expose API usernames or passwords in the PowerShell log.

General Hardening Steps

Restrict RDP Connections

- Limit RDP connections to all PAM Server, except for PAM admins and some users from the hosting team.
- If there is no firewall segmentation in LAN network, you can accomplish this with the Windows OS firewall.

Restrict Incoming Port Access to All DE Servers

- Allow only RDP port access from some internal IPs.
- Allow a SSH proxy port coming from the user's LAN.

- Block all other incoming ports.

Remove Unnecessary User Groups

For administrator and Remote Desktop user groups:

- Remove default domain admins, administrator and some common groups.
- Create one group that is going to have access these servers.
- Disable the built-in local administrator user.

Rename Default Accounts

- Change the names of both the administrator and guest accounts to names that do not indicate their account permissions.
- Create a new locked and unprivileged "administrator" user name as bait.

Disable Services

Disable these services:

- Routing and remote access
- Smart card
- Smart card removal policy
- SNMP trap
- Special administration console helper
- Windows error reporting service
- WinHTTP Web proxy auto-discovery service

Restrict Network Protocols

Keep these:

- Client for Microsoft network
- File and printer sharing for Microsoft network
- Internet protocol version 4 (TCP/IPv4)

Remove these:

- QoS packet scheduler
- Link-layer topology discovery mapper IO driver
- Link-layer topology discovery responder

Validate Server Roles

Ensure only the minimum roles and features that are required are defined on the DE Servers. Remove all unnecessary roles and features.

The following roles are removal candidates, not ones to keep.

Roles

Application Server

- TCP port sharing
- Windows process activation service support
- Named pipe activation
- TCP activation

Remote Access

- Direct access and VPN (RAS)
- Routing
- Web application proxy (with dependent features)

Web Server (IIS)

- Web server
- Health and diagnostic
- Logging tools
- Tracing

Security

- Centralized SSL certificate support
- Client certificate mapping authentication
- Digest authentication
- IIS client certificate mapping authentication
- IP and domain restrictions
- URL authentication

Application Development

- Server side includes
- Web socket protocols
- Windows deployment services (with dependent features), including all child roles

Features

- Group policy management
- IIS hostable Web core
- Ink and handwriting services
- Media foundation
- RAS connection manager administration kit (CMAK)
- Remote server administration tools, including all child features.
- Windows internal database
- SMB 1.0/CIFS file sharing support

SSL/TLS Settings

Keep your server SSL/TLS settings up to date. Among other settings, the different protocols and cipher suites can be vulnerable to different attacks on SSL/TLS.

- Disable SSL 2.0
- Disable SSL 3.0
- Disable TLS 1.0
- Disable TLS 1.1
- Enable TLS 1.2

GPO Hardening

The following are recommended settings for Microsoft Group Policy Objects (GPO).

User Configuration > Policies > Administrative Templates > Control Panel/Personalization

Vulnerability:

There is no protection against a user with physical and remote desktop access to the server.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Enable screen saver	Enabled
Force specific screen saver	Enabled
Password protect the screen saver	Enabled
Screen saver timeout	Enabled Seconds: 600

Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies /Security Options

This setting enables advanced auditing in the operating system.

Policy	Recommended Value
Audit: Force audit policy subcategory settings to override audit policy category settings	Enabled

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Logon Account

Vulnerability:

Lack of information on unauthorized user login attempt. Lack of this type of information prevents identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Credential Validation	Success, Fail
Other Account Logon Event	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Account Management

Vulnerability:

Lack of information on user management in the system (addition and removal of users). Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Application Group Management	Success, Fail
Computer Account Management	Success, Fail

Policy	Recommended Value
Distribution Group Management	Success, Fail
Other Account Management Events	Success, Fail
Security Group Management	Success, Fail
User Account Management	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Logon\Logoff

Vulnerability:

Lack of information on unauthorized user login attempt. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Account Lockout	Success, Fail
Logoff	Success, Fail
Logon	Success, Fail
Network Policy Server	Success, Fail
Other Logon\Logoff Event	Success, Fail
Special Logon	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Object Access

Vulnerability:

Lack of information on access to sensitive files and folders in the system. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

Applying Auditing for Success can overload the system. In case an overload is created, it is recommended to apply the auditing for Failure only.

Policy	Recommended Value
Application Generated	Success, Fail
Certification Services	Success, Fail
Detailed File Share	Fail
File Share	Success, Fail
File System	Success, Fail
Kernel Object	Success, Fail
Registry	Success, Fail
Removable Storage	Success
SAM	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Policy Change

Vulnerability:

Lack of information on changes in the policy. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Audit Policy Change	Success, Fail
Authentication Policy Change	Success, Fail
Authorization Policy Change	Success, Fail
Filtering Platform Policy Change	Success, Fail
MPSSVC Rule-Level Policy Change	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Privilege Use

Vulnerability:

Lack of information on the use of system authorizations. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Non Sensitive Privilege Use	Success, Fail
Sensitive Privilege Use	Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > System

Vulnerability:

Lack of information on system start-up, shutdown and system changes. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Other System Events	Success, Fail
Security State Change	Success, Fail
Security System Extension	Success, Fail
System Integrity	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Event Log

Vulnerability:

There is a risk that many log records will not be saved due to the file's size.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Maximum application log size	100032 KB
Maximum security log size	100032 KB
Maximum system log size	100032 KB
Prevent local guests group from accessing application log	Enabled
Prevent local guests group from accessing security log	Enabled
Prevent local guests group from accessing system log	Enabled
Retention method for application log	As needed
Retention method for security log	As needed
Retention method for system log	As needed

Computer Configuration > Policies > Windows Settings > Security Settings > Registry

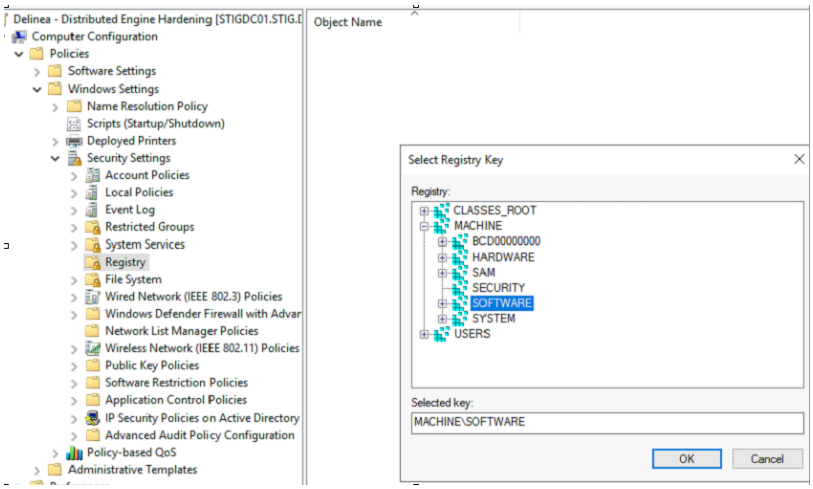
The purpose of this GPO setting is to add auditing to the following registry keys:

- `HKLM\SYSTEM`
- `HKLM\SOFTWARE`

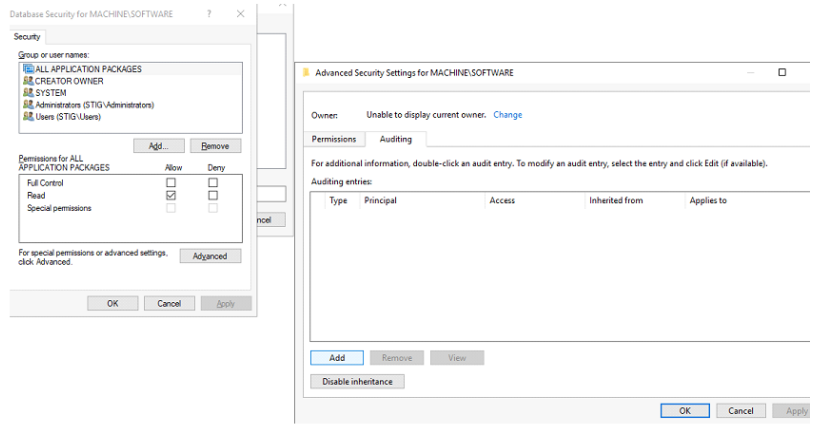
Auditing should be applied according to the following parameters:

- Audit - Success only: Set Value
- Audit - All: Create Subkey, Create Link, Delete, Read Permissions, Change Permissions

1. Right click on Registry, select Add Key, then select MACHINE\SOFTWARE.

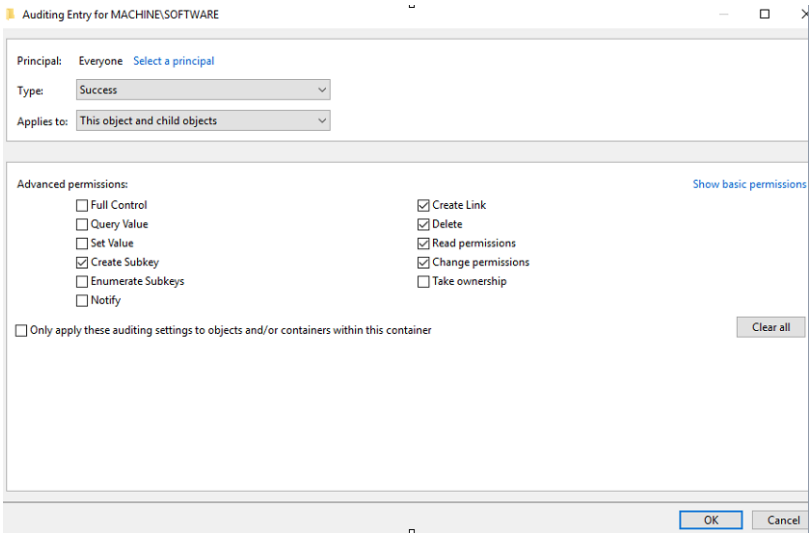


2. Click Advanced, select Auditing tab, click Add.

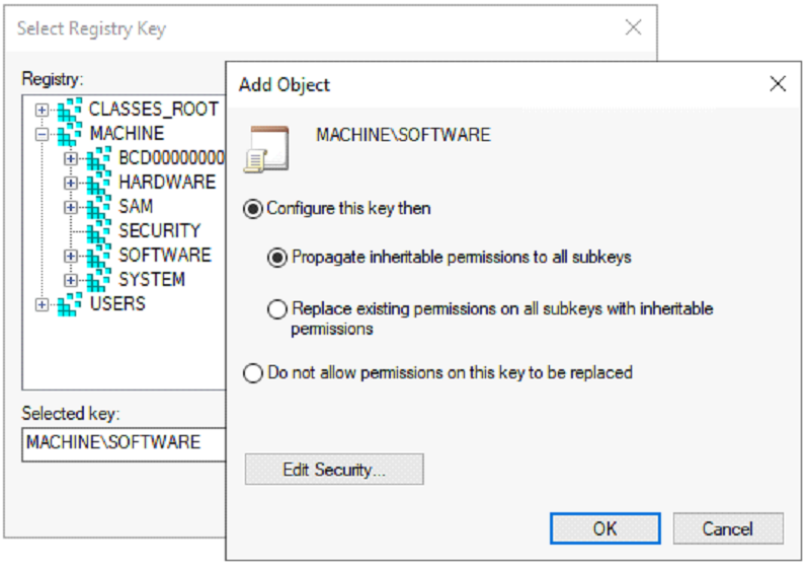


3. Change Principal to Everyone, select Show Advanced Permissions, select the following boxes:

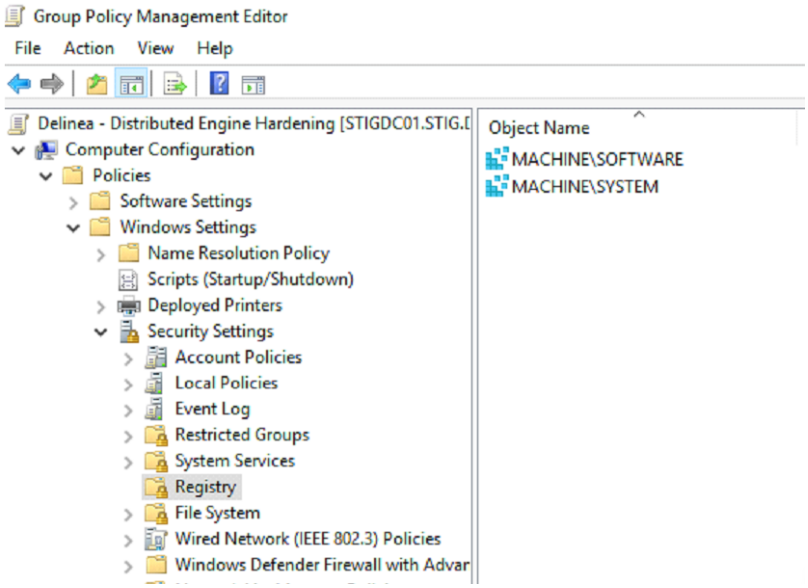
- Create Subkey
- Create Link
- Delete
- Read Permissions
- Change Permissions



4. Click OK, then click Apply Settings.



5. Perform the same steps above for MACHINE\SYSTEM.



Computer Configuration > Policies > Windows Settings > Security Settings > File System

The purpose of this GPO setting is to add auditing to the following directories:

- `%SystemRoot%\System32\Config`
- `%SystemRoot%\System32\Config \RegBack`

Vulnerability:

Lack of information on delete, change of authorizations, gain ownership of sensitive files, or any attempt to do so, will prevent the ability to identify unauthorized access and therefore will make it difficult to prevent such attempts.

Severity of the damage:

Medium

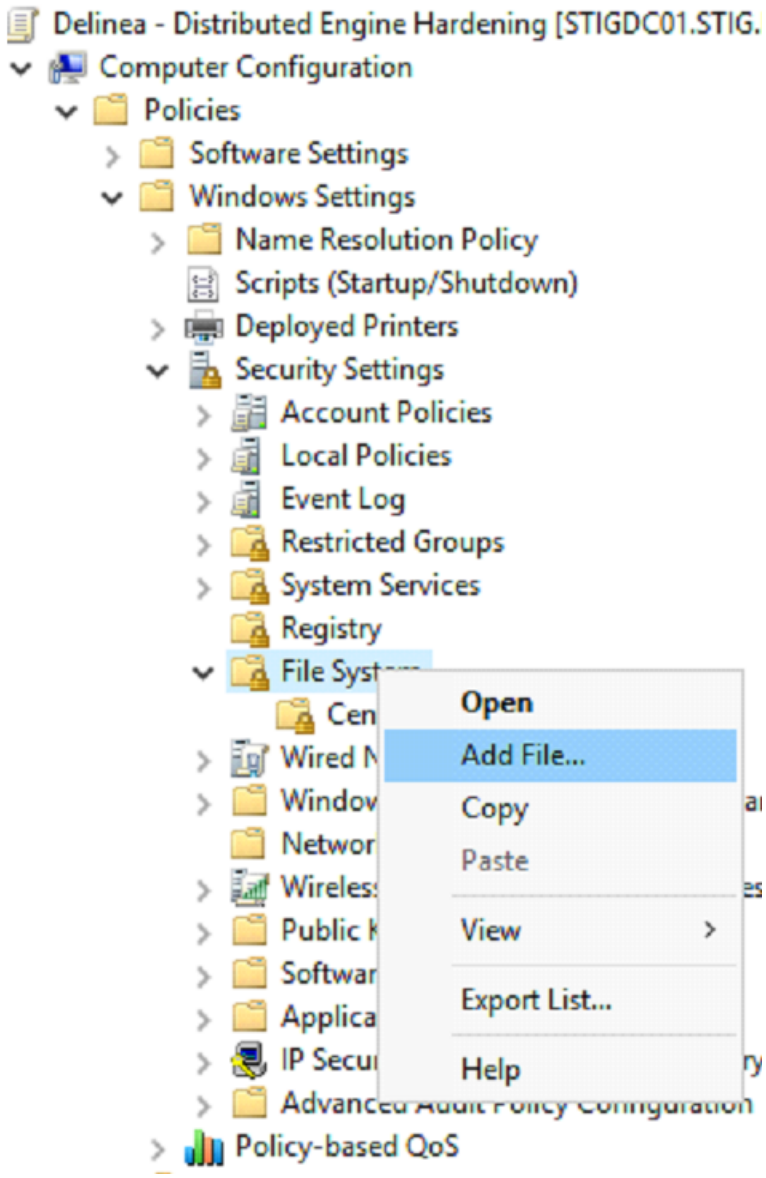
Operational aspects:

None

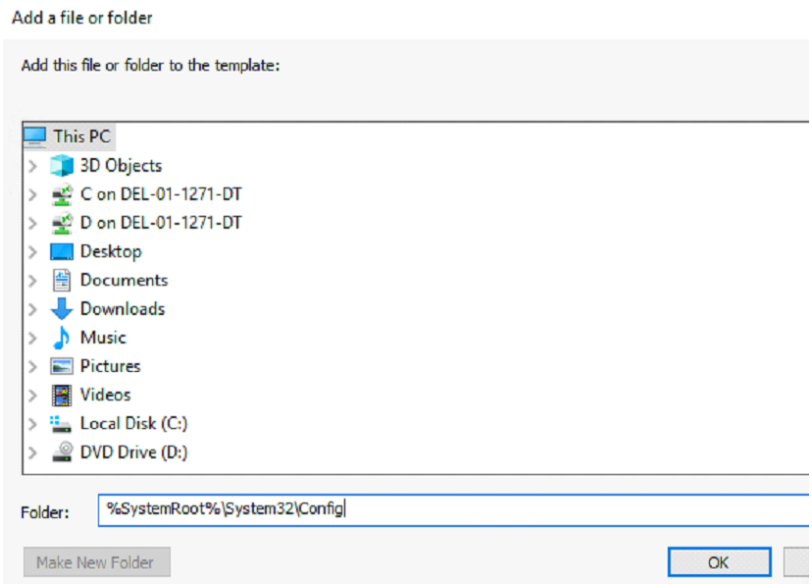
Windows permissions and auditing should be applied according to the following parameters:

- Audit-Failure only: Traverse Folder\ Execute File, List Folder\ Read Data, Read Attributes, Read Extended Attribute.
- Audit - All: Create Files\ Write Data, Create Folders\ Append Data, Write Attributes, Write Extended Attributes, Delete Subfolders And Files, Delete, Change Permissions, Take Ownership.
- Permissions: Administrator, System - Full

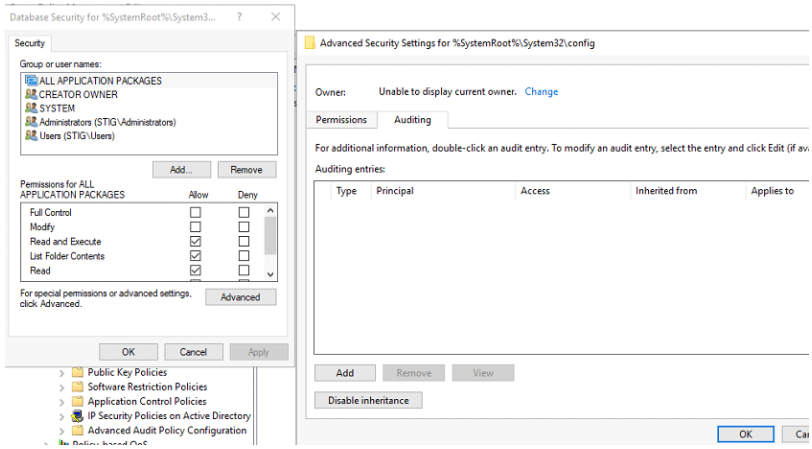
1. Right click File System, click Add File.



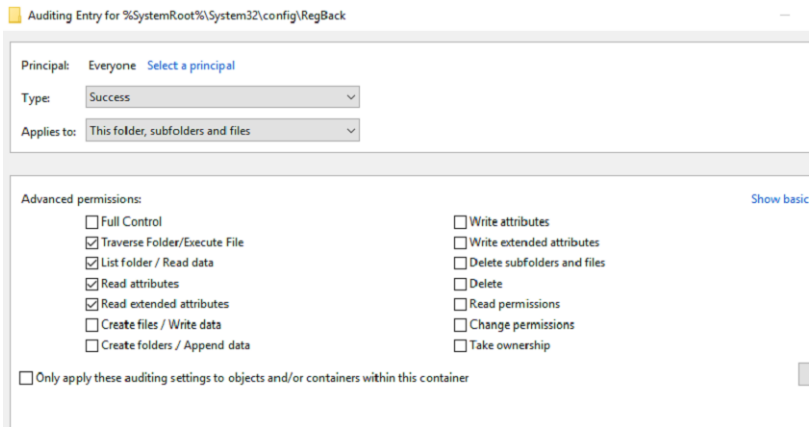
2. Add the folder path *%SystemRoot%\System32\Config*



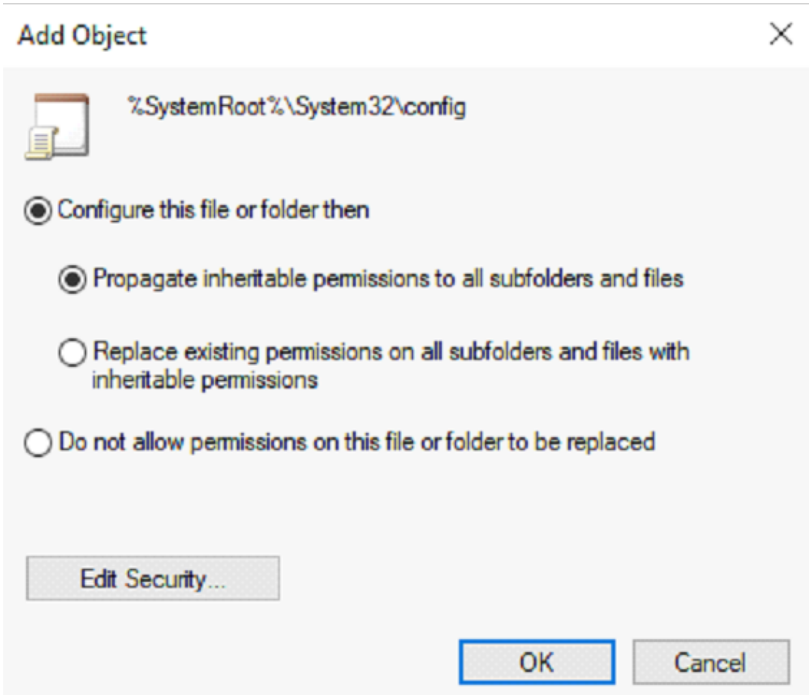
3. Click Advanced, then click Auditing tab, and click Add.



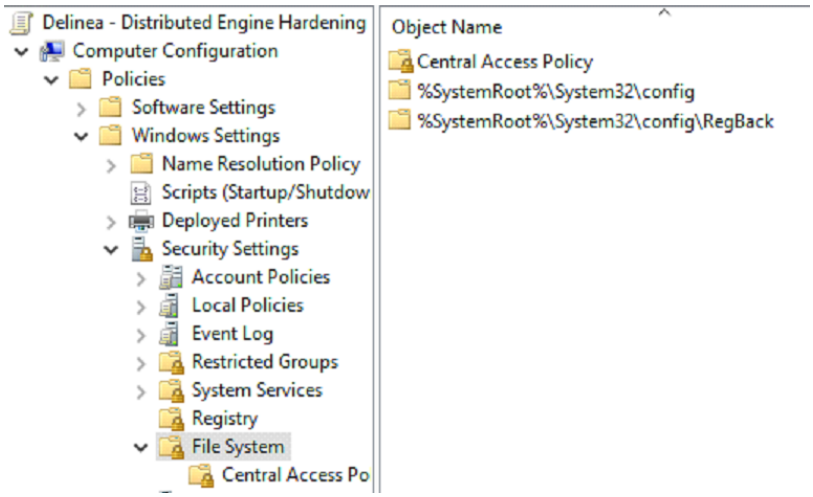
- Change Principal to Everyone, select Show Advanced Permissions, and select the following boxes:
- Traverse Folder\ Execute File
- List folder\ Read data
- Read attributes
- Read extended attribute



4. Click OK, then click Apply Settings.



5. Perform the same steps above for *SystemRoot%\System32\Config\RegBack*



Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies/Security Options

Policy	Recommended Value	Comment or Vulnerability
Accounts: Administrator account status	Enabled	
Accounts: Guest account status	Disabled	
Accounts: Limit local account use of blank passwords to console logon only	Enabled	
Accounts: Rename administrator account	It is recommended to change both the Administrator and the guest names to a name that will not testify about their Windows permissions, and also to create a new locked and unprivileged user name Administrator as bate	Comment: Apply this parameter according to the organization security policy. Vulnerability: The administrators default name is known as a high privilege user. This user is a target for hacking attempts. Severity of the damage: Medium Operational aspects: None
Audit: Audit the use of Backup and Restore privilege.	Enabled	Vulnerability: The system does not monitor backup and restore activities of files, therefore it does not allow exposing unusual activities in this area. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Devices: Allowed to format and eject removable media	Administrator	Vulnerability: Users may be able to move data on removable disks to a different computer where they have administrative privileges. The user could then take ownership of any file, grant themselves full control, and view or modify any file. The fact that most removable storage devices will eject media by pressing a mechanical button diminishes the advantage of this policy setting. Severity of the damage: Low Operational aspects: None
Devices: Prevent users from installing printer drivers	Enabled	Vulnerability: A malicious user could install inappropriate printer drivers in a deliberate attempt to damage the computer, or a user might accidentally install malicious software that masquerades as a printer driver. Severity of the damage: Low Operational aspects: None
Domain member: Disable machine account password changes	Disabled	Vulnerability: Computers that cannot automatically change their account password are at risk from an attacker who could determine the password for the computer's domain account. Severity of the damage: Low Operational aspects: None
Domain member: Maximum machine account password age	30 days	Vulnerability: Setting this parameter to 0 will allow an attacker to execute Brute Force attacks to find the computer account password. Severity of the damage: Low Operational aspects: None
Domain member: Require strong (Windows 2000 or later) session key	Enabled	Vulnerability: Session keys that are used to establish secure channel communications between domain controllers and member computers are much stronger in Windows 2000 than they were in previous Windows operating systems. Severity of the damage: Low Operational aspects: None
Interactive logon: Do not display last user name	Enabled	Vulnerability: An attacker with access to the console (for example, someone with physical access or someone who is able to connect to the server through Remote Desktop Services, also known as Terminal Services) could view the name of the last user who logged on to the server. The attacker could then try to guess the password, use a dictionary, or use a brute force attack to try to log on. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Interactive logon: Do not require CTRL+ALT+DEL	Disabled	Vulnerability: If users are not required to press CTRL+ALT+DEL, they are susceptible to attacks that attempt to intercept their passwords, If this setting is enabled, an attacker could install a Trojan horse program that looks like the standard logon dialog box in the Windows operating system, and capture the user's password. Severity of the damage: Low Operational aspects: None
Interactive logon: Number of previous logons to cache (in case domain controller is not available).	0	Vulnerability: Users who access the server console will have their logon credentials cached on that server. An attacker who is able to access the file system of the server could locate this cached information and use a brute force attack to attempt to determine user passwords. Severity of the damage: Medium Operational aspects: The local Administrator password should be known in case of DC unavailability.

Policy	Recommended Value	Comment or Vulnerability
Interactive logon: Require Domain Controller authentication to unlock workstation	Enabled	Vulnerability: By default, the computer caches in memory the credentials of any users who are authenticated locally. The computer uses these cached credentials to authenticate anyone who attempts to unlock the console. When cached credentials are used, any changes that have recently been made to the account-such as user rights assignments, account lockout, or the account being disabled-are not considered or applied after the account is authenticated. User privileges are not updated, and (more important) disabled accounts are still able to unlock the console of the computer. Severity of the damage: Medium Operational aspects: The local Administrator password should be known in case of DC unavailability
Microsoft network client: Send unencrypted password to third-party SMB servers.	Disabled	Vulnerability: The server can transmit passwords in plaintext across the network to other computers that offer SMB services. These other computers might not use any of the SMB security mechanisms that are included with Windows Server 2003 and above. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Microsoft network server: Amount of idle time required before suspending session	15 minutes	Vulnerability: Each SMB session consumes server resources, and numerous null sessions will slow the server or possibly cause it to fail. An attacker could repeatedly establish SMB sessions until the server's SMB services become slow or unresponsive. Severity of the damage: Medium Operational aspects: None
Microsoft network server: Attempt S4U2Self to obtain claim information	Disabled	Vulnerability: Enabling this policy setting allows you take advantage of features in Windows Server 2012 and Windows 8 for specific scenarios to use claims-enabled tokens to access files or folders that have claim-based access control policy applied on Windows operating systems prior to Windows Server 2012 and Windows 8. Severity of the damage: Medium Operational aspects: None
Microsoft network server: Server SPN target name validation level	Off	Vulnerability: This policy setting controls the level of validation that a server with shared folders or printers performs on the service principal name (SPN) that is provided by the client computer when the client computer establishes a session by using the SMB protocol. The level of validation can help prevent a class of attacks against SMB servers (referred to as SMB relay attacks). This setting will affect both SMB1 and SMB2. Severity of the damage: Low Operational aspects: None
Network access: Do not allow anonymous enumeration of SAM accounts	Enabled	Vulnerability: An unauthorized user could anonymously list account names and shared resources and use the information to attempt to guess passwords or perform social engineering attacks. Severity of the damage: Medium Operational aspects: None
Network access: Do not allow anonymous enumeration of SAM accounts and shares	Enabled	Vulnerability: An unauthorized user could anonymously list account names and shared resources and use the information to attempt to guess passwords or perform social-engineering attacks. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Network access: Do not allow storage of passwords and credentials for network authentication.	Enabled	Vulnerability: Passwords that are cached can be accessed by the user when logged on to the computer. Although this information may sound obvious, a problem can arise if the user unknowingly runs malicious software that reads the passwords and forwards them to another, unauthorized user. Severity of the damage: Medium Operational aspects: This parameter could affect windows schedule task services
Network access: Let Everyone permissions apply to anonymous users	Disabled	Vulnerability: The system will allow all users, including users who have not identified themselves in the Domain, perform operations of reading information related to user accounts and the names of the shares. Severity of the damage: Medium Operational aspects: None
Network access: Named Pipes that can be accessed anonymously	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: Ability to remotely access data on the system by an unauthorized user. Severity of the damage: Low Operational aspects: None
Network access: Remotely accessible registry paths	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: An attacker could use information in the registry to facilitate unauthorized activities. To reduce the risk of such an attack, suitable ACLs are assigned throughout the registry to help protect it from access by unauthorized users. Severity of the damage: Low Operational aspects: None
Network access: Remotely accessible registry paths and subpaths	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: An attacker could use information in the registry to facilitate unauthorized activities. To reduce the risk of such an attack, suitable ACLs are assigned throughout the registry to help protect it from access by unauthorized users. Severity of the damage: Low Operational aspects: None
Network access: Restrict anonymous access to Named Pipes and Shares.	Enabled	Vulnerability: Null sessions are a weakness that can be exploited through shared folders on computers environment. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Network access: Shares that can be accessed anonymously	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: Any shared folders that are listed can be accessed by any network user, which could lead to the exposure or corruption of sensitive data. Severity of the damage: Medium Operational aspects: None
Network access: Sharing and security model for local accounts	Classic - Local users authenticate as themselves	Vulnerability: With the Guest only model, any user who can authenticate to the server over the network does so with guest privileges, which means that they will not have write access to shared resources on that server. Although this restriction does increase security, it makes it more difficult for authorized users to access shared resources on the server because ACLs on those resources must include access control entries (ACEs) for the Guest account. With the Classic model, local accounts should be password protected. Otherwise, if Guest access is enabled, anyone can use those user accounts to access shared system resources. Severity of the damage: Low Operational aspects: None
Network security: Do not store LAN Manager hash value on next password change	Enabled	Vulnerability: The SAM file can be targeted by attackers who seek access to user name and password hashes. Such attacks use special tools to discover passwords, which can then be used to impersonate users and gain access to resources on your network. Severity of the damage: Medium Operational aspects: None
Network security: Force logoff when logon hours expire	Enabled	Vulnerability: Users can remain connected to the computer outside of their allotted logon hours. Severity of the damage: Low Operational aspects: None
Network security: LAN Manager authentication level	Send NTLMv2 Responses Only/Refuse LM & NTLM	Vulnerability: The system allows identification of users in the old LM and NTLM protocols. The old identification protocols are vulnerable to attacks. Severity of the damage: Medium Operational aspects: These parameters could effect on legacy system if the system don't support NTLMv2

Policy	Recommended Value	Comment or Vulnerability
Network security: Minimum session security for NTLM SSP based (including secure RPC) clients	Require NTLMv2 session security Require 128-bit encryption	Vulnerability: Network traffic that uses the NTLM Security Support Provider (NTLM SSP) might be exposed such that an attacker who has gained access to the network can create man-in-the-middle attacks. Severity of the damage: Medium Operational aspects: None
Network security: Minimum session security for NTLM SSP based (including secure RPC) servers	Require NTLMv2 session security Require 128-bit encryption	Vulnerability: Network traffic that uses the NTLM Security Support Provider (NTLM SSP) might be exposed such that an attacker who has gained access to the network can create man-in-the-middle attacks. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Recovery console: Allow automatic administrative logon	Disabled	Vulnerability: The Recovery Console can be very useful when you need to troubleshoot and repair computers that do not start. However, it is dangerous to allow automatic logon to the console. Anyone could walk up to the server, disconnect the power to shut it down, restart it, select Recover Console from the Restart menu, and then assume full control of the server. Severity of the damage: Medium Operational aspects: None
Recovery console: Allow floppy copy and access to all drives and all folders	Disabled	Vulnerability: An attacker who can cause the system to restart into the Recovery Console could steal sensitive data and leave no audit or access trail. Severity of the damage: Low Operational aspects: None
Shutdown: Allow system to be shut down without having to log on	Disabled	Vulnerability: Users who can access the console locally could shut down the computer. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Shutdown: Clear virtual memory pagefile	Enabled	Vulnerability: Important information that is kept in real memory may be written periodically to the paging file to help the operating system handle multitasking functions. An attacker who has physical access to a server that has been shut down could view the contents of the paging file. The attacker could move the system volume into a different computer and then analyze the contents of the paging file. Although this process is time consuming, it could expose data that is cached from random access memory (RAM) to the paging file. Severity of the damage: Low Operational aspects: It takes longer to shut down and restart the computer, especially on computers with large paging files.
System Settings: Optional subsystems	No one	Enable the policy and delete the existing list of users that will be populated by default. Vulnerability: The POSIX subsystem introduces a security risk that relates to processes that can potentially persist across logons. If a user starts a process and then logs out, there is a potential that the next user who logs on to the computer could access the previous user's process. This would allow the second user to take actions on the process by using the privileges of the first user. Severity of the damage: Low Operational aspects: None
System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies	Enable	Vulnerability: Without the use of software restriction policies, users and computers might be exposed to the running of unauthorized software, such as viruses and Trojans horses. Severity of the damage: Medium Operational aspects: None
User Account Control: Use Admin Approval Mode for the built-in Administrator account	Enable	Vulnerability: Malicious software running under elevated credentials without the user or administrator being aware of its activity. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
User Account Control: Allow UIAccess applications to prompt for elevation without using the secure desktop	Disable	Vulnerability: Without the use of software restriction policies, users and computers might be exposed to the running of unauthorized software, such as viruses and Trojans horses. Severity of the damage: Medium Operational aspects: None
User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode	Prompt for consent for non-Windows binaries	Vulnerability: Malicious programs running under elevated credentials without the user or administrator being aware of their activity. This setting raises awareness to the user that a program requires the use of elevated privilege operations and requires that the user be able to supply administrative credentials in order for the program to run. Severity of the damage: Medium Operational aspects: None
User Account Control: Behavior of the elevation prompt for standard users	Prompt for credentials on the secure desktop	Vulnerability: Malicious programs running under elevated credentials without the user or administrator being aware of their activity. This setting raises awareness to the user that a program requires the use of elevated privilege operations and requires that the user be able to supply administrative credentials in order for the program to run. Severity of the damage: Low Operational aspects: None
User Account Control: Run all administrator in admin approval mode	Enable	Vulnerability: This is the setting that turns on or off UAC. If this setting is disabled, UAC will not be used and any security benefits and risk mitigations that are dependent on UAC will not be present on the system. Severity of the damage: Medium Operational aspects: None
User Account Control: Switch to the secure desktop when prompting for elevation	Enable	Vulnerability: Elevation prompt dialog boxes can be spoofed, causing users to disclose their passwords to malicious software. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
User Account Control: Virtualize file and registry write failures to per-user locations	Enable	Severity of the damage: Low Operational aspects: None

Computer Configuration > Administrative Templates > Windows Components > Security Settings > Remote Desktop Services

Vulnerability:

An unlimited number of open connections can cause denial of Service attack on the Remote Desktop services, also known as Terminal Services.

If a disconnected session kept alive that can lead a session hijacking by an attacker.

Clipboard mapping enables the client to transfer a virus or a malicious application to the server as well as copy configuration or sensitive data from the server back to the client machine. There is a risk of infecting to the whole network or damaging the system.

Severity of the damage:

Medium

Operational aspects:

None

Path	Policy	Recommended Value

Policy	Recommended Value	Comment
Access Credential Manager as a trusted caller		Vulnerability: If an account is given this right, the user of the account can create an application that calls into Credential Manager and is then provided the credentials for another user. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Access this computer from the network	BUILTIN\Administrators	Vulnerability: This right allows the users to use the SMB communications protocol in front of the server. This protocol allows access to the operating resources, such as: sharing and remote system administration using the operating system's built-in tools. Severity of the damage: Medium Operational aspects: None
Act as part of the operating system		Vulnerability: Users with the Act as part of the operating system user right can take complete control of the computer and erase evidence of their activities. Severity of the damage: Medium Operational aspects: None
Adjust memory quotas for a process	NT AUTHORITY\NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE, BUILTIN\Administrators	Vulnerability: A user with the Adjust memory quotas for a process user right can reduce the amount of memory that is available to any process, which could cause business-critical network applications to become slow or to fail. This privilege could be used to start a denial-of-service (DoS) attack. Severity of the damage: Medium Operational aspects: None
Allow log on locally	BUILTIN\Administrators	Vulnerability: Any account with the Allow log on locally user right can log on at the console of the computer. If you do not restrict this user right to legitimate users who must log on to the console of the computer, unauthorized users could download and run malicious software to elevate their privileges. Severity of the damage: Medium Operational aspects: None
Allow log on through Remote Desktop Services	BUILTIN\Administrators	Vulnerability: Any account with the Allow log on through Remote Desktop Services user right can log on to the remote console of the computer. If you do not restrict this user right to legitimate users who must log on to the console of the computer, unauthorized users could download and run malicious software to elevate their privileges. Severity of the damage: Medium Operational aspects: None
Back up files and directories	BUILTIN\Administrators	Vulnerability: Users who can back up data from a computer could take the backup media to a non-domain computer on which they have administrative privileges and restore the data. They could take ownership of the files and view any unencrypted data that is contained within the backup set. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Bypass traverse checking	NT AUTHORITY\ NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE, NT AUTHORITY\Authenticated Users, BUILTIN\Administrators	Vulnerability: This right allows the user to access files and partitions although he is not authorized to view files and change them. Severity of the damage: Medium Operational aspects: None
Change the system time	BUILTIN\Administrators, NT AUTHORITY\LOCAL SERVICE	Vulnerability: Users who can change the time on a computer could cause several problems. For example, time stamps on event log entries could be made inaccurate, an attacker who changes a computer's time may cause that computer to be unable to obtain or grant Kerberos protocol tickets. Severity of the damage: Medium Operational aspects: None
Change the time zone	BUILTIN\Administrator	Vulnerability: Changing the time zone represents little vulnerability because the system time is not affected. This setting merely enables users to display their preferred time zone while being synchronized with domain controllers in different time zones. Severity of the damage: Low Operational aspects: None
Create a token object		Vulnerability: A user account that is given this user right has complete control over the system, and it can lead to the system being compromised. Severity of the damage: High operational aspects: None
Create global objects	NT AUTHORITY\SERVICE, NT AUTHORITY\NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE, BUILTIN\Administrators	Vulnerability: Users who can create global objects could affect processes that run under other users' sessions. This capability could lead to a variety of problems, such as application failure or data corruption. Severity of the damage: Medium Operational aspects: None
Create permanent shared objects		Vulnerability: Users who have the Create permanent shared objects user right could create new shared objects and expose sensitive data to the network. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Create symbolic links	Administrators	Vulnerability: Users who have the Create symbolic links user right could inadvertently or maliciously expose your system to symbolic link attacks. Symbolic link attacks can be used to change the permissions on a file, to corrupt data, to destroy data, or as a DoS attack. Severity of the damage: Low Operational aspects: None
Debug programs	BUILTIN\Administrator	Vulnerability: The Debug programs user right can be exploited to capture sensitive computer information from system memory or to access and modify kernel or application structures. Some attack tools exploit this user right to extract hashed passwords and other private security information or to insert rootkit code. Severity of the damage: Low Operational aspects: None
Deny access to this computer from the network	BUILTIN\Guests	Vulnerability: Users who can log on to the computer over the network can enumerate lists of account names, group names, and shared resources. Users with permission to access shared folders and files can connect over the network and possibly view or modify data. Severity of the damage: Medium Operational aspects: None
Deny log on as a batch job	BUILTIN\Guests	Vulnerability: Accounts that have the Deny log on as a batch job user right could be used to schedule jobs that could consume excessive computer resources and cause a DoS condition. Severity of the damage: Medium Operational aspects: None
Deny log on as a service	BUILTIN\Guests	Vulnerability: Accounts that can log on as a service could be used to configure and start new unauthorized services, such as a keylogger or other malicious software. Severity of the damage: Medium Operational aspects: None
Deny log on locally	BUILTIN\Guests	Vulnerability: Any account with the ability to log on locally could be used to log on at the console of the computer. If this user right is not restricted to legitimate users who must log on to the console of the computer, unauthorized users might download and run malicious software that elevates their privileges. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Deny log on through Remote Desktop Services	BUILTIN\Guests	Vulnerability: Any account with the right to log on through Remote Desktop Services could be used to log on to the remote console of the computer. If this user right is not restricted to legitimate users who need to log on to the console of the computer, malicious users might download and run software that elevates their privileges. Severity of the damage: Medium Operational aspects: None
Enable computer and user accounts to be trusted for delegation	BUILTIN\Administrators	Vulnerability: Misuse of the Enable computer and user accounts to be trusted for delegation user right could allow unauthorized users to impersonate other users on the network. An attacker could exploit this privilege to gain access to network resources and make it difficult to determine what has happened after a security incident. Severity of the damage: Medium Operational aspects: None
Force shutdown from a remote system	BUILTIN\Administrators	Vulnerability: Any user who can shut down a computer could cause a DoS condition to occur. Therefore, this user right should be tightly restricted. Severity of the damage: Low Operational aspects: None
Generate security audits	NT AUTHORITY\NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE	Vulnerability: Accounts that can write to the Security log could be used by an attacker to fill that log with meaningless events. If the computer is configured to overwrite events as needed, attackers could use this method to remove evidence of their unauthorized activities. If the computer is configured to shut down when it is unable to write to the Security log and it is not configured to automatically back up the log files, this method could be used to create a DoS condition. Severity of the damage: Low Operational aspects: None
Increase scheduling priority	BUILTIN\Administrators	Vulnerability: Increasing the working set size for a process decreases the amount of physical memory that is available to the rest of the system. Severity of the damage: Low Operational aspects: None
Load and unload device drivers	BUILTIN\Administrators	Vulnerability: Device drivers run as highly privileged code. A user who has the Load and unload device drivers user right could unintentionally install malicious software that masquerades as a device driver. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Lock pages in memory	BUILTIN\Administrators	Vulnerability: Users with the Lock pages in memory user right could assign physical memory to several processes, which could leave little or no RAM for other processes and result in a DoS condition. Severity of the damage: Low Operational aspects: None
Manage auditing and security log	BUILTIN\Administrators	Vulnerability: Anyone with the Manage auditing and security log user right can clear the Security log to erase important evidence of unauthorized activity. Severity of the damage: Medium Operational aspects: None
Modify an object label		Vulnerability: Anyone with the Modify an object label user right can change the integrity level of a file or process so that it becomes elevated or decreased to a point where it can be deleted by lower-level processes. Either of these states effectively circumvents the protection offered by Windows Integrity Controls and makes your system vulnerable to attacks by malicious software. Severity of the damage: Low Operational aspects: None
Modify firmware environment values	BUILTIN\Administrators	Vulnerability: Anyone who is assigned the Modify firmware environment values user right could configure the settings of a hardware component to cause it to fail, which could lead to data corruption or a DoS condition. Severity of the damage: Medium Operational aspects: None
Perform volume maintenance tasks	BUILTIN\Administrators	Vulnerability: A user who is assigned the Perform volume maintenance tasks user right could delete a volume, which could result in the loss of data or a DoS condition. Also, disk maintenance tasks can be used to modify data on the disk such as user rights assignments that might lead to escalation of privileges. Severity of the damage: Low Operational aspects: None
Profile single process	BUILTIN\Administrators	Vulnerability: The Profile single process user right presents a moderate vulnerability. Attackers with this user right could monitor a computer's performance to help identify critical processes that they might want to attack directly. Attackers may be able to determine what processes run on the computer so that they could identify countermeasures that they may need to avoid, such as antivirus software or an intrusion-detection system. They could also identify other users who are logged on to a computer. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Restore files and directories	BUILTIN\Administrators	Vulnerability: An attacker with the Restore files and directories user right could restore sensitive data to a computer and overwrite data that is more recent, which could lead to loss of important data, data corruption, or a denial-of-service condition. Attackers could overwrite executable files that are used by legitimate administrators or system services with versions that include malicious software to grant themselves elevated privileges, compromise data, or install programs that provide continued access to the computer. Severity of the damage: Medium Operational aspects: None
Shut down the system	BUILTIN\Administrators	Vulnerability: The ability to shut down the server should be limited to a very small number of trusted administrators. Severity of the damage: Low Operational aspects: None
Take ownership of files or other objects	BUILTIN\Administrators	Vulnerability: Any users with the Take ownership of files or other objects user right can take control of any object, regardless of the permissions on that object, and then make any changes that they want to make that object. Such changes could result in exposure of data, corruption of data, or a DoS condition. Severity of the damage: High Operational aspects: None

Distributed Engine Job Function Optimization

In the context of optimizing Distributed Engine (DE) operations, it is essential to understand the rationale behind the separation of DE job functions. This approach is a recommended architectural strategy that enhances system reliability, transparency, and diagnostic capabilities.

Technical Justification for Separating DE Job Functions

Resource Allocation and Efficiency

Different workloads demand varying levels of computational resources, such as CPU cores and memory. By dedicating DEs to specific tasks, we can ensure that resources are allocated efficiently, thereby optimizing performance. For instance, increasing CPU cores allows more tasks to be processed concurrently, while additional memory reduces the need for data swapping, enhancing overall system responsiveness.

DE is heavily CPU/core bounded, which is the biggest factor in its throughput.

Performance and Stability Benefits

Isolating DE job functions minimizes contention, which can lead to session routing failures, or delays in job execution. This separation allows for more predictable and efficient consumption of resources, improving system performance and stability.

Improvement in Customer Environments

In cloud or hybrid scenarios, separating DE jobs ensures that workloads are handled with precision, reducing the risk of disruptions. Heavy workloads, such as discovery tasks, can be isolated to prevent interference with other operations, while less resource-intensive tasks can share DE resources without compromising efficiency.

Technical Breakdown of DE Jobs

Job Isolation

Each DE job has specific requirements and potential issues when not isolated. For example, directory services workloads require rapid response times for user authentication, while proxy workloads are resource-intensive and frequently used. Remote password change and heartbeat tasks, though not heavy, are executed frequently and benefit from dedicated resources. Therefore, proxy workloads should almost always have dedicated DEs or sites, and RPC or heartbeat would benefit from isolation but do not require it.

RPC and heartbeat cannot be separated, so they always run on the same sites.

Discovery Isolation

It is particularly important to isolate discovery jobs from other high-traffic (RPC, Heartbeat, and AD logins) or session-heavy jobs (like RDP/SSH proxy or session recording). Separating discovery from other job types ensures that finding accounts does not delay other operations such as heartbeat and password changing. It also aids troubleshooting—log messages for discovery are not mixed with the numerous other operations that a DE can run. With dedicated DEs for discovery, discovery can also be run more frequently without risking impacting other functions.

In short, **discovery should have a dedicated DE or site**. Having both is better still.

Role of Azure Service Bus

Azure Service Bus plays a crucial role in job queuing, execution, and routing. It facilitates the distribution of messages and job payloads between platform components and DEs. By isolating jobs, Service Bus consumers operate more predictably, enhancing overall system performance.

Azure Service Bus plays a crucial role in managing distributed engines within Secret Server by facilitating efficient message-based communication between various components. Here's how it functions:

- Message Transport: Azure Service Bus acts as the primary transport mechanism for messages in Secret Server Cloud environments. It ensures that messages are published to a queue, where they can be consumed by distributed engines for processing. This setup allows for asynchronous communication, which is essential for handling distributed workloads efficiently.
- Queue Management: Messages are queued in Azure Service Bus, and distributed engines consume these messages to perform tasks such as password changes, heartbeats, and discovery processes. The queuing mechanism ensures that tasks are processed in an orderly manner, reducing the risk of contention and race conditions.

- Priority Handling: Messages in the queue have internal priorities, which dictate the order in which they are processed. For example, directory services authentication messages may have a higher priority than heartbeat messages, ensuring that critical tasks are handled promptly.
- Scalability and Reliability: By using Azure Service Bus, Secret Server can scale its operations across multiple distributed engines. This scalability is crucial for handling large volumes of tasks in cloud or hybrid environments. The reliability of Azure Service Bus ensures that messages are delivered and processed without loss, even in the event of network disruptions.
- Configuration Flexibility: Distributed engines can be configured to consume all message types or a subset, depending on the site and engine settings. This flexibility allows for tailored resource allocation, optimizing performance based on specific workload requirements.

Overall, Azure Service Bus is integral to the architecture of Secret Server, providing a robust framework for managing distributed engines and ensuring efficient, reliable task execution across the system.

For more information, see "Distributed Engine Operations " below.

Conclusion

The separation of DE job functions is a strategic approach that ensures optimal resource utilization, enhances system performance, and provides a robust framework for handling diverse workloads. Separation is especially important in large environments using many features, such as discovery and RPC. This methodology is integral to maintaining system reliability and transparency, particularly in complex cloud or hybrid environments. By understanding and implementing these principles, customers and support teams can achieve a more efficient and stable operational landscape.

Distributed Engine Operations

Secret Server Operations

Secret Server is a message-based system where components can publish or consume messages. The transport of these messages is via a bus:

- Azure Service Bus for Secret Server Cloud
- RabbitMQ for Secret Server On-Premises

Message Processing

- Messages are published to a queue and consumers of those queues will remove the message and process the work associated with the message.
- Messages have internal (non-configurable) priorities, for instance, Directory Services authentication has a higher priority than HB.
- Messages can fall into one of three categories:
  1. One-way workflow: Single message, for instance, change DE logging levels.
  2. Two-way workflow asynchronous: First message performs HB, second message HB response.

3. Two-way workflow synchronous: First message DE requests a status update of a proxied session, SS engine worker sends a relatively immediate second message response.

Code Functionality

- The code limits the amount of messages it can consume in a single sitting before attempting to consume additional messages.
- No message routing to specific DEs is implemented.
- No equal distribution of various workloads to individual DEs is attempted.

Primary Architectural Goal

- High availability and allowing multiple endpoints to process workloads.

Distributed Engine Configuration

- Via site and engine settings, a DE can be configured to consume all message types or a subset of the message types.
- A DE can only consume messages from a single site.

Summary

- DE message consumption is a non-deterministic algorithm; the bus manages which consumer will consume a message.
- There is no round-robin distribution.
- There is no mechanism in place for the SSH/RDP proxy workflow to choose a specific DE for a business user.

Distributed Engine Offline and Online Events

Delinea considers a distributed engine to be offline if it has not successfully communicated with Secret Server for a duration equal to three times the configured heartbeat interval. For example, if the heartbeat interval is set to 5 minutes, the engine will be marked offline after 15 minutes without communication.

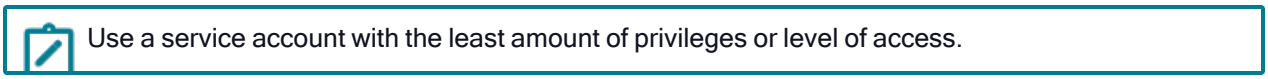
Additionally, engine online and offline status changes can now trigger subscription actions, allowing administrators to receive notifications when an engine's state changes.

As of DE version 8.4.68, environment metadata collection is included as part of the Secret Server heartbeat functionality. To verify platform connectivity, Secret Server periodically connects to https://delinea.app. This connection is expected behavior and may appear in firewall inspection logs. If detected, no firewall rule changes are required unless local policies restrict this outbound traffic.

Downloading and Installing a Distributed Engine

1. Search for and navigate to **Sites and Engines**. The Distributed Engine page loads.
2. Click **Add Engine**. The Download Engine popup appears.
3. For **Processor architecture**, select the bit value for your machine, either 64 or 32.
4. For **Preconfigured Site**, select **Default**.
5. Click **Download Now** to save and download your engine `.zip` file.

   Note the location of the download, which defaults to Downloads on Windows.
6. Open the download directory on your machine and extract the `Thycotic.DistributedEngine.Service.Default.x64 zip` file.
7. Open the unzipped folder and run `setup.exe`.
8. Open **Services** on the App Server and right-click the **Thycotic Distributed Engine**.

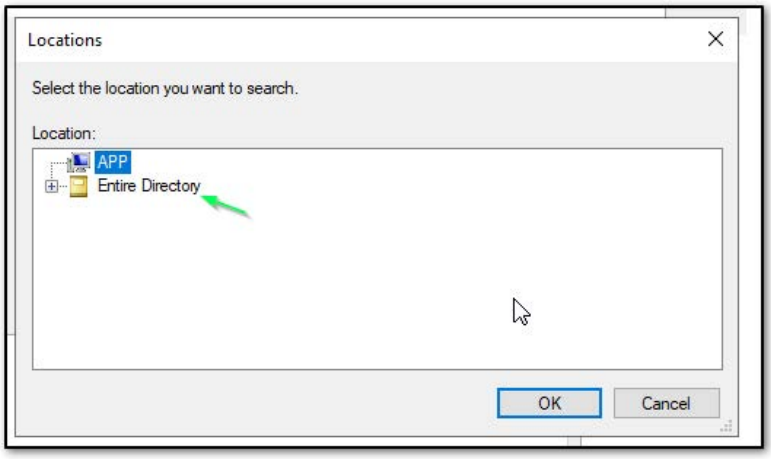
9. Switch back to your browser and reload the **Distributed Engine** page.
10. Expand the **Default** site by clicking the half-arrow next to it.
11. Hover over the engine that is now showing and click the three-dot menu on the far right.
12. Select **Activate**, then click **OK** in the pop-up.

    Green circled checkmarks will appear for **Connection Status** and **Activation Status**, indicating that your engine is now installed.

Running a Distributed Engine as a Service Account

If you are running a distributed engine as a service account:

1. Select **Properties** and click the **Log On** tab.
2. Click **This account** and click **Browse**.
3. Click **Locations** and select **Entire Directory**:



4. Type the Service Account you would like to run in the **Enter the object** text box, check Names, and then click **OK**.
5. Switch back to your browser and reload the **Distributed Engine** page.
6. Type the password for the Administrator, and click **OK**.

Facilitating Auto Upgrades of Your Distributed Engine

We have seen issues getting engines auto-upgraded when the service is running as a domain account instead of the built-in account. From our research and testing, the important things to have in order to use an AD service account and to have successful, hands-free upgrades are the following:

- The service account should be in the local Administrators group (so the account can start/stop the service).
- The service account needs full Windows permissions to the DE installation directory.
- After setting the service account as the DE login account, the service must be restarted to have the login identity change take effect.

After changing the service account, the DE will show up as a **Pending** engine. The old engine with the local login identity should be deactivated and removed from the **Site**, with the new engine/identity instance added back to the **Site** upon activation.

Distributed Engine Configuration and Sizing

The distributed engine sizing guide is in development and will be available here when completed.

Requirements

Supported Windows Server OS Versions

As of Secret Server version 11.9.x:

- Windows Server 2019 or newer is required for both the Web Server and Database Server in the minimum configuration.
- Windows Server versions 2016-2022 are supported, with 2025 pending further QA validation.

Secret Server DEs require that one of the following two server features be installed when the Secret Server website is running on a Windows Server. This depends on which protocol is selected in the engine's callback settings. If HTTPS is selected, the HTTP activation is required. If TCP is selected, then TCP activation is required.

This is accomplished by going to one of the following in the Windows Server:

- **.NET Framework 4.5 Features > WCF Services > HTTP Activation**
- **.NET Framework 4.5 Features > WCF Services > TCP Activation**

If the feature is not installed, there will be an error message in the DE logs: `(405) Method Not Allowed. ---> System.Net.WebException: The remote server returned an error: (405) Method Not Allowed.`

Distributed Engine Installation

All interaction between the Secret Server Cloud tenant and your on-premises network uses our distributed engine service to communicate. The work tasks that distributed engine completes includes Active Directory authentication, password changing, and performing heartbeats. The machine where the engine is installed must be able to communicate outbound on port 443.

For more information, see the "Distributed Engine Overview" on page 718.

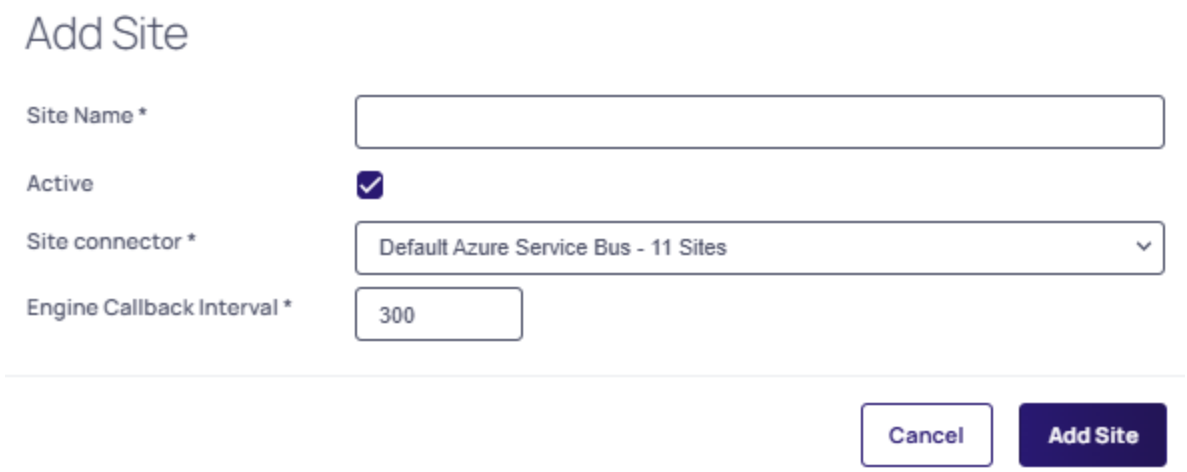
To install the Distributed Engine:

1. Access Secret Server.
2. Search for **Distributed Engine**. The Distributed Engine page loads.
3. Click the **Add Engine** button. The Download Engine popup appears.
4. Select the related **Processor Architecture** for either 64-bit or 32-bit from the dropdown list.
5. Select the related **Preconfigured Site** from the dropdown list.
6. Click **Download now**.

> You can install a distributed engine on your workstation or laptop for testing purposes, but for production installations, the distributed engine server should be installed on a server. Secret Server uses the distributed engine to communicate with your domain, so if your machine is turned off, users cannot log in with their domain accounts. This will also cause heartbeat and remote password changing to fail.

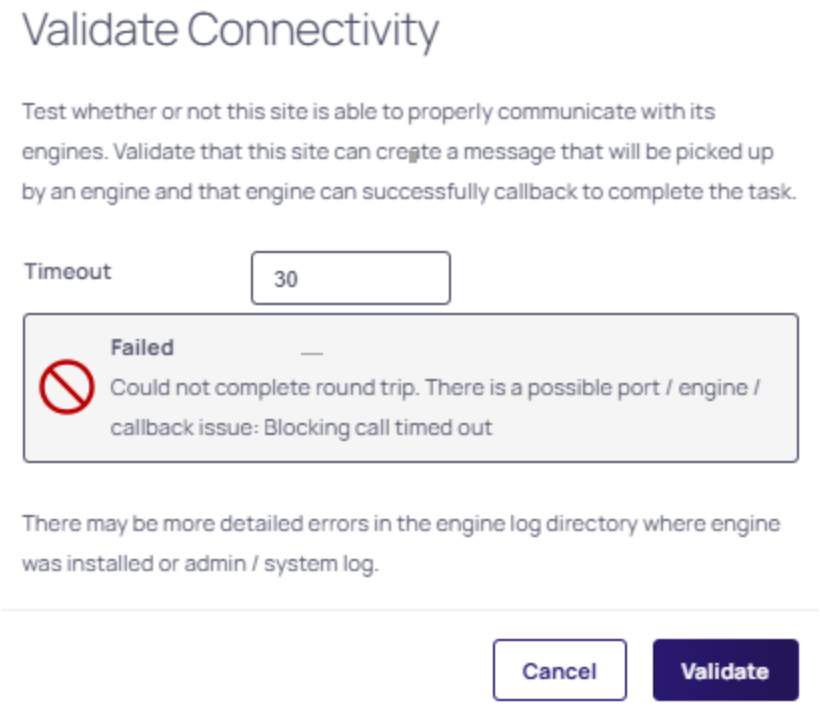
7. Access your downloaded `.zip` file and perform an extraction to an appropriate location.
8. Run `setup.exe` as an administrator to install the engine service and verify the folder location of the installation on your local machine.
9. Go back to the **Distributed Engine** page. The Sites and Engines tab loads automatically.
10. Expand the **Pending Engines** section. The engine you installed should appear here.

11. Select the engine by clicking on it. Its details will automatically expand.
12. Hover over the details of the engine and the 3-dot vertical menu appears.
13. Select the **Activate** option. The Activate popup asking for confirmation will appear.
14. Select **New Site** to add a new site. The Add site popup appears:



15. Add a **Site Name**, select the **Active** checkbox and leave the **Engine Callback Interval** at the default 300 value.
16. For the **Site Connector**, leave the Default Azure Service Bus - 11 Sites option unless otherwise directed.
17. Click **Add Site** to save your changes.
18. Access the newly created site by clicking on its name (it's a link). The **Site** tab loads by default.
19. In the **Site** section, click **Validate Connectivity**. The Validate Connectivity popup appears.
20. Set the **Timeout** in seconds (which represents how long, in seconds, to wait for a successful round trip from site to bus to engine and then back to site).
21. Click **Validate**.

It may take several minutes for the engine to register. If it does not immediately validate, wait a few minutes and try again. If an error occurs it appears in the popup window, for example:



Configuring Engines for PowerShell Use

Secret Server can be configured to use PowerShell for several key task types:

- Discovery
- Heartbeat
- Password Change
- Script Tests

Customers using PowerShell extensively for these tasks may, however, experience high CPU usage, as PowerShell is more resource-intensive compared to `cmd` or `bash`. To address this, you can limit the number of "shells" (tasks) a user can run on a machine. These "shells" represent the tasks the engine is executing under the user account associated with the Engine Service.

This limit is controlled by the **MaxShellsPerUser** setting for WinRM, which PowerShell uses. You can configure this setting through Group Policy, the registry, or directly with PowerShell. If MaxShellsPerUser is set, the engine will only execute the allowed number of PowerShell tasks and queue any additional tasks in the Service Bus for later execution. If it's not set, the engine will run tasks as normal without restriction.

In cases where PowerShell scripts are unreliable or prone to timeouts—especially under heavy loads from Secret Server—the engine may encounter issues. Since the Distributed Engine allows scripts to run for up to 15 minutes, extended timeouts can cause problems. To mitigate this, you can use the **Prefetch** feature, which controls how many tasks the engine can consume at one time. For instance, you could limit the number of concurrent Heartbeats by setting a specific prefetch value.

Additionally, a configuration setting allows you to match the prefetch count for all consumers that use PowerShell to the MaxShellsPerUser value. This setting can be found in the `app-prefetch.config` file located in the application directory.

General Networking

General networking topics, including site status, IP address filtering, clustering, and ports.

Checking Secret Server Site Status

To query Secret Server status without authentication for basic latency check, follow the steps below.

1. In a web browser, go to https://yoursecretserverurl/healthcheck.aspx
2. Compare the information displayed in your browser to the information below:

   ```
   {"healthy":true,"now":"2019-04-08T12:59:06.0455458-04:00","utcNow":"2019-04-
   08T16:59:06.0455458Z"}
   ```

   - If your information is similar, your Secret Server should be operational.
   - If your information displays other text such as **timed out** or **service unavailable**, there may be issues with the web site where the application is installed.

Restricting IP Addresses

IP address restrictions allow you to control which IP address ranges users can use to log in to Secret Server.

This topic can be used with legacy Secret Server Cloud and Secret Server On-Premises, but does not apply to Secret Server Cloud with the Delinea Platform. When users log in to Secret Server Cloud, only the public IP address is provided to Secret Server.

Only use Secret Server IP address if you are allowing direct logins to Secret Server Cloud.

If you overly locked down then you could block Delinea Platform access to Secret Server Cloud. Please reach out to Support for additional questions

Creating IP Address Ranges

To create an IP address range:

1. Search for **IP Addresses** under Administration. The IP Address Management page appears.
2. Click the **New IP Address** button. The Add New IP Address Range popup page appears.
3. In the **IP Address User/Network Name** text box, type a descriptive name for your range.
4. In the **IP Address Range** text box, enter an IP Address or IP Address range. Secret Server supports single IP Addresses (10.0.0.4), a range separated by a hyphen (10.0.0.1-10.0.0.255), and CIDR notation (10.0.0.0/24).
5. Click the **Save** button. The new address or range appears in the IP Address Management table.

You can show or hide columns in the table by clicking the button.

Editing and Deleting IP Address Ranges

To edit an IP address range, go to the **IP Address Management** page, click on a range, and click **Edit**. To delete a range, click on the range and click the **Delete** button.

Assigning an IP Address Range

1. To assign a range to a user:
2. Search for **Users** page. The View User page appears.
3. Scroll to the bottom of the page and click the **Change IP Restrictions** button. The Edit IP Address Restrictions Page appears.
4. Click to select or deselect check boxes next to the ranges to choose which IP Addresses a user can use to access Secret Server. If no boxes are checked, the user can access Secret Server through any IP Address.
5. Click the **Save** button.

Regardless of the restrictions, users can always log in when accessing Secret Server on the server using a local IP address (127.0.0.1). This prevents total lockout from Secret Server.

To put in a whitelist restriction at the Web Application Firewall (WAF) layer, you need to put in a ticket to support to have that in place.

Refer to the Delinea Platform documentation for more information about IP restrictions.

This topic applies to **Secret Server On-Premises** and standalone **Secret Server Cloud**.

Ports and IP Addresses Used by Secret Server

This article lists ports and addresses typically used in Secret Server.

Notes

Microsoft Remote Procedure Call (RPC) Functionality

- The Remote Procedure Call (RPC) dynamic port ranges are a range of ports used by RPC. This port range varies by operating system. For Windows Server 2008 or greater, this port range is 49152 to 65535 and this entire port range must be open for RPC technology to work. The RPC range is needed to perform Remote Password Changing (also RPC) since you will need to connect to the computer using DCOM protocol.
- The range can vary separately for MS Exchange servers. For more information about changing the Remote Procedure Call (RPC) port range, see How to configure RPC dynamic port allocation to work with firewalls.

- To see your ipv4 dynamic range on a given machine, type netsh int ipv4 show dynamicport tcp in the command line.
- To specify a specific port on your environment to communicate with, see the related article on enabling WMI ports on Windows client machines.

Source and Target Designations

- Secret Server On-Premises has an initial site named **local** that you can configure to perform actions within the environment using the application server or distributed engines.
- Configure local at **Settings > Configuration Search > Distributed Engine > Sites > <site name> > Processing Location** or **Settings > Configuration Search > Administration > Setup and Operation > Distributed Engine > Sites > <site name> > Processing Location.**
- Secret Server Cloud and Delinea Platform have an initial site named **Default** that performs all actions through distributed engines.

Port Listing

Active Directory Sync Ports

Table: Active Directory Sync Ports

Type of Traffic	Port Number	Source	Target	Purpose
Kerberos	TCP/88, UDP/88	Web server or engines assigned to site	Domain controllers	Authentication
LDAP	TCP/389, UDP/389	Web server or engines assigned to site	Domain controllers	AD sync, authentication, and authorization
LDAPS*	TCP/636, UDP/636	Web server or engines assigned to site	Domain controllers	AD sync, authentication, and authorization
SMB/Microsoft-DS	TCP445, UDP/445	Web server or engines assigned to site	Domain controllers	AD sync, authentication, and authorization

*For LDAPS to work, the LDAP port (389) must also be open.

Database Server Incoming Ports

Table: Database Server Incoming Ports

Type of Traffic	Port Number	Source	Target	Purpose
SQL connection	TCP/1433, UDP/1434	Web servers	Microsoft SQL Server or availbility group listener	Database communication. Can be customized

Discovery Ports

Table: Discovery Ports

Type of Traffic	Port Number	Source	Target	Purpose
RPC dynamic port range	TCP/49152-65535, UDP/49152-65535	Web server or engines assigned to site	Windows servers	Windows Server discovery scanning for user and service accounts
RPC endpoint mapper	TCP/135	Web server or engines assigned to site	Windows servers	Windows Server discovery scanning for user and service accounts
SMB/Microsoft-DS	TCP/445, UDP/445	Web server or engines assigned to site	Windows servers	Windows Server discovery scanning for user and service accounts
SSH	TCP/22	Web server or engines assigned to site	Unix and Linux Servers	Unix and Linux server discovery scanning for user and SSH keys

Distributed Engines and Application Servers

Table: Distributed Engines and Application Servers

Type of Traffic	Port Number	Source	Target	Purpose
RDP proxy	TCP/3390	Client workstations	Web server or engines assigned to site	Proxied RDP sessions
RDP Proxy Outbound	TCP/3389	Webserver or engines assigned to site	Windows servers	Proxied RDP sessions

Type of Traffic	Port Number	Source	Target	Purpose
SSH proxy	TCP/22	Client workstations	Web server or engines assigned to site	Proxied SSH sessions
SSH proxy	TCP/22	Webserver or engines assigned to site	Unix and Linux Servers	SSH proxy and terminal sessions
SSH terminal	TCP/22	Client workstations	Web server or engines assigned to site	SSH terminal traffic

Email Ports for On-Premise installations

Table: Email Ports for On-Premise installations

Type of Traffic	Port Number	Source	Target	Purpose
SMTP	TCP/25, TCP/465, TCP/2525, or TCP/587	Web servers	Mail servers	Email alerts and reporting. Port can be customized to suit environment

Message Queuing Site Connector Ports

Table: Message Queuing Site Connector Ports

Type of Traffic	Port Number	Source	Target	Purpose
MemoryMQ	TCP/8672 (non-SSL), TCP/8671 (SSL)	Web servers and distributed engines	MemoryMQ server	Non-production AMQP message queueing
RabbitMQ	TCP/5672 (non-SSL), TCP/5671 (SSL)	Web servers and distributed engines	RabbitMQ servers	AMQP message queueing
RabbitMQ CLI tools communication	TCP/25672-25682	Localhost	RabbitMQ nodes	Used by rabbitmqctl and other management tools to communicate with nodes.

Type of Traffic	Port Number	Source	Target	Purpose
RabbitMQ management interface	TCP/15672 (non-SSL) or TCP/15671 (SSL)	Localhost	RabbitMQ nodes	HTTP API and management UI (not directly related to clustering). Can be configured to use HTTP or HTTPS

On-Premise Web Server Incoming Ports

Table: On-Premise Web Server Incoming Ports

Type of Traffic	Port Number	Source	Target	Purpose
HTTP	TCP/80	Client devices	Web server	Optional HTTP access for legacy devices to web application and API
HTTPS	TCP/443	Client devices	Web server	HTTPS access to web application and API
HTTPS	TCP/443	Distributed engine	Web server	Distributed engines use callback flow for initial activation, periodic check of site and site connector settings, log file uploads, and software updates. This callback can also be configured to communicate over HTTP or TCP

RabbitMQ Clustering Ports

Table: RabbitMQ Clustering Ports

Type of Traffic	Port Number	Source	Target	Purpose
EPMD (Erlang Port Mapper Daemon)	TCP/4369	All RabbitMQ cluster nodes	All RabbitMQ cluster nodes	Used for node discovery. The EPMD maps node names to network ports
Inter-node communication	TCP/25672-25682	All RabbitMQ cluster nodes	All RabbitMQ cluster nodes	Used for communication between cluster nodes, including data replication and heartbeats

RADIUS Server Ports

Table: RADIUS Server Ports

Type of Traffic	Port Number	Source	Target	Purpose
RADIUS authentication	UDP/1812	Web servers or Secret Server Cloud	Radius server	Authentication

Remote Password Changing Ports

Table: Remote Password Changing Ports

Type of Traffic	Port Number	Source	Target	Purpose
Encrypted Telnet	TCP/23, TCP/22, otTCP/992	Web server or engines assigned to site	iSeries Mainframes and zSeries Mainframes	RPC and heartbeat
Entra ID Microsoft Graph API	TCP/443	Web server or engines assigned to site	Entra Graph API	RPC and heartbeat
Kerberos password change	TCP/464, UDP/464	Web server or engines assigned to site	Microsoft Active Directory domain controllers	RPC and heartbeat
LDAP	TCP/389, UDP/389	Web server or engines assigned to site	Microsoft Active Directory domain controllers or LDAP-based domains	RPC and heartbeat
LDAPS	TCP/636, UDP/636	Web server or engines assigned to site	Microsoft Active Directory domain controllers or LDAP-based domains	RPC and heartbeat
Microsoft SQL	TCP/1433, UDP/1434	Web server or engines assigned to site	SQL servers	RPC and heartbeat

Type of Traffic	Port Number	Source	Target	Purpose
Oracle listener	TCP/1521	Web server or engines assigned to site	Oracle servers	RPC and heartbeat
RPC dynamic port range	TCP/49152-65535, UDP/49152-65535	Web server or engines assigned to site	Windows computers	RPC and heartbeat
RPC endpoint mapper	TCP/135	Web server or engines assigned to site	Windows servers	RPC and heartbeat
SMBv2/Microsoft-DS	TCP/445, UDP/445	Web server or engines assigned to site	Windows computers	RPC and heartbeat
SSH	TCP/22	Web server or engines assigned to site	SSH-based servers and devices	RPC and heartbeat
Sybase	TCP/2638, TCP/5000	Web server or engines assigned to site	Sybase Servers	RPC and heartbeat
Telnet	TCP/23	Web server or engines assigned to site	Networking equipment and Unix servers	RPC and heartbeat
Windows privileged account (WinNT ADSI service provider)	TCP/139	Web server or engines assigned to site	Windows servers	RPC and heartbeat

SMBv2 requirement for Windows RPC operations

Secret Server uses Windows APIs and RPC-based operations for remote password changing on Windows systems. Some of these operations require SMBv2 to be enabled on the target system. If SMBv2 is disabled, remote password changing and related RPC functionality may fail even when port 445 is open.

Secret Server Cloud Specific Traffic

Table: Secret Server Cloud Specific Traffic

Type of Traffic	Port Number	Source	Target	Purpose
Distributed engine communication	TCP/443 (Web Sockets) or TCP/443 (Web Sockets), TCP/5671, TCP/5672 (AMQP)	Distributed engine	Azure service bus	Message queueing

Syslog Ports

Table: Syslog Ports

Type of Traffic	Port Number	Source	Target	Purpose
Syslog	TCP/514, UDP/514	Web server or engines assigned to site	Syslog collector	SEIM logging

IP Addresses

Web Application Firewall (WAF) for Traffic to Secret Server Cloud

> These firewall rules must be configured with SSL Inspection disabled. The services will not function if they detect an intermediate certificate for SSL inspection.

> IP Address allow-listing is not necessary unless outbound firewall rules are in place.

The Delinea Platform leverages Imperva Cloud Web Application Firewall to help secure our edge services. Customers who are interested in applying outbound filtering should be able to lock down their access to the ingress Imperva IP ranges.

Your outbound requests to SSC will primarily go to the following six IPs:

- 45.60.32.37
- 45.60.34.37
- 45.60.36.37
- 45.60.38.37
- 45.60.40.37
- 45.60.104.37

Note: Your outbound requests to SSC will primarily go to the above six IPs. However, we recommend that all the IPs below should be allowed on your outbound firewall rules to maintain connectivity during some failover events where the traffic is routed through alternate network paths. Your tenants may resolve to one of the IPs in the below list during such a case.

The IP ranges from the Imperva Cloud WAF may change periodically; it is important to check frequently and stay up to date. IP ranges can be retrieved via the Imperva API. Example range output may include (but is not limited to):

- 199.83.128.0/21
- 198.143.32.0/19
- 149.126.72.0/21
- 103.28.248.0/22
- 185.11.124.0/22
- 192.230.64.0/18
- 45.64.64.0/22
- 107.154.0.0/16
- 45.60.0.0/16
- 45.223.0.0/16
- 131.125.128.0/17

IPv6 range:

2a02:e980::/29

For current WAF IP ranges, query the Imperva API:

```
curl -s --data "resp_format=json" https://my.imperva.com/api/integration/v1/ips
```

Ensure your firewall allows outbound access to these Imperva WAF ingress ranges to maintain uninterrupted Secret Server Cloud connectivity.

How to configure RPC dynamic port allocation to work with firewalls (Microsoft)

Secret Server Clustering

This document is a guide to Delinea's Secret Server clusters for administrators and advanced users. Secret Server can run with multiple front-end Web servers. For a critical instance, clustering offers a redundant system to limit potential down time from a single point of failure. Clustering also allows users to load balance for better performance.

Overview

Clustering and Background Thread Changes in 10.7.

There are two major architectural changes in Secret Server 10.7:

> The first change is obvious in the Secret Server user interface, and the second is hidden but very important to those supporting Secret Server.

- **Primary Node:** We eliminated "primary nodes." Previously, some important background operations, such as password changing and heartbeat, would only run from the primary node. Now they run from all nodes. Given that, there is no longer a "Make Primary" button, and the ValidPrimaryNode setting no longer applies.
- **Background Operations:** There are no longer background threads for scheduled operations. Instead, operations are scheduled by Quartz.

Clustering Overview

With Secret Server clustering, you can easily scale Secret Server for redundancy and performance. Basic Secret Server clustering is simple—you install Secret Server and then copy the installation to another machine. Secret Server clustering has four core concepts or components:

Nodes

Each machine with Secret Server installed on it, pointing to the same database, is a *node*. All nodes respond to Web requests and thus are Web servers.

Backbone Bus

The backbone bus Internally handles all communication between the roles. In a clustered environment, the backbone bus should always be an installed RabbitMq messaging queue. This allows every node in the cluster to help with the workload. If the backbone bus is set to "internal," then each node is using its own internal backbone bus.

Engine Response Bus

The engine response bus facilitates communication from Secret Server to distributed engines and back.

Worker Roles

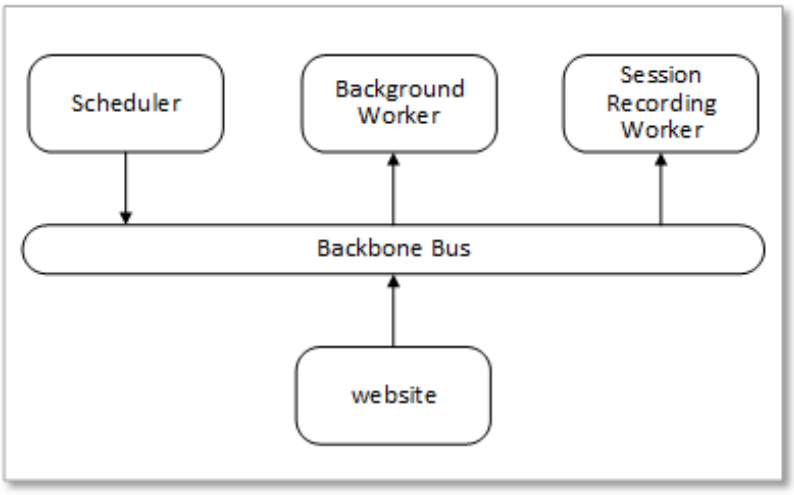
Each node can optionally run one or more worker roles: background Worker, engine worker, and session recording worker. Though they may run on the same machine, the roles do not directly communicate with each other.

Each node that is set to run the background worker role automatically runs the scheduler role as well. The scheduler role is responsible for running the vast majority of Secret Server background operations. It uses Quartz to run "trigger jobs" that send a message on the backbone bus for each scheduled operation. One or more background worker roles then processes those messages.

See the article "Quartz Trigger Jobs" on page 270 for more information about Quartz.

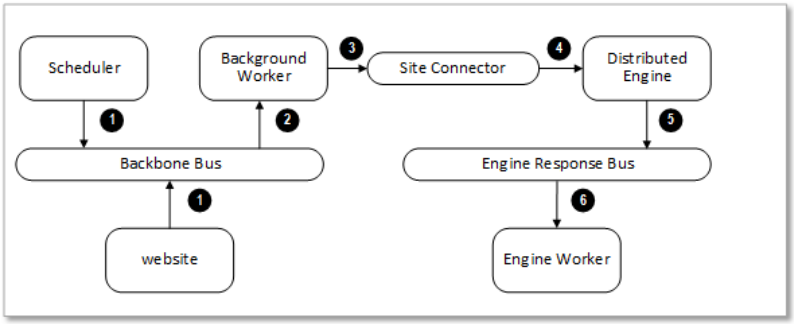
Component Communication

Figure: Secret Server Internal Cluster-Component Communication



Messages are placed on the backbone bus by the Scheduler role and the website. Messages are retrieved from the backbone bus.

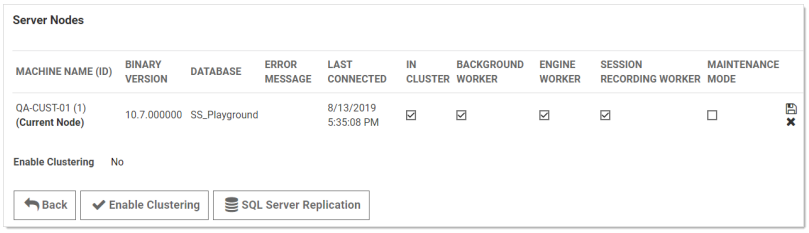
Figure: Secret Server Distributed Engine Communication



1. Manual or scheduled operation.
2. Background worker processes a message.
3. Outbound messages (password changes, heartbeats, and others) are placed on the site connector.
4. Distributed engine performs the operation.
5. Engine worker processes the response.

Server Node Configurations

The work an individual node handles depends entirely on which boxes are checked on the Server Nodes page (in edit mode):



- **In Cluster** is a toggle that turns a server node on or off. If enabled this node can process Web requests, and (if configured) will run the background, engine, and session recording roles. If disabled, the node is just a backup—it cannot run any roles, and trying to access the website on the node will redirect to the server nodes page.
- **Background Worker** is a toggle for all background operations, such as password changing, heartbeat, and discovery. When it is set to false, only the bulk operations, password generation, email, and secret import operations run on the node. See the list of background operations below.
- The **Background Worker**, **Engine Worker**, and **Session Recording Worker** check boxes enable the corresponding roles for that node.
- **Engine Worker** enables or disables the engine worker role, which processes responses from distributed engines.
- **Session Recording Worker** enables or disables the session recording role, which encodes session videos.
- **Maintenance Mode** enables or disables a read-only mode where the node cannot change secrets or related data.

Scheduled Background Operations

The current scheduled background operations in Secret Server are:

- ActiveDirectorySynchronizationMonitor
- BackgroundWorkerTaskTriggerJob
- BackupMonitor
- Bulk Operations When triggered by user
- CheckOutMonitor
- ComputerScanMonitor

- ConnectWiseMonitor
- DatabaseCleanupTriggerJob
- DiscoveryMonitor
- EventQueueMonitor
- ExpiredSecretPasswordChangeTriggerJob
- ExpiringLicenseTaskTriggerJob
- ExpiringSecretTaskTriggerJob
- HeartbeatMonitor
- Local Heartbeat Trigger Job
- Local Password Change Trigger Job
- NodeClusteringMonitor
- NodeTaskTriggerJob
- PasswordRequirementTriggerJob
- PbaDirectiveTriggerJob
- PbaMetadataUploadTriggerJob
- PrimaryNodeTaskMonitor
- Process Field Encryption Changes Task
- ProcessDashboardJsonValidationTask
- ProcessSecretPolicyChangesMessage
- ScheduledReportMonitor
- SecretComputerMatcherMonitor
- SecretItemHashMonitor
- SqlReplicationConflictMonitor
- TelemetryTriggerJob
- ThycoticOneSyncUserTriggerJob
- TruncateDatabaseCacheTriggerJob
- TruncateEngineLogTriggerJob
- VideoConversionTriggerJob

To see the current state of these jobs, such as the last time they ran and how long until they run again, Search for **Diagnostics**.

Procedures

Setting up Clustering

> Clustering requires a Secret Server Premium add-on or Enterprise Plus edition license.

1. Have Secret Server upgraded or installed and running on a server.
2. Enable clustering on the node:
   a. In Secret Server, click **Admin > See All**. The Administration page appears:

   b. Click the **Server Nodes** button in the **Setup** section. The Server Nodes page appears:

   c. Click the **Enable Clustering** button.
3. Copy the entire Secret Server application folder (typically `c:\inetpub\wwwroot\SecretServer`) from the existing node to the secondary node.
4. Follow the steps in the Installation Guide for setting up the "Step 3: Configuring IIS" on page 73 and "Step 4a: Installing Secret Server as a Virtual Directory" on page 74.

> If you use DPAPI encryption for your encryption.config file, you need to transfer the non-DPAPI-encrypted version of the file to the secondary node. You can turn on DPAPI encryption from that server node locally after Secret Server is running. This setting can be found at **ADMIN > Configuration** on the **Security** tab.

5. If running Secret Server 8.9.300000 or later, ensure that both servers are using the same date and time.
6. Once the secondary server is running, navigate to its Secret Server using a Web browser.
7. Reset the database connection, following the instructions at "Changing SQL Server Connection Parameters" on page 198.
8. Activate licenses for the new node. You can do this on either server once the database connection is established on the secondary node.
9. Configure your load balancer for the two sites to have "sticky sessions" to prevent a user from bouncing between server on each request.

> We recommend cookie-based session persistence at the load balancer. Cookie stickiness is more reliable than source-IP-based affinity (which can break with NAT, VPNs, mobile clients, or proxy chains) and helps ensure each user's authenticated session stays on a single node.

10. Configure the worker roles for the cluster:
    - Each server node can optionally run the background worker, engine worker, and session recording worker roles.
    - At least one instance of **each** type of those roles must be active in the cluster for the clustered Secret Server application to function.
    - You may run more than one instance of each role as desired to improve the performance of the clustered Secret Server application.

> For more information on what the various roles do, please see the Worker Roles section.

Upgrading Secret Server in a Clustered Environment

Overview

Secret Server has a built-in Web installer. That installer is a series of pages inside Secret Server for downloading and updating Secret Server. Secret Server is accessible by users for most of the upgrade process. You can stop outside access to the site if you want to prevent users from making changes during the upgrade. Preventing user access will make restoring the database and site backups simpler if you decide to roll back the upgrade immediately afterward.

> Before upgrading, **backup your Secret Server folder and database**. See Upgrading Secret Server - Single Instance and Web Clustering for important steps for ensuring your data is backed up.

> Upgrading to Secret Server version 8.9.000000+ requires Windows Server 2008 R2 or greater.

Upgrading to Secret Server 10.0.000000 and above requires configuring integrated pipeline mode on the Secret Server application pool. Please see "Changing IIS to Not Stop Worker Process in IIS 7.0 and Later" on page 254 for details.

If using Integrated Windows authentication you will also need to update IIS authentication settings as detailed in "Configuring Integrated Windows Authentication" on page 389. If you are at version 9.1.000000 and below, you will need to first upgrade to 9.1.000001 before you can upgrade to 10.0.000000+.

You do **not** need to download the Secret Server installer to perform an upgrade.

Procedure

1. Before you start:
   - Ensure that you have account credentials information and access for the server hosting Secret Server and the SQL Server instance hosting your Secret Server database.
   - Have a recent backup of the application files and database available.
   - Stop the application pools on all of the servers except the one that you have chosen to upgrade.
2. Choose one Secret Server server to upgrade
3. Perform a backup of that server.
4. Stop the Web servers of all other nodes.
5. Perform the upgrade using the same procedure as a single instance.

   If applicable, see "Upgrading Secret Server Without Outbound Access" on page 167.
6. Once Secret Server is upgraded and working, copy the Web application folder (without the database.config or encryption.config files) to all other servers.

   Never overwrite or delete the encryption.config file on a Secret Server server.

   Both encryption.config and database.config are automatically propagated to the new servers from the original. If you need to copy those files because of database configuration changes and are using DPAPI, disable DPAPI encryption in Secret Server by going to **Admin > Configuration** on the **Security tab**. and clicking **Decrypt Key to not use DPAPI***before* copying those files to secondary servers. Please note, that DPAPI is system specific. Do not copy the database.config or the encryption.config from machine to machine if they are protected by DPAPI.

> EFS encryption is tied to the user account running the Secret Server application pool, so it is not machine-specific. Thus, it is not necessary to copy EFS encrypted files between Secret Server instances, but it is allowed.

7. If Delinea management server (TMS) is installed and clustered, copy the TMS directory to the secondary servers as well. The TMS directory is included by default for new installs of Secret Server 10.2+. TMS is used by advanced session recording and Privilege Manager. If the TMS folder and site does not exist in IIS, then no additional actions are needed.
8. Start the secondary servers to confirm they still work.

Upgrading Database Mirroring

1. If there is more than one Web server running Secret Server, ensure all instances are pointing to their primary database.
2. Select one server to perform the upgrade on, stop all other web servers.
3. Perform the upgrade on the single instance.
4. Once upgraded and working, copy the Web application folder to all other Web servers.
5. Start all other Web servers and confirm they work
6. Ensure all instances are properly activated
7. Ensure that the primary database changes have been replicated to the mirror database.
8. If one of the servers was pointing originally to the secondary database, adjust it to point there again.

Upgrading Disaster Recovery Installations

> This section does not refer to Resilient Secrets disaster recovery nodes.

1. Perform the upgrade on the production instance.
2. Backup the production instance.
3. Copy the database backup to the remote DR instance and restore the database.
4. Once the database is upgraded and working, copy the web application folder (but not the database.config or encryption.config files) to the remote DR instance, overwriting the existing files.
5. Restart IIS or recycle the application pool running Secret Server on the remote DR instance.
6. Confirm that the remote DR instance is working correctly.

Load Balancing Secret Server Clusters

In a clustered Secret Server environment set up behind a load balancer, the accessible outside URL may be something other than the server name.

> Customers often configure the service monitor on the load balancer to hit `login.aspx`. This can cause performance issues and memory leaks. We strongly suggest hitting `healthcheck.aspx` instead.

> We recommend using cookie-based persistence on the load balancer. Cookie stickiness is generally more stable than source-IP or SSL-ID persistence, especially for clients behind NAT/VPN or changing IPs, and helps prevent users from bouncing between nodes during an authenticated session. If supported, prefer a load-balancer-inserted cookie; alternatively, persist on the application session cookie provided it is consistently present across requests.

Custom URL Configuration

In Secret Server 8.5 and later, the Custom URL setting can be configured to ensure that links and resources are resolved correctly and are not based upon the server name. The Custom URL sets a definitive URL for Secret Server. Without it, features in Secret Server that need to build a link back to the server must construct the link using the host value on the request, which is susceptible to manipulation.

1. Search for **Configuration**.
2. On the **General** tab, click the **Edit** button.
3. Go to the **Application Settings** section.
4. Click to select the **Custom URL** check box.
5. Type the desired URL in the **Secret Server Custom URL** text box.

SSL Recommendations

For the best security, we recommend placing the SSL certificate on each of the Web servers. This ensures the traffic leaving the server is encrypted by SSL. Optionally, the load balancer would need the certificates as well for adding the client's IP address.

If the connection between the load balancer and the server is isolated in a security zone, you could leave HTTP between the load balancer and the server and have the SSL on the load balancer.

Configuring Client's IP Address (X-Forwarded-For)

Routing traffic through a load balancer will cause Secret Server to audit the IP address of the load balancer instead of the business user. To avoid this:

First, configure the load balancer to pass along the client's IP address in the header.

Then add the `appSettings` key `IpAddressHeader` with the value of the name of the header field containing the client's IP address. This setting must be added to **all** Secret Server Web servers. Depending on your Secret Server version, do this in one of two ways:

For Secret Server prior to 10.5.000000:

In the `web-appSetting.config` file in your Secret Server directory, add the following key:

```
<?xml version="1.0" encoding="utf-8" ?>
<appSettings>
  <add key="IpAddressHeader" value="X-Forwarded-For" />
</appSettings>
```

For Secret Server 10.5.000000 and later:

1. Go to `https://<SecretServerAddress>/ConfigurationAdvanced.aspx`.
2. Scroll to the bottom and click **Edit**.
3. Locate the **IP Address Header** text box, type `X-Forwarded-For`.
4. Click the **Save** button.

> The SSL certificate needs to exist on the load balancer and the Web server to ensure it has access to add the client IP address header.

Clustering Errors

The following error may arise when setting up or operating Secret Server clustering:

- Server dates do not match: If the Web server dates do not match, the audit records could be bad. The fix is to set the servers to the same time.

  > This only applies to Secret Server before version 8.9.300000.

- Secret Server version does not match: If some of the cluster nodes have been upgraded and others have not, their versions will conflict, producing this error. Nodes which have the wrong (older) version will not function correctly. To fix this issue, ensure that all the nodes in your cluster are upgraded. For nodes that are having this issue, you can copy the application folder (minus the database.config file) to replace the server files with the correct version.

HTTP

Topics related to HTTP in Secret Server.

Secret Server Support for HTTP/2

HTTP/2 is supported in IIS 10. HTTP/2 is handled within IIS, so this is primarily a Microsoft question in regards to compatibility. Please see HTTP/2 on IIS. At the end of this article, it clarifies when HTTP/2 is not supported

Secret Server does support Windows Integrated Authentication where a user's windows session is passed through for authentication to Secret Server. That is, there is no log on page for Secret Server. The majority of our customers are (and the default configuration for Secret Server is) using forms-based authentication with a log on page. Only the latter is HTTP/2 compliant.

HTTP/2 is only compatible with HTTPS protocol. Secret Server can also be configured to operate only on HTTPS (Admin > Configuration > Security > Force HTTPS/SSL), which we strongly recommend.

Securing Traffic with HTTP Strict Transport Security

HTTP Strict Transport Security (HSTS) is an additional security layer for HTTPS that ensures anybody accessing a given Web site or entity is forced to use HTTPS and not HTTP *prior* to making any HTTP requests, eliminating man-in-the-middle attacks. HSTS is an IETF Internet Standards Track protocol as specified in RFC 6797.

When the Force HTTPS/SSL option in enabled in Secret Server, the **Enable HSTS** check box is displayed. After the option is turned on, you can click the **Advanced** link to specify the **Maximum Age** in seconds, which is how long

the policy is in affect before re-evaluating. The default value is 31536000 seconds or one year, which is also recommended value. We recommend that you set the value as high as possible, if the site should never be accessed without SSL. Even after HSTS is disabled, your browser automatically redirects to over SSL for the duration of the configured maximum age.

> We recommend using the IISReset command-line utility or restarting IIS in IIS manager after enabling the setting for the setting to take effect.

This feature is available in Secret Server version 8.6.000009 and higher and Password Reset Server version 4.0.000000 and higher.

> To see which browsers support HSTS, please refer to the Strict Transport Security page on the Can I Use website.

Messaging

> This topic only applies to **Secret Server On-Premises**.

Secret Server utilizes RabbitMQ as its primary messaging bus to facilitate efficient and secure communication between various components, such as distributed engines and site connectors. RabbitMQ ensures that operational instructions and data are passed asynchronously and securely, enhancing the system's scalability and reliability. Site connectors, which can be either RabbitMQ or MemoryMQ, act as intermediaries that hold work items for multiple sites and distribute these tasks among engines. This setup allows Secret Server to manage large-scale operations like password changes, heartbeats, and discovery processes efficiently. The use of RabbitMQ, with its robust message queuing capabilities, ensures that messages are encrypted during transit and provides high availability through clustering, making it a critical component for maintaining seamless and reliable operations in Secret Server environments.

Internal Site Connector

> This topic only applies to **Secret Server On-Premises**.

You can change how Secret Server processes messages by searching for **Admin > See All**.

Messages are generated and placed on the internal site connector, or backbone bus, every time a background operation is triggered whether by a schedule or on-demand.

The internal site connector receives and processes messages as a result of numerous "actions":

- Bulk Operations
- Generate Password
- Secret Import (CSV and XML)
- Run Heartbeat Now
- Run Heartbeat (Scheduled)

- Run Password Change Now
- Run Password Change (Scheduled)
- Run Discovery Now
- Run Discovery (Scheduled)
- Run AD Sync Now
- Run AD Sync (Scheduled)
- Elements of Session Recording

The internal site connector, using the internal hosted bus, is adequate for bulk operations, heartbeat, discovery, and the like, but some Secret Server features, such as a clustered Web server node configuration or session recording, require a scalable messaging solution to boost processing performance. Our choice is RabbitMQ, which is an intermediary messaging broker that can handle large-scale message processing.

For the highest scalability and reliability, Delinea recommends using RabbitMQ Helper. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.

The following is a typical internal hosted bus operation (for a bulk operation):

1. A Secret Server user triggers a bulk operation.
2. A message is formed and sent over a TCP connection to the internal hosted bus.
3. Secret Server (on the same machine) receives the message.
4. Secret Server (on the same machine) processes the message.

We continually improve the internal hosted bus but still recommend RabbitMQ Helper for a scalable performance boost. See "Installing RabbitMQ" on page 104 for more information.

RabbitMQ Durable Exchanges

This topic only applies to **Secret Server On-Premises**.

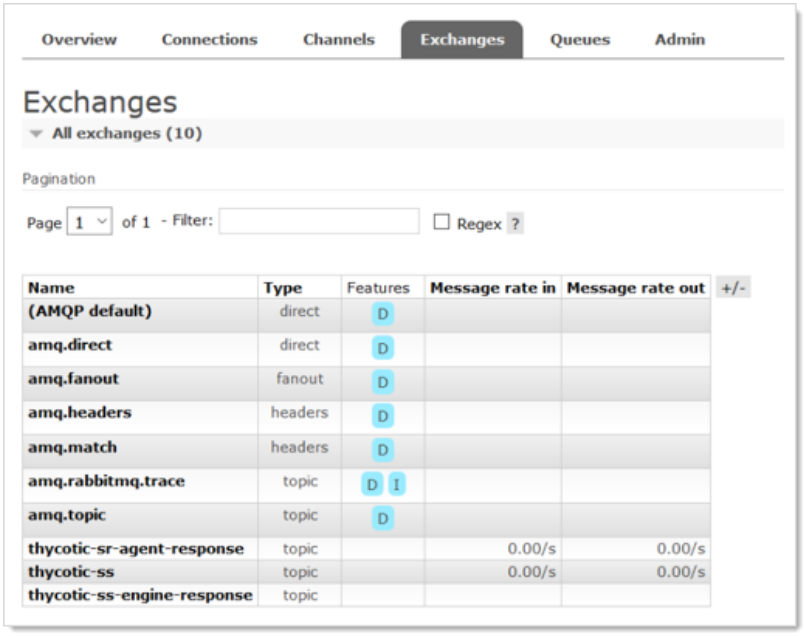
Overview

The Secret Server MessageQueue Client attempts to create RabbitMQ durable exchanges, logging the activity. A durable exchange is normally automatically re-created if RabbitMQ restarts for any reason. Any legacy non-durable exchanges disappear when RabbitMQ goes down and can only be manually recreated.

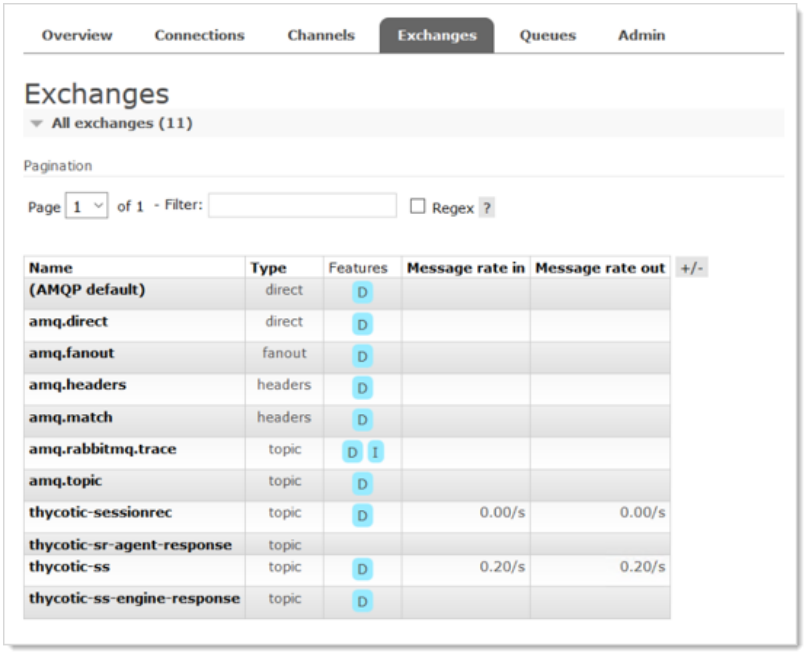
If the MessageQueue client detects that creating a durable exchange failed, it will log an error and attempt to create a non-durable one.

Any existing non-durable exchanges, from previous versions of Secret Server, will also cause durable exchange creation to fail. See Manually Creating Durable RabbitMQ Exchanges.

Non-durable RabbitMQ exchanges for Secret Server would look similar to this, whether created by an earlier Secret Server version or by a durable-version-creation failure:



Note the absence of a 'D' in the Features column, meaning that exchange is not durable. Durable exchanges, created by the current Secret Server version (11.8.1+), look like this:



Earlier versions of Secret Server (before 10.7.59) created non-durable RabbitMQ exchanges during a Secret Server server or IIS restart. If the environment is clustered, the same is true of every node in that cluster. The

current durable exchanges persist during any IIS restart, eliminating the need to restart Secret Server or recreate the exchanges.

However, any existing non-durable exchanges prevent the creation of the newer durable ones. To remedy that, you need to restart all of the RabbitMQ servers in the cluster at the same time or manually delete the non-durable exchanges.

Manually Creating Durable RabbitMQ Exchanges

To enjoy the benefits of the durable exchanges, you must first eliminate any legacy non-durable exchanges from your RabbitMQ server or servers. There are two ways to do this:

- Restart the RabbitMQ server or all of the RabbitMQ servers in the cluster at the same time. You can also stop the RabbitMQ service in `services.msc`.

Customers usually reset or turn off all servers via third party tools, but some prefer to shut off the service via services.msc because of their system configuration.

- Delete the exchanges manually:
  1. Click to select each Secret Server non-durable exchange, including distributed engine ones.
  2. Scroll to the bottom of the window.
  3. Click the **Delete** button.
  4. Restart all of the Secret Server instances and distributed engines to recreate the exchanges and connections.

Creating Durable RabbitMQ Exchanges with a PowerShell Script

Using the Script

```
powershell.exe -file exchangedurability.ps1 -username "guest" -password "guest" -
computerName "localhost" -port "15672"
```

The user has access to the RabbitMQ admin interface. The computername and port is where the admin interface is located.

The script:

1. Removes all of the exchanges that are not durable and any that are not the `thycotic-sr*` ones for legacy ASRAs.
2. Kills all of the connections. This forces the distributed engines and Secret Server to reconnect to the durable exchanges.

Script

```
param([string] $computerName = "",
    [string] $userName = "",
```

```
    [string] $password = "",
    [string] $port = ""
)
$defaultComputerName = if ($computerName -eq "") { "localhost" }else { $computerName }
$defaultVirtualhost = "/"
$defaultUserName = if ($userName -eq "") { "guest" }else { $userName }
$defaultPassword = if ($password -eq "") { "guest" }else { $password }
$defaultPort = if ($port -eq "") { "15672" }else { $port }
$defaultHttp = "http" #Use https if ssl
$defaultCredentials = New-Object System.Management.Automation.PSCredential

RabbitMQ Naming Conventions for Queues

This topic only applies to **Secret Server On-Premises**.

Introduction

This document addresses RabbitMQ naming conventions for its queues. These queues are useful for application troubleshooting and proactive application monitoring.

Secret Server is an asynchronous message-based system where operational instructions and data are passed back and forth between various components running in Web nodes or distributed Engines. A GUI interaction to perform an action, such as heartbeat, remote password change, or bulk operations publishes a message and then returns control back to the user. RabbitMQ is the message bus or broker that facilitates the message traffic.

All Secret Server messages are encrypted on the bus, so you cannot peek into the message contents during transit.

Messages have a lifetime, and consumers discard expired messages. Therefore, any accumulation or backup of messages in any queue is abnormal and indicative of an application problem.

Secret Server Roles

Secret Server divides its functionality by named and unnamed roles, and only named roles are configurable in a Web node via the GUI.

Table: Secret Server Roles Related to Message Queues

Role	Type	Comment
Background Worker	Named	Background work initiated by a task, schedule or UI interaction. Final action of the work might be done in the current Web node, another Web node or sent to a distributed Engine to complete.
Engine	Unnamed	Processes work related to but not limited to: Active Directory synchronization, discovery, heartbeat, and remote password change.
Engine Worker	Named	Processes the response sent back from an engine.
Session Recording Worker	Named	Background work dedicated to session recording processing.
UI	Unnamed	IIS/ASP.NET processing, inbound access controlled by a load balancer.
API	Unnamed	IIS/ASP.NET processing, inbound access controlled by a load balancer.

Queue Names

A queue name is divided into three major sections with a colon (:) delimiter between each section:

```
Section1:Section2:Section3
```

Section1

Section1 represents a RabbitMQ exchange name. There are three predetermined exchange names, two legacy predetermined exchange names, and then a variable number of exchanges determined by the number of Secret Server sites.

Table: RabbitMQ Exchange Names

Role	Exchange Name	Type	Consumer Component Location	Comment
Background Worker	thycotic-ss	Predetermined	Web Node	
Engine	Site Name	Variable	Web Node or Distributed Engine	The out-of-the-box local site can be configured for either a Web node or a distributed engine. Any other site name is processed by a distributed engine.
Engine Worker	thycotic-ss-engine-response	Predetermined	Web Node	
Session Recording Worker	thycotic-sessionrec	Predetermined	Web Node	
Session Recording Worker	thycotic-sr	Predetermined-Legacy	Web Node	Legacy: background work dedicated to session recording processing.
Session Recording Worker	thycotic-sr-agent-response	Predetermined-Legacy	Web Node	Legacy: processes data sent by an advanced session recoding agent.

Variable site exchanges: If the Secret Server site is called local, then `local:` will also be the exchange name. If the Site is called Mars, then `Mars:` will be the exchange name.

Section2

Section2 typically has a name which represents a functional area in Secret Server code that is a consumer of the message.

Section3

Section3 represents the message name.

Secret Server Roles and Queues

This section of the message associates roles with queues and breaks the down by product functionality. Functionality can span multiple roles, for example, discovery is done by background worker, engine and engine worker roles while event pipelines is only done by a background worker role.

Classic Queue Name

```
thycotic-ss-engine-
response:Thycotic.MessageQueue.Common.Consumers.AutomaticSink.CreateAutomaticSinkConsumer:Th
ycotic.MessageQueue.Common.Messages.AutomaticSink.Request.CreateAutomaticSinkMessage
```

Quorum Queue Name

```
QQ-thycotic-ss-engine-
response:Thycotic.MessageQueue.Common.Consumers.AutomaticSink.CreateAutomaticSinkConsumer:Th
ycotic.MessageQueue.Common.Messages.AutomaticSink.Request.CreateAutomaticSinkMessage
```

Background Worker Role Queues

List of queues for background worker's functional areas:

Active Directory Synchronization

- `thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.ActiveDirectorySynchronization.SynchronizationConsumer:Thycotic.ihawu.Business.Messages.Areas.ActiveDirectorySynchronization.Request.RunNowSynchronizationMessage-SecretServer:`
- `thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.ActiveDirectorySynchronization.SynchronizationConsumer:Thycotic.ihawu.Business.Messages.Areas.ActiveDirectorySynchronization.Request.SynchronizationMessage`

Bulk Operation

- `thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.BulkOperation.BulkOperationConsumer:Thycotic.ihawu.Business.Messages.Areas.BulkOperation.Request.BulkOperationMessage`

ConnectWise Integration

- `thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.ConnectWise.ConnectWiseConsumer:Thycotic.ihawu.Business.Messages.Areas.ConnectWise.Request.ConnectWiseMessage-SecretServer:`
- `thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.ConnectWise.ConnectWiseConsumer:Thycotic.ihawu.Business.Messages.Areas.ConnectWise.Request.RunNowConnectWiseMessage`

Discovery

- `thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.Discovery.ComputerScanConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.ComputerScanMessage`

- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Discovery.ComputerScanConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.RunNowComputerScanMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Discovery.DiscoveryConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.DiscoveryMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Discovery.DiscoveryConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.RunNowDiscoveryMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Discovery.DiscoveryRuleApplierConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.RunDiscoveryRuleApplierMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Discovery.SecretComputerMatcherConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.RunNowSecretComputerMatcherMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Discovery.SecretComputerMatcherConsumer:Thycotic.ihawu.Business.Messages.Areas.Discovery.Request.SecretComputerMatcherMessage

Duo Integration

- thycotic-SecretServer:Thycotic.ihawu.BackgroundWorker.Logic.Areas.Duo.DuoAuthConsumer:Thycotic.Messages.ihawu.Areas.Duo.DuoRequestMessage

Email Processing

- thycotic-SecretServer:Thycotic.ihawu.BackgroundWorker.Logic.Areas.Email.SendEmailConsumer:Thycotic.Messages.ihawu.Areas.Email.Request.SystemSendEmailMessage
- thycotic-ss:Thycotic.ihawu.BackgroundWorker.Logic.Areas.Email.VerifySendEmailConsumer:Thycotic.Messages.ihawu.Areas.Email.Request.VerifySendEmailRequest

Event Pipelines

- thycotic-SecretServer:Thycotic.ihawu.BackgroundWorker.Logic.Areas.EventPipelines.EventPipelineActivityConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.EventPipelineActivityEventMessage
- thycotic-ss:Thycotic.ihawu.BackgroundWorker.Logic.Areas.EventPipelines.PipelinePolicyProcessConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.PipelinePoliciesProcessBlockingMessage
- thycotic-ss:Thycotic.ihawu.BackgroundWorker.Logic.Areas.EventPipelines.PipelinePolicyProcessConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.PipelinePoliciesProcessMessage
- thycotic-ss:Thycotic.ihawu.BackgroundWorker.Logic.Areas.EventPipelines.PipelineProcessConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.PipelineProcessBlockingMessageWithPolicies
- thycotic-

ss:Thycotic.ihawu.BackgroundWorker.Logic.Areas.EventPipelines.PipelineProcessConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.PipelineProcessMessageWithPolicies

- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.EventPipelines.PipelinePolicyProcessEventConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.PipelinePolicyProcessEventBlockingMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.EventPipelines.PipelinePolicyProcessEventConsumer:Thycotic.Messages.ihawu.Areas.EventPipelines.Request.PipelinePolicyProcessEventMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.EventPipelines.PipelineProcessScheduledEventConsumer:Thycotic.ihawu.Business.Messages.Areas.EventPipelines.ProcessPipelineScheduledEventMessage

Heartbeat and Remote Password Change

- thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.CheckinExpiredCheckedoutSecretConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.CheckinExpiredCheckedoutSecretMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ExpiredSecretLocalPasswordChangeConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.ExpiredSecretLocalPasswordChangeMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ExpiredSecretLocalPasswordChangeConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.RunNowExpiredSecretLocalPasswordChangeMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ExpiredSecretPasswordChangeConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.ExpiredSecretPasswordChangeMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ExpiredSecretPasswordChangeConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.RunNowExpiredSecretPasswordChangeMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ProcessHeartbeatConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.ProcessHeartbeatMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ProcessHeartbeatConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.RunNowProcessHeartbeatMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ProcessLocalHeartbeatConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.ProcessLocalHeartbeatMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.RemotePasswordChanging.ProcessLocalHeartbeatConsumer:Thycotic.ihawu.Business.Messages.Areas.RemotePasswordChanging.Request.RunNowProcessLocalHeartbeatMessage

Import

- thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.Import.SecretImportConsumer:Thycotic.ihawu.Business.Messages.Import.SecretImportBulkMessage
- thycotic-ss:Thycotic.ihawu.Business.Logic.Areas.Import.SecretImportFileConsumer:Thycotic.ihawu.Business.Messages.Import.SecretImportFileMessage

Management: Backup, and Cleanup

- thycotic-SecretServer:Thycotic.ihawu.Business.Logic.Areas.OnPremisesOnly.BackgroundWorkerTaskConsumer:Thycotic.ihawu.Business.Messages.Areas.OnPremisesOnly.BackgroundWorkerTaskMessage

RDP Proxy

The RDP Proxy feature in Secret Server enhances security by routing Remote Desktop Protocol (RDP) connections through Secret Server, ensuring that secret credentials are protected during remote access sessions. This proxying mechanism can be configured in two ways: the recommended method, which uses temporary credentials to connect to the RDP proxy and then to the remote server, and an alternative method that tunnels the RDP connection through an SSH proxy. The recommended method is preferred as it prevents secret credentials from reaching the client machine, thereby enhancing security. The RDP Proxy supports up to 100 concurrent connections and ensures that all RDP traffic is securely monitored and recorded if session recording is enabled.

This setup mitigates risks associated with direct RDP access and helps prevent lateral movement of malware between machines.

RDP Proxy Technical Notes

Overview

Delinea's RDP Proxy is a feature of Secret Server that allows protection of secret credentials when launching or connecting to remote servers with privileged credentials. The RDP Proxy simulates the RDP connection handshake process when a client connects to retrieve the short-lived temporary credentials that are generated by Secret Server. When it retrieves these credentials, it then queries Secret Server to find the mapped to real secret or privileged credentials to connect to the remote host and begin proxying the data back and forth between the remote host and the client machine.

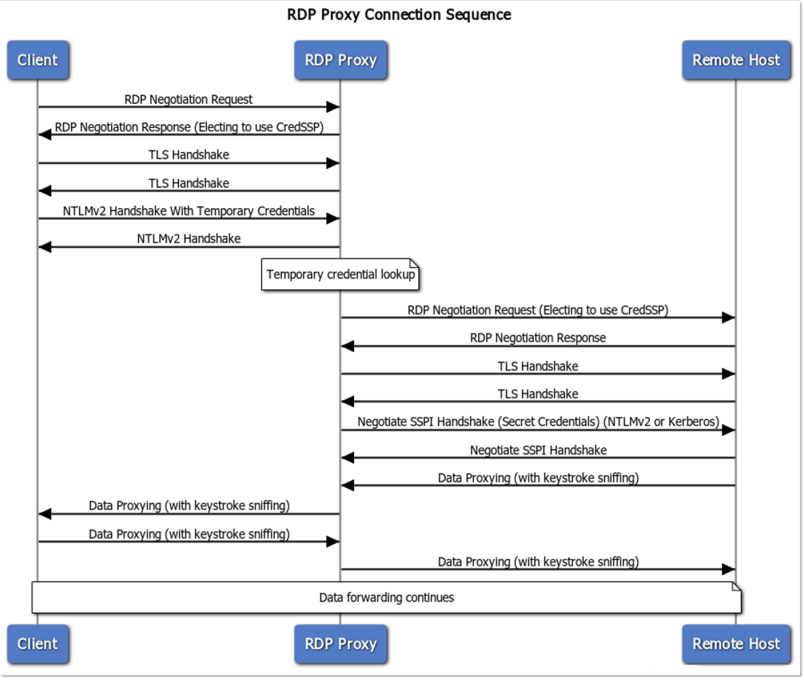
Requirements

Because of the way in which the RDP proxy expects to retrieve the temporary credentials, there are a few requirements which must be met in order to use the RDP proxy:

- The RDP Proxy only supports TCP as a transport, not UDP.
- Client machines must be able to negotiate using the CredSSP external security provider in the RDP protocol. They must have enabled network-level authentication, Microsoft recommends the NLA.
- Client machines must be able to use NTLMv2 to connect to the RDP proxy. The RDP proxy needs to retrieve the temporary credentials from the client machine in order to validate them, which is only possible using the NTLMv2 protocol and not Kerberos.
- Because the RDP Proxy is pretending to be an RDP host, the certificate that is served from the actual remote host must be trusted. Otherwise, the configuration setting "Validate Remote Certificates" must be disabled. The certificate that is served to the client is the configured "RDP Server Certificate."
- The RDP Proxy is currently unable to support certain niche protocol features. These include: Extended Client Data, DYVNC Graphics Pipeline, Restricted Administrative Mode, and Redirected Authentication.
- The RDP Proxy does not support Windows XP.

Connection Sequence

Figure: RDP Proxy Connection Sequence



Performance Testing

The RDP Proxy has undergone performance testing with the following results:

- **Infrastructure**: We ran the proxy on one Secret Server Web node with 4 vCPUs, 16 GB RAM, Azure D4s_v3 VMs with CPU Intel Xeon 8171M at 2.1 GHz.
- **Concurrent sessions**: 50 sessions. There was no degradation of performance as the session count rose.
- **Session activity**: Medium to high. Simulation watched videos and windows screensavers, both of which are graphically intensive and require large amounts of data transfer.
- **CPU results**: 15-25% CPU usage fluctuation during the 50 concurrent sessions with no observed large spikes.
- **Bandwidth results**: All sessions collectively used 100-125 Mbps. This will vary wildly based on the type of connecting client and in-session activity.

RDP Proxy Configuration

> RDP Proxy requires .NET 4.7.2 or later. Also, CredSSP, NTLMv2, and NLA must be enabled. LAN Manager authentication must be set to NTLMv2 (Lmcompatibilitylevel configured to 3 or above). See the "RDP Proxy Technical Notes" on the previous page for details.

Overview

The RDP Proxying feature allows RDP connections, established using a launcher, to be routed through Secret Server. You can set it up one of two ways:

- Recommended method: The launcher connects to the newer RDP proxy with temporary credentials, and the RDP proxy connects to the remote server using the protected credentials from the secret. This method is preferred because it prevents the secret credentials from reaching the client machine. For this method, you simply configure the RDP proxy.
- Alternative method: The launcher uses an SSH proxy to tunnel a local RDP connection to a remote server. This method does not protect the credential from reaching the client machine. For this method you configure the SSH proxy and enable SSH tunneling.

> We provide the alternate method to support legacy installations and troubleshooting (it can potentially be more stable when the RDP proxy does not work).

These two approaches to RDP proxying are not compatible—you may use one or the other but not both. We performance tested both methods. Either can support 100 concurrent connections.

Recommended Method

How It Works

1. The user clicks the RDP launcher in Secret Server.
2. The launcher executes on the client's machine.
3. The launcher establishes a connection to the RDP Proxy using credentials generated for the session.

   > These credentials are short-lived and can only be used within a 15-minute window. To support reconnects in keeping with the RDP protocol, the window resets upon reconnect.

4. Once the launcher has successfully authenticated with the RDP proxy, the RDP proxy looks up the credentials and target hostname to connect to.

   > The secret credentials *do not* get served to the client machine in this flow, which improves credential security.

5. The RDP proxy connects to the desired remote host with the secret credentials.
6. The RDP session is established.
7. RDP traffic is sent back and forth over the RDP proxy, session keystrokes are monitored if session recording is enabled.

Configuration

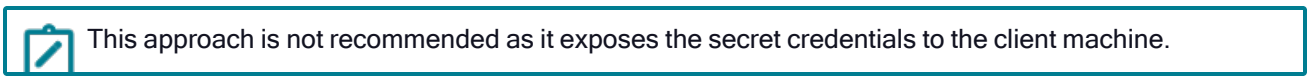
1. Navigate to the **Admin > RDP Proxy**.
2. If necessary, enable the RDP proxy.
3. Click the **Endpoints** tab to ensure that your server nodes, sites, and engines have RDP Proxy enabled.
4. Proxied RDP secrets now launch into the RDP proxy using short-lived credentials, protecting the secret credentials from the client machine.

Configuration Settings

The RDP proxy configuration settings for the recommended method (**Admin > RDP Proxy**):

- **Enable RDP Proxy:** This setting determines whether or not the RDP proxy is enabled
- **RDP Proxy Port:** This setting is the port that the RDP proxy runs on (defaulting to 3390). You usually cannot set this to 3389 as that port is already occupied by default by the Windows operating system.
- **Validate Remote Certificates:**Delinea recommends that you operate in an environment where RDP server certificates are created by a controlled CA and are trusted by machines in the domain. If that is not possible, you can disable remote certificate validation to allow connection to machines that do not serve trusted certificates. See Remote Certificate Validation for more details.
- **Allow AD site selection (SSH and RDP):** This setting allows you to select any configured sites when using the RDP launcher on an Active Directory secret. This allows a secret credential to access machines that may exist in different network boundaries.
- **Proxy New Secrets By Default:** This setting determines if SSH and RDP secrets are created with "Proxy Enabled" set by default. This setting is shared with the SSH proxy configuration.
- **Days To Keep Operational Logs:** This setting determines how long, in days, the operational logs for the RDP proxy are kept.
- **RDP Server Certificate:** This setting is the certificate that is served to the clients who connect to the RDP proxy. You can generate a certificate for a given DNS name, or you can upload your own. Please see Microsoft's documentation for instructions on creating Certificates for more details on how to create a certificate via a Windows Trusted Domain.
- **Use Secret Server RDP Client:** When using protocol handler and this is disabled, the RDP window label only displays the proxy server name. When this setting is enabled, the RDP window label also displays the target server and that the connection is proxied. This setting is found under the launcher itself in **Admin > Launchers**.

Alternative Method



How It Works

1. The user clicks the RDP launcher in Secret Server.
2. The launcher executes on the client's machine.
3. The launcher establishes a connection to the SSH proxy to begin port forwarding.
4. The launcher authenticates with the SSH Proxy.
5. The launcher opens a socket.
6. The launcher listens for a connection on an available ephemeral port (the forwarding port) on the client's machine.
7. RDP launches on the client machine using the secret credentials and connects locally to the forwarding port.

8. All RDP traffic for this session is routed through the SSH tunnel to Secret Server, then forwarded to the target machine.
9. The RDP session is established.

Configuration

1. Navigate to the **Admin > SSH Proxy**.
2. Enable the **Tunnel RDP connections** option. If enabled, RDP launchers will tunnel through a SSH Proxy if possible. This option predates the RDP Proxy which is now recommended instead.
3. Click the **Endpoints** tab to ensure that your server nodes, sites, and engines are properly configured.
4. Proxied RDP secrets now launch into the SSH proxy using local port forwarding.

Known Issues

"Could not load file or assembly..." Error

Error appears in Secret Server.log or DE.log. Install the most recent version of the .NET Framework to correct it.

RDP Proxy Does Not Work with FIPS Validation

RDP proxy does not work on machines the have the FIPS validation security policy active. No fix is currently available.

Using Remote Certificate Validation with Secret Server RDP Proxy

Configure Certificate from Trusted Source

The most correct and complete way of configuring the certificate is replacing the RDP certificate with a certificate signed by a trusted certificate authority. There are various ways to achieve this by for example manually generating certificates from a trusted source and configuring these certificates on the target machines on the RDP listener by utilizing the following command:

```
wmic /namespace:\\root\cimv2\TerminalServices PATH Win32_TSGeneralSetting Set
SSLCertificateSHA1Hash="<thumbprint of the certificate>"
```

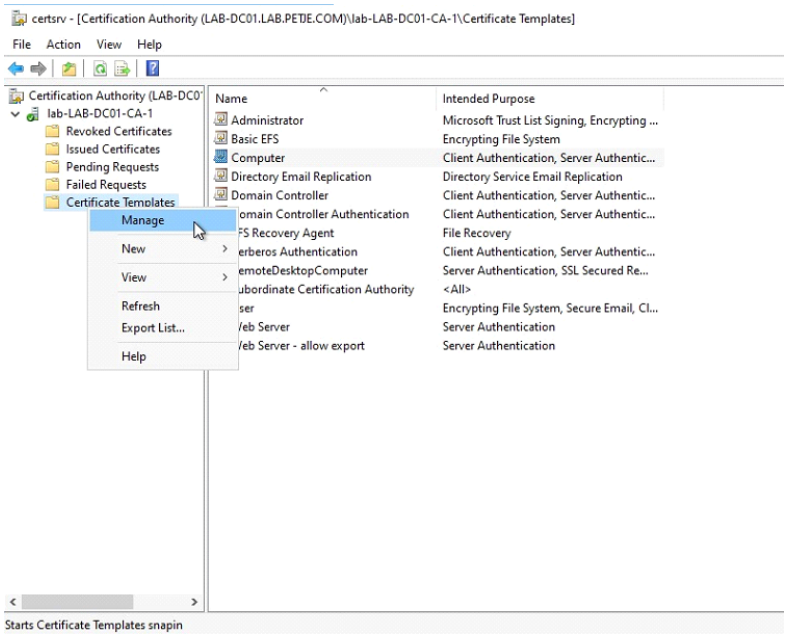
> Note that the certificates need to have at least the following key usage policy configured: Server Authentication (1.3.6.1.5.5.7.3.1)

A more efficient way is to configure an Active Directory Certificate Authority, which will issue the respective certificates combined with GPO settings to reconfigure the RDS listener to utilize that was issued by the Certificate Authority. The steps to configure a Windows CA and GPO are outlined below.

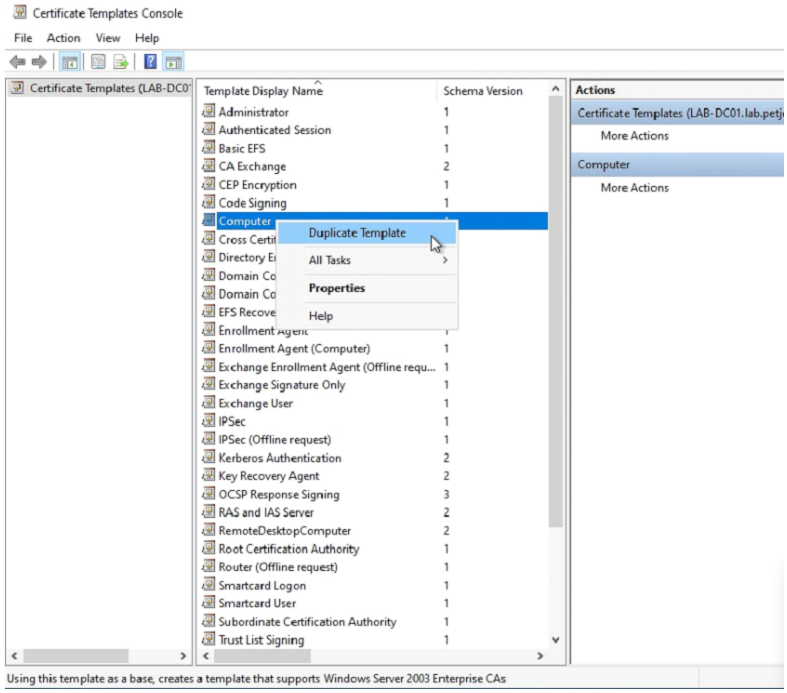
Configure Windows Certificate Authority Configuration

Base requirement for deploying RDP certificates is to have a configured and functioning Microsoft Certificate Authority. Configuration of this is outside of the scope of this document.

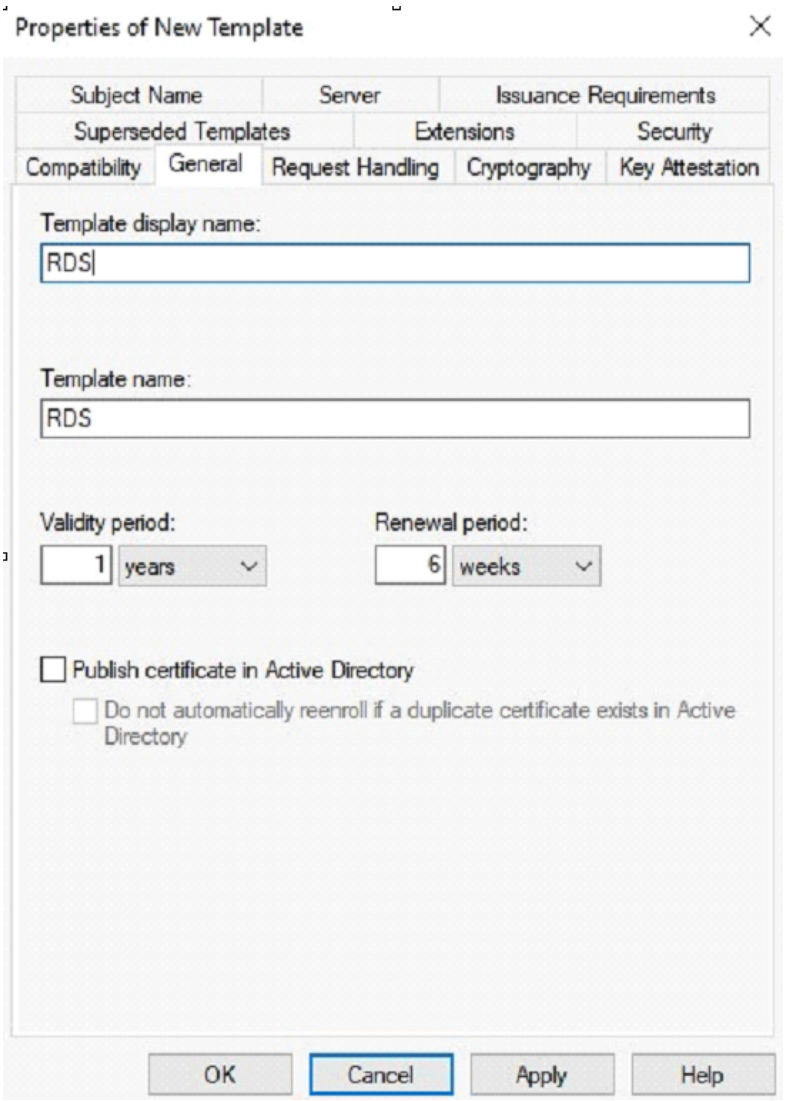
1. First step is to prepare a certificate template which will be used to issue RDP Certificates. To do so, open the Certificate Manager and navigate to the Management of Certificate Templates.



2. In the Certificate Templates Console, select the Computer template and duplicate this template.

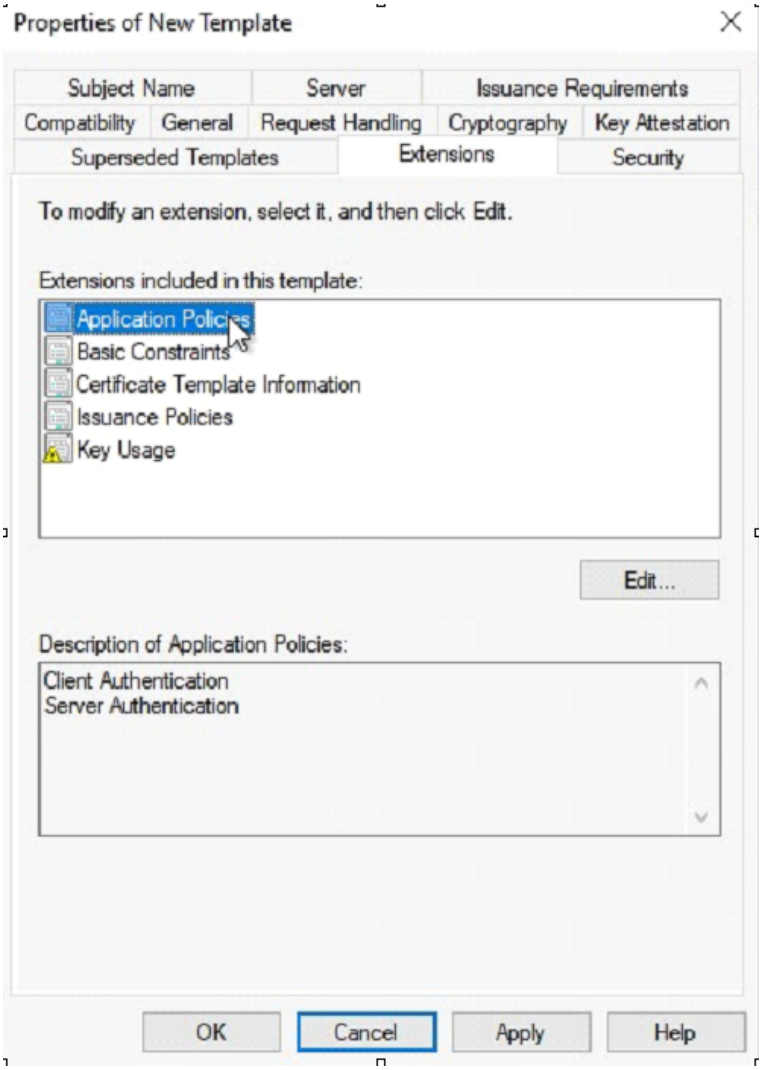


3. Provide a new name for the template. In the example below the name is RDS (any name can be provided). Depending on the company requirements, the validity period and renewal period can be adjusted. This however is not mandatory.

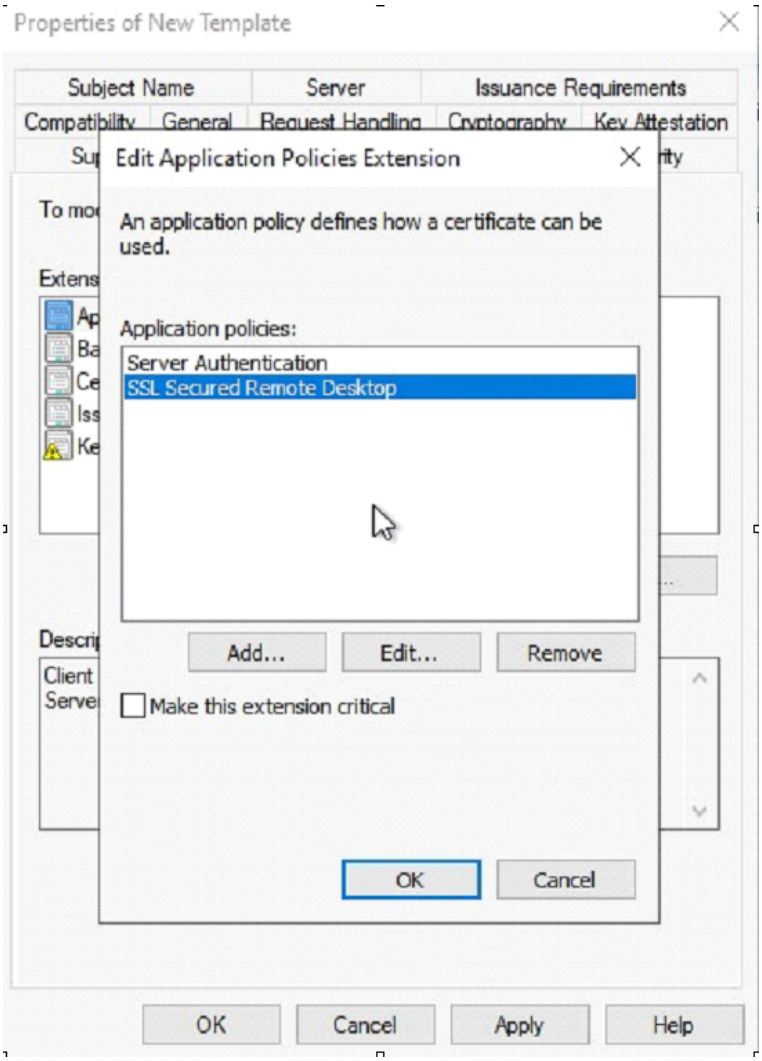


4. Next, configuration of the usage of the certificate needs to be adjusted.

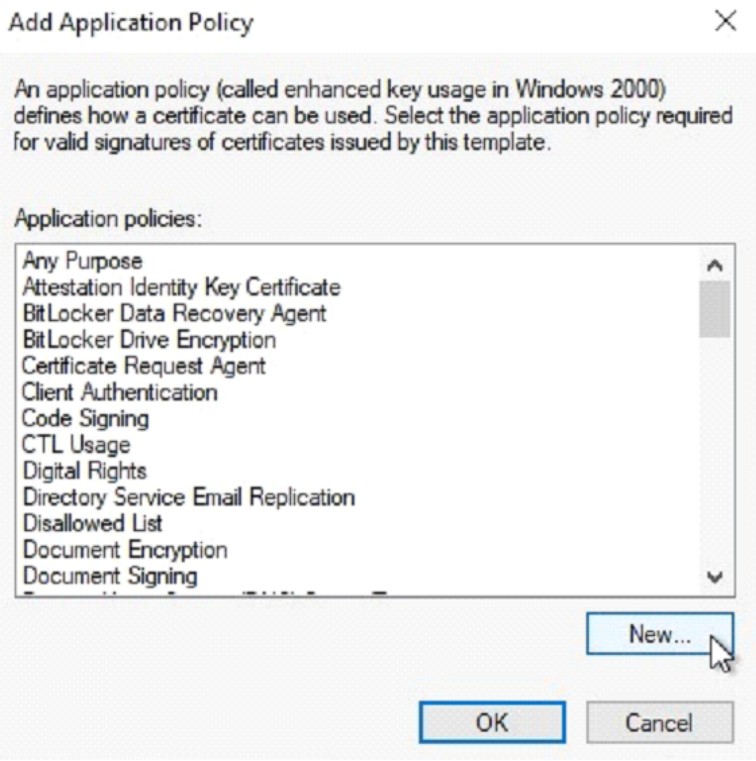
- Navigate to the Extension Tab and edit the application policies.



- Make sure to configure the application policies to contain `Server Authentication` and `SSL Secured Remote Desktop`. Depending of the version of Windows and configuration it is possible the SSL Secured Remote Desktop is not available. In that case, create a new application policy.



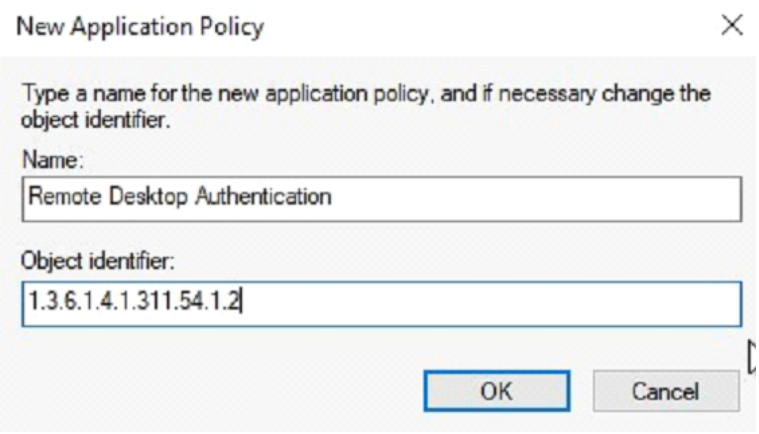
- When adding the application policy, a list with configured policies is being showed, and the correct policies can be added as per previous step.



- When indeed the SSL Secured Remote Desktop is not available, it can be created by pressing the New button, with the following details. The actual name is not really relevant, just make sure to name it logically as it will show on the certificate.

  Name = `Remote Desktop Authentication`

  Object Identifier = `1.3.6.1.4.1.311.54.1.2`



5. When the certificate template has been created it needs to be published on the Certificate Server.

After following these steps, the created template should be available in the Certificate Templates of the Certificate Authority.

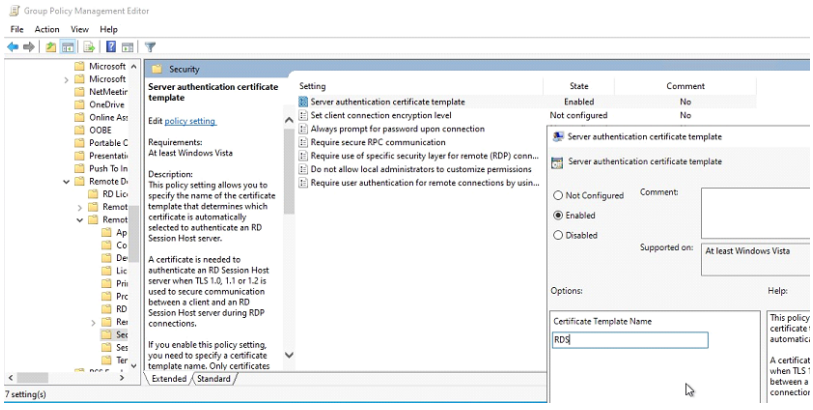
Configure GPO

Final step is to configure a GPO to have the respective machines request the correct certificate and assign that to the RDP listener. The default domain GPO can be adjusted, but a specific GPO with this setting can also be configured.

The settings are:

`Computer Configuration\Policies\Administrative Templates\Windows components\Remote Desktop Services\Remote Desktop Session Host\Security\Server Authentication Certificate Template`

Enter the Certificate Template name as configured in previous steps. In our example `RDS`.

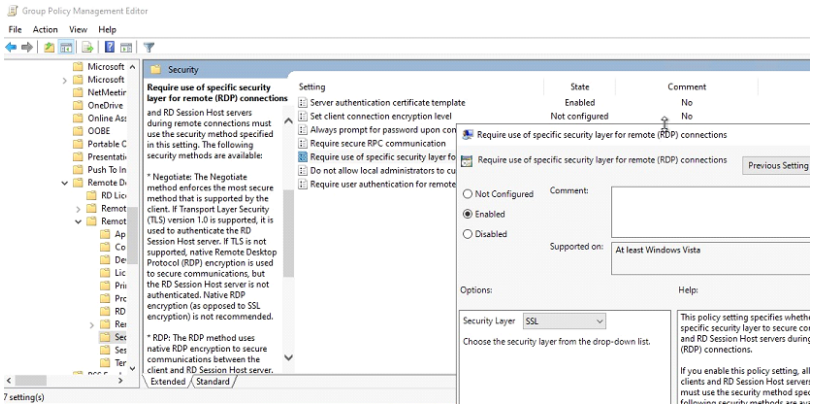


A second setting can optionally be set to force all RDP session to go over SSL. This is however not specifically required for the RDP proxy, but makes RDP connections overall more secure.

The following setting needs to be changed for this:

`Computer Configuration\Policies\Administrative Templates\Windowscomponents\Remote Desktop Services\Remote Desktop Session Host\Security\Require use of specific security layer for remote (RDP) connections`

Change this value to `SSL`.



Next, make sure to have the respective GPO assigned to the target machines in the environment.

After following these steps, Secret Server RDP Proxy should be able to do remote certificate validation against all machines, as long as the issuing CA is trusted by the proxy.

Troubleshooting

In case of errors, make sure to look in the respective proxy logs.

When only web nodes are being used, the proxy information is logged in the Secret Server log files that can be found in: `C:\inetpub\wwwroot\SecretServer\log\ss.log`.

When distributed engines are being used, the relevant log file is on the distributed engine, and can be found in: `C:\Program Files\Thycotic Software Ltd\Distributed Engine\log\ssde.log`.

Error codes can be converted to hex via the following site: https://www.binaryconvert.com/convert_signed_int.html

Enter the decimal error code and perform the conversion. Then search for the resulting HEX value combined with hresult.

Some examples of error codes and explanation can be found below:

1. **HRESULT -2146893019** - Not a trusted authority. The certificate is issued by a certificate authority that is not trusted. Check the certificate to identify the issuing certificate authority and add that in the trusted root certification authorities store on the proxy host.

   ```
   2021-01-14 09:45:00,999 [CID:] [C:] [TID:103] ERROR
   ```

```
Thycotic.RDPProxy.CLI.Session.ProxyConnection - Error encountered in RDP handshake for
client 192.168.178.52:59642 - (null)

System.Exception: HRESULT -2146893019 (SEC_E_UNTRUSTED_ROOT) encountered:

RDP Proxy - Understanding Certificate Options

Remote Desktop Protocol utilizes SSL to secure connections. To enable this process, all Windows machines present an RDP Server SSL certificate when a client initiates the process to establish a connection.

In a default configuration, this is a self-signed certificate generated by Windows when the RDP service is first enabled.

RDP Proxy context

The Secret Server RDP Proxy also has a default, shared, self-signed SSL certificate, with the facility to create a new self-signed certificate, or to provide your own. In the case of RDP Proxy, Remote Certificates refers to the target machine specified at the time of secret launch.

Configuration

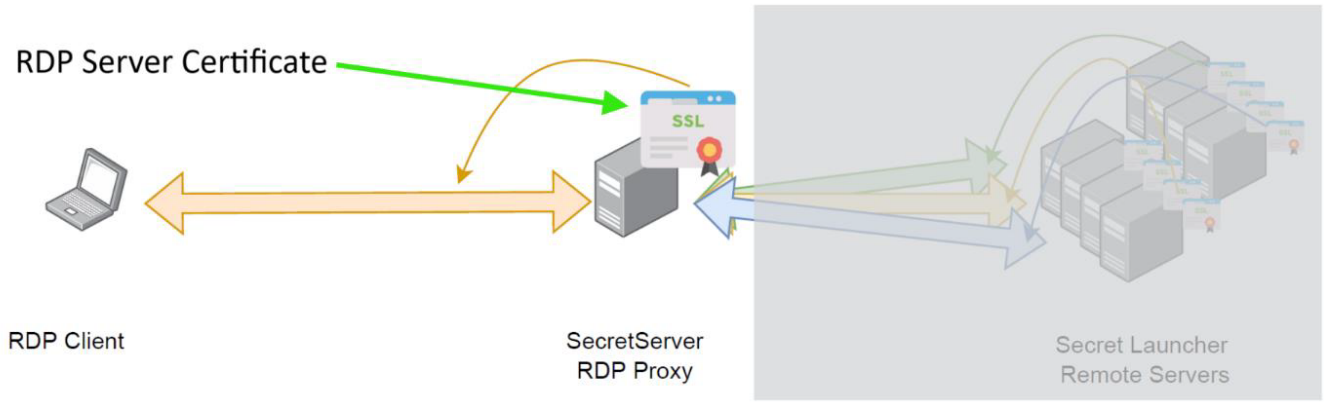
Secret Server provides 2 distinct area of configuration for SSL Certificates in relation to the RDP Proxy. This page describes what their configuration means, along with the options available to best utilize or mitigate user experience objections.

Accessing the RDP Server Certificate

1. Access Secret Server.
2. Access **Settings > Proxying > RDP** and locate **RDP Server Certificate** on the page, next to it is the downloadable `.pfx` file. This is always in use when utilising the RDP Proxy.

This is the SSL certificate presented by the RDP Proxy to the user's RDP Client (`MSTSC.exe` or Connection Manager) when a user launches from a secret.

Figure 1. RDP Server certificate – presented by the RDP Proxy to the connecting client.



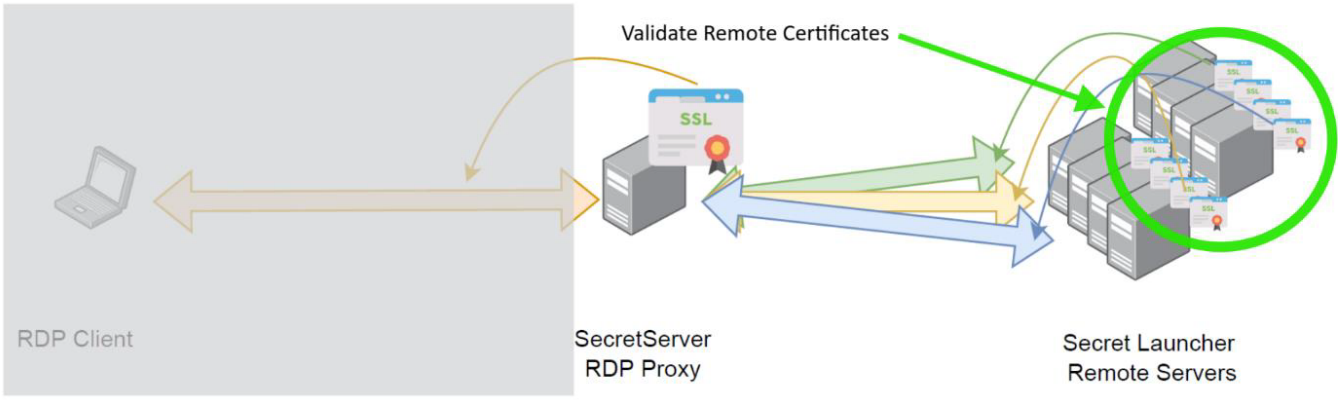
Validating Remote Certificates

1. Access **Settings > Proxying > RDP**.
2. On the **RDP Proxy** tab find **Validate Remote Certificates**. This option determines whether the RDP Proxy should validate the launch target's RDP certificate.

a. Yes – the target's RDP certificate will under go the SSL validation process – failure to validate will cause the connection to be dropped.

b. No – the target's RDP certificate will not be subject to validation checks – any failure to connect will not be due to target RDP-certificate validation.

Figure 2. Normal Remote Certificate Validation for RDP Proxy

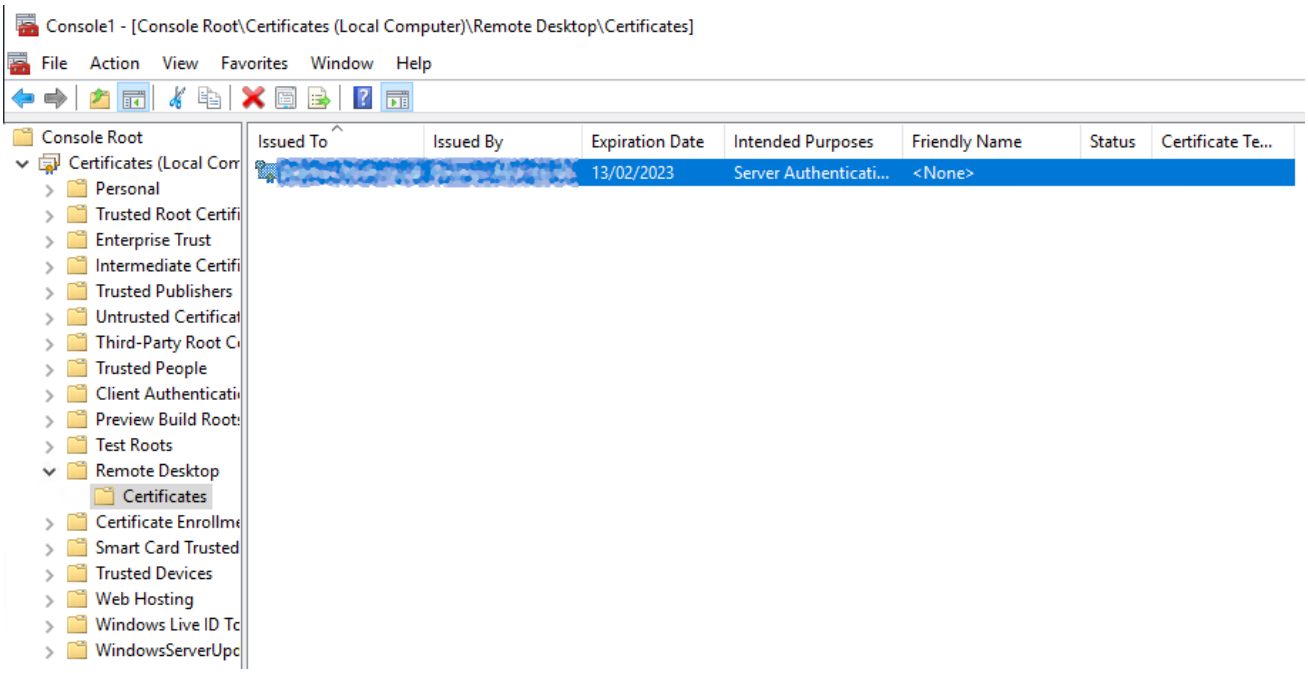


Disabling Remote Certificate Validation for RDP Proxy

Delinea recommends that you operate in an environment where RDP server certificates are created by a controlled CA and are trusted by machines in the domain. If that is not possible, you can disable remote certificate validation to allow connection to machines that do not serve trusted certificates.

To change the certificate settings, in Windows:

1. Go to **Console Root\Certificates(Local Computer)\Remote Desktop\Certificates**. The Console appears:



2. Note that these remote server Remote Desktop certificates are self-signed by default.

   Secret Server RDP proxy cannot validate these unless one of two conditions apply:

   - Each target server certificate is imported in to all the servers hosting RDP proxy.
   - Trusted RDP certificates are deployed.

     Microsoft describes a process for the second condition in Using certificates in Remote Desktop Services.

Creating Self-Signed Certificates with Multiple Aliases

To create a self-signed certificate that can be used with multiple domain names and IP addresses, use the following PowerShell command. This example demonstrates how to specify multiple aliases for the certificate:

```
New-SelfSignedCertificate `
  -Subject "DelineaSecretServer" `
  -DnsName `
    "phobos",
    "phobos.hkdr.co.uk",
    "mars1",
    "mars1.hkdr.co.uk",
    "deimos1",
    "deimos1.hkdr.co.uk",
    "10.12.60.X",
    "10.12.60.X",
    "10.12.60.X" `
  -CertStoreLocation "cert:\LocalMachine\My" `
  -HashAlgorithm SHA256 `
  -KeyLength 4096 `
  -Provider "Microsoft Enhanced RSA and AES Cryptographic Provider" `
  -NotAfter (Get-Date).AddYears(10)
```

The names and IP addresses in the command are examples. Replace them with your own values to suit your environment.

Parameters Explained:

- `subject`: Specifies the subject name of the certificate.
- `DnsName`: Lists the domain names and IP addresses the certificate will be valid for. Replace these with your own values.
- `CertStoreLocation`: Defines where the certificate will be stored.
- `HashAlgorithm`: Sets the hash algorithm to be used.
- `KeyLength`: Determines the length of the cryptographic key.
- `Provider`: Specifies the cryptographic provider.
- `NotAfter`: Sets the expiration date of the certificate.

SSH and Secret Server

Secret Server provides robust SSH management capabilities, including SSH proxy, command restrictions, terminal administration, and jumpbox routes. The SSH proxy feature routes SSH sessions through Secret Server, ensuring secure and monitored access to endpoints. Command restrictions allow administrators to define and enforce specific commands that users can execute during SSH sessions, enhancing security and compliance. The SSH terminal administration feature enables users to connect to Secret Server via SSH, view and launch secrets, and utilize custom command menus with session recording capabilities. Additionally, SSH jumpbox routes facilitate secure access to internal systems by routing connections through one or more intermediary servers, known as jumpboxes or bastion hosts, which are hardened and monitored to reduce security risks.

SSH Proxy Configuration

This topic applies to **Secret Server On-Premises**, standalone **Secret Server Cloud**, and **Delinea Platform**.

The Secret Server proxy routes SSH and RDP sessions and helps protect the endpoint credentials. There are two configuration options for proxying:

- Proxy through the Secret Server Web application.

> This option only applies to On Premise. With cloud (SSC or Platform) it is only possible to SSH proxy via a distributed engine.

- Proxy through a distributed engine.

> To learn more about RDP Proxying, please see "RDP Proxy Configuration" on page 817.

Enabling Proxy

1. Search for **SSH Proxying**.
2. Next to **Enable SSH proxy** click **Edit**, and select **Enable SSH proxy**.
3. To generate the related SSH Proxy Host Key, in the **SSH Proxy Host Fingerprint** section generate a new key - click **ECDSA** or **RSA**.
4. To enable proxying on Web nodes, under the **Endpoints** tab, in the **Nodes** section, click **Edit**, to set the **Public hostname or IP** and **Bind IP Address**. For a standard server, these can be the same, but if the public IP of the server is not set on the server (such as a load balancer or an EC2 instance with an elastic IP), they will be different. Enter the **Available Port Range** if prompted.
5. To enable proxying for a specific site and all engines within that site, edit the row in the **Sites:** section. In the Update Proxy Configuration For Site popup specify:
   - **Enable SSH Proxy:** Check to enable SSH Proxy.
   - **SSH Proxy Port:** Specify the related SSH Proxy Port if prompted.
   - **Inherited (Port 22):** Check to enable the defaulted Port 22.
   - **Available Port Range:** Specify the range of the available ports.

- **Enable RDP Proxy:** Check to enable RDP Proxy. See RDP Proxy Configuration for more details.
- **RDP Proxy Port:** Specify the related RDP Proxy port if prompted.
- **Inherited (Port 3390):** Check to enable the defaulted Port 3390.

6. The engines for the sites are listed in the **Engines** section below. The **Public Hostname or IP Address** is the public host or IP the launcher connects to and the **Bind IP Address** is the IP on the server that the SSH proxy is listen on. Again, these will typically be the same, but may be different if the resolvable IP or host of the engine machine is different than the IP on the network adapter on the machine.
7. Enable proxying on a secret with a PuTTY launcher. The launcher now connects to the assigned site, which is set on the **General** tab. If the site has proxying enabled, it will go through the engines available in the site, otherwise it will use the Secret Server Web application proxy.

Web Application Proxy Performance

Minimum Hardware

- Intel 3.7 GHz Quad Core
- 16 GB of RAM
- 100 MB/s plus network capability

Session Activity

We tested sessions with standard usage, such as opening and modifying files and navigating the file system on Linux. On Windows, the activity was opening MMC snap-ins, editing files, and copying files through the RDP session. If you have constant large file transfers across multiple concurrent sessions or otherwise transferring large amounts of data (such as streaming a video through an RDP session), the maximum concurrent sessions will be significantly reduced.

Table: Concurrent Proxy Sessions

Protocol	Concurrent Sessions
SSH	300
RDP	100

Note that the file transfer speeds when using SSH Proxy with tools such as FileZilla or WinSCP in Secret Server may be slower than direct, non-proxied transfers. Recent improvements have enhanced transfer speeds compared to previous performance; however, some degradation is still expected due to the nature of the proxying process.

For optimal performance:

- Ensure your network connection has low latency and sufficient bandwidth.
- Consider alternatives for large file transfers, such as direct SCP commands or other non-proxied methods, if proxying is not essential for your use case.

This behavior is inherent to the security and architecture of the SSH Proxy feature and is not indicative of a system malfunction.

Proxy Connections

Connections from the user to the proxy are over SSH, and you can configure the port. The user's machine will connect to either an engine SSH proxy or the Secret Server Web application SSH proxy.

Figure: Default Secret Server Web Application Proxy (example)

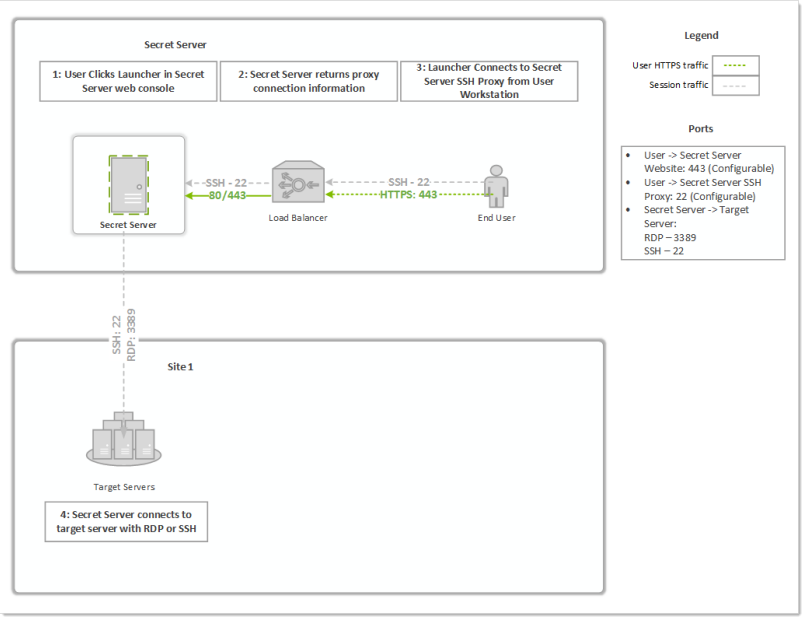


Figure: Proxy through a Distributed Engine (example)

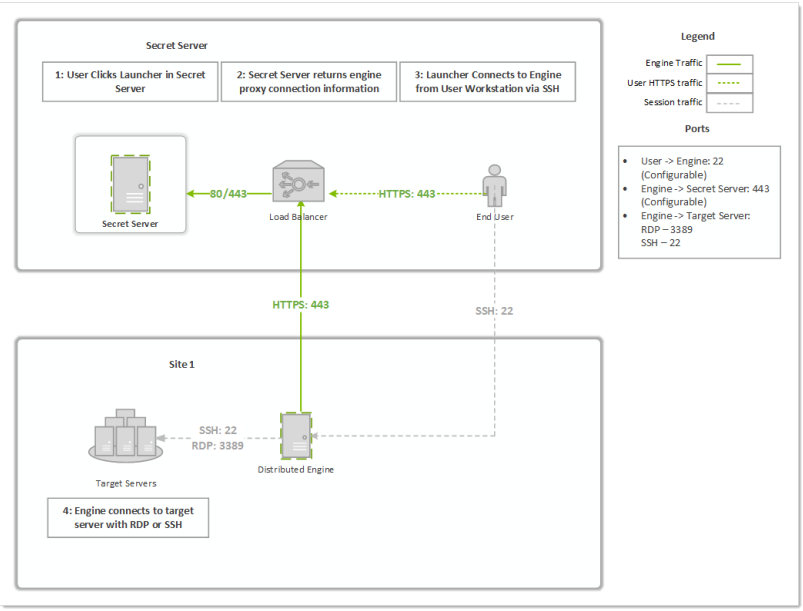

For the modern non-tunneled RDP proxy see "RDP Proxy Technical Notes" on page 816.

SSH Proxy with Multiple Nodes

If you are using clustering with Secret Server, you can pick exactly which of your nodes act as a SSH proxy.

Search for **SSH Proxy**, and select the Endpoints tab. In the **Nodes** section, for each node you wish to be a proxy, click **Edit** and configure the **SSH Public hostname or IP** (must be an IP address, not a DNS name) and the **SSH Bind IP Address** (use 0.0.0.0 to easily bind to all IPv4 Ps on a server). There is no need to configure all nodes if you do not want them all to be proxies.

As soon as the IPs are saved for each node, the node should start listening on the SSH proxy port. You can verify that with netstat. If you do not see the node listening on your chosen port, perform an IIS reset and hit its Secret Server website. It should be listening once Secret Server starts up again. For example:

```
C:\Users\Administrator>netstat -ano | find ":22"
TCP  0.0.0.0:22  0.0.0.0:0  LISTENING  3600
```

Now, when a user connects to the Secret Server Web page, if the node they are hitting is setup to be a SSH proxy, they will connect to that node's SSH public host IP. If the node they are connected to is not setup to be a SSH proxy, then users will round robin between the other nodes that are SSH proxies and connect to their SSH public host IP.

SSH Terminal Administration

Introduction

This document discusses using an SSH terminal with Delinea Secret Server.

Feature Summary

- Connect using SSH to a terminal hostname and port to log in to terminal and run commands
- Display custom terminal banner after successful connection
- Display available commands on successful login (display again with `man` command)
- Log in to the terminal as a Secret Server user (SSH Proxy must be enabled)
- Can set an inactivity timeout. Can be set to *disabled* or with a two-minute minimum.
- Start a terminal connection and launch in a single line. For example:
  `ssh <user>@<ss_ip> -t launch <secret_id>`
- Use two-factor authentication (2FA) for access (optional)
- Use the SSH terminal interface to Secret Server for viewing and launching secrets
- Use these commands:
  - `Man` command to display detailed command description
  - `Search` command to display matching secrets

  - `Cat` command to display secret details of with specified secret ID
  - `Launch` command to begin a Proxy launch session with specified secret ID
- Use up and down keystrokes for command history
- Supports custom SSH command menus and session recording logging

Requirements

System Requirements

- Secret Server 10.7.000000 Secret Server
- Secret Server**Professional** or **Platinum** Edition license

Recommended

"Installing RabbitMQ" on page 104

Secret Server Permission Requirements

Admin:

- Administer Configuration
- Administer Proxying Configuration
- View Configuration
- View Proxying Configuration

User: View Secret

Configuring SSH Terminal

Enabling SSH Terminal on Secret Server

1. Prerequisites:
   - Must meet Admin permission requirements (see Secret Server Permission Requirements)
   - Secret Server**Professional** or **Platinum** Edition license
2. Search for **SSH Proxying**, and select the **SSH Terminal** tab.
3. Next to **Enable SSH terminal** click **Edit**, and in the SSH proxy restart required popup click **OK**. In the next Edit SSH terminal settings popup, check to select **Enable SSH terminal**, and click **Save**.
4. Type your SSH proxy configuration settings (see "Configuring SSH Proxies for Launchers" on page 661):
   a. (optional) Customize the **SSH terminal banner** for your environment.
   b. (optional) Click to enable **Terminal Inactivity Timeout** (in seconds).

> To launch a secret via the terminal, the secret must have proxy enabled. Only SSH-based credentials can be launched in the terminal.

5. Specify the IP address for nodes (and engines) that will run SSH proxy:
   a. Navigate to the **Endpoints** tab and in the nodes section click **Edit** next to the related node.
   b. Set the **SSH Public hostname or IP** This is the public hostname or IP that the client launcher connects to. In most cases, this is the same as the SSH bind address; however, there are cases where the public IP or host differs from the private IP that Secret Server should bind to, such as NAT or Amazon EC2 instances.
   c. Set the **SSH Bind IP Address**. This defaults to (0.0.0.0). The IP Address of the network adapter that the Secret Server SSH listener should bind to. This should not be localhost or 127.0.0.1. If you are not sure which bind IP address to use, you may use 0.0.0.0, which binds to all IPv4 interfaces on the machine.

Enabling Terminal on Secret Server Distributed Engine

SSH terminal can also run on each proxy-enabled distributed engine (DE) site.

> To launch secrets on non-local sites, users **must** connect to an SSH terminal over an engine on this site.

1. Search for **SSH Proxy** and select the **Endpoints** tab.
2. In the **Sites** section, click **Edit** next to the related site.
3. In the Update Proxy Configuration For Site popup, click to select **Enable SSH proxy**.
4. Type an **SSH Proxy Port** or check to select **Inherited** to inherit the port from the site.
5. Optionally specify **Available port range**
6. Click **Save**.
7. In the **Engines** section, click **Edit** next to the related Engine.
8. Specify **Public hostname or IP**
9. Specify **Bind IP Address**.
10. When done, save the changes.

Logging into the SSH Terminal

1. From any SSH terminal, connect to hostname or IP address and port, as specified in the SSH Proxy Configuration page. Use the DE hostname or IP if connecting to an engine. Examples:

   ```
   ssh 127.0.0.1 -p 22
   ssh user54@127.0.0.1 -p 22
   ```

2. If not provided in the SSH connect command, enter your Secret Server username and password at the **Login as:** prompt.
3. If successful, you will see the terminal banner displayed, along with a list of available commands.

SSH Terminal Login with Two Factor Authentication

SSH terminal is considered a Web service and can be used with two factor authentication (2FA). To enable 2FA for terminal:

1. Follow the steps under "Multi-Factor Authentication" on page 446 to set up 2FA.
2. Search for **Two Factor**, click **Edit** and select one of these:
   - **Website and Web Service Login**
   - **Web Service Log on Only**

   FIDO2 authentication is not supported in this version of SSH terminal.
3. From any SSH terminal, connect to hostname or IP address and port, as specified in the SSH Proxy Configuration page. Use the distributed engine hostname or IP if connecting to an engine. Examples:

   ```
   ssh 127.0.0.1 -p 22
   ssh username@127.0.0.1 -p 22
   ```
4. If not provided in the SSH connect command, enter your Secret Server username and password at the **Login as:** prompt.
5. You will be prompted for a PIN or custom challenge message by your 2FA provider. Example:

   login as: `duouser`**<Enter>**

   Using keyboard-interactive authentication:

   duouser@127.0.0.1's password: `uewori#$%tdtd`**<Enter>**

   Using keyboard-interactive authentication:

   Pin Code: `3787`**<Enter>**
6. If successful, you will see the terminal banner displayed, along with a list of available commands.

Escaping Special Characters

When manipulating secrets containing special characters, such as single quotes and double quotes, you must escape those characters in the command.

Example: To search for an item with a space in the name, put the name in single or double quotes:

`search "My Secret"` or `search 'My Secret'`

Example: To search for an item with a single quote embedded in the name, there are two options:

- Encase the term in double quotes:

  ```
  search "Bob's Secret"
  ```
- Escape the single quote with a backslash:

  ```
  search 'Bob\'s Secret'
  ```

Example: Similarly, to search for an item with a double quote embedded in the name, there are two options:

- Encase the term in single quotes:
  `search '"Weird" Secret'`
- Escape the internal double quotes with a backslash:
  `search "\"Weird\" Secret"`

Terminal Commands

man

Syntax

```
man [command name]
```

Description

Displays command help for specific or all commands. *Man* is short for *manual*.

Examples

`man`

Short help for all commands.

`man cat`

A detailed description of the `cat` command.

search

Syntax

```
search [-st] <search_text> [-f <folder_id>] [-fav] [-r] [-sf <search_field>] [-skip <skip_
results>] [-s] [-t <secret_template_id>] [-take <max_results>]
```

Description

Returns a list of Secret Server secrets by keyword, which you can filter using several command-line switches.

Parameters

`-st <search_text>`

Required. Text to search for. `-st` is optional. Returns 25 results by default. Use `-take` to change from the default.

`-f <folder_id>`

ID of the secret folder to limit the search to.

`-fav`

Only search "favorite" secrets.

`-r`

Ignore restricted secrets in the search. Restricted secrets are included by default.

`-s`

Ignore subfolders in the search. Subfolders are included by default.

`-sf <search_field>`

ID of the secret field to limit the search to. Potential fields, which vary by secret template, can include the following examples:

- Address1
- Address2
- Address3
- Blog
- CardType
- City
- Combination
- Contact Number
- Country
- Email Address
- ExpirationDate
- Fax
- First Name
- FullName
- Home Phone
- Last Name
- Machine
- Mobile Phone
- Notes
- Number
- Password
- Pin
- PinCode
- Server
- SSN
- State
- Username
- Website
- Work Phone
- Zip

These fields match those on the REST API endpoint.

`-skip <skip_results>`

Skip this number of initial results. Useful for processing "pages" of results.

`-t <secret_template_id>`

Only search secrets based on the template with this template ID.

`-take <max_results>`

Take a total of only this number of results. Useful for processing "pages" of results. Defaults to 25 results.

Examples

`search -st admin`

Find a list of secrets matching "admin." Returns 25 results (the default).

`search admin`

Same search using alternate syntax. `-st` is not required.

`search -st jones -fav`

Find a list of "favorite" secrets matching "jones" in any field Returns 25 results (the default).

`search admin -take 50`

Outputs a list of secrets matching "admin", up to 50 results.

`search Zardoz -take 50 - skip 50 -sf "Secret Name"`

Find a list of secrets with "Zardoz" in the "Secret Name" field. Return 50 results, starting with the 51st secret found.

`search admin -skip 25 -r`

Find a list of secrets matching "admin" in any field. Return 25 results, which is the default. Skip the first 25 results. Ignore restricted secrets.

cat

Syntax

```
cat [-s|-id|-secret-id] <secret_id> [-c|-comment <comment_or_access_request>] [-t|-ticket
<ticket_number>] [-ticketsystemid <ticket_system_id>]
```

Description

- Displays information on a secret. The available information depends on the secret's template. *cat* is short for *concatenate*.
- Catches access errors, such as "comment required" or "requires approval", and displays them on the terminal
- Audits "view" comments.
- Provides launch connection command instructions. Shows the correct launch parameter and a connection string (if the terminal connection and the site on the secret do not match).

If a required access element is not provided in the command, the terminal will respond with an error that should indicate what is missing.

Parameters

`[-s|-id|-secret-id] <secret_id>`

Required. The secret ID. Three optional switches.

`[-c|-comment <comment_or_access_request>]`

The text for the comment or access request.

`[-t|-ticket <ticket_number>]`

The ticket number for the request.

`[-ticketsystemid <ticket_system_id>]`

The unique ticket system ID.

Examples

```
cat 24
```

Display the contents of the secret with the ID 24. Only works after access is approved.

```
cat -id 24
```

Alternate syntax. Display the contents of the secret with the ID 24.

```
cat -id 25 -comment "Viewing this secret"
```

Add a "view" comment to, and then display the contents of the secret with the ID 25.

```
cat -id 26 -comment "Requesting view access to install software" -ticket 123 -ticketsystemid
2
```

Add an "access request" comment to the secret with the ID 26. Assign the request the ticket number 123 and the ticket system ID of 2 to that request.

The most common secret restrictions are "requires view comment" or "requires access request." The `-comment` parameter takes care of both of these because the underlying API call (`SecretAccessCreateArgs`) is agnostic.

launch

Syntax

```
launch [-s|-id|-secret-id] <secret_id> [-m|-Machine <machine_name>] [-c|-comment <view_
comment_or_approval_request_reason>] [-t|-ticket <ticket_number>] [-ticketsystemid <ticket_
system_id>]
```

Description

- Creates a proxy connection to the machine
- Secret must have proxy enabled

- Supports launch from secrets with private keys
- Audits launches

Parameters

`[-s|-id|-secret-id] <secret_id>`

Required. The secret ID. Three optional switches.

`[-c|-comment <comment_or_access_request>]`

The text for the comment or approval request.

`[-m|-Machine <machine_name>]`

Machine name for the launch. This may be required if a customized secret template does not contain a machine field or a launcher requires a machine entry on launch.

`[-t|-ticket <ticket_number>]`

The ticket number for the request.

`[-ticketsystemid <ticket_system_id>]`

The unique ticket system ID.

Examples

```
launch 24
```

Begins the SSH proxy session with the secret with the ID 24 and the specified credentials and machine. Only works after access is approved.

```
launch -id 24
```

Alternate syntax. Begins the SSH proxy session with the secret with the ID 24 and the specified credentials and machine. Only works after access is approved.

```
launch -id 25 -comment "Launching this secret"
```

Submits a "view" comment to the secret with ID 25. Begins the SSH proxy session with secret credentials and machine.

```
launch -id 26 -machine XYZ -comment "Requesting view to launch temporary sudo account for the XYZ machine"
```

Submits an "access request" comment to the secret with ID 26 on the machine XYZ with the ticket number 123 and ticket system ID 2.

Launching a Secret with the SSH Terminal

Launching a Secret on a Local Site

1. To launch, the secret must be:
   - Enabled for proxy **(Secret Server > Secret > Security > Enable Proxy)**
   - Shared with the terminal user
2. Log in to the terminal with Secret Server user credentials:

```
login as: sshuser
Keyboard-interactive authentication prompts from server:
sshuser@127.0.0.1's password:
End of keyboard-interactive prompts from server
Pre-authentication banner message from server:
======== WELCOME TO THYCOTIC TERMINAL (ThyTTY) ========
End of banner message from server

Available Commands
------------------
cat - concatenate Secrets and print on the standard output
launch - begin SSH Proxy session using credentials on specified Secret
man - an interface to the on-line reference manuals
search - search for Secrets by keyword
exit - exits this terminal session
[sshuser@127.0.0.1 ~] $
```

3. If the secret ID is unknown, search for the desired secret with the search command:

```
[sshuser@127.0.0.1 ~] $ search ubuntu
Folder  Id      Template        Secret Name     Proxy Enabled
--------------------------------
Everyone Owns   68      Unix Account (SSH)      ubuntu\steph    True
Showing 1 - 1 of 1 results
[sshuser@127.0.0.1 ~] $
```

4. To view secret detail, get the secret ID from search results, and run `cat <secret_id>`

```
[sshuser@127.0.0.1 ~] $ cat 68
Secret Name:    ubuntu\steph
Secret ID:      68
Secret Type:    Unix Account (SSH)
Folder:         \Everyone Owns
Launch Enabled: True
Machine:        [redacted].thycotic.com
Username:       steph
Password:       **********

Can be launched with command:

launch 68

[sshuser@127.0.0.1 ~] $
```

5. To launch the secret, enter the launch command as specified in the last line of secret details: `launch <secret_id>`

```
[sshuser@127.0.0.1 ~] $ launch 68
Secret Server Launch: Secret ID 68 found. Attempting launch...
Connected to Target! Attempting Authentication...

  Swap usage:   0%                IP address for docker0: 172.17.0.1

  Graph this data and manage this system at:
    https://landscape.canonical.com/

82 packages can be updated.
63 updates are security updates.

Last login: Wed Jul 24 12:59:59 2019 from 192.168.68.137
To run a command as administrator (user "root"), use "sudo <command>".
See "man sudo_root" for details.

steph@ubuntu:~$
```

6. To exit the launch session and return to the terminal, type `exit`.

```
Last login: Wed Jul 24 12:59:59 2019 from 192.168.68.137
To run a command as administrator (user "root"), use "sudo <command>".
See "man sudo_root" for details.

steph@ubuntu:~$ exit
logout
Socket was shutdown.
[sshuser@127.0.0.1 ~] $
```

7. To exit the terminal session, type `exit` again.

Launching a Secret on a Distributed Engine Site

1. To launch, the secret must be:
   - Enabled for proxy **(Secret Server > Secret > Security > Enable Proxy)**
   - Shared with the terminal user
2. Log in to the terminal with Secret Server user credentials:

```
login as: sshuser
Keyboard-interactive authentication prompts from server:
| sshuser@127.0.0.1's password:
End of keyboard-interactive prompts from server
Pre-authentication banner message from server:
| ======== WELCOME TO THYCOTIC TERMINAL (ThyTTY) ========
End of banner message from server

Available Commands
------------------
cat - concatenate Secrets and print on the standard output
launch - begin SSH Proxy session using credentials on specified Secret
man - an interface to the on-line reference manuals
search - search for Secrets by keyword
exit - exits this terminal session
[sshuser@127.0.0.1 ~] $
```

3. If secret ID is unknown, search for the desired secret with the search command:

```
[sshuser@127.0.0.1 ~] $ search ubuntu
Folder  Id      Template        Secret Name     Proxy Enabled
---------------------------------
Everyone Owns   68      Unix Account (SSH)      ubuntu\steph    True
Showing 1 - 1 of 1 results
[sshuser@127.0.0.1 ~] $
```

4. To view secret detail, get the secret ID from search results, and run `cat <secret_id>`

```
[sshuser@127.0.0.1 ~] $ search "engine site"
Folder  Id      Template        Secret Name     Proxy Enabled
---------------------------------
Everyone Owns   69      Unix Account (SSH)      ubuntu\steph (Engine Site)      True
Showing 1 - 1 of 1 results
[sshuser@127.0.0.1 ~] $ cat 69
Secret Name:    ubuntu\steph (Engine Site)
Secret ID:      69
Secret Type:    Unix Account (SSH)
Folder:         \Everyone Owns
Launch Enabled: True
Site:           ihawu-mmq (ID: 9)

Active Proxy Engines:

Engine Host/Port: [redacted].thycotic.com:23

Machine:        [redacted].thycotic.com
Username:       steph
Password:       **********
Different Site: Unable to launch Secret '69' with current Terminal connection.
Exit and connect to Terminal host with the command below to launch.
---------------------------------

LAUNCH INSTRUCTIONS:
To launch this Secret on a different Site, SSH to the following Terminal host/port:

SSH Host: [redacted].thycotic.com
SSH Port: 23

Command:

ssh sshuser@[redacted].thycotic.com -p 23 -t launch 69

[sshuser@127.0.0.1 ~] $
```

5. Note that the connection is not made, and instructions are displayed for logging into another distributed engine terminal to launch the secret.
6. Note the suggested parameters in the **Launch Instructions**.
7. Type `exit` and press **<Enter>** to disconnect from the current session:

```
Last login: Wed Jul 24 12:59:59 2019 from 192.168.68.137
To run a command as administrator (user "root"), use "sudo <command>".
See "man sudo_root" for details.

steph@ubuntu:~$ exit
logout
Socket was shutdown.
[sshuser@127.0.0.1 ~] $
```

8. Open a new SSH session suggested parameters:
   `ssh <secret_server_username>@<engine_hostname_or_ip> -p <Port> -t launch <secret_id>`
9. Enter the password to log in, and the secret should immediately launch.

Launching a Secret upon Terminal Connection

1. To launch, the secret must be:
   - Enabled for proxy **(Secret Server > Secret > Security > Enable Proxy)**
   - Shared with the terminal user
2. If the secret ID and connection string is known, you can log in and immediately launch the secret with the following command:

   ```
   ssh <secret_server_username>@<hostname_or_ip> -p <Port> -t launch <secre_id>
   ```
3. If you do not know that connection string, log into terminal and run:

   ```
   cat <secret_id>
   ```
4. Look at the **Launch Instructions** at the end of secret details, and note the parameters.

> Note that if a secret is not checked-out, it will be silently checked-out when launching via SSH Terminal. The secret will be silently checked-in when the SSH session is terminated. If the secret is already checked-out by a different user, Terminal will display that it is checked-out.

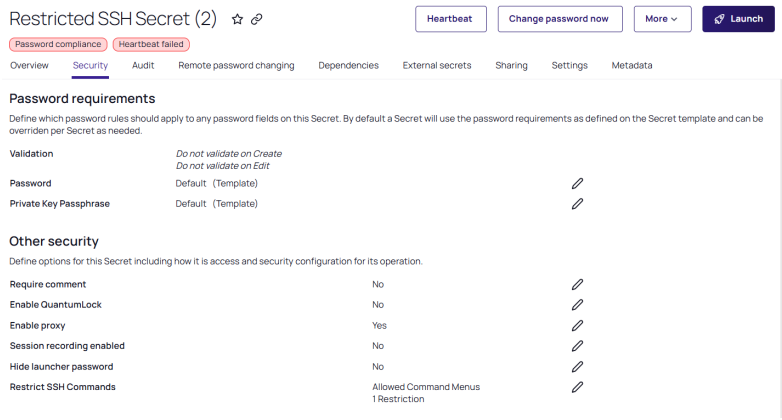
SSH Terminal Launching with a Custom SSH Command Allowlist

Secret Server terminal can launch secrets with custom SSH Command restrictions. For detailed instructions on SSH command menus, please see "Managing Superuser Privilege" on page 679.

> Custom SSH command menus require either the Secret Server Platinum or Unix SUPM add on license.

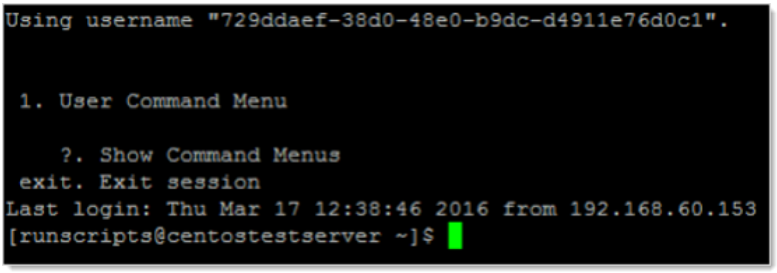
1. Search for **SSH command restrictions**.
2. Click **Create allowed command menu**.
3. Type a Name, Description and the SSH commands. Check to select Enabled.

   Once one or more command menus have been created, access can be controlled to individual Unix SSH secrets.
4. On the **Security** tab of a secret that can use a proxied SSH session, proxy must be enabled, as well as command menu restrictions. If **Allow Owners Unrestricted SSH Commands** is enabled, any user who is an owner of the secret has unrestricted use of the launched session. That is, that user is able to type in commands as in a normal SSH session. Additionally, other groups can be assigned the unrestricted role as well.
5. In the following example, the "admin" group is unrestricted, and everyone who is not in that admin group is restricted to only being able to run the allowlisted commands that are specified in the user command menu created above.

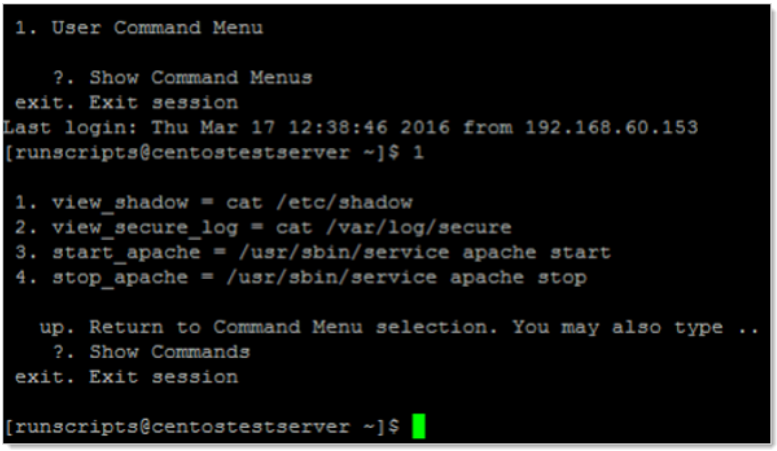


Click the Edit link next to **Edit SSH command restrictions**, and check to select **Allow Owners Unrestricted SSH Commands**, and then select **Overrides for** from the dropdown next to **Permission overrides**.

6. A user who is subject to SSH command restrictions is presented with a screen similar to the following when launching this secret from Secret Server terminal:



The user simply enters the number of the command menu to see available commands or types "?" to display the options again:



Only the commands listed can be run by this user. The user can either enter the number of the command to be run, or the name of the command, which is the word to the left of the equal = sign. Other options are available (as shown) to navigate through the available command menus, display help, or exit the session.

SSH Terminal Launching with Session Recording

Secret Server SSH terminal launches also support session recording for session client or server data. When a user launches a secret with session recording enabled through SSH terminal, session data is available in the Secret Audit tab as session data.

> Session recording requires either Secret Server Platinum or the session recording add-on license.

> See the Session Recording section for more information.

To enable session recording:

1. Search for **Session recording general settings** and click **Edit**.
2. Ensure the **Enable Session Recording** check box is selected.
3. Modify other settings as desired.
4. Click **Save**.

To enable session recording on a secret:

1. Open a secret.
2. Click the **Security** tab.
3. Click the **Edit** link to the right of the **Session Recording Enabled** setting in the **Other security** section.
4. Click to select the **Session Recording Enabled** check box.
5. Click **Save**.

To view session data following a terminal secret launch:

1. Open a secret.
2. Click the **Audit** tab.
3. Find the **LAUNCH** action in the table.
4. Click the **View SSH Session Log** link.

SSH Key Pairs for Terminal

Overview

SSH key pairs allow users to authenticate to Secret Server terminal without using a password. The user generates a key pair in Secret Server, at which time the private key can be downloaded by the user locally in the format they require. The key pair generation process is the only time the private key will be provided to the user. If this private key is lost, the user must log back into Secret Server and generate a new public/private key pair.

User Public SSH Keys

User public SSH keys are used to authenticate users to Secret Server itself through the SSH Terminal (CLI) interface. This authentication method allows users to access Secret Server without using a password when

connecting via SSH.

Only the public portion of each SSH key is stored in Secret Server and associated with the user account. Private keys are generated and stored locally by the user and are never stored in Secret Server.

User public SSH keys are not used for authentication to target systems or servers. SSH keys used to authenticate to external systems are stored and managed separately as secrets.

Users manage their public SSH keys from the User Preferences page. For user-focused information, see Public SSH Keys under User Preferences.

To view your public SSH keys, Search for **Users**, select the related user, and click **Administer Public SSH Keys**.

Each key entry displays the key name, key type, and fingerprint.

To authenticate using SSH, the user must configure their SSH client to use the private key corresponding to one of the public keys stored in Secret Server. Authentication is performed against the stored public keys when connecting to the SSH Terminal endpoint.

User public SSH keys are distinct from SSH keys stored as secrets. User public SSH keys are used only to authenticate users to Secret Server through the SSH Terminal. SSH keys stored as secrets are used to authenticate to target systems and support additional features such as rotation and automation.

Limitations

- Currently users can only authenticate to Secret Server using SSH keys by using Secret Server's SSH terminal.
- Only PuTTY and OpenSSH keys can be generated.

Enabling Users to use SSH Key Pairs to Authenticate

There are three requirements for enabling Public SSH Keys:

- SSH Proxy is enabled in Secret Server.
- SSH Terminal is enabled in SS.
- SSH key integration is enabled in SS's Configuration > Login settings. To do so:
  1. **Unix Authentication Method**: choose **Public Key only**, **Password or Public Key** or **Password and Public Key** to enable SSH key pair authentication.
  2. Once done, the admin can also set an optional expiration time frame for the public SSH keys, which applies to all users.

Once these 3 requirements have been met, users can use the main navigation to create SSH key pairs.

Creating SSH Key Pairs

An SSH key pair consists of a private key and a public key. Only the public key is stored in the user's settings–the private key downloaded during generation is **not** saved inside Secret Server and should only be available to the user, to remain secure.

During terminal login, if the user provides a private key for authentication, Secret Server validates the provided private key against the user's available (and enabled) saved public keys. If a key pair match is found, the authentication succeeds (or the next required authentication step, for example a password prompt, is shown).

For security reasons, only users can create their own SSH key pairs. However, Secret Server Administrators can deactivate any user's public SSH keys as follows:

1. Navigate to the **Public SSH Keys** page using the main navigation at the top right of the page.
2. Click the **Create SSH Key** button above the grid, then fill out the form in the popup page.
3. Click the **Create SSH Key** button in the popup. After a moment you will be able to save the private key.

Administering Public SSH Keys

1. Navigate to the User by going to **Admin > Users**.
2. Locate the user in the dropdown list and select it.
3. Under the **General** tab click the **Administer Public SSH Keys** button. You can now deactivate the user's public SSH keys.

Using SSH Keys for Authentication (PuTTY Example)

1. In PuTTY, fill in the **Session** view to match your SSH proxy connection settings in Secret Server.
2. In the **SSH > Auth** section of PuTTY, add the private key file that was saved when generating the key in Secret Server.
3. You will be prompted to enter your passphrase for the key if one was set.
4. You will be prompted to enter your password if **Unix Authentication Method** also requires a password.

Effective SSH Key Management

Managing SSH keys, especially in Unix/Linux environments, poses significant security challenges. A compromised private key can lead to unauthorized access to critical systems, making robust key management essential.

The security risks associated with compromised private keys are substantial. Additionally, providing secure third-party access can be complex without proper key management practices in place.

How Secret Server Addresses this:

- **Centralized Management**: Secret Server provides a comprehensive solution for generating, rotating, controlling, and protecting SSH keys, all within a centralized platform.

Key Features:

- **Role-Based Access Control**: Implement detailed access controls to specify who can access particular sets of SSH keys, regardless of their location or IP address.
  - Search for **Roles**.
  - Create or edit a role to include permissions for SSH key access.
  - Assign users or groups to the role.
  - Verify access by attempting to use SSH keys with the assigned role.
- **Workflow Integration**: Integrate SSH key management with workflows such as Secret Checkout to facilitate secure third-party access without compromising security.

- Configure a secret with SSH key details - on a related Secret, under the **Overview** tab, click **Edit** in the **Details** section, and add or edit the SSH Key.
- Enable the Secret Checkout feature for the secret - on a related Secret, under the **Security** tab, click **Edit** in the **Check out** section, and check to enable **Require check out**. Set the Checkout time - 30 mins by default. Click the **Check Out** button. This will grant you exclusive access to the secret.
- Access SSH Client - open your preferred SSH client (e.g., PuTTY, OpenSSH).
- Configure SSH Connection:
  - Enter the hostname or IP address of the server you wish to connect to.
  - Navigate to the SSH authentication settings.
- Add SSH Key:
  - Load the private SSH key file that was downloaded from Secret Server.
  - Enter the passphrase for the SSH key if prompted.
- Connect to the Server:
  - Initiate the SSH connection using the configured settings.
  - Authenticate using the SSH key, bypassing the need for a password.
- Check In the Secret - on the related Secret, click on the Checkout button at the top right, and in the dropdown select **Check In** to release the secret. If configured, the password will automatically change upon check-in.
- Ensure the secret is marked as available for other users.
- Highlight the audit trail generated during the checkout process.

- **Automated SSH Key Rotation**: Schedule or initiate on-demand SSH key rotations to ensure that key pairs are consistently updated both within Secret Server and across all endpoints. For more details see SSH Key Rotation.
- **Comprehensive Audit Trails**: Maintain detailed audit logs to provide evidence of controlled, managed, and monitored access to systems, supporting compliance and security oversight.
  - On the related Secret select the Audit tab, and filter Actions to display SSH key-related activities.
  - Review entries for key generation, rotation, and access.
  - Use audit logs to verify compliance and security measures.

SSH Command Restrictions

SSH command restrictions in Secret Server enhance security by allowing administrators to define and enforce specific commands that users can execute during SSH sessions. This feature, part of the privilege management capabilities, requires SSH proxy to be enabled and supports the creation of command menus that map user-friendly command names to system commands. Administrators can configure these menus to restrict users to a predefined set of commands, preventing unauthorized or potentially harmful actions. Command restrictions can be applied to individual secrets or through secret policies, ensuring consistent enforcement across the organization. This setup

not only minimizes the risk of misuse and accidental errors but also supports compliance with security policies by providing detailed audit logs of all executed commands.

SSH Blocked Command Lists

Overview

Secret Server supports privilege management and command restrictions for UNIX and other platforms with SSH interfaces. Privilege management is an additional layer of access control that you can apply to secrets with SSH launchers over SSH proxy. With privilege management, you can grant users access to a machine to block specific commands that a user may run as root or any other privileged account.

To use command restrictions, Secret Server must have SSH Proxy and Enable Block Listing enabled.

With SSH blocked command lists, you can define disallowed commands when connecting as a privileged account. The blocked command list is defined by a series of regular expressions.

Upon launching a secret with an assigned SSH command blocklist, each command sent to the target is evaluated for a match on the blocklist. If the command is found to match a list entry, that command is blocked from execution. Blocked output is shown to the user at the terminal.

Requirements

System requirements:

- Secret Server 10.11 or later
- Secret Server Platinum Edition license or Secret Server Professional and Unix SUPM license
- SSH proxy must be enabled

Creating SSH Blocked Command Lists

The format for specifying a blocked command follows a regular expression syntax that is typical to most scripting languages. The blocked commands are surrounded with `\b` word boundary anchors. For example, to block the `sudo` command, you use:

```
\bsudo\b
```

This expression blocks the execution of any command with the `sudo` string in it (as a separate word), for example, these are blocked:

- `sudo`
- `sudo root`
- `sudo ls /usr/local/protected`
- `sudo shutdown -r +15 "quick reboot"`

And these are not:

- `cat sudoku`
- `echo "sudo"`

To create a list of blocked commands:

1. Search for**SSH command restrictions**to get to the SSH command restrictions page.
2. Click the **Blocked Command List** tab.
3. Click the **Create Blocked Command List** button. The New Blocked Command List page appears.
4. Type the list name in the **Name** text box.
5. Ensure the **Enabled** check box is selected.
6. **Either** select a predefined regex from the **Add Commands to Blocked Command List** dropdown list. **Or** add a custom regex of your own:
   a. Scroll to the bottom of the dropdown list.
   b. Click the **Create New Command** link. The Create Command and Add to Blocked Command List popup appears.
   c. Type the name for the command in the **Command Name** text box.
   d. Type or paste the regex in the **Command Pattern** text box.
   e. Click the **Create and Add** button. The command is added to the dropdown list.
7. Click the **Create Blocked Command List** button.

Applying SSH Command Blocked Lists in Secret Settings

To enable privilege management for an account:

1. Navigate to a PuTTY secret's **Settings** tab.
2. Go to the **SSH Launcher** section.
3. Click the **Edit** link.
4. Click the **Connect Using** dropdown list and select **Credentials on Another Secret**.
5. Click the **No Secret Selected** link to choose a secret containing your log on credentials, which the launcher uses when logging on the SSH service.
6. Enable command restrictions:
   a. Click the **Security** tab.
   b. Go to the **Other Security** section.
   c. Click the **Edit** link to set **Enable Proxy** to Yes.
   d. Click the **Edit** link for the **Enable SSH Command Restrictions**. The Edit SSH Command Restrictions popup appears.
   e. Ensure the Restrict SSH Commands check box is selected.
   f. Click to select the Blocked Command Lists selection button.
   g. Click the **Owner**, **Edit**, and **View Permission** dropdown lists to map the blocked command lists to users via those permissions. You can also leave them as unrestricted.
   h. Click the **Save** button.

SSH Command Restrictions via a Secret Policy

You can apply SSH command restrictions to a secret policy for ease of management. You can apply secret policies to secret folders or directly to a secret itself. To apply command restrictions, set a policy as follows:

Table: Secret Policy Security Settings for SSH Command Restrictions

Section	Item	Setting	Value
Security Settings	Enable Proxy	Enforced	Checked
Security Settings	Enable SSH Command Restrictions	Enforced	Checked
Security Settings	SSH Command Restriction Type	Enforced	Blocked List
Security Settings	SSH Command Blocklist for Secret Owners	Enforced or Not Set	Desired Block Command List or Not Set
Security Settings	SSH Command Blocklist for Secret Editors	Enforced or Not Set	Desired Block Command List or Not Set
Security Settings	SSH Command Blocklist for Secret Viewers	Enforced or Not Set	Desired Block Command List or Not Set

SSH Command Menus

Secret Server supports privilege management and command restrictions for UNIX and other platforms with SSH interfaces. Privilege management is an additional layer of access control that can be applied to secrets with SSH Launchers over SSH Proxy. Privilege management gives the ability to grant users access to a machine with specific command restrictions to define the available commands that a user may run as root/admin or as another privileged account.

To use command restrictions, Secret Server must have SSH Proxy enabled.

With command menus, you can configure predefined commands that users or groups will be able to access when connecting as a privileged account. A command menu is a list of command names mapped to system commands. The format for specifying a command is to separate a name and a command with an equals symbol.

For example: `restart_apache = /usr/sbin/service apache restart`

You may also use parameters in commands so users can execute more complex commands.

For example: `move_file = /bin/mv $src $dst`

You can specify environmental variables by escaping dollar signs in commands.

For example: `go_home = cd $$HOME`

Command restrictions currently do NOT support complex commands, such as multiple commands on one line, piping, or output redirection. To support these functions, you may add a script to the system that has these capabilities and map the command to that script.

> We highly recommend that generated scripts have proper user permissions and that the absolute path is used. The absolute path ensures that the correct script is being executed.

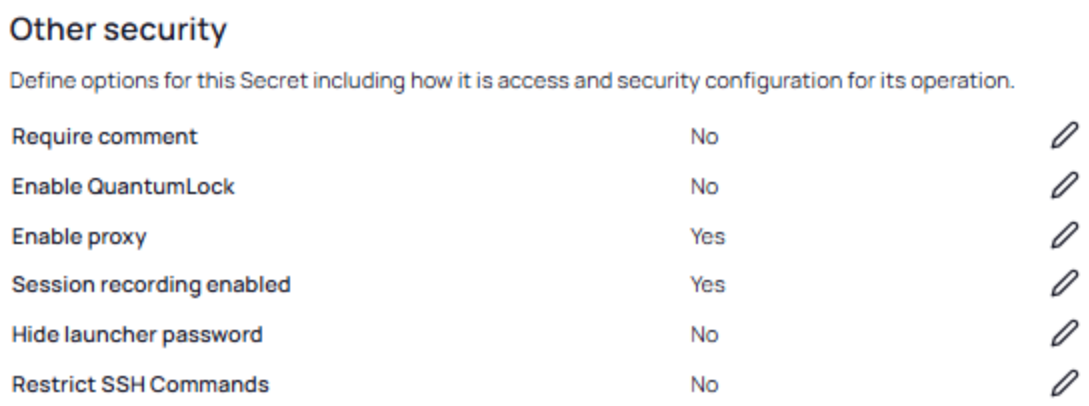
Commands may NOT be named as numbers or one of the following predefined commands:

- `..`
- `up`
- `-help`
- `?`
- `-more`
- `logout`
- `exit`

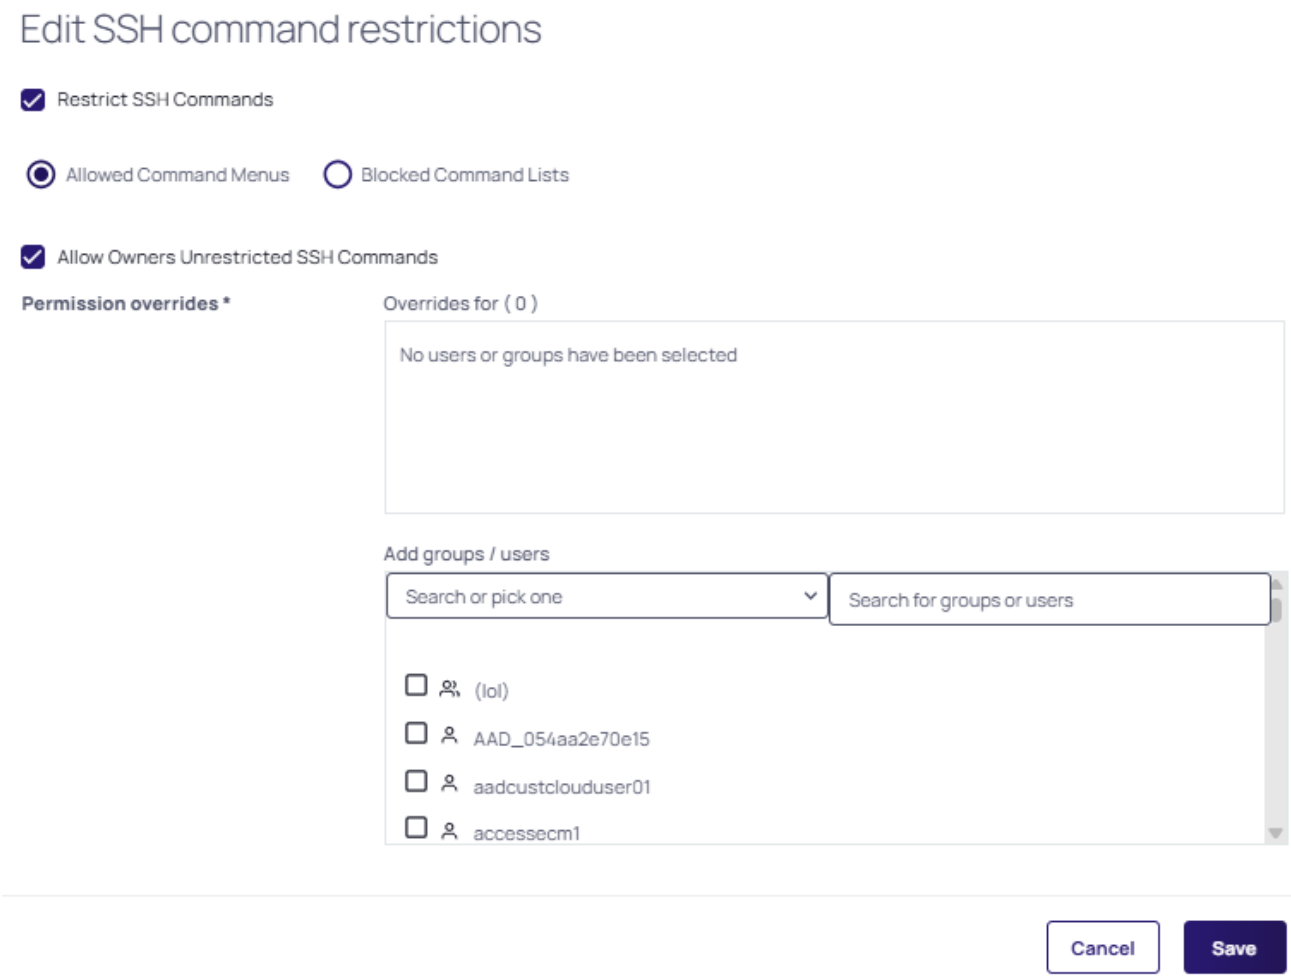
Using SSH Command Menus in an SSH Remote Session

To enable command restrictions:

1. Navigate to an SSH secret and access the **Security** tab.
2. Set both **Enable Proxy** and **Restrict SSH Commands** to **Yes**. This gives you the ability to map users and groups to command menus:



3. For the second option, the following popup appears:



4. Keep the **Allowed Command Menus** option selected.
5. Select the **Allow Owners Unrestricted SSH Commands** checkbox if you wish for the owners of the secret to also be launched into a normal shell environment without command restrictions.
   a. Add groups and / or users into the **permissions overrides** section and click **Save**.
6. Click the **Launch** button on the secret to start a PuTTY session.
7. At the top of the SSH window that opens, there is a number followed by the name that was provided when creating the list of defined commands.
8. Select the number next to the allowed command menu you wish to use by entering it in the command line. This will show the list of commands users are allowed to run within that SSH session.

> At least one command menu must be selected unless **Allow Owners Unrestricted SSH Commands** is enabled. You can apply command restrictions to a secret policy for ease of management.

SSH IP Block Listing

Introduction

SSH IP block listing is a feature that reduces the attack surface of the Secret Server SSH proxy and SSH terminal services.

Enabled by default, the feature adds to a block list any single IP address that fails to authenticate a number of connections across a defined time period. Once on the block list, the client IP is rejected when initiating an SSH connection, reducing the chances of a successful brute-force credential or denial of service (DOS) attack.

SSH Block Listing Rules

Client Override Settings

Client override settings allow creating allow/block lists, and blocked IP administration is provided via IP restriction administration.

Examples:

- A blocked IP is allowed if in a bypass allow-list entry
- A normally unblocked IP is blocked if included in a block list entry

Default Rules

The defaults are:

- SSH block listing is enabled
- Five connection attempts are allowed in a 30-minute period
- The amount of history kept per client can be adjusted but must be greater than or equal to the Max Attempts

That is, any single IP that fails to authenticate five times in any one 30 minute period is added to a permanent block list.

SSH Proxy Block List Settings

The feature is administered via **Admin > SSH Proxy** in the **SSH proxy block-list settings** section:

- **Enable Block Listing:** Enable or disable the SSH block listing feature. When enabled, IPs reaching the defined blocking threshold are automatically added to the SSH IP restrictions block list. When disabled, all IP addresses are able to connect and attempt to authenticate an unrestricted number of times.
- **Auto Block Max Attempts:** The maximum failed or unauthenticated connections allowed.
- **Auto Block Max History:** The maximum number of attempts to keep in each clients history.
- **Auto Block Time Frame (minutes):** The period length during which the "Auto Block Max Attempts" must reach before a client IP is added to the block list.

Client Override IP Address Ranges

You can configure specific IP address ranges to always allow or always block an incoming connection. If allowed, authentication is still required to access the SSH proxy or SSH terminal services.

To add a range:

1. Under the same tab, scroll down to Client Override IP Address Ranges, and click the **Add** link. An Add New Client Override IP Address Ranges popup appears.
2. Type an IP address or range in the **Range** text box. You can use CIDR notation. Examples:
   - 192.168.3.12
   - 192.168.42.147-192.168.42.194
   - 192.168.3.52/22
3. Click the **Client Type** dropdown list to select **Allow List** or **Block List**.
4. Click **Save**. The new range will appear in the list below.

These rules have priority over individual IP client settings in the SSH IP restrictions list.

IP Address Management

SSH IP Restrictions

Client IP address management is accessed via **Admin > SSH IP Restrictions**.

This page lists client IP addresses that were added by a connection exceeding the limits allowed for failed or unauthenticated attempts to one of the proxy endpoints, including any that have been previously reclassified.

The list has a number of built in display filters:

- All
- Allow List
- Block List
- Unknown

Use the search feature to locate specific IP addresses.

Managing IP Addresses

If an IP address is located on the SSH IP Restrictions page, you can view or edit its current SSH proxy block status. For example, a user may have inadvertently blocked her client IP for a number of reasons, such as testing the connection too many times in a short time period or performing a vulnerability or port scan against the proxy endpoint IP addresses.

Client Types

The SSH IP Restrictions page categorizes clients as follows:

Client Type	Access	Rule Type	Description	Notes
Allow List	Yes	Static	These IPs are allowed. Meeting the automatic blocking thresholds will not result in block listing.	Could be useful to allow list a vulnerability scanner. Is overridden by a matching override block list.
Block List	No	Static	These IPs are always blocked.	Is overridden by a matching override allow list.
Unknown	Yes	Dynamic	These are IPs that have previously accessed the SSH proxy and have not met the automatic block thresholds. They are in neither static allow nor block states	This is a client default, even if covered by a override allow or block list.

IP Address Activity

The SSH IP Restrictions page allows you to view the connection history for an IP address.

This shows the authentication status of each connection attempt, which is especially helpful when troubleshooting SSH terminal connectivity.

Blocking or Unblocking Client IPs

1. Go to the **SSH IP Restrictions** tab.
2. Locate the desired IP address in the list using the filter and search features.
3. Click the **Edit** link to the right of that IP address in the list. A popup appears.
4. Click the **Client Type** dropdown list to select either **Allow List** or **Block List** for the client type.
5. Click the **Save** button.

Troubleshooting

If a user reports he or she is unable to connect an SSH proxied or tunneled secret launcher for IPs included in the block list, you will see the following logging:

Secret Server On-Premises

For Secret Server On-Premises where the SSH proxy is on a web-node (IIS):

Path: `c:\inetpub\wwwroot\SecretServer\log\SS.log`

Message:

```
INFO Thycotic.SSHProxy.SSHServer - SSHProxy_Server_ConnectionReceivedINFO
Thycotic.SSHProxy.Logic.ConnectionBridge - SSHProxy_Client_Stopped_NoAuthWARN
Thycotic.SSHProxy.Logic.ConnectionBridge - SSH Proxy host 10.12.60.148:22 refused a
connection from client 10.12.60.106:52572 for too many failed authentication attempts. If
```

```
this was in error, please go to Admin > Proxying, click the SSH IP Restrictions tab and
update the Client Type to Allow List for this client IP.
```

Distributed Engines

For Secret Server Cloud or On-Premises with a distributed engine:

Path: `C:\ Program Files\Thycotic Software Ltd\Distributed Engine\log\SSDE.log`

Message:

```
INFO Thycotic.SSHProxy.SSHServer - SSHProxy_Server_ConnectionReceived - String[]
{10.12.60.148:22, 10.12.60.106:50182}INFO Thycotic.SSHProxy.Logic.ConnectionBridge -
SSHProxy_Client_Stopped_NoAuth - String[] {}~WARN Thycotic.SSHProxy.Logic.ConnectionBridge -
SSHProxy_Server_ConnectionRefused - (null)INFO
Thycotic.SSHProxy.Logic.ClientToServerConnection - ClientToServerConnection, buffer, and
tunnel disposed - (null)
```

SSH Jumpbox Routes

An *SSH jumpbox route*, is a series of regular Linux servers, accessible from the Internet, that is a gateway to other Linux machines on a private network using the SSH protocol. This topic and its subtopics address discuss using jumpbox routes.

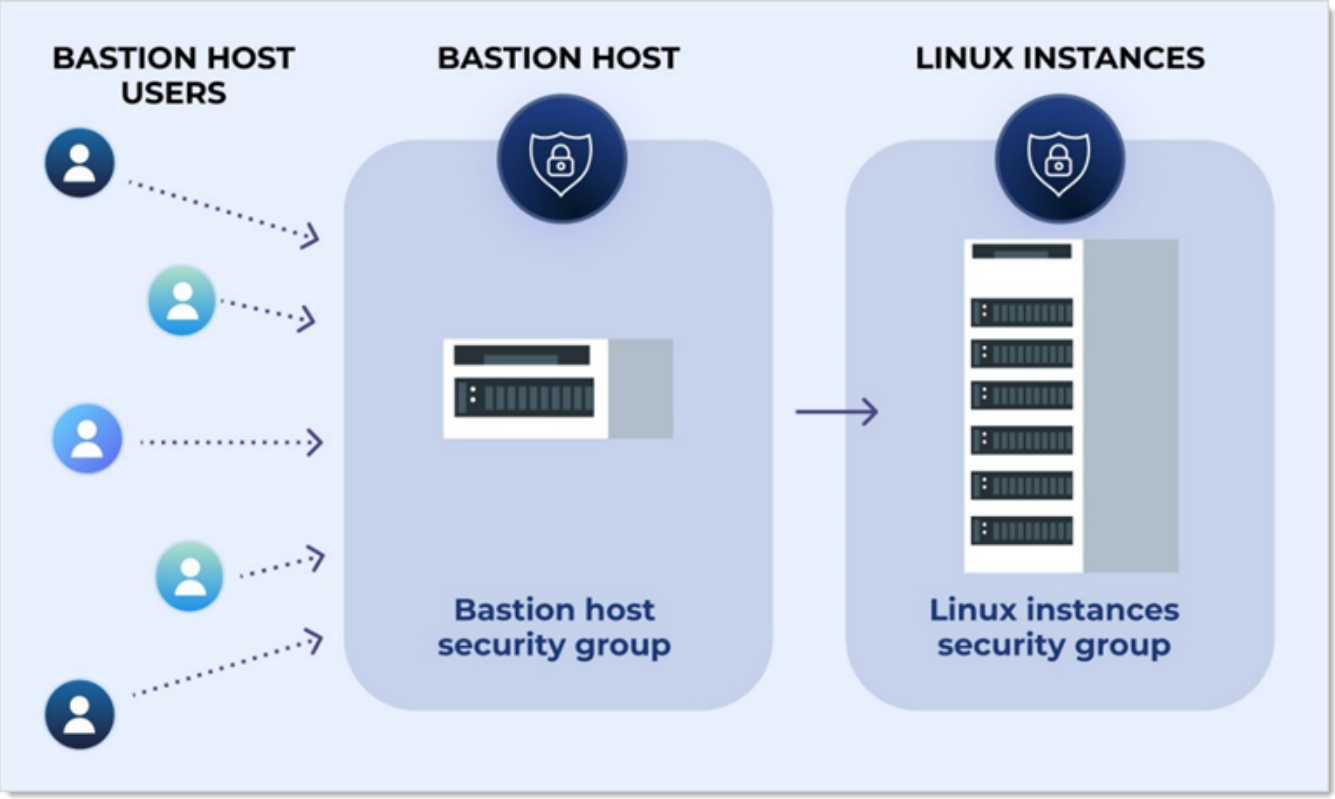
> SSH jumpboxes are also called *bastion hosts*, *jump hosts*, or *jump box servers*. *Bastion* is a military term meaning *a projecting part of a fortification*. Bastion hosts are hardened and monitored servers that reside outside of an organization's security zone, usually exposed to the internet. All jumpboxes are bastion hosts, but all bastion hosts are not necessarily jumpboxes.

Because SSH jumpboxes usually reside on the Internet, they run a minimum of services to reduce their attack vulnerability. Similarly, limiting the Internet access to your infrastructure to one hardened gateway server also reduces risk. In addition, a dedicated SSH access point makes it easier to have an aggregated audit log of all SSH connections.

With early SSH, users had to SSH into a jump host and then type `ssh` again to manually jump to a destination host. Today, this is done automatically using the built-in SSH `-J` ProxyJump option.

Secret Server can now create a chain of jumpbox secret connections to reach an otherwise inaccessible Linux instance. This sequence is called a *jumpbox route* and can contain up to 20 jumpbox levels (hops between instances).

Figure: SSH Jumpbox Route Setup



Best Practices for Jumpbox Routes

See "SSH Jumpbox Routes" on the previous page for an introduction.

Overview

This topic discusses configuring an SSH jumpbox route using OpenSSH.

We strongly recommend a dedicated SSH jumpbox without any other publicly accessible software on the machine. Occasionally, multiple jumpboxes (a jumpbox route) may be required to access a target machine that is behind several layers of network security.

Assumptions

We want:

- The jumpbox to forward SSH connections to our internal hosts. Users must authenticate to the SSH jumpbox and the internal target host. Users need valid credentials for both hosts.
- A single shared user for everyone with no interactive terminal sessions allowed.
- Users to connect to internal target hosts using Secret Server's jumpbox route feature, which uses the jumpboxes as jump route "levels" to ultimately launch a target secret that has this jumpbox route selected.

Best Practices

We recommend not allowing users to log into a jumpbox directly because they might introduce security issues by:

- Inadvertently updating the jumpbox configuration
- Using the jumpbox machine for unrelated tasks.
- Making copies of cryptographic keys used to access destination servers.

We recommend changing the default TCP port on the SSH jumpbox from 22 to something else.

Example Setup

The following example uses these conventions:

- The organization domain is example.com.
- The DNS name of the jumpbox is proxy.example.com, which is the only machine accessible from the Internet.

Task 1: Launching a New Linux Instance

- Stand up a Linux instance on your cloud provider. We use Ubuntu 20.04 LTS because it is simple, well-supported, and includes the recently released OpenSSH 8.2.
- Set up a firewall or security group policy to restrict connections to the jumpbox to port 22 (SSH).
- Allow connections only from IPs you trust.

Task 2: Configuring OpenSSH

- Read and apply Mozilla's OpenSSH Security Guidelines.

  The guidelines only cover up to OpenSSH 6.7. Most are still relevant to OpenSSH 8.2.

- OpenSSH is bundled by default with most Linux distributions. It is almost certain your Linux machine already has it installed. If the server is accessible via proxy.example.com, clients can access other servers behind the same NAT boundary via the `-J` command line flag. For instance: `$ ssh -J proxy.example.com 10.2.2.1`

  In the example above, the jumpbox is used to access another host on an AWS VPC with an address of 10.2.2.1.

Task 3: Configuring Public Key Authentication and Disabling Root Logins

Configuring the sshd_config File

In your new jumpbox's `/etc/ssh/sshd_config` file, consider adding the following SSHD config parameters:

```
# Supported HostKey algorithms by order of preference.
HostKey /etc/ssh/ssh_host_ed25519_key
HostKey /etc/ssh/ssh_host_ecdsa_key
HostKey /etc/ssh/ssh_host_rsa_key
# Password based logins are disabled - only public key based logins are allowed.
AuthenticationMethods publickey
```

```
# LogLevel VERBOSE logs user's key fingerprint on login. Needed to have a clear audit
track of which key was using to log in.
LogLevel VERBOSE
PermitRootLogin no
# Log sftp level file access (read/write/etc.) that would not be easily logged otherwise.
Subsystem sftp  /usr/lib/ssh/sftp-server -f AUTHPRIV -l INFO
```

The setup above works only when the public SSH keys are properly distributed, not only between clients and the jumpbox but also between the clients and the destination servers. With these settings, password authentication is disabled.

Setting Key Exchange Algorithms, Ciphers, and MACs

Consider which algorithms and key types you want to support. Mozilla recommends the following key types (more restrictive than the OpenSSH defaults):

In `/etc/ssh/sshd_config`, add:

```
KexAlgorithms curve25519-sha256@libssh.org,ecdh-sha2-nistp521,ecdh-sha2-nistp384,ecdh-
sha2-nistp256,diffie-hellman-group-exchange-sha256
Ciphers chacha20-poly1305@openssh.com,aes256-gcm@openssh.com,aes128-
gcm@openssh.com,aes256-ctr,aes192-ctr,aes128-ctr
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-
etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

Task 4: Disabling Forwarding

Next, harden the server configuration by disabling interactive SSH sessions on the jumpbox for regular users, leaving it turned on for the administrators. To do this, update the sshd configuration `/etc/ssh/sshd_config` with the following:

```
# Do not let SSH clients do anything except be forwarded to the destination:
AllowAgentForwarding no
AllowStreamLocalForwarding no
X11Forwarding no
```

If you only have a few users, consider creating a separate user account on the jumpbox dedicated to “jumping users.” For example, call it "jumpuser" and update the configuration `/etc/ssh/sshd_config`:

```
Match User jumpuser
  PermitTTY no
  X11Forwarding no
  PermitTunnel no
  GatewayPorts no
```

Task 5: Changing the Default SSH Port

If you do not want to restrict access by IP address in your security group rules, consider changing your default SSH port. This will deter many basic bots.

In `/etc/ssh/sshd_config`, add `Port 37271`.

Task 6: Testing Configuration and Restarting SSHD Service

You can test your configuration with `sshd -t`, then restart the SSHD server. Make sure you can still ssh into the machine before you continue!

Task 7: Send Your Users' SSH Keys to the Jumpbox

Add the jump user's public keys to the `/home/jumpuser/.ssh/authorized_keys` file. These keys can be stored in Secret Server and used during the Jumpbox Route launch session.

Using Bastion Hosts with Secret Server and Jumpbox Routes

Please see "Creating and Testing Secrets for Jumpbox Routes" on page 870.

Creating and Editing SSH Jumpbox Routes

> SSH jumpbox routes are only supported for SSH launchers. RPC and heartbeats through the jumpbox routes are not currently supported.

See "SSH Jumpbox Routes" on page 862 for an introduction.

Introduction

You can add jumpbox routes to Unix secrets when SSH proxying is enabled. A jumpbox route assigned to a target secret specifies a series of Unix servers called *jumpboxes*, *jumpbox servers*, or *bastion hosts*. The proxied connection is forwarded through the jumpbox route before reaching the server specified in the target secret.

Prerequisites

Using jumpbox routes requires these prerequisites:

- Only use Unix servers and secrets: At this time, jumpbox routes are only supported by Unix secrets. The option to add a jumpbox route does not appear on any target secret that is not base on the Unix secret template.

Similarly, a jumpbox route that attempts to connect to jumpbox servers that do not use a Unix secret template will also fail.

- Enable SSH proxy on Secret Server: For more information on how to enable proxying on Secret Server, see "SSH Proxy Configuration" on page 833.
- Enable the SSH Proxy setting for the target secret using a jumpbox route: To assign a jumpbox route to a target secret, the target secret itself must have SSH proxying enabled. The enable SSH Proxy check box appears in the secret's Security tab if proxying is enabled on Secret Server itself.

Secret Permissions

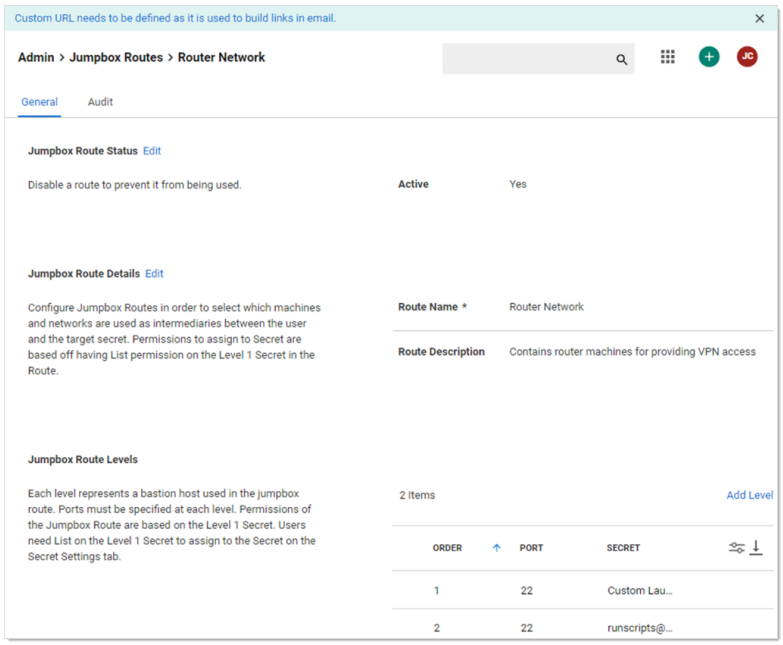
Using jumpbox routes requires these Delinea permissions:

- Adding a jumpbox route to a target secret: A user must have owner permissions on a secret to assign, change, or remove that secret's jump server route. Additionally, users are only able to pick from a list of routes where they have at least list permission on the first jump route server.
- Editing Jumpbox Routes: Users must have the "Administer Jumpbox Route" permission to create, edit, or deactivate jump server routes. Users with the "View Jumpbox Route" permission can view the details of all jump server routes in the Admin Jumpbox Route page, but they cannot make any changes.

Creating, Editing, and Deactivating Jumpbox Routes

1. Search for **See All**.
2. Search for and select **Jumpbox Routes**. The Jumpbox Routes page appears:

   This page lists all existing jumpbox routes.
3. Select an existing route to edit or create a new route by clicking the **Create Jumpbox Route** button.
4. If you chose to create a new route, a popup appears. Type the name and description and click the **Create Jumpbox Route** button.
5. In either case, the Jumpbox Routes page appears for the new or edited route:



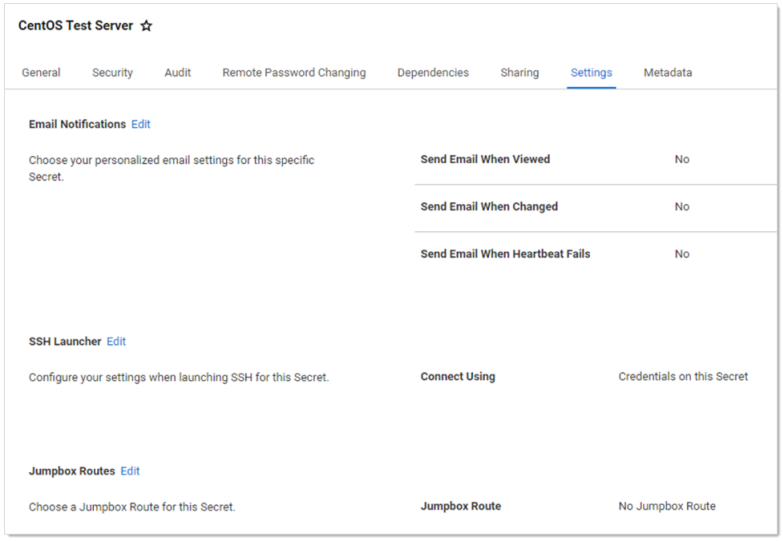
6. Note that routes can only be deactivated, not deleted, in the **Jumpbox Route Status** section.
7. You can view or edit the route's jump servers in the **Jumpbox Route** Levels section. Each row in the grid represents a *level*, each of which has these attributes:
   - Secret: Each level contains one secret that represents a jump server.
   - Port: The port used on the jump server for the route. Choose an available port on which the server listening for SSH connections. Typically, this is port 22, but we recommend changing it to deter basic script bots, see "Best Practices for Jumpbox Routes" on page 863 for more information.

     This value overrides any port specified on the secret.

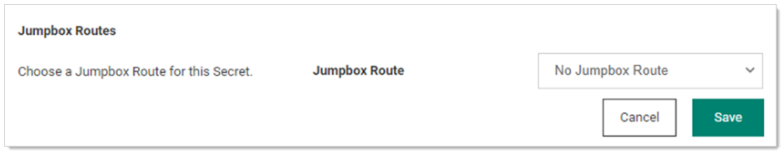
   - Order: The sequence of jumpboxes forwarding the proxied connection, starting with 1. You can hover over any level to present a handle for dragging it to reorder the list.
8. Click the **Add Level** hyperlink to add a jumpbox to the route. An Add Level popup appears.
9. Select or type your desired port in the **Port** list box.
10. Click the **No Secret Selected** hyperlink to choose the secret for the new level (server).
11. Click the **Save** button.
12. Hover over any level to present a handle (on the left) for dragging the level to reorder the list.
13. Hover over any level to present an ellipsis icon (on the right).
14. Click the icon and choose **Edit** or **Delete** to change or remove the level. You can change the port or related secret. Deletion permanently removes the level from the jumpbox route. It is not deactivated as with the route itself.

Assigning a Jumpbox Route to a Secret

1. Select or create a Unix secret for the route. Ensure that proxying and all other prerequisites described above are met.
2. Navigate to the secret's **Settings** tab and go to the **Jumpbox Route** section.



3. Click the **Edit** hyperlink. The section becomes editable:



4. Click to select the desired jumpbox route from the drop-down. Only active jump server routes to which you have access are visible. You can unassign the jumpbox route by selecting **No Jumpbox Route** in the dropdown list.

> If the jumpbox route becomes deactivated, "Router Network (inactive)" appears in the Jumpbox Route dropdown list. You should select a new one.

> You can also assign jumpbox routes though a secret policy. See "Creating Secret Policies" on page 1146.

Global Jumpbox Settings

The **Admin > Proxying** page has these jumpbox settings that impact your jumpbox routes:

- **Tunnel Keep Alive:** This setting is to stop intermediaries (such as firewalls or proxies) from deeming your connections inactive and timing them out and closing them. The default is 50 seconds (just shy of a common timeout setting). Adjust this to be just short of your network's timeout setting. Type 0 to disable the setting.

- **Available Port Range:** This sets the port range for the SSH proxy endpoint for jumpbox forwarding. Type a range separated by a hyphen, such as 10000-15000. The ports are used for local port forwarding for jumps. You cannot use the ports for other processes, so we recommend using a high range (ports above 10000).

Creating and Testing Secrets for Jumpbox Routes

Overview

This topic shows how to create secrets used for jump server routes by way of an extended example.

Please see "Best Practices for Jumpbox Routes" on page 863 for creating hardened jump servers for use in jump server routes.

We use following scenario:

A target Ubuntu host is only accessible via an SSH `proxyjump` directive. The sequence is Secret Server to `bastion01.thycotic.com` to `bastion02.thycotic.com` to `remote-hostname.thycotic.com`, the target Ubuntu host.

As suggested in the **Bastion Design Best Practices** guide:

- Both bastion hosts 01 and 02 have changed their default SSH ports for all incoming connections to 2222 and 3333, respectively.
- Both use a single jump user, betty on bastion01 and wilma on bastion02.
- Both users have SSH public key authentication enabled and have an `/home/<username>/.ssh/authorized_keys` file storing all the public keys.

You can connect to the target server without Secret Server from any SSH client using the following SSH command, with the built-in SSH ProxyJump directive -J and defined aliases:

```
$ ssh -J <jumpbox1>, <jumpbox2> <remote-host-target>
```

...with local `~/.ssh/config` aliases configured this way:

```
### First Jumpbox
Host jumpbox1
  HostName bastion01.thycotic.com
  Port 2222
  User betty
  IdentityFile /home/betty/.ssh/jumpbox1_ssh_rsa
### Second Jumpbox
Host jumpbox2
  HostName bastion02.thycotic.com
  Port 3333
```

To replicate this jump scenario using Secret Server, we need to create three new secrets and a new jumpbox route, and then assign that route to the target secret. Once that is done, launching the remote-host-target secret is as simple as clicking the PuTTY launcher icon–the jumpbox route is automatically set up for you.

Task 1: Creating Jumpbox and Target Host Secrets

All three connections require SSH public key authentication.

1. Create a new secret based on the Unix Account (SSH Key Rotation) template with these particulars:
   - Secret name: bastion01
   - Machine: bastion01.thycotic.com
   - Username: betty
2. Upload or generate the private/public key pair. Set a passphrase if necessary.
3. If the key pair is generated, save the public key on the secret to the user's `/home/betty/.ssh/authorized_keys` file on the jumpbox.
4. Create a second new secret also based on the Unix Account (SSH Key Rotation) template with these particulars:
   - Secret name: bastion02
   - Machine: bastion02.thycotic.com
   - Username: wilma
5. Upload or generate the private/public key pair. Set a passphrase if necessary.
6. If the key pair is generated, save the public key on the secret to the user's `/home/wilma/.ssh/authorized_keys` file on the jumpbox.
7. Create a third new secret also based on the Unix Account (SSH Key Rotation) template with these particulars:
   - Secret name: remote-host-target
   - Machine: remote-hostname.thycotic.com
   - Username: remote_user
8. Upload or generate the private/public key pair. Set a passphrase if necessary.
9. If the key pair is generated, save the public key on the secret to the user's `/home/remote_user/.ssh/authorized_keys` file on the target host.

Task 2: Creating a Jumpbox Route with Secret Levels

See "Creating and Editing SSH Jumpbox Routes" on page 866 for more on creating jumpbox routes.

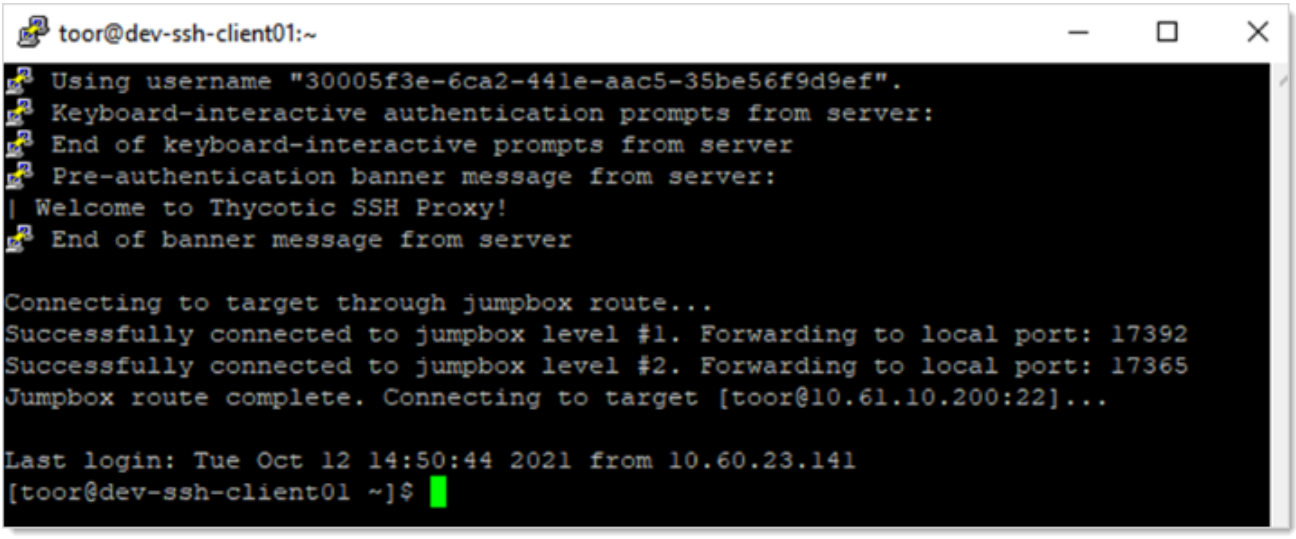
1. Create a new jumpbox route named flintstone.
2. For level 1, select the bastion01 secret and choose 2222 as the port.
3. For level 2, Select the bastion02 secret and choose 3333 as the port.

Task 3: Assigning a Jumpbox Route on the Target Secret

1. Open the remote-host-target secret.
2. Ensure SSH proxying is enabled (Security > Enable SSH Proxy) on the secret.
3. Navigate to the secret's **Settings** tab.
4. Scroll down to edit the **Jumpbox Route** section.
5. Select the **Flintstone Route** in the drop-down.
6. Save your changes.

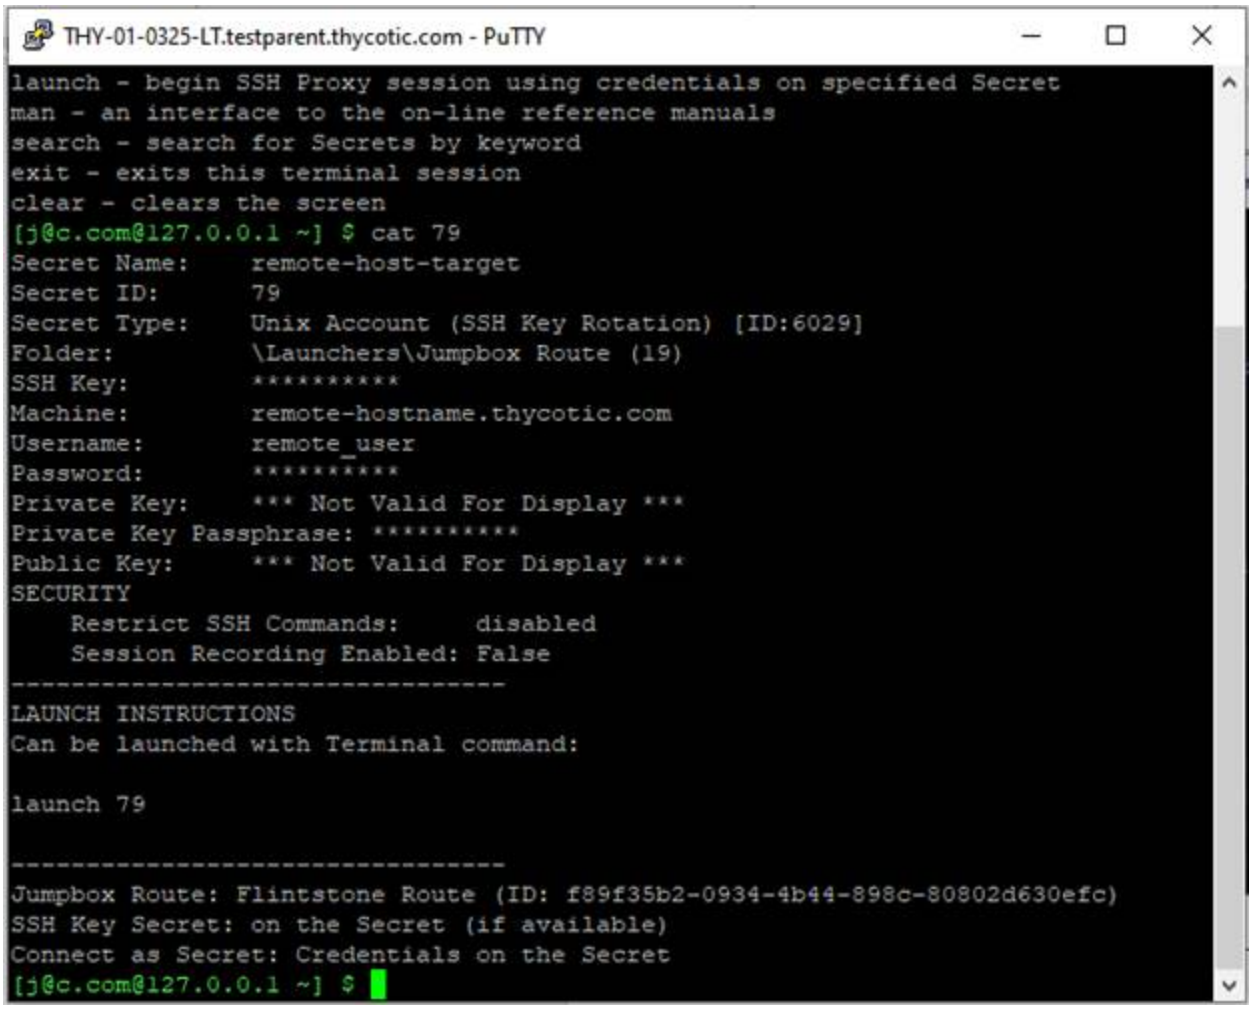
Task 4: Test Launching the Target Secret with PuTTY Launcher over SSH Proxy

1. Open the remote target secret.
2. Click the **General** tab.
3. Click the **PuTTY Launcher** link to begin a new SSH proxy session with a jump server route. The launcher connects to the target via the jump server route:

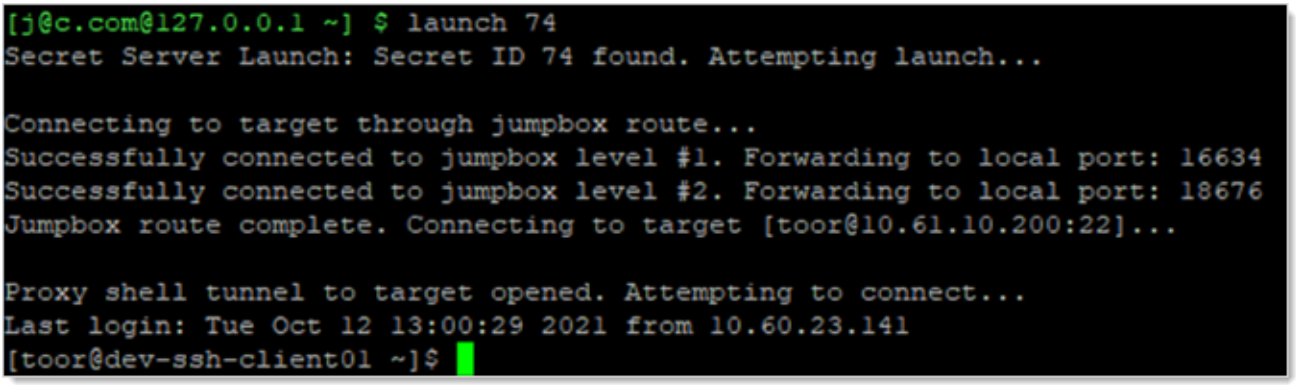


Task 5: Test Launching the Target Secret with SSH Terminal

1. Note the secret ID of your remote target secret.
2. Using an SSH client, log in to SSH Terminal. See "SSH Terminal Administration" on page 836 for details.
3. Enter `cat <secret id>` to view the remote target secret's details:



4. Enter `launch <secret id>` to launch the remote target secret with a jumpbox route:



5. You should now be connected to remote-hostname.thycotic.com as remote_user.
6. Enter `exit` to return to the terminal.

SSH Cipher Support

This topic details SSH cipher suite encryption, key exchange, and MAC algorithms.

Enable FIPS in Secret Server On-Premises to ensure all algorithms are FIPS-certified. FIPS 140-2 compliance is built-in to Secret Server Cloud and is always on.

SecureBlackbox enables all available SSH encryption, key exchange, and MAC algorithms by default.

This information applies to the following as of Secret Server On-Premises 11.8.X (June 2025).

- SSH Server: Used by SSH proxy
- SSH Client: Used by SSH proxy, RPC, heartbeat, discovery, and script runners.
- Local port forwarding: Used by SSH proxy Jumpbox routes)

Secret Server On-Premises with FIPS Enabled

Default Encryption Algorithms, FIPS

Connecting to a Target using a Second Account

To connect to a target using a separate account:

1. Navigate to an SSH secret (e.g. Account1), that has the **Launchers** section and a PuTTY launcher available.
2. Specify another secret (e.g Account2) as the **Connect As** secret that you wish to connect as in the PuTTY Launcher.
3. Click the **Launch** button, and "Account2" logs in.
4. Secret Server will run this command as "Account2" automatically: `su - Account1`
5. The SSH session will prompt for a password, which Secret Server will also populate automatically.

"Account2" then *becomes* "Account1" and from that point on you are logged in as "Account1".

Reports Overview

The reporting interface comes with a set of standard reports. These reports include a variety of 2D and 3D charting and graphing components and a full grid of data. Some of the reports are purely data detailed and have no charts. You can also create your own reports based on any Secret Server data, such as user, audit, permissions, and folders. You can create report categories to aid in the organization of your reports. Reports can be arranged to provide access to auditors and meet compliance requirements. These reports can be accessed in the **General** tab on the **Reports** page.

> Reports using SQL queries are displayed in UTC.

The *Security Hardening Report* checks aspects of Secret Server to ensure security best practices are being implemented. While Secret Server runs with all the items failing, administrators should be aware of possible security issues within an installation. For details on this, see "Report Page" on page 890.

The User Audit Report shows all secrets accessed by a user during a specified period.

Built-in Reports

Secret Server includes many pre-configured reports that you can run or use as templates for creating custom reports. Below are the reports shipped with current release of Secret Server:

> Unless otherwise designated, reports listed are available in all editions. However, older releases may not include all reports listed here.

Activity

- **Active Secret Sessions**: A list of all currently active Secret sessions.
- **Active Secret Sessions Count**: Total of all currently active Secret sessions.

- **Custom Report Activity**: Shows all custom report activity for a given date range. This report can be used to quickly verify custom report activity by all users.
- **Database Configuration Audit**: Shows audited database configuration changes.
- **Distributed Engine Activity**: The Distributed Engine Activity report shows the audit of all Engine-related activity.
- **Dual Control Audit**: Shows audited Dual Control changes.
- **Engine Status**: A list of all engines and their status.
- **Event Subscription Activity**: Shows all event subscription activity for a given date range. This report can be used to quickly verify event subscription activity by all users.
- **Folder Activity**: Shows all folder activity for a given date range. This report can be used to quickly verify folder activity by all users.
- **Heartbeat Status**: Total of Heartbeat status for Pending, Success, and Failure.
- **Heartbeat Status by Day**: Number of heartbeats status items record in Secret audit log.
- **Internal Communication Changes**: Shows all internal communication changes.
- **IP Address Range Audit**: Shows audited IP Address Range changes.
- **License Audit**: Shows audited license changes.
- **RPC by Day**: Count of remote password changes by day for distinct Secrets recorded in Secret audit log.
- **Secret Activity**: Shows all Secret activity for a given date range. This report can be used to quickly verify Secret activity by all users.
- **Secret Activity Today**: Shows all Secret activity for today. This report can be used to quickly verify Secret activity by all users.
- **Secret Activity Yesterday**: Shows all Secret activity for yesterday. This report can be used to quickly verify Secret activity by all users.
- **Secret Template Activity**: The Secret Template report shows the audit of all Secret Template related activity.
- **Session Recording Errors**: Shows all session recordings within the last seven days more than five seconds long that encountered an error while being created.
- **Unlimited Vault Access behavior**: This report shows all actions performed by Unlimited Vault Accesss during the specified date range, including any events outside the date range that were part of the Unlimited Vault Access's session.
- **Users Activity**: Shows all user activity for a given date range. This report can be used to quickly verify user activity by all users.

Discovery Scan

- **Discovery Scan Status**: Shows the breakdown of machines that have been successfully scanned, existing machines that have not yet been successfully scanned, and machines that are in Active Directory but no longer exist. For detailed info on each part of the breakdown, view the other discovery reports.
- **GCP Discovery**: What Instances do Service Accounts have access to?: Shows a list of GCP Service Accounts and which Instances they have access to.

- **What computers have been successfully scanned?**: Shows all the computers that have been successfully scanned at some point in the past.
- **What computers that exist have not been successfully scanned?**: Shows all computers that have not yet been successfully scanned. (For Active Directory, computers that have not connected to the domain in the last 3 months are excluded.)
- **What Secrets are pending import by Discovery?**: Shows Secrets that have not been imported by Discovery yet and contain incomplete information.
- **What Secrets failed to import by Discovery?**: Shows Secrets that were unable to be completely imported by Discovery. These Secrets may have incorrect passwords.

Folders

- **What folder permissions exist for groups?**: Shows all the folders in the system along with their assigned or inherited group permissions. This report can be used to verify that all folders have the correct group permissions.
- **What folder permissions exist?**: Shows all the folders in the system along with their assigned or inherited folder permissions. This report can be used to verify that all folders have the correct folder permissions.
- **What folders can a user see?**: Shows the folders permissions for a particular user. This report is useful from an auditing perspective to ensure that a user is not able to access inappropriate folders.
- **What folders can all users see?**: Shows the folders permissions for all users. This report is useful from an auditing perspective to ensure that users are not able to access inappropriate folders.

Groups

- **Group Membership**: Shows all the groups in the system and who is a member of each. Use this report to verify group membership - this can be used to monitor both local groups and Active Directory groups.
- **Group Membership By Group**: Shows all the members of the group. Use this report to verify group membership - this can be used to monitor both local groups and Active Directory groups.

Legacy Reports

- **Secret Expiration Health**: The Secret Expiration Health report shows the number of Secrets in the system in various stages of expiration. This is a good indicator for the overall health of the Secrets in terms of age (frequently changed passwords are more secure).
- **Secret Server Usage**: The Secret Server Usage report shows the number of Secret audit activity records (view, edit, sharing) by month over a period of time. This report is an indicator of overall usage of the system.
- **Secret Template Distribution**: The Secret Template Distribution report shows the number of Secrets based on their Secret Template within the system. This typically indicates the types of information being stored.
- **Top Ten Viewers**: The Top Ten Viewers shows the ten users who have viewed the most Secrets over a date period.

Password Compliance

- **Secret Password Compliance Statuses**: This report displays all Secrets and their current password compliance validation status.
- **What Secrets Do Not Meet Password Requirements?**: This report displays secrets with one or more password fields that do not meet the requirements.

Report Schedules

- **Report Schedules**: Shows a list of all Report schedules. In order to edit a schedule, open the report and click the 'Schedule' button.

Roles and Permissions

- **What role assignments exist?**: Shows the roles and which users have been assigned to the role and how (directly or through a group). This report can be used to quickly verify that all users have been assigned to the correct roles.
- **What role permission assignments exist?**: Shows the assignment of Delinea permissions to users based on role assignments and group memberships. This report can be useful when auditing that permissions are assigned correctly.
- **What role permissions does a user have?**: Shows the role permissions for a particular user and where they are getting the role permission from (group, role). This can be useful in diagnosing complex role assignments.

Secret Policy

- **What Folders have Policies assigned?**: Shows all the folders and what Policy is assigned and whether it is inherited from a parent folder.
- **What Secrets have different Policies than their folders?**: Shows all the Secrets that have a different Policy than their parent folder.
- **What Secrets have policies assigned?**: Shows all the Secrets and what Policy is assigned and whether it is inherited from a parent folder.

Secrets

- **Secret Count per Site**: Shows all the Sites and how many active Secrets are assigned to them.
- **Secret Dependency Failures**: A list of all Secrets that have dependencies that have failed.
- **Secret Dependency Not Run**: A list of all Secrets that have dependencies that have not been run yet.
- **Secret Dependency Overview**: An overview of the statuses for all dependencies.
- **Secret Dependency Status**: A list of all Secrets with dependencies and their status.
- **Secret Permissions Mismatch**: Shows all Secrets with Inherit Permissions turned off when Default Inherit Permission is on.
- **Secret Templates without an expiration field?**: Shows all the Secret Templates that have password fields that don't have an expiration field selected.

- **Secrets Failing Heartbeat**: All Secrets that have currently failed Heartbeat.
- **Secrets Pending Heartbeat**: A list of all Secrets that are pending heartbeat.
- **Secrets with Failed Password Change**: Secrets that have failed password change during the time frame specified.
- **What file types have been uploaded to Secrets?**: Shows the distribution of file types that have been uploaded to Secrets. Use this report to help tailor file attachment restrictions in configuration.
- **What file types have been uploaded to Secrets? (Pie Chart)**: Shows the top 10 file types that have been uploaded to Secrets. Use this report to help tailor file attachment restrictions in configuration.
- **What Secret permissions exist for a group?**: Shows all the permissions on Secrets for the group along with where the Permission has been set. This report can be used to verify that a group has the correct permissions on Secrets.
- **What Secret permissions exist for a user?**: Shows all the secret permissions on Secrets for the user along with where the Permission has been set. This report can be used to verify that a user has the correct permissions on Secrets.
- **What Secret permissions exist?**: Shows all the permissions on Secrets in the system along with where the Permission has been set. This report can be used to verify that all Secrets have the correct Delinea permissions.
- **What Secrets are expiring this week?**: Secrets that have passwords that will expire within the next 7 days.
- **What Secrets can a user see?**: Shows the Secrets that are viewable by a particular user (user has view permission). This report is useful from an auditing perspective to ensure that a user is not able to access inappropriate Secrets.
- **What Secrets can all users see?**: Shows the Secrets that are viewable by all users. This report is useful from an auditing perspective to ensure that users are not able to access inappropriate Secrets.
- **What Secrets changed passwords in the last 90 days?**: Shows all the Secrets whose passwords have changed in the last 90 days, based on the Secret Template expiration field.
- **What Secrets Do Not Have Distributed Engines?**: Shows all the secrets that do not have Distributed Engines.
- **What Secrets don't require approval?**: Shows all the secrets that don't have approval for access enabled.
- **What Secrets have been accessed by a user?**: Shows all the Secrets that have been accessed within the date range for the user. This report shows the last accessed date for each Secret for the user.
- **What Secrets have been accessed by an impersonated user?**: Shows all the Secrets that have been accessed within the date range by an impersonated user through web services.
- **What Secrets have been accessed?**: Shows all the Secrets that have been accessed within the date range. This report shows the user and last accessed date for each Secret.
- **What Secrets Have Distributed Engines?**: Shows all the secrets that have Distributed Engines.
- **What Secrets have Expiration?**: Shows the Secrets that have expiration with the Expiration Type (Template, Custom Interval, Custom Date), Expiration Interval and Expiration Date.
- **What Secrets have failed Heartbeat?**: Shows all the secrets that have failed Heartbeat password verification. This report can be used to monitor all Heartbeat failures and why they failed.

- **What Secrets have not changed passwords for over 90 days?**: Shows all the Secrets whose passwords have not changed in the last 90 days, based on the Secret Template expiration field.
- **What Secrets require approval?**: Shows all the secrets that have approval for access enabled.
- **What Secrets require Comments?**: Shows the Secrets that are wired to prompt for a comment before the user is allowed to view.
- **What SSH Command Menus do Secrets have?**: View the SSH Command Menus that each Secrets have access to.

System Reports

- **Folder Permissions Report**
- **Folder Secrets Report**
- **Group Lookup Report**
- **Permission Lookup Report**
- **Privileged Behavior Analytics Configuration Activity**
- **Role Permissions Report**
- **User Access Report**

User

- **Active Users Custom Report**: This displays a user list with all active user activity on view and returns an user id. This defaults to the current logged in user.
- **Failed login attempts**: Shows all failed login attempts to the Secret Server. This report can be used to show any attempts to compromise a user account.
- **Secret Template Permissions by User**: Shows what secret template permissions a user will have to either create a Secret of a specific Template or edit an existing Secret Template.
- **What SSH Command Menus do users have access to?**: Shows what SSH Command Menus Users have access to.
- **What users have had an admin reset their password?**: Shows any password resets performed on a user account by another user.
- **Who hasn't logged in within the last 90 days?**: Shows user accounts that are not being used on a regular basis. Access by these users should be re-evaluated to determine if they really need access to the system.

Creating and Editing Reports

Secret Server provides robust reporting capabilities to help you analyze and manage your privileged access data effectively. With customizable reports, you can gain insights into user activity, security compliance, and system performance.

This guide walks you through the process of creating, modifying, and customizing reports in Secret Server. Whether you need to generate pre-built reports or tailor them to specific security and compliance requirements, you'll find the tools and options necessary to streamline reporting for your organization.

You may see the "The SQL that was provided is not valid for reporting" error when creating a custom report.This most commonly occurs when cutting and pasting a built-in report's query code. This is because that code can contain elements that are not allowed in your SQL queries via the UI. These elements include reserved keywords for Microsoft SQL Server. See Reserved Keywords (Transact-SQL) for a list of reserved words.

Secret Server reports do not yet cover the Platform. Platform reports are in development.

Creating a Custom Report

1. Click **Reports** on the main menu. The **Reports** page appears.
2. Click the **New Report** button. The **New Report** page appears.q
3. Type the report name in the **Name** text box. This is the name that is displayed on the Reports page as a link underneath its containing category.
4. Type a description in the **Description** text box. This is displayed in the View Report tab of a report. It is also used as the Tooltip when hovering over the report name on the Reports page.
5. Click the **Category** dropdown list to select the category the report will appear in on the Reports page.
6. Click the **Page Size** dropdown list to select the page size limit for the data displayed in the grid.
7. Select the **Use Database Paging** checkbox if desired. See Database Paging for details.
8. Click the **Chart** dropdown list to select the type of chart to use for displaying results. If set to <None>, a grid displays.
9. Paste your script in the **Report SQL** text box. See Report SQL Scripts for details.
10. Click the **Save** button. The new report's page appears and now appears on the reports page.

Editing Reports

To edit a report:

1. Click the **Reports** menu item. The Reports page appears, listing all reports.
2. Click the name of the report you wish to edit, which is a link. The report's page appears.
3. Click the **Edit** button. The Edit Report page appears. See Creating a Custom Report for details about the parameters.

The SQL script text cannot be edited for (non-custom) system reports.

Report SQL Scripts

Overview

The best way to create SQL scripts is to view existing ones and the Secret Server database structure. Click any existing report link from the **Reports** page and select the **Edit** button. The SQL script appears in the **Report SQL** text box.

You cannot edit (non-custom) system reports. You can view their parameters in the Edit page, including their SQL script, which you can copy for use, but no modifications can be made or saved.

Dynamic Parameters

Reports support the embedding of certain parameters into the SQL so you can dynamically change the resulting data set. Another option available for custom reports is to apply a different color to returned rows dependent on certain conditions. For more information as well as examples, see "Using Dynamic Parameters in Reports" on page 895 for details.

Viewing Secret Server SQL Database Information

You can show the SQL database information of Secret Server to assist with creating custom reports.

When "Creating a Custom Report" on the previous page, in the **New Report** page select the **Chart and SQL Editor** link. **The Report SQL** page appears and it is blank. Click **Help** and search for specific tables with examples of data, data types and whether they are nullable. This data is available for search to assist in creating custom reports.

You can click the **Run SQL** button at the bottom of the page to see a preview of the chart generated by the report. The resulting chart displays in the Report Preview section at the bottom of the page.

Database Paging

Database paging allows the database to load large reports more quickly. We recommend database paging if the query is expected to pull large amounts of data for a report.

Implementing database paging may not work if the SQL query uses certain keywords, including `TOP`, `OPTION`, `INSERT`, `UNION`, `WITH`, or aliases containing the word `FROM`.

Example queries:

- Successful query: `SELECT * FROM tbSecret WHERE NAME LIKE 'Test%'`.
- Failing query: `SELECT TOP 10 * FROM tbSecret WHERE SecretName LIKE 'Test%'`.

Deleting or Undeleting Reports

To delete or undelete a report.

- **Delete:** To delete a report, select the related report and click the **Delete** button.
- **Undelete:** To undelete a report, you must navigate to the Reports Edit page as deleted reports are not visible on the Reports View page. On the Reports Edit page, click the **Show Deleted** button. This displays a Deleted Report category, which contains all the deleted reports. Either drag the report to a report category that is not deleted or click the report name to go into its Report View page. In there, click the **Undelete** button.

Modifying Report Categories

For details on the Show Deleted button, see "Deleting or Undeleting Reports" above

- **Rearrange:** Any item with the icon can be dragged and dropped to a new location. Report categories can be moved anywhere within the page. Reports can be moved from one report category to another.
- **Create New:** Click **Create Report Category** and specify a category name and description on the following page. Note that the Report Category Description is used as the tooltip for the report category on the Reports View page.
- **Delete:** Click the icon next to the report category name. This deletes all the reports in the category. To undelete the reports, see "Deleting or Undeleting Reports" on the previous page.
- **Edit:** Click the icon next to the report category name to change the name or description of the category.

Report Page

Reports General Tab

See "Built-in Reports" on page 882 for the most up-to-date list of reports included.

The reports are listed under the report categories. To view a report, click on its name. This takes you to the **Report View** page.

You can view a record of all the actions performed on reports by clicking on the **View Audit** button.

For details on the **Edit** button, see "Creating and Editing Reports" on page 887.

The **Create it** link is a shortcut for creating a new report.

You can adjust the look of the Reports View page. The report categories as well as the reports can be rearranged on the page. To do this, click **Edit** on the Reports page.

Reports Security Hardening Tab

The Security Hardening Tab configures aspects of Secret Server to ensure security best practices are being implemented. While Secret Server runs with all the items failing, administrators should be aware of possible security issues within an installation. Below is an explanation of the different features:

Configuration Section

- **Allow Approval for Access from Email:** This is a convenience option that allows users to approve or deny a secret access request by clicking a link in the request email sent by Secret Server. Allow Approval From Email does not require a user to authenticate with Secret Server when approving access to a secret. This can be a security concern if the approver's email account becomes compromised. Turn Allow Approval From Email off to get a pass result. Secret Server.
- **Browser AutoComplete:** Browser AutoComplete allows Web browsers to save the login credentials for the Secret Server login screen. These credentials are often kept by the Web browser in an insecure manner on the user's workstation. Allowing AutoComplete also interferes with the security policy of your Secret Server by not requiring the user to re-enter their login credentials on your desired schedule. To prevent the AutoComplete feature, disable the Allow AutoComplete option on the Configuration page.
- This security check will fail if the file attachment restrictions is not enabled. This check will return warnings if a potentially dangerous file extension is allowed, maximum file size is not specified, or maximum file size is greater than 30 MB.

- **Force Password Masking:** Password masking prevents over-the-shoulder viewing of your passwords by a casual observer (when masked, passwords show as *). To activate this option, click to select the **Force Password Masking** option on the **Configuration** page.
- **Frame Blocking:** Frame blocking prevents the Secret Server site from being placed in an iFrame. This is to prevent clickjacking attacks. There may be legitimate reasons for placing Secret Server in a frame, such as embedding the UI in another site. To turn frame blocking on, enable the setting under the Security tab in Configuration.
- **Login Password Requirements:** Login passwords can be strengthened by requiring a minimum length and the use of various character sets. A minimum password length of 8 characters or longer is recommended. In addition, all character sets (lowercase, uppercase, numbers and symbols) are required to get a pass result. Turn on these login password settings on the Configuration page.
- **Maximum Login Failures:** The maximum number of login failures is the number of attempts that can be made to login to Secret Server as a user before that user's account is locked. A user with user administration permissions is then required to unlock the user's account. The maximum failures allowed should be set to 5 or less to get a pass result. Change the "Maximum Login Failures" settings on the Configuration page. Secret Server
- **Remember Me:** Remember Me is a convenience option that allows users to remain logged in for up to a specific period. This setting can be a security concern as it does not require re-entry of credentials to gain access to SS. Turn Remember Me off on the Configuration page to get a pass result. It must be set to be valid for 1 day or less to not get a fail result.
- **Secure Session and Forms Auth Cookies:** Cookies contain potentially sensitive information that can allow users to log onto application. By default, cookies are not marked with the secure attribute. That is, **they are transmitted unencrypted when a user accesses Secret Server through HTTP instead of HTTPS**.

  For more information about how to secure your cookies, see Secure ASP Session and Forms Authentication Cookies (KB).

- **Web Service HTTP Gets Allowed:** Web service HTTP get requests are allowed. Allowing HTTP GET requests allows REST-style calls to many Secret Server Web service methods. This can be a security concern because simply clicking a link to the Web service, created by a malicious user, would cause it to be executed.
- **Zero Information Disclosure Error Message:** Replace all error messages with a custom "contact your admin" message. Error messages can be very helpful when diagnosing installation and configuration issues. However, having errors displayed to a potential attacker can provide him or her with the critical information they need to perform a successful attack.

File Attachment Restrictions

File attachment restrictions allows administrators to configure what kind of file attachments can be uploaded to secrets. This helps protect users from being tricked into downloading a malicious secret attachment. The file extension and maximum file size can be specified, such as:

```
*.7z, *.bmp, *.ca-bundle, *.cer, *.config, *.crt, *.csr, *.csv, *.dat, *.doc, *.docx, *.gif,
*.gz, *.id-rsa, *.jpeg, *.jpg, *.json, *.key, *.lic, *.p7b, *.pcf, *.pdf, *.pem, *.pfx,
*.pkey, *.png, *.ppk, *.pub, *.tar, *.tif, *.tiff, *.tpm, *.txt, *.vdx, *.vsd, *.vsdx, *.xls,
*.xlsx, *.xml, *.zip
```

This security check will fail if the file attachment restrictions is not enabled. This check will return warnings if a potentially dangerous file extension is allowed, maximum file size is not specified, or maximum file size is greater than 30 MB.

Database Section

- **SQL Account Using Least Permissions:** Use the fewest Secret Server permissions as possible in the SQL Account used to access the database. We recommend using a least permission approach where the account only has dbOwner. See "SQL Server 2016 Standard Edition Installation" on page 128.
- **SQL Server Authentication Password Strength:** SQL Server authentication requires a username and password. The password must be a strong password to get a pass result. Strong passwords are 8 characters or longer and contain lowercase and uppercase letters, numbers and symbols. The SQL Server authentication credentials in use can be changed by going to the installer (installer.aspx) and changing them on Step 3. A pass result is also given if Windows authentication is used to authenticate to SQL Server.
- **SQL Server Authentication Username:** The SQL Server authentication username should not be obvious. The use of "sa", "Secret Server" or "secretserver" triggers a fail result. The SQL Server authentication credentials in use can be changed by going to the installer (installer.aspx) and changing them on Step 3. A pass result is also given if Windows authentication is used to authenticate to SQL Server.
- **Windows Authentication to Database:** Windows authentication takes advantage of Windows security to provide secure authentication to SQL Server. The SQL Server authentication options can be changed by going to the installer (installer.aspx) and changing them on Step 3. Please see "Installation" on page 72 for instructions on configuring Windows authentication to SQL Server.

Environment Section

- **Application Pool Identity:** The Application Pool identity `GAMMA\ss_iis_svc` appears to be a member of the administrators group on the system. This puts the system at risk by giving more access than necessary.
- **DPAPI or HSM Encryption of Encryption Key:** Encrypt your Secret Server encryption key, and limit decryption to that same server. Data Protection API (DPAPI) is an encryption library that is built into Windows operating systems. It allows encryption of data and configuration files based on the machine key. Enabling DPAPI Encryption in Secret Server protects the Secret Server encryption key by using DPAPI, so even getting access to the Secret Server encryption key is not enough to be useful—the machine key is required. If you enable this option, back up your encryption key first, as a DPAPI encrypted file can only be used by the machine it was encrypted on.

SAML Section

Ensure Secret Server only accepts signed SAML response messages. See "SAML" in the Secret Server Security Hardening Guide.

Require signed responses from SAML identity providers: An Identity Provider is configured to allow unsigned SAML response messages. Unsigned response messages are a security concern, as a knowledgeable malicious user could craft a SAML response message. Without a digital signature, Secret Server cannot distinguish between a legitimate response and a forged response. To pass this check require signed response messages in your Identity Provider configuration.

SSL Section

SSL needs to be running with at least a 128-bit key size to get a pass result. A warning result indicates your key size is less than 128 bits. A fail result indicates you are not using SSL.

- **Require SMTP SSL:** SMTP SSL is required to ensure that all communication between Secret Server and the email server is encrypted. Enable the "Use SSL" option in Secret Server to get a pass result.
- **Require SSL:** Secure Sockets Layer (SSL) is required to ensure that all communication between the Web browser and Secret Server is encrypted and secure. Once the SSL certificate is installed, Force HTTPS/SSL in Configuration to get a pass result. Please see the "Installing Self-Signed SSL Certificates" on page 443 Knowledge Base article for instructions.
- **SSL/TLS Hash:** Check the digest algorithm of the certificate. If the algorithm is SHA1, this check returns a warning because SHA1 is being phased out. If the digest algorithm is MD2, MD4, or MD5, the check will fail because they are not secure. SHA256, SHA384, and SHA512 will pass. This check fails if Secret Server cannot be loaded over HTTPS.
- **SSL/TLS Key:** Check the key size of the HTTPS certificate used. If it is RSA or DSA, the key must be at least 2048-bit to pass. If the signature algorithm of the certificate is ECDSA, the key size must be at least 256-bit to pass. If the algorithm of the certificate is unknown, the result shows "unknown. This check fails if Secret Server cannot be loaded over HTTPS.
- **SSL/TLS Protocols:** Check for legacy SSL or TLS protocols, which should not be used in a secure environment. If the server accepts SSLv2 or SSLv3 connections, this check will fail. SSLv2 is not considered secure for data transport, and SSLv3 is vulnerable to the POODLE attack. If this server does not support TLSv1.1 or TLSv1.2, this check will give a warning because they are recommended. The SSL certificate used may affect what protocols can be used, even if they are enabled. This check will fail if Secret Server cannot be loaded over HTTPS.
- **Using HTTP Strict Transport Security:** HTTP Strict Transport Security (HSTS) is an additional security layer for SSL. HSTS allows SS, Password Reset Server, or Group Management Server to inform browsers that it should only be accessible over HTTPS. With this setting enabled, visitors are automatically are redirected by their browser to the HTTPS-enabled site.

Reports User Audit Tab

User Audit Reports show all secrets accessed by a user during a specified period. For a more detailed explanation, see "Built-in Reports" on page 882.

Reporting and Dual Controls

If there are requirements around protecting potentially personally identifying information when running reports or viewing recorded sessions, you can enforce that another user has authorized you by enabling dual control for a secret or Report. When enabled a user in the approver group must enter in their credentials before a report or session can be viewed.

Once the approver has entered their credentials, the resource can be accessed.

To configure dual control, perform the following steps:

1. Search for**Dual control**to get to the Dual controls page.
2. On the Dual Controls page, click the **Create new** button.
3. On the **Create new** page in the **Type** drop-down box, select the report type you wish to modify.
4. In the **Report** dropdown, select the related report.
5. In the drop-down list below **Add**, click the box next to each party you'd like to add as a Valid Approver. Their identities will automatically appear in the **Valid Approvers** field.

   When you are finished, click the **Create new** button. The Dual Control page appears, displaying the parameters you have set.

Saving Reports to File

1. Click the **Reports** menu item. The Reports page appears.
2. Click the link for the desired report. Its page appears.
3. Click the button in the top right of the item table. The download popup appears.
4. Select the number of records that you would like to include in the list with the slider.
5. Click the **Date Format** dropdown list to choose the date format.
6. Click the **Download** button. The reports save as a CSV file to your browser's default download location.

Scheduled Reports

Creating New Schedules for Reports

1. To create a schedule for a report, select the related report and select the **Schedules** tab on the **Report View** page.
2. Click the **Create Schedule** button. The Report Schedule page appears.
3. Configure the report settings as listed in Editing Schedule Settings
4. Click the **Save** button. The page for the new report schedule appears.
5. The report will now be saved for you, saving only one report at a time. If you want more saved or want it emailed to you according the schedule:
   a. Click the **Edit** link in the **Report Distribution** section. The section becomes editable.
   b. Either click to select the **Save All** check box or type a new number in the **Number of Saved Reports** text box. Remember, saving reports can use a lot of disk space.
   c. Click the **Format** dropdown list to select the report format:
      - HTML: Save the report as an HTML file.
      - CSV: Save the report as a comma separated value file for importation into a spreadsheet.

a. Click to select the **Send Email** check box to have the report emailed to you at the reporting interval. An email section appears:
b. Click the **All** dropdown list in the **Report Subscribers** section to choose the domain to look for users and groups.
c. Click the check boxes next to the users or groups you want to send the report to in the **Report Subscribers** section. You can also search for the same in the provided search box at the top of the section. The users or groups appear in the Selected Groups text box.
d. Type any additional email addresses in the **Additional Email Recipients** text box.
e. Click the **Save** button.

Viewing Existing Report Schedules

1. To view existing schedules for a report, click **Schedule** on the Report View screen. A list of existing schedules for the report appear in the grid.
2. To view the details of a schedule, click the schedule name in the grid.
3. (Optional) Deleted schedules can be made visible by checking the **Show Deleted** box at the bottom of the grid.
4. Click the **View** link in the History column of the grid to view the history of all generated reports for that schedule.

Editing Schedule Settings

When viewing a report, click Schedule and then the name of the report schedule to modify it. The following configuration options are available:

- **Schedule Name:** This is the name of the schedule for the report. This name must be unique to the Secret Server installation.
- **Health Check:** This sends an email notification only when the report contains data.
- **Start recurring on:** This specifies the schedule runs every X number of days, weeks, or months, with the option to specify days of the week or month as well. The date and time that the report schedule is effective can be specified in this section as well.
- **Schedule type**: Select daily, monthly, or weekly.

The following configuration options appear if the report being scheduled contains at least one dynamic parameter in the SQL of the report:

- **User Parameter Value:** Value of the `#USER` parameter to set in the report when it is generated.
- **Group Parameter Value:** Value of the `#GROUP` parameter to set in the report when it is generated.
- **Start Date Parameter Value:** Value of the `#STARTDATE` parameter to set in the report when it is generated.
- **End Date Parameter Value:** Value of the `#ENDDATE` parameter to set in the report when it is generated.

Using Dynamic Parameters in Reports

As version 7.0, Secret Server allows creation of Reports using custom SQL.

Reporting supports embedding certain parameters into the SQL to give the viewer controls to dynamically change the report. The supported parameters are:

Primary Parameters

#STARTDATE

This displays a calendar picker on view and returns a date. This defaults to beginning of the year and truncates the hours and minutes to 12:00 AM.

Example: display all users who have logged in after a certain date:

```
SELECT
  Domain,
  Username,
  LastLogin
FROM tbUser
  LEFT JOIN tbDomain ON tbUser.DomainId = tbDomain.DomainId
WHERE
  LastLogin > #STARTDATE
```

#ENDDATE

This displays a calendar picker on view and returns a date. This defaults the current day and truncates the hours and minutes to 11:59 PM.

Example: display all users who have logged on a certain date:

```
SELECT
  Domain,
  Username,
  LastLogin
FROM tbUser
  LEFT JOIN tbDomain ON tbUser.DomainId = tbDomain.DomainId
WHERE
  LastLogin > #STARTDATE
AND
  LastLogin < #ENDDATE
```

#USER

This displays a user dropdown list with all active users on view and returns an user id. This defaults to the current logged in user.

Example: display all audit entries for a certain user:

```
SELECT
  tau.UserIdAffected,
```

```
  tau.[Action],
  tau.Notes,
  tau.DateRecorded,
  tau.IpAddress,
  tau.MachineName,
  tau.DatabaseName,
  tu.UserId,
  tu.UserName
FROM tbAuditUser tau INNER JOIN tbUser tu ON tau.UserId=tu.UserId WHERE tu.UserId=#USER
```

#ORGANIZATION

This is an internal parameter that returns the current instance's organization code. This is only useful for Secret Server Online (a legacy product, which is *not* the same as Secret Server Cloud). Do not use this parameter in your reports for either Secret Server On-Premises or Secret Server Cloud.

#GROUP

Displays a group dropdown list with all active groups on view and returns a group id. This defaults to the All Vault Users group.

Example: display the group details of the selected group:

```
SELECT
  GroupID,
  GroupName,
  Active
FROM tbGroup
WHERE GroupID = #GROUP
```

#FOLDERID

Displays a folder picker that shows all Folders and returns a folder id.

Example: Display secret names in a selected folder:

```
SELECT
  s.SecretName
FROM tbSecret s
WHERE s.Folderid = #FOLDERID
```

#FOLDERPATH

Displays a folder picker that shows all folders and returns the path of the folder.

Example: display folders that are child folders of the selected path:

```
SELECT *
FROM tbFolder f
WHERE FolderPath LIKE '%' + #FOLDERPATH + '%'
```

#CUSTOMTEXT

Displays a text input where a user can put in arbitrary free text for searching.

Example: display secrets that have names that contain the text input:

```
SELECT *
FROM tbFolder f
WHERE FolderPath LIKE '%' + #CUSTOMTEXT + '%'
```

Additional Parameters

The following additional parameters can be used to make your report more dynamic:

Parameters

Table: Additional Parameters

Parameter Name	Description
#ENDCURRENTMONTH	The last day of current month
#ENDCURRENTYEAR	December 31st of the current year
#ENDPREVIOUSMONTH	The last day of the previous month at 11:59:59 PM
#ENDPREVIOUSYEAR	December 31st of the previous year
#ENDTODAY	End of today at 11:59:59 PM
#ENDWEEK	End of the current week (Sunday) at 11:59:59 PM
#ENDYESTERDAY	End of Yesterday at 11:59:59 PM
#STARTCURRENTMONTH	The first day of current month
#STARTCURRENTYEAR	January 1st of the current year
#STARTPREVIOUSMONTH	The first day of the previous month at 12:00 AM
#STARTPREVIOUSYEAR	January 1st of the previous year

Parameter Name	Description
#STARTTODAY	Beginning of today at 12:00 AM
#STARTWEEK	Beginning of the current week (Monday) at 12:00 AM
#STARTYESTERDAY	Beginning of yesterday at 12:00 AM

Example

For example, the following script would give you a list of all users who have logged on during the last calendar month:

```
SELECT
  Domain,
  Username,
  LastLogin
FROM tbUser
  LEFT  JOIN tbDomain ON tbUser.DomainId = tbDomain.DomainId
WHERE
  LastLogin BETWEEN #STARTPREVIOUSMONTH AND #ENDPREVIOUSMONTH
```

As of Secret Server 7.8.000048, the #STARTWEEK and #ENDWEEK parameters are available.

Coloring Your Reports

Another option when creating reports is to include a Column in your SQL query called "Color" this will give the row that particular color. See HTML Color Names.

For example, to show users who haven't logged in within 90 days in Red:

```
SELECT DisplayName
  CASE
    WHEN LastLogin < GetDate() - 90 THEN 'Red'
    ELSE 'White'
  END AS Color
FROM tbUser
```

Viewing Auditing for a Report

To view auditing for all actions performed on a report, do the following:

1. Click Reports from the left navigation panel.
2. Click the report for which you wish to view an audit.

3. At the far right end of the page, click the button labeled **View Audit**. The audit information for the record appears in a pop-up message. For more information, See "Built-in Reports" on page 882

Viewing Reports

On this page you see the graph, chart, grid, and more for the report. To see a grid representation of the report, click the **Show Data** link to expand that area. If there is no data, then no graph is visible and the text "There are no items" displays in the Show Data section.

Some reports use dynamic values like user, start date, and end date. Adjust these values to generate the report you need. Click the **Update Report** button to generate the new report.

The **Edit** button allows you to alter the report to fit your requirements. See the Creating and Editing a Reports topic for details.

RPC, Heartbeat, and Key Rotation

In Secret Server:

- Remote Password Changing (RPC) allows for automatic updating of remote account passwords when a secret expires. This ensures synchronization with domain password policies and enhances security by generating strong passwords ("RPC Overview" below).
- Heartbeat functionality verifies the validity of stored credentials by attempting to authenticate with the target system. This has the potential to flag any discrepancies and prevent out-of-sync credentials ("Heartbeat Overview" on page 1058).
- Key rotation, including SSH key rotation, involves regenerating and updating public and private key pairs and their passphrases, ensuring that keys remain secure and compliant with organizational policies.

RPC Overview

Remote Password Changing (RPC) allows secrets to automatically update a corresponding remote account. You can set secrets for automatic expiration, followed by automatic strong password generation and a remote password update to keep the subject accounts synchronized with Secret Server.

RPC allows Secret Server to rotate passwords to meet domain password policy requirements. In most cases, RPC is configured with the secret "auto change" setting set to true. This causes the secret to rotate the password as soon as it expires. The "auto change schedule" setting changes the password on a set schedule, rather than when it expires. This provides the ability to change passwords when network activity is lower. You have a choice of changing the password as soon as the schedule interval arrives or only after the secret expires *and* the interval arrives. It is important to choose a large enough interval to complete all your password changes, otherwise any excess changes will have to wait for the next interval. Because the smallest interval is one day, this is only relevant if you have thousands of changes. If Secret Server fails to change a remote password, an alert states there are secrets out of sync.

You can pair secrets with Secret Server checkout, which is Delinea's one-time password functionality (not the same as "TOTP" on page 457). This allows you to rotate the password on a particular expiration schedule and limit the password to a single user for a set time period, after which it is changed. This is for situations where you need the

password to change after every use, such as vendors who need temporary access to a server or system. For additional security on sensitive systems, approval workflow or session recording can be paired with checkout to add layers of authentication to gain access to the secret and track how that secret is used.

Regardless of the timing of password change, you may want to rotate dependent resources (dependencies) right after you rotate the password on a secret. For example, a Windows domain account could be a service account that starts many windows services. In the event that you rotate that password, you would need to also rotate the password for this account on the services which start using that account. If you do not, starting those services will fail the next time they are restarted, which could cause other components to fail too. You can create dependencies on a secret for scheduled tasks, application pools, or services (with or without using PowerShell to undertake tasks at rotation time).

We have a large number of out-of-the-box RPC changers, which are expandable by writing your own SSH, SQL or PowerShell scripts to do RPC, which can get information from the secret. See "Secret Dependencies for RPC" on page 930 and the "Password Changer List" on page 904.

Custom Password Changers

The Password Changers Configuration page can be accessed by navigating to **Admin > Remote Password Changing > Configure Password Changers**.

There are a few password changing types that allow the user to enter in specific commands that are sent to the computer where the password is changing. This enables the system to accommodate for differences in the standard password change procedure. For example: The Unix system that is being changed prompts for the current password twice instead of only once before asking for the new password.

Creating a Custom Password Changer

> Before attempting to change a password through Secret Server using your new custom password changer, we recommend that you test the command set you are using.

> Any term in these commands preceded by `$` will reference a secret template field. Any term preceded by `$[1]$` refers to the Secret template field of a linked Secret. If you need to reference a secret template field, make sure you are using the exact secret template field name.

> To use your new password changer, you will need to assign it to a secret template.

To create a custom password changer, follow the procedure below.

1. Go to **Remote Password Changing > Password Changers** in the **Settings** menu. The Password Changers page appears.
2. Click the **Create Password Changer** button. A New Password Changer popup appears.
3. Choose a **Base Password Changer** with a command set that most closely matches the type of password changer you are creating, as this determines which customizable parameters and test actions are available to you. To create a custom SSH password changer, choose a base password changer with a name that ends in `(SSH)`.

4. Give your new password changer a **Name** and click **Save**. The page for the new changer appears.
5. Click the **Custom Commands** tab.
6. Click the **Edit** button.
7. Click the **Script** tab for the **Password Change Commands** section.
8. Edit the **Password Change Commands** to contain the command set you need.
   - Use the Delete button (trash can) to remove a row.
   - Click and drag the dots on the left to move a row.
   - Click the **+ Add Command** button to create a new row.
9. Edit the **Verify Password Changed Commands** to create the command set for checking that the password is valid. These commands are used by heartbeat and after a password change to verify that the change was successful.
10. Using the same procedure, change the commands as desired in the under **Post Successful Change Commands** and **Post Failure Change Commands**.
11. When you are finished editing the commands, scroll to the bottom and click **Save**. To edit advanced commands and settings, see the instructions below.

Advanced Settings

To modify advanced settings, do the following:

1. Go to **Remote Password Changing > Password Changers** in the **Settings** menu. The Password Changers page appears.
2. Click the name of the desired password changer. Its page appears, set to the General tab.
3. Click the **Edit** button.
4. Adjust the settings as desired:
   - **Remote Password Changing Timeout (minutes)**:
     Type: Integer (minutes)
     What it does: Sets the timeout (in minutes) used by the password changer when changing a password remotely.
   - **Bypass Verify After Password Change**:
     Type: Boolean (enable/disable)
     What it does: When enabled, bypasses the Heartbeat verification check after a successful password change. Note: Bypassing verification can lead to issues.
   - **Heartbeat Unknown Error–Unable to Connect Translation (regex)**:
     Type: Regular expression
     What it does: Provides a regex used to reclassify an Unknown Error as "Unable To Connect" based on the contents of the error message.
   - **Attempt Password Change with New Password When Error Contains (regex)**:
     Type: Regular expression (evaluated against the failure message)
     What it does: If an RPC password change fails, this regex runs against the failure message, which includes

a `FailureCode`. If the regex matches and the number of failed attempts is five or fewer, a new password is generated for the next password attempt. Only the **password** field is updated; no other fields are changed. Examples (copy/paste):

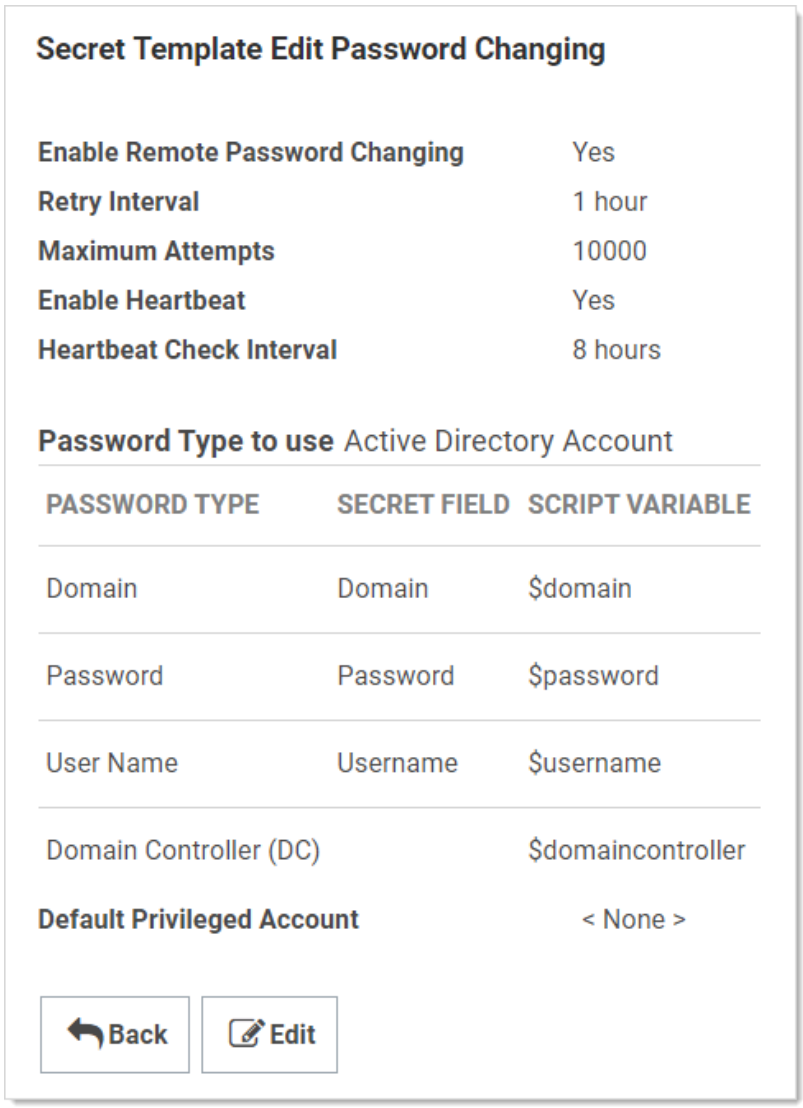
- `.*UnknownError.*` – Any error with `UnknownStatus`
- `.*` – Any error
- `.*minimum.*` – Minimum Password Requirements
- `.*0x80072035.*` – Server rejects password
- `.*(0x80072035|minimum).*` – Match either of the two above

- **Advanced: Delay Verify After Password Change (seconds)**:
  Type: Integer (seconds)
  What it does: Sets how many seconds to wait after a password has been changed before verifying the password.
  Limits/Defaults: Max: 90 seconds; Default: blank.

5. Click the **Save** button.

Mapping Account Fields for Custom Templates Using RPC

All the secret templates with the prefix RPC have RPC configured by default. For creating a custom template that uses RPC it can be configured from the Secret Template Designer. **Enable Remote Password Changing** must be turned on for secrets created from the template to make use of this feature. Select the password type for the account and map the text-entry fields to be used for authenticating to the remote server. The secret fields must be mapped to the corresponding required text-entry fields based on the password change type. Do that in the **Secret Template Edit Password Changing** page for the secret template:



The **Retry Interval** text box is the amount of time that a secret waits before once again attempting to change a password after a password change is unable to succeed.

The **Default Privileged Account** text box is the secret that is set as the privileged account for all new secrets that are created with this secret template. Changing this does not affect any existing secrets.

General Information

Privileged Accounts and Reset Secrets and Password Changer List.

Password Changer List

Overview

Secret Server includes many pre-configured password changers that are used by Remote Password Changing (RPC). The following are commonly used password changers, and the list is always growing.

To see the latest list, go to Admin > RPC > Configure RPC.

Secret Server can use scripted password changers for devices that support SSH or Telnet (this allows for flexibility in changing passwords on less common devices). You can also run custom RPC PowerShell scripts to conduct password changes to other platforms.

The AD password changer has an RPC "timeout minutes" advanced setting. This setting only applies when using "Password Change By Admin Credentials."

List

The following are the current built-in password changers (click the link to see the supporting secret template's page, if available):

- "Microsoft AD Secret Template for RPC" on page 970
- Active Directory LDS
- AD LDS
- Amazon IAM Console Password Privileged Account
- Amazon IAM Key
- AS/400 IBM iSystem
- Azure AD
- Blue Coat Account Custom (SSH)
- Blue Coat Enable Password Custom (SSH)
- Cisco Account Custom (SSH)
- Cisco Account Custom (Telnet)
- Cisco Enable Secret Custom (SSH)
- Cisco Enable Secret Custom (Telnet)
- Dummy PowerShell Changer
- Entra ID
- ESX/ESXi (API)
- F5 BIG-IP Root Account (SSH)
- Generic Discovery-Only Credentials
- Generic ODBC (DataSource)
- Generic ODBC (PostgreSQL DataSource)
- Generic ODBC (SQL DataSource)
- Google IAM Service Account Key

- HP iLO Account Custom (SSH)
- IBM iSeries Mainframe
- Juniper Account Custom (SSH)
- LDAP (Active Directory)
- LDAP (DSEE)
- LDAP (OpenLDAP)
- MySQL Account
- New Cisco PW Changer
- New PW Changer
- "Okta Secret Template for RPC" on page 972
- Oracle Account
- Oracle Account (AS SYS)
- Oracle Account (DataSource)
- Oracle Account (TCPS)
- Oracle Account (Template Ver 2)
- PostgreSQL Account (x64)
- Powershell Secret Template for RPC
- PowerShell Script **
- SAP Account**
- "ServiceNow Template for RPC" on page 978
- Snowflake Secret Template for RPC
- SonicWall NSA Web Admin Account
- SonicWall NSA Web Local User Account
- SQL Server Account
- SSH Key Rotation **
- SSH Key Rotation (No Password) **
- SSH Key Rotation Privileged Account **
- SSH Key Rotation Privileged Account (No Password) **
- Sybase Account
- Teradata
- Unix Account (SSH)
- Unix Account (Telnet)
- Unix Account Custom (SSH)

- Unix Account Custom (Telnet)
- Unix Account SU Takeover (SSH)
- Unix Account SUDO Takeover (SSH)
- Unix Root Account Custom (SSH)
- WatchGuard Custom (SSH)
- Websphere Account
- Web User Account (built-in support for AWS, Google, Salesforce)
- Windows Account
- Workday
- z/OS Mainframe
- z/OS Mainframe (Priv Account)

* Does not require an Advanced Scripting Add-On License. Will require PowerShell installation.

** Professional Edition add-on/Platinum Edition only

Other platforms that Secret Server can change passwords on include:

- AS/400
- Linux / Mac
- Check Point
- Enterasys
- Dell DRAC (May require Pro Services, and is not covered by Delinea Support).

Privileged Account Credentials and Associated Secrets

By default, the Remote Password Changer (RPC) uses the credentials stored within a secret to initiate a password change. For Windows and Active Directory accounts, you can opt to use a privileged account by selecting the **Privileged Account Credentials** option. This allows you to choose an Active Directory secret that has the necessary AD permissions to change the account's password.

> The privileged account secret must have Remote Password Changing (RPC) enabled in its template for it to be eligible to perform password changes. Without RPC enabled, assigning the account will appear successful, but password change operations will fail.

For secret templates that use a custom command password type, you can assign multiple **Associated Secrets** for use within the custom commands.

When a secret is linked with Privileged Account Credentials or Associated Secrets, editing the username, host, domain, or machine is restricted for users who do *not* have access to those linked secrets. In the **Remote Password Changing** tab, users without access will see the message **This Secret references another Secret for Remote Password Changing to which you do not have access. You will not be able to edit some fields on this Secret**.

Additionally, on the **Edit** page, all text-entry fields mapped for RPC, except for the password, are disabled. This added layer of security prevents unauthorized users from altering the username and resetting another account's password.

> To support both dashboard visibility and password change operations, privileged account secrets must have RPC enabled in their originating template or the Active Directory secret.

> If you attempt to use a secret that has checkout enabled as a Privileged Account on another secret, that second secret's password change will fail with an error that indicates that the associated secret has checkout enabled.

RPC Procedure

Various procedures related to RPC.

Automatic Remote Password Changing

The Remote Password Changing tab contains the settings for configuring RPC on an individual secret. Enabling RPC *auto change* on a secret allows Secret Server to remotely change the password when it expires. The user must have owner permission on the secret to enable auto change.

> If the password change fails, Secret Server flags the secret as out of sync and continue to retry until it is successful. If the secret cannot be corrected or brought In sync, manually disabling auto change stops the secret from being retried.

Auto Change Schedule

To set Autochange schedule, on a secret page, under the Remote password changing tab, click Edit in the RPC / Autochange section and check to select Auto Change Enabled.

The Auto Change Schedule section, which appears when you set the Auto Change Schedule list box to other than "When password expires," allows you to specify an interval (daily, weekly, or monthly), start date, start time, and time frame (interval count) for when the password can be changed.

This setting is useful for having the RPC occur during off-hours in order to prevent disruptions. By default, this setting is "When password expires," which allows the secret to be changed immediately upon expiration.

> There is a check box in the auto change schedule settings labeled "Only change password if the secret is expired." When it is enabled, auto change will not change the password until after the secret expires. The auto change occurs on the first scheduled time after the secret expires. If the box is unchecked, auto change occurs on the defined schedule, whether or not the secret has expired.

> While the password change is waiting for this next scheduled time, the RPC Log (visible by navigating to **Configuration > Remote Password Changing**) reports the secret could not be changed because of a time schedule. The secret also remains expired until this auto change schedule is reached, even if the secret was forced to expire.

Understanding Expiration, Auto Change and Auto Change Schedules

Definition

What is the difference between expiration, auto change and auto change schedules?

- **Expiration**: sets whether or not a secret in Secret Server is marked as expired and the period Secret Server counts down before marking the secret as expired.
- **Auto Change**: sets Secret Server to automatically initiate a password change after a secret expires.
- **Auto Change Schedule**: sets the day and time to initiate the password change after the secret has expired. This cannot be configured without also enabling Auto Change.

Examples

Some examples to illustrate this:

Scenario One: Expiration with Auto Change and No Auto Change Schedule

- A Secret has an expiration period of 30 days, and auto change is enabled. No auto change Schedule has been set.
- At the end of the 30-day expiration period, the secret will expire.
- Immediately after the secret expires, it will be queued for a password change.
- Once the password has been changed, the secret is no longer marked as expired and expiration is reset to count down again from 30 days.

Scenario Two: Expiration with Weekly Auto Change

- A secret has an expiration period of 30 days, auto change is enabled, and an auto change schedule is configured for Weekly, recurring once a week on on Tuesday, changing at 0300.
- At the end of the 30-day expiration period, the secret will expire.
- Immediately after the secret expires, Secret Server will comply with the auto change schedule to determine when a password change occurs.
- The secret is queued for a password change as soon as it becomes 0300 on a Tuesday.
- Once the password is changed, the secret is no longer marked as expired. Expiration is reset to count down again from 30 days.

Scenario Three: Expiration with No Auto Change

- A Secret has an expiration period of 30 days, and auto change is not enabled.
- At the end of the 30-day expiration period, the secret expires.
- The secret remains expired until the field it applies to (usually the password field) is updated on the secret. This happens by manually updating the field or by using the "Change Password Remotely" button on the Remote Password Changing tab of the secret.

- Once the password is changed, the secret is no longer be marked expired, and expiration is reset to count down again from 30 days.

Important Considerations and Best Practices

- If you want to rely strictly on expiration for password changing, enable auto change but set the schedule to none. Leave "Only change password when Secret is expired" checked.
- If you want to set an auto change schedule to run daily at a specific time, the change will only happen at maximum once per day at that given time. If a change happens already within that same day for the same secret, you cannot adjust the auto change schedule to run later within the same day and then have a password change occur again within that same 24-hour period. For example, if the password was already changed earlier in the day. The schedule is then adjusted to run a few minutes later within the same day. In that case, another password change will not occur until 24 hours has passed since the last change.
- If you set the auto-change schedule to run once per week, for example, on a Thursday, and "Only change password when secret is expired" is checked. Even if the secret expires on a Monday, a password change would not occur until the secret has expired and the scheduled time on Thursday has passed.
- If you set the auto change schedule to run once per week on a Thursday and "only change password when Secret is expired" is not checked, the password would be changed every Thursday, regardless of the secret's expiration status.
- If a secret has an expiration period but auto change is not enabled, no password change occurs automatically. The expiration would only update when the password is manually updated or a remote password change is manually triggered through Secret Server.
- If you want to change a password more frequently than once per day, we recommend using some of the advanced security features at the secret level or controlling the change through a secret policy. Use the check out feature combined with "Change Password on Check In" on the Security tab of a Secret. You can specify a custom interval to check out the secret. After the password check out interval expires or a user manually checks in the secret, the password is automatically changed.

For the configuration above, ensure that these accounts have a password-related group policy in Active Directory that specifies that the "Minimum Password Age" is set to 0. We recommend creating fine-grained password policies to achieve this. Add all the accounts that need rotation more frequently than once per day to an AD security group assigned to the fine-grained password policy. See Password and account lockout policies on Azure Active Directory Domain Services managed domains for more information.

Assigning a Password Changer to a Secret Template

To assign any type of password changer to a Secret template, use the procedure below.

1. Search for **Secret Templates**. The Secret Templates page appears.
2. Click the name of the desired template in the list. The page for that template appears.
3. Under the **Mapping** tab, click **Edit** next to the **Password Changing** section. The section becomes editable
4. Click to select the **Enable remote password changing** check box. An editable section appears.

> This enables the feature, but auto RPC is set through policies or secret settings.

Specify the following:

- **Remote password changing max attempts**: The maximum number of times that Remote Password Changing will be attempted after failures.
- **Remote password changing interval days**: The amount of time in days in between each remote password changing attempt.
- **Remote password changing interval hours**: The amount of time in hours in between each remote password changing attempt.
- **Remote password changing interval minutes**: The amount of time in minutes in between each remote password changing attempt.
- **Enable heartbeat**: Enables heartbeat capability on Secrets of this template and features that support heartbeat.
- **Password type to use**: Password type to use for RPC and Heartbeat. For this instruction, we chose Active Directory Account. New controls appear for that specific type.

5. Click to select or type text for each item to configure your desired setup. For more on configuring your choice, refer to the applicable configuration in the "RPC Overview" on page 900 section for details. For example, for Active Directory, go to "Configuring Delegation Control for the Administrative Account" on page 1015.
6. When finished, click the **Save** button.

Changing Ports and Line Endings

To change the port or line ending used on a password changer, click the password changer on the **Configure Password Changers** page and then click **Edit**. There, you can choose the line ending and port used by the device. By default, line endings are set to New Line (\n), however some devices and applications (such as HP iLO) use a different line ending system. The port defaults to 22 for SSH connections and 23 for Telnet connections.

For the built in Windows password changer there is a ports text-entry field available that can be filled in to help ensure a computer is listening. This can be used if DNS returns multiple IP addresses for a single box and only one is valid. For example, a laptop might get two IP addresses for an Ethernet and wireless connection, but if it is unplugged the Ethernet IP is invalid. In this case, Secret Server can do a reverse lookup and test each IP until it is able to connect on one of the specified ports. When it gets a response, it uses that IP for the password change.

Creating RPC Scripts

PowerShell scripts, SSH scripts, and SQL scripts for password changing (PowerShell only), dependencies, and discovery custom actions can be created by administrators with the role permission called Administer Scripts. The scripts can be accessed by going to **Administration > Remote Password Changing > Scripts**.

> Secret Server requires that WinRM is configured on the Web server. For instructions please see "Configuring WinRM for PowerShell" on page 1500.

Creating Scripts

On the **Scripts** screen, select desired script tab and click **Create New** to enter the name of the script, a description, and the commands to run, then click **OK**. The script now shows up in the grid. Scripts can be deactivated and reactivated from the grid.

Testing Scripts

All scripts run from the machine that Secret Server is installed on, or the site assigned to the secret. To test a script, click the **Test** button on the grid next to the corresponding script.

PowerShell scripts run as the identity of the secret, so enter in an Active Directory credential to run the script as or select a secret to pre-fill the run-as credentials. Then enter in any command line arguments that the script requires. The output of the script is displayed above the grid for debugging purposes. To test the script over an engine, select a site from the **Site** list. This helps in diagnosing server specific issues where engines are installed.

Using Scripts

To use a script as a password changer or Dependency, it must be wired up to the appropriate action under **Admin > Remote Password Changing** on the password changer or dependency changer.

Discovery scripting is done under **Admin > Discovery > Extensible Discovery**. For more information on configuring extensible discovery see "Extensible Discovery" on page 584.

Viewing Audits

A full history of each PowerShell script is kept and can be downloaded from the audit trail. Click **View Audit** to view the audit trail for PowerShell. Each time a script is updated, the previous one can be downloaded from the corresponding audit record.

For additional information on setting up PowerShell scripts, please read the following topic: "Creating and Using PowerShell Scripts" on page 1496.

Deactivating Password Changers

To make a password changer unavailable for use and to hide it from view in your list of password changers, you must mark it inactive:

1. From the **Password Changers Configuration** page, click the password type name of the password changer you would like to make inactive.
2. Click **Edit**.
3. Uncheck the **Active** box.
4. Click **Save**.

To view inactive password changers, check the **Show Inactive** box at the bottom of the list of password changers. The Active column in the table indicates the status of the password changer.

Enabling RPC

RPC is enabled under the Administration, Remote Password Changing page. Click **Edit** to enable RPC, secret heartbeat, and secret checkout. Once enabled, all secret templates with RPC configured are available to use with RPC.

Migrating Secrets from Azure AD to Entra ID RPC

Microsoft is retiring the Azure AD PowerShell module that powers our Azure AD remote password changer. Thus, you must migrate any secret templates using that password changer to the Entra ID changer to maintain functionality. You also must set privileged accounts for all secrets based on that template.

To accomplish this:

1. Go to the **Secret Template** page for the template you want to change via the **Settings** page.
2. Click the **Mapping** tab.
3. Click the **Edit** button.
4. Click the **Password type to use** dropdown list and select **Entra ID Password**. The Password type fields appear.
5. Ensure the fields are set to **Domain**, **Username**, and **Password**.
6. Click the **Save** button.
7. Go to the **All Secrets** page (Secrets > All Secrets).
8. Click to select the secrets based on the template you just changed.
9. Click the **Bulk Actions** button. The bulk action choices appear.
10. Click **Set Privileged Account** link in the **Remote password changing** section. The Set privileged account section appears.
11. Click to select the **Privileged account credentials** selection button.
12. Click the **No secret selected** link. The Select Secret popup appears.
13. Select a secret that uses the Azure Application Registration template.

    The Entra ID template has OAuth App Registration extended mapping by default. You can also choose to use a custom template, but make sure that it also has the OAuth App Registration extended mapping.

14. Click the **Confirm Action** button.
15. If you need different privileged accounts for different secrets, select all the secrets for each privileged account and repeat the bulk operation described above.

Modifying Password Changers

To modify a password changer, click the password changer name under **Admin > Remote Password Changing > Configure Password Changers** and then use the **Edit** or **Edit Commands** buttons to make changes. For more information about editing the custom PowerShell password changer, see "Running RPC with PowerShell" on page 915.

You can find the full, up-to-date list of password changers included with Secret Server by default in "Password Changer List" on page 904.

Running a Manual RPC

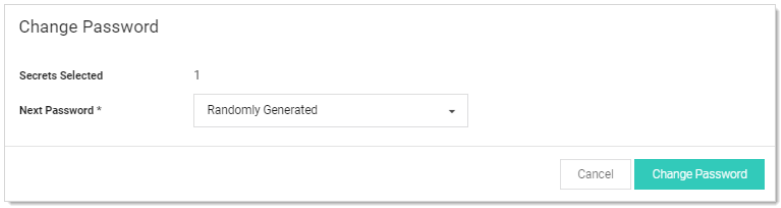
On the RPC tab there is a button called Change Password Remotely button that allows the use to change the password immediately instead of waiting for it to expire. When this button is clicked the user is taken to the Change Password Remotely page where they can enter in or generate the new password for the account. When the user clicks the Change button the secret enters the queue for having its password changed. The RPC Log found on the Remote Password Changing page details the results of the password change attempts and can be used for debugging.

If the secret is a Unix or Linux account and uses a password changer that supports SSH key rotation, the user can change the account's password, public and private keypair, and the private key passphrase. The user can enter or generate any of these items.

If the password change fails, Secret Server continues to retry until it is successful, or the change is canceled by the user. To manually cancel the change, click Cancel Password Change on the RPC tab.

To run a manual RPC:

1. From **Dashboard**, click its check box to select secret you want to test.
2. Click the Change Password Remotely button. The Change Password popup page appears:



3. Click to select the **Next Password** dropdown list and select **Manual** or **Randomly Generated**. If you chose manual:
   a. The Password text box appears.
   b. Type the new password in the **Password** text box.
   c. Click the **Change Password** button.

   Otherwise, click the **Change Password** button. The password change is now queued.
4. You can verify that the password change completed either by unmasking the password on this screen (click the lock icon beside the password field) or by looking at the **Remote Password Changing** log. You can find the Remote Password Changing log by going to **Admin > Remote Password Changing**.

Running RPC with PowerShell

Overview

Secret Server supports running PowerShell scripts for Remote Password Changing (RPC) and heartbeat. Below are the steps for creating an Active Directory (AD) password changer that uses PowerShell scripts. The example is meant as a simple guide for how to wire-up the template to scripts as a proof of concept. Your actual PowerShell password changer scripts may be more complex depending on your environment and needs.

> Before you begin, please ensure password changing and heartbeat are enabled in **Admin > Remote Password Changing** and review the information on "Configuring CredSSP for WinRM with PowerShell" on page 1502, which will be necessary for most PowerShell password changing tasks.

> Do not use quotation marks (") in passwords for PowerShell scripts for RPC. Quotation characters are dropped from passwords when passing the $PASSWORD token to a custom password changer PowerShell script, resulting in an authentication failure.

Procedure

The PowerShell scripts are created and accessed through the **Admin > Scripts** page. To create a PowerShell password changer, you need to create two scripts. The first script verifies the account's current password. The second script changes the account's password. These two scripts are linked to a new secret template.

Task 1: Creating the Active Directory Verify Password Script

1. Search for **Scripts**.
2. Click the **+Create New** button on the **PowerShell** tab.
3. Type the following information in the dialog:
   - **Name**: Active Directory Verify
   - **Description**: Script used to verify an Active Directory account
   - **Category**: Heartbeat
   - **Script**:

```
$domain = "LDAP://"+$Args[0];
$dn = New-Object System.DirectoryServices.DirectoryEntry($domain, $Args[1], $Args[2]);
if ($dn.name -eq $null){ throw "Authentication failed - please verify your username and
password." };
```

4. Click the **OK** button to save the script.

Task 2: Creating the Active Directory Change Script

1. On the **PowerShell** tab, click the **+ Create New** button.
2. Type the following information in the dialog:

- **Name**: Active Directory Change
- **Description**: Script used to change the password of an Active Directory account
- **Category**: Password Changing
- **Script**:

```
$Domain = $args[0]
$UserToChange = $args[1]
$NewPassword = $args[2]
$P_User = $args[0] + "\" + $args[3]
$P_PWord = ConvertTo-SecureString -String $args[4] -AsPlainText -Force
$Creds = New-Object -TypeName System.Management.Automation.PSCredential -ArgumentList $P_
User, $P_PWord
$pwd = ConvertTo-SecureString $NewPassword -AsPlainText -Force;
Set-ADAccountPassword -Server $Domain -Identity $UserToChange -NewPassword $pwd -Reset -
Credential $creds
```

3. Click the **OK** button to save the script.

Task 3: Testing the Scripts

For the AD verification script:

1. Go to **Scripts > PowerShell tab**.
2. Click the Run Script arrow icon on the AD verify script. The Test Script popup appears.
3. Type the arguments (separated by spaces) in the **Arguments** text box: domain name (for you), username (yours), password (yours). For example: `my.company.com ssadmin FD#@789Uik4$`
4. Type your domain name for the script-running account in the **Domain** text box.
5. Type the username in the **Username** text box for account that can run PowerShell scripts on the domain.
6. Type that user's password in the **Password** text box.
7. Click the **OK** button to test your script the with provided parameters.

For the Active Directory change script:

1. Go to **Scripts > PowerShell tab**.
2. Click the Run Script arrow icon on the AD change script. The Test Script popup appears.
3. Type the arguments (separated by spaces) in the **Arguments** text box: domain name (for you), username (yours), new password (yours), domain admin username, domain admin password. For example: `my.company.com ssuser O8sSKthsoidPW ssadmin FD#@789Uik4$`
4. Type your domain name for the script-running account in the **Domain** text box.
5. Type the username in the **Username** text box for account that can run PowerShell scripts on the domain.
6. Type that user's password in the **Password** text box.

7. Click the **OK** button to test your script the with provided parameters.

> If successful, this will change the password on the account that is used for testing.

The remaining steps depend on the version of Secret Server you are using. In Secret Server 10.0.000006 we introduced the ability to create multiple PowerShell password changers, each with their own set of password change and verify scripts. These password changers can be assigned to different scan templates to automatically assign different PowerShell password changer scripts to different types of local accounts when creating local account import rules in discovery. For more information about how scan templates and password changers are used in discovery and local account import rules, please see "Discovery Overview" on page 534. Prior to 10.0.000006, there was only one PowerShell password changer and the scripts were assigned on the secret template.

Task 4: Configuring a Password Changer for Secret Server Version 10.0.000006 and Later

In Secret Server versions 10.0.000006 and later, after the scripts are tested and working correctly, the next step is to create a PowerShell password changer.

1. Search for **Remote Password Changing**.
2. Click the **Configure Password Changers** button.
3. Click the **New** button.
4. In the **Base Password Changer** dropdown list, select **PowerShell Script**.
5. Type the name of the new password changer.
6. Click the **Save** button. On the next page you will select the scripts to use for password changing and verification (heartbeat).
7. Under **Password Change Commands**:
   a. Select the script that you created to do password changes.
   b. Type the following in the **Script Args** text box: `$DOMAIN $USERNAME $NEWPASSWORD $[1]$USERNAME $[1]$PASSWORD`
   c. Click the **Save** button next to the **Script Args** text box.
8. Under **Verify Password Changed Commands**:
   a. Select the script that you created to do heartbeats and verification.
   b. Type the following in the **Script Args** field: `$DOMAIN $USERNAME $PASSWORD`
   c. Click the **Save** button next to the **Script Args** text box.

> When Secret Server runs the script, it replaces the fields with the matching secret field values. `$NEWPASSWORD` is a special case for the new password that is generated by Secret Server or specified by the user when performing a password change. For more information see "Using Secret Fields in Scripts" on page 1516.

You must specify scripts for both sections and you must click the Save button next to each one for both to save.

Task 5: Creating a Secret Template

The next step is to create the secret template:

1. Search for **Secret Templates**.
2. Click the **Create New** button.
3. Name the template `PowerShell Active Directory`.
4. Create the following new fields:
   - Domain Field Type: Text
   - Username Field Type: Text
   - Password Field Type: Password
   - Notes Field Type: Notes
5. Click the **Configure Password Changing** button.
6. Click the **Edit** button.
7. Click to select the **Enable Remote Password Changing** and **Enable Heartbeat** checkboxes.

Task 6a: Finishing the Secret Template Configuration for Secret Server 10.0.000006 and later

Complete either 6a or 6b, not both.

1. Select the password changer created in the previous section from the **Password Type to use** dropdown list.
2. Click to select **Domain** next to the **Domain** field.
3. Click to select **Username** next to the **User Name** field.
4. Click to select **Password** next to the **Password** field.
5. Click the **Save** button to save the mapping.

Task 6b: Finishing the Secret Template Configuration for Secret Server 8.8.000000 to 10.0.000000

Complete either 6a or 6b, not both.

1. Select **PowerShell Script** from the **Password Type to use** dropdown.
2. Click to select **Domain** next to the Domain field.
3. Click to select **Username** next to the User Name field.
4. Click to select **Password** next to the Password field.
5. Click to select **Active Directory Change** next to the **Remote Password Change Script** field.

6. Enter the following to the **Remote Password Change Args** field: `$DOMAIN $USERNAME $NEWPASSWORD $[1]$USERNAME $[1]$PASSWORD`.
7. Click to select **Active Directory Verify** next to the **Heartbeat Script** field.
8. Type the following next to the **Heartbeat Args** field: `$DOMAIN $USERNAME $PASSWORD`.

   When Secret Server runs the script, it replaces the fields with the matching secret field values. $NEWPASSWORD is a special case for the new password that is generated by Secret Server or specified by the user when performing a password change.

9. Click the **Save** button to save the mapping.

Task 7: Creating Secrets Using PowerShell Remote Password Changing

Create the AD account secret PowerShell account:

1. Create three secrets (The first two **must** be different secrets):
   - One that is an Active Directory Account that has the necessary rights to run PowerShell on your domain
   - One that is an Active Directory Account that has the necessary rights to run a password change on your domain
   - One that is based on the new PowerShell Active Directory Template.
2. Create the Active Directory account secret PowerShell account.
3. On the dashboard, use the dropdown on the **Create Secret** widget and select **Active Directory Account**. Use the following parameters:
   - **Secret Name:** PowerShell Admin
   - **Domain:** Domain that the account exists on
   - **Username:** Account name that can run PowerShell scripts in the domain
   - **Password:** Password for the account
4. Click the **Save** button to save your secret and verify that it passes heartbeat.
5. Click the **Home** button to return to the dashboard.

Create the AD account secret for password changing:

1. On the dashboard, use the dropdown on the **Create Secret** widget and select **Active Directory Account**. Use the following parameters:
   - **Secret Name:** Password changing Admin
   - **Domain:** Domain that the account exists on
   - **Username:** Account name that can change passwords in the domain
   - **Password:** Password for the account
2. Click the **Save** button to save your secret and verify that it passes heartbeat.
3. Click the **Home** button to return to the dashboard.

Create the PowerShell Active Directory secret:

1. On the dashboard, use the dropdown on the **Create Secret** widget and select **PowerShell Active Directory Account**. Use the following parameters:
   - **Secret Name:** PowerShell AD user
   - **Domain:** Domain that the account exists on
   - **Username:** samAccountName of the account to be managed
   - **Password:** Password for the account
2. Click the **Save** button to save your secret and verify that it passes heartbeat.
3. Click the **Remote Password Changing** tab for the secret.
4. Click the Edit button.
5. Click to select **Privileged Account Credentials** in **Execute PowerShell**. The Privileged Account selector appears.
6. Click the **No Selected** Secret link.
7. Locate click on the **PowerShell Admin** secret.
8. Click the **Home** button to return to the dashboard.
9. In the **The following Secrets are available to be used in Custom Password Changing Commands and Scripts** section:
   a. Click the **No Selected Secret** link.
   b. Select your AD account secret for password changing.
   c. Click on the **Save** button.

Everything should now be configured for heartbeat and RPC on the Secret. Run **Heartbeat** (from the **General** tab in the Secret) to confirm that it works and run an RPC ** (from the **Remote Password Changing** tab of the secret) to confirm that it also works.

Errors

If you receive the "The term 'Set-ADAccountPassword' is not recognized as the name of a cmdlet, function, script file, or operable program. Check the spelling of the name, or if a path was included, verify that the path is correct and try again." error, install the AD-Domain-Services in PowerShell. To do this start PowerShell as an administrator then run the following command:

```
Install-windowsfeature -name AD-Domain-Services –IncludeManagementTools
```

Additionally you may need to install the Remote Server Administration Tools for your version of Windows and then in PowerShell run:

```
Import-Module Servermanager
```

Using RPC for Secrets with Shared Credentials

In most environments, we recommend using a separate password for each account for optimal security. However in environments where identical credentials are used in multiple secrets, we recommend using RPC to change the password on one primary parent account secret, and then using a PowerShell dependency script to update values in child secrets. The PowerShell script calls back to Secret Server's API, retrieves a list of comma-separated values

representing child secret IDs, and updates the values stored in the child secrets. We recommend using this process for no more than 25 child secrets.

Requirements

- A Secret Server instance version 10.1.000000 or newer with a premium add-on or Enterprise Plus
- A PowerShell implementation enabled and working properly. See "Configuring WinRM for PowerShell" on page 1500
- The PowerShell Wellness Checker

For this procedure you will need to create the four types of user accounts listed below, and for each account you will need to create a corresponding secret in Secret Server with the account's login credentials and other information.

Create the user accounts and secrets described below:

- An API User account and a corresponding secret. This API User account will NOT take up a user license. Recommended templates for the secret include the Active Directory template and the Web Password template. Credentials may be a local account or an Active Directory service account assigned to the Synchronization group, but must be stored in Secret Server to be passed to the PowerShell script.
- A primary parent account and a corresponding secret that has RPC set up and the PowerShell dependency script from this page attached. The primary parent account credentials may be either a local account or an Active Directory service account assigned to the Synchronization group.
- Child accounts with a corresponding secret for each account containing the child secret ID, with secret edit permissions granted to the API User account.
- A privileged Active Directory account and a corresponding secret that can run PowerShell on the Secret Server machine.

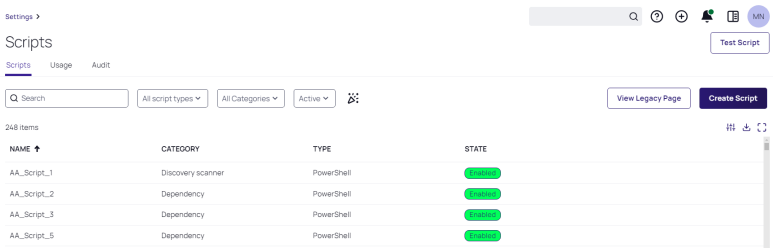
To create a new dependency changer for synchronizing passwords during RPC, first:

1. On the server that the script will be processed from, whether DEs or web nodes, download the WellnessChecker tool ZIP file.
2. Extract the ZIP file and run this command:

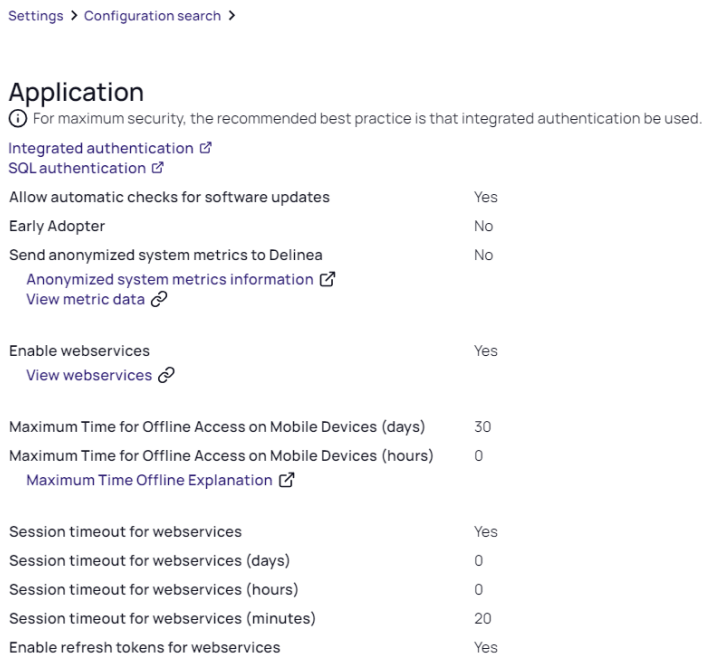
```
PowerShell.WellnessChecker.exe -fixerrors
```

Then follow the steps below:

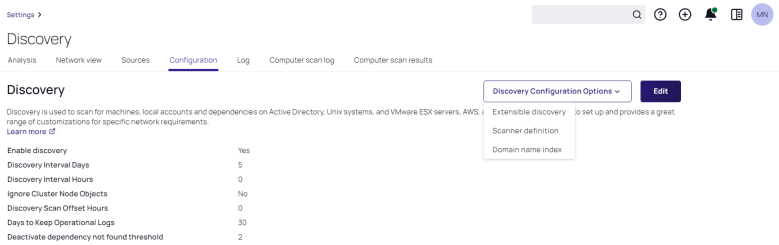
1. In Secret Server, browse to **Admin > Scripts**.
2. Click **Create Script**.



3. In the **New Script** dialog, fill in the fields for **Name** and **Description**, for the **Script Type** select **PowerShell** and specify**Category**.
4. Check **Enabled** next to the **State** option.
5. In the **Script** field, paste in the script provided at the bottom of this page.
6. Click **Save** at the bottom of the page to save the file.
7. Browse to **Admin > Application**, and make sure **Enable Webservices** is set to **Yes**.

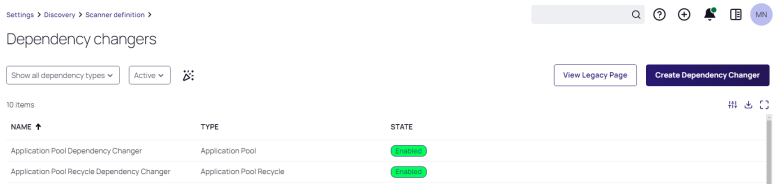


8. Browse to the primary parent account secret and ensure that RPC is setup on it.
9. In the primary parent account secret, click the **RPC** tab.
10. Click **Edit**.
11. In the secret grid at the bottom, select the API User account secret you created. The API User account secret should be the only secret in the grid.
12. Browse to **Admin > Discovery** and click the **Configuration** tab.
13. Click **Discovery Configuration Options** and select **Extensible Discovery** from the drop-down list.



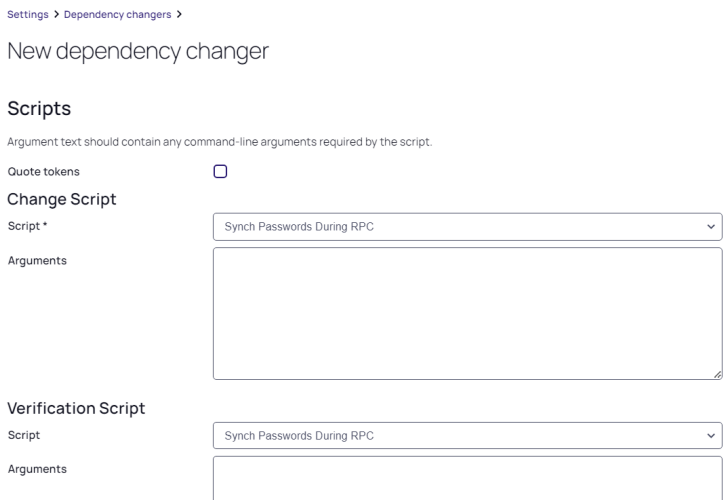
14. On the **Extensible Discovery Configuration** page, click **Configure Dependency Changers**.

15. On the **Secret Dependency Changers** page, click **Create Dependency Changer**.



16. In the **New Dependency Changer** dialog, enter the **Name**, check the **State** to **Enabled**, for **Dependency Type** select **PowerShell script**, for the **Scan template** select **Computer Dependency (Basic)**, check the **Create template** checkbox.

17. In the **Scripts** section below enter the related **Change Script**, **Verification Script**, **Change Success Script**, and **Change Fail Script**.



18. In the **Arguments** field, paste the following:

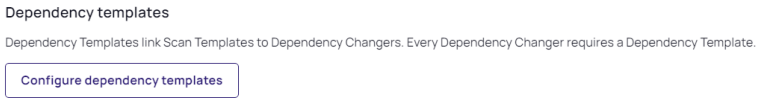
    `$[1]$USERNAME $[1]$PASSWORD $PASSWORD $NOTES $[1]$DOMAIN`

    The actions of the Arguments are as follows:

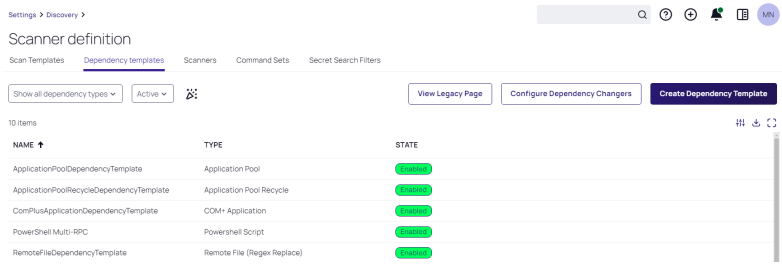
    - `$[1]$USERNAME` pulls the username from the privileged account on the primary parent account, which will be used to execute the PowerShell script.
    - `$[1]$PASSWORD` pulls the password from the associated secret on the primary parent account, which will be used to execute the PowerShell script.
    - `$PASSWORD` pulls the password from the primary parent account, which will be set for all secrets listed in the **Notes** field.
    - `$NOTES` pulls the **Notes** content from the primary parent account, and parses the comma separated list of secret IDs to find the other secrets to update.
    - `$[1]$DOMAIN` pulls the **Domain** field from the associated secret on the primary parent account. For local accounts, leave the **Domain** field on the associated secret empty. It must be listed last because of the way PowerShell parses empty fields.

    > The `$[1]$DOMAIN` argument is not needed for Platform service user.

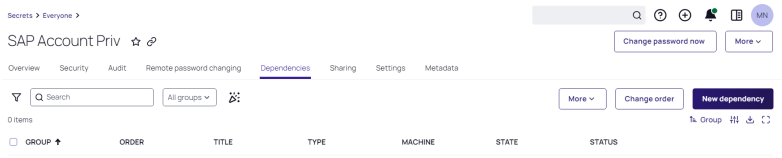
19. Browse back to the **Extensible Discovery Configuration** page and this time, click **Configure Dependency Templates**.



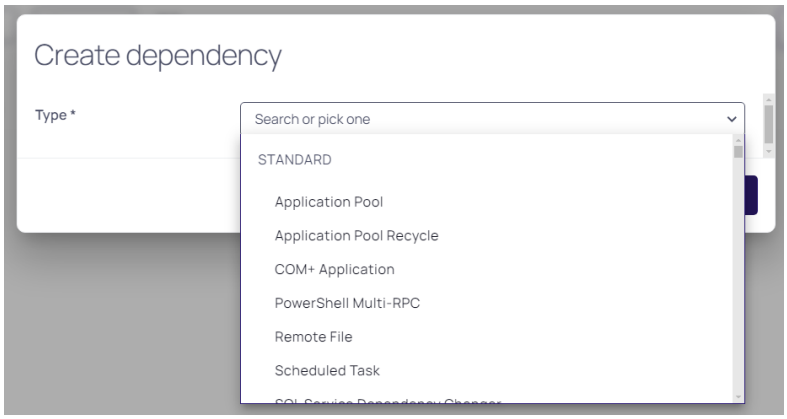
20. On the **Secret Dependency Templates Designer** page, select the new dependency changer you configured in the last step.



21. Browse to the primary parent account secret and click the **Dependencies** tab.
22. Click **New Dependency**.



23. In the **Create dependency** dialog, click the **Type** dropdown and select the PowerShell dependency template you created.



24. In the **Create dependency** dialog, select **Dependency group**, enter **New group name**, enter **New group site name**, enter **ServiceName**, check the **Enabled** checkbox, enter `default` in the **Machine Name** field, and click **Save**.
25. In the primary parent account secret's **Notes** field, ensure that the child secret IDs appear in a comma-separated-values list, for example `19,39,81...`

Now the dependency has been added and you can test the full process by running a remote password change on the primary parent account. All of the secrets listed by ID in the **Notes** field should be updated with the same password.

PowerShell Script

> Do not use quotation marks (") in passwords for PowerShell scripts for RPC. Quotation characters are dropped from passwords when passing the $PASSWORD token to a custom password changer PowerShell script, resulting in an authentication failure.

Replace $baseUrl with the name of the machine hosting your Secret Server instance.

REST API Script for Secret Server

```
$baseUrl = 'https://MySecretServerURL'
$apiUrl = "$baseUrl/api/v1"
$username = $Args[0]
$password = $Args[1]
$newpassword = $Args[2]
$secretIdArray = $Args[3]
$domain = $Args[4]
# Authentication - Get Access Token
$authUrl = "$baseUrl/oauth2/token"
$authBody = @{
 username = $username
 password = $password
 grant_type = 'password'
}
# Add domain if provided
if ($domain) {
 $authBody.domain = $domain
}
try {
 $authResponse = Invoke-RestMethod -Uri $authUrl -Method Post -Body $authBody -
ContentType 'application/x-www-form-urlencoded'
 $token = $authResponse.access_token
 Write-Debug "Authentication successful"
} catch {
 Write-Debug "Authentication failed: $($_.Exception.Message)"
 exit 1
}
# Set up headers for authenticated requests
$headers = @{
 'Authorization' = "Bearer $token"
 'Content-Type' = 'application/json'
}
# Process each secret ID
$secretIds = $secretIdArray -split ","
foreach ($secretId in $secretIds) {
 try {
 # Get Secret
 $getSecretUrl = "$apiUrl/secrets/$secretId"
 $secret = Invoke-RestMethod -Uri $getSecretUrl -Method Get -Headers $headers

 $secretName = $secret.name
 Write-Debug "Updating Secret: $secretName"
```

```
  # Find password fields and update them (matching original SOAP logic)
  foreach ($item in $secret.items) {
  if ($item.isPassword -eq $true) {
  $item.itemValue = $newpassword
  }
  }

  # Update Secret - pass the entire modified secret object
  $updateSecretUrl = "$apiUrl/secrets/$secretId"
  $updateBody = $secret | ConvertTo-Json -Depth 5

  $updateResponse = Invoke-RestMethod -Uri $updateSecretUrl -Method Put -Headers
$headers -Body $updateBody
  Write-Debug "Updated Secret: $secretName"

  } catch {
  Write-Debug "Error processing secret ID $secretId`: $($_.Exception.Message)"
  continue
  }
}
```

REST API Script for Platform

```
$platformTenant = "https://your-tenant.delinea.app"
$sscTenant = "https://your-tenant.secretservercloud.com"
$global:TOKEN_URL = "$platformTenant/identity/api/oauth2/token/xpmplatform"
$apiUrl = "$sscTenant/api/v1"
$global:CLIENT_ID = $Args[0]
$global:CLIENT_SECRET = $Args[1]
$newpassword = $Args[2]
$secretIdArray = $Args[3]

Secret Dependencies for RPC

Secret dependencies are items that rely on the username, password, or SSH private key stored in the secret. By adding them to the Dependencies tab, they are automatically updated when the secret's password is changed, ensuring they are up to date with the account on which they depend.

Adding a custom dependency template may require additional settings (these settings are described in the subtopics in this section).

COM+ Dependency Scanner

The COM+ Dependency Scanner allows for an Active Directory domain discovery source to locate COM+ Applications running on machines on the domain that are being run by Domain Accounts.

Firewall concerns may be addressed by ensuring that Port 135 is open between the target machine being scanned and the machine that engine is installed on.

Requirements for Discovery

Windows Services

For all supported versions of Windows and Windows Server, ensure that **Remote Procedure Call (RPC)** and **Remote Procedure Call (RPC) Locator** services are running. To help prevent any errors that would stop the services, set the **Startup Type** to **Automatic**.

Component Services

For all supported versions of Windows and Windows Server, ensure that **NETWORK** has remote access permissions to the machine.

1. Open **Component Services** (dcomcnfg.exe).
2. Under **Console Root**, expand **Component Services** and the **Computers** folder.
3. Right-click **My Computer**
4. Select **Properties**.
5. Under the **Default Properties** tab, ensure that the **Default Authentication Level** is set to **Connect** and that **Default Impersonation Level** is set to **Identify**.
6. On the **COM Security** tab, for both the **Access Permissions** and **Launch and Activation Permissions** sections, click **Edit Limits** and then add **NETWORK**.
7. Check **Allow** for all Remote permissions.

If the **Edit Limits** button is disabled, open the **Local Security Policy**. Under **Security Settings** expand **Local Policies** and select **Security Options**. There will be two **DCOM: Machine Access/Launch Restrictions**. Edit the one that corresponds to the disabled **Edit Limits** buttons, adding **NETWORK** and giving Remote permissions there.

Editing or altering the existing Windows permissions on the machine or editing the **Default Permissions** listed can have a negative impact on the machine.

COM+ Network Access

For all supported versions of Windows Server, ensure that COM+ Network Access is enabled by installing the Application Server Role. During the installation process, check the box next to **COM+ Network Access** under **Features**.

Versions Supported

- Windows 7
- Windows 8
- Windows 10
- Windows Server 2008
- Windows Server 2008 R2
- Windows Server 2012
- Windows Server 2012 R2

Versions Not Supported

- Windows Vista and earlier versions of Windows
- Versions of Windows Server pre-2008
- Windows Server 2016

Configuring COM+ Discovery for a New Domain

1. Search for **Discovery**
2. Click **Edit Discovery Sources**.
3. Click **Create New**.
4. Select **Active Directory Discovery Source** and click **OK**.
5. In the wizard, click **Next**.
6. Select a **Site** that is set up with **Distributed Engine**
7. Click **Next**.

> The COM+ Dependency Scanner will only run when a Distributed Engine Site is applied to the Discovery Source. The Engine will need to be installed either on the Domain to be scanned, a Child Domain relative to the Domain being scanned, a Parent Domain relative to the Domain being scanned, or another Trusted Domain relative to the Domain being scanned.

8. Check the box next to **COM+ Application**.
9. Click **Next**.
10. Enter your **Fully Qualified Domain Name**.
11. Select or create a Secret for an Active Directory account that will scan for your COM+ dependencies.
12. Click **Next**.

Your new domain is now configured in Secret Server and Discovery will search for COM+ dependencies in it.

Configuring COM+ Discovery for an Existing Domain

1. Search for **Discovery**.
2. Click **Edit Discovery Sources**.
3. Click on the domain where you wish to search for COM+ dependencies.
4. Click the **Scanner Settings** tab.
5. Scroll down to the **Find Dependencies** section and click **Add New Dependency Scanner**.
6. Click the plus symbol to the left of **COM+ Application**.

   You will be unable to make additional changes.
7. Click **OK** to proceed. Discovery will now search for COM+ dependencies.

Creating Custom Dependencies

If there are different dependency types that you want to manage that are not supported out of the box, new ones can be created based on a script. A custom dependency consists of two components:

- **Dependency Template:** The dependency template defines how a dependency is matched to discovered accounts and how it updates the target after a password change occurs on the account. to create a new dependency template, Search for **Secret Templates** and click the **Dependency Templates** button.
- **Dependency Changer**: A dependency changer is a script and the associated parameters to be passed into the script. Dependency changers can be created and modified by going to **Admin > Remote Password Changing > Configure Dependency Changers**.

> Please see "Discovery Overview" on page 534 for comprehensive guidance on configuring and using dependency changers and dependency templates.

Dependency Groups

By default, all dependencies are updated in the order listed. There are cases where you may want to split out different sets of dependencies into separate groups. Typically, this is because a single service account may run

services across different segregated networks that can communicate with the domain but not each other and have different distributed engine sites assigned. In this case you can create two dependency groups and assign them to different distributed engine sites to solve connectivity issues.

Dependency Settings and Information

Dependencies have the following settings:

> Not all dependency types have all these settings.

- **Change Fail Script:** For SSH key rotation and SSH key rotation privileged dependency types, this is the built-in script that determines if Secret Server was unable to update the public key on the dependency.
- **Change Script:** For SSH key rotation and SSH key rotation privileged dependency types, this is the built-in script that updates the public key on the dependency.
- **Change Success Script:** For SSH key rotation and SSH key rotation privileged dependency types, this is the built-in script that determines if Secret Server was able to update the public key on the dependency.
- **Database:** For SQL script dependency types, the database name for the script.
- **Dependency Group:** Name of the group to run the dependency update in.
- **Description:** Description of the dependency for documentation purposes.
- **Enabled:** Whether Secret Server attempts to update the dependency. A disabled dependency is ignored by Secret Server.
- **File Path:** For Remote File Dependency types, this is the UNC file path on the remote server where the embedded password exists.
- **Machine Name:** Computer name or IP address on which the dependency is located.
- **Name:** Name of the dependency on the remote machine.
- **Port:** For SQL and SSH script dependency types, the port name for the script.
- **Privileged Account:** The account Secret Server authenticates as when changing the dependency's credentials, so it must have privileges on the remote machine to edit the dependency.
- **Public Key:** For SSH key rotation and SSH key rotation privileged dependency types, this text-entry field holds the value of the public key stored on the dependency.
- **Regex:** For Remote File Dependency types, the regular expression used to locate the password embedded in the configuration file.
- **Restart:** Determines if the dependency is restarted once the account has been updated.
- **Run Condition:** Allows the dependency to run conditionally depending on the outcome of the dependencies above it. Run Conditions are not applied when dependencies are run directly from the Dependency grid.
- **Script:** Name of the PowerShell script, SSH script, or SQL script in the scripts repository configured on the Dependency Template. The actual script selected can be previewed by clicking the eye icon.
- **Server Key Digest:** For SSH key rotation and SSH key rotation privileged dependency types, a text-entry field that serves as a security control for specifying the SHA1 hash of the SSH host key on the remote server.
- **Server Name:** For SQL script dependency types, the server name for the script.

- **SSH Key Secret:** An account with SSH Key that Secret Server uses to authenticate when executing the SSH Script or SSH Key rotation dependency types.
- **Template:** Whether the dependency is an IIS application pool, Scheduled Task, windows service, remote file, COM+ application. Custom dependencies can also be created using a SQL, SSH, or PowerShell script.
- **Verification Script:** For SSH key rotation and SSH key rotation privileged dependency types, this is the built-in script that verifies that the new public key on the dependency matches the private key on the secret.
- **Wait(s):** Time in seconds that Secret Server pauses before changing the dependency.

Example values for a Windows service dependency on a remote computer might be: `192.11.158.99`, `Windows Service`, `aspnet_state`, or `DOMAIN\admin`.

The following operations can be performed in the Dependency grid:

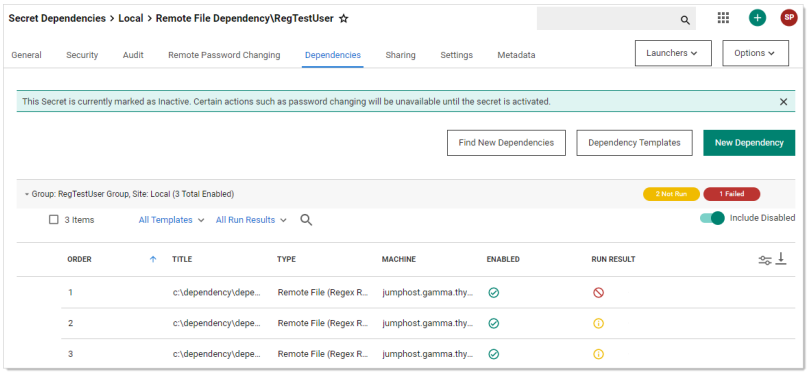
- **Edit:** Click on three dots next to a dependency name, and select Edit from the drop down. The Edit dependency window will open. In the Edit dependency window fill in:
  - **Type:** Select the related dependency type from the dropdown.
  - **Dependency group:** Select existing or add new dependency group.
  - **Sort order:** Select the related sort order.
  - **Description** Add the description if prompted.
  - **Enabled:** Check to enable dependency.
  - **Run As:** Click **No secret** selected to add a secret, or click on the selected secret to replace it. In the Select Secret window select the related secret to run the script and set the password on the dependency to the current password for the secret.
  - **Wait (s):** Set the number of seconds.
  - **Restart on Password Change:** Check to enable restart when password is changed.
  - **Machine name:** Enter the related machine name.
- **View log:** Click on three dots next to a dependency name, and select View log from the drop down to see the Secret dependency history with dates of events and related messages.
- **Enable:** Click on three dots next to a dependency name, and select Enable to enable the dependency, click OK to confirm. This will enable the selected Dependency. Alternatively, select a dependency (or several) from the list by checking them, and click Enable in the pop up above - in this way you can enable several dependencies at a time.
- **Disable:** Click on three dots next to a dependency name, and select Disable to disable the dependency, click OK to confirm. This will disable the selected Dependency. Alternatively, select a dependency (or several) from the list by checking them, and click Disable in the pop up above - in this way you can disable several dependencies at a time.
- **Delete:** Click on three dots next to a dependency name, and select Delete to delete the dependency, click OK to confirm. This will delete the selected Dependency. Alternatively, select a dependency (or several) from the list by checking them, and click Delete in the pop up above - in this way you can delete several dependencies at a time.

- **Run:** Select a dependency (or several) from the list by checking them, and click Run in the pop up above - this will run the selected Dependencies. Alternatively, click the return arrow icon next to a dependency to run it, the tests results are displayed afterward.

> Due to security constraints, scheduled tasks require an Active Directory domain user as the privileged account.

Dependency Status

You can see a list and status of all dependencies for a secret when viewing that secret in the UI. For example:



Account Dependence

You can use a single account (username and credential) for OS login and also for running Windows services, scheduled tasks, IIS application pools, and more. This is especially common for functional accounts. You can link the credentials of one account object to such usages. The link is independent of the actual system that the dependency is running on.

For example, given this scenario:

- The Windows domain account DOM\svc_app1 is managed on windows domain controller, where it is located.
- SRV1 is running a Windows service under the user DOM\svc_app1.
- SRV2 is running a scheduled task under the user DOM\svc_app1.
- When the account DOM\svc_app1 is changed, the dependencies of that account on SRV1 and SRV2 need to be updated too.
- The Windows service on SRV1 may have to be restarted for the password change to work.

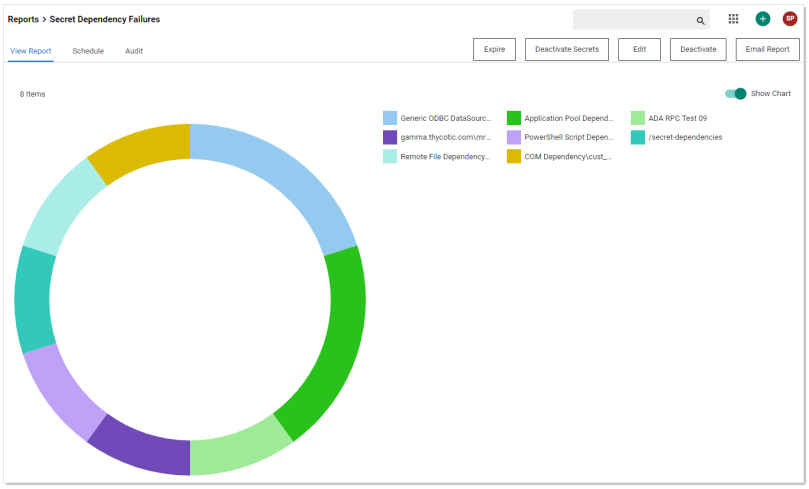
The modeling of the dependency would take place in / with the master object, which in this case is the windows domain account DOM\svc_app1. When selecting the master account object in the UI, it shows the dependencies along with their status.

Viewing Dependency Status

We offer four reports for viewing your secret dependency status:

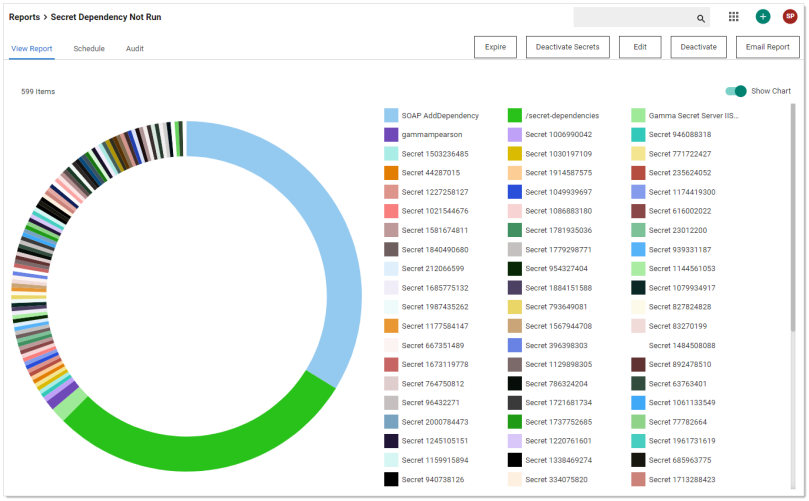
Secret Dependency Failures

Figure: Secret Dependency Failures Report



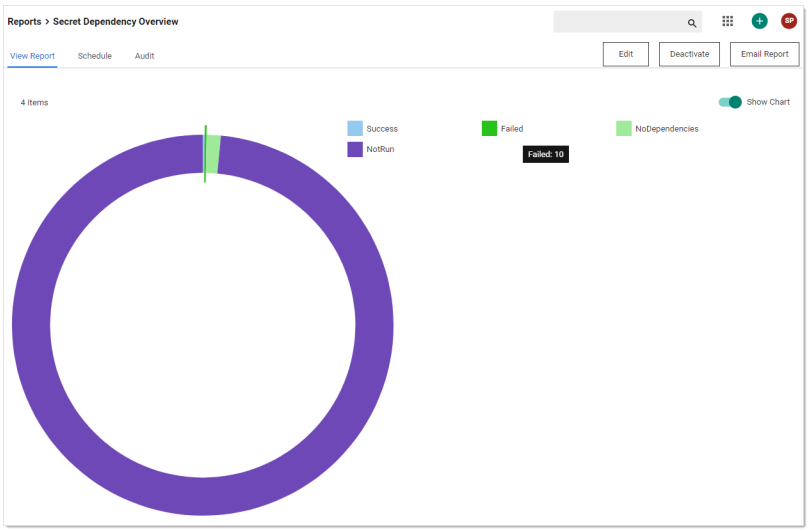
Secret Dependency Not Run

Figure: Secret Dependency Not Run Report



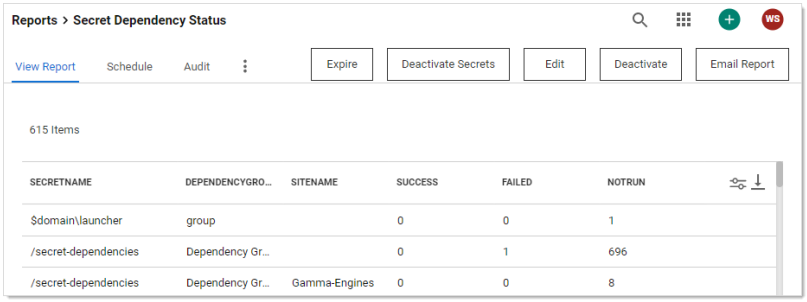
Secret Dependency Overview

Figure: Secret Dependency Overview Report



Secret Dependency Status

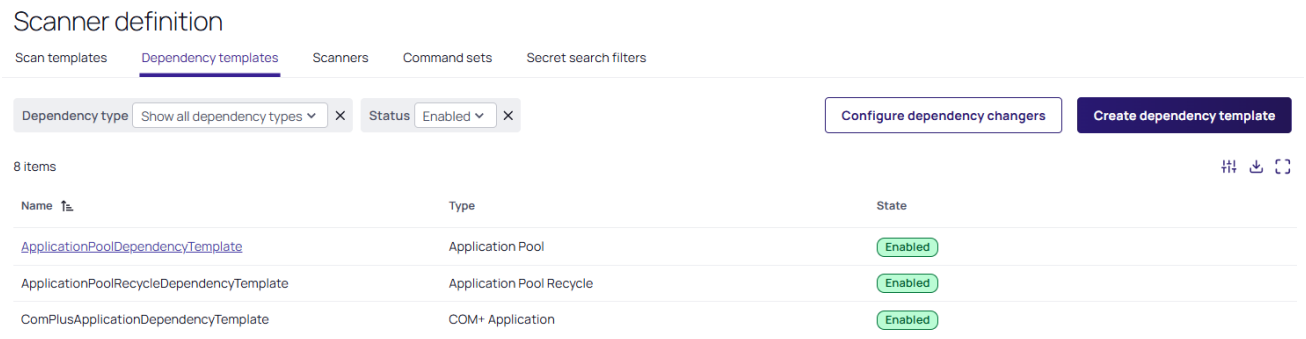
Figure: Secret Dependency Status Report



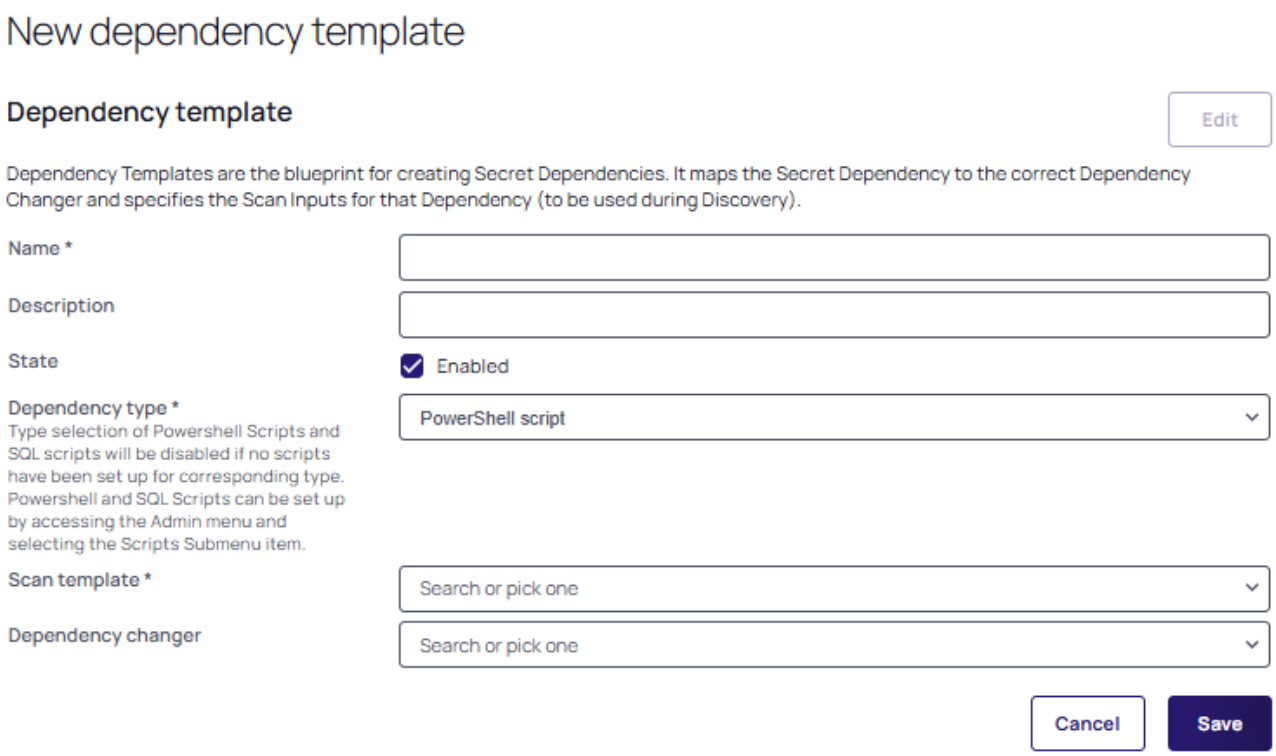
Manually Adding Dependencies

To manually add a dependency:

1. Search for **Settings > All Settings > Discovery > Configuration > Dependency Templates**. The Scanner definition page appears on the **Dependency templates** tab:



2. Click **Create Dependency Templates**. The New dependency template page appears:



3. Choose an appropriate **Name**.
4. Optionally add a description.
5. The **State** is automatically set to **Enabled**.
6. Choose your **Dependency type** from the dropdown list.

> Type selection of PowerShell Scripts and SQL scripts will be disabled if no scripts have been set up for these corresponding types. PowerShell and SQL scripts can be set up by accessing the Admin menu and selecting the Scripts sub-menu item.

7. Select a **Scan Template** from its dropdown list.
8. Select your desired dependency changer from the **Dependency Changer** dropdown list.
9. Click the **Save** button to finish adding the dependency.

Using Regex with Dependencies

Overview

In release version 7.8.00010 and later, Secret Server allows a secret to have file dependencies. File dependencies allow text files with embedded credentials to be changed via Regex.

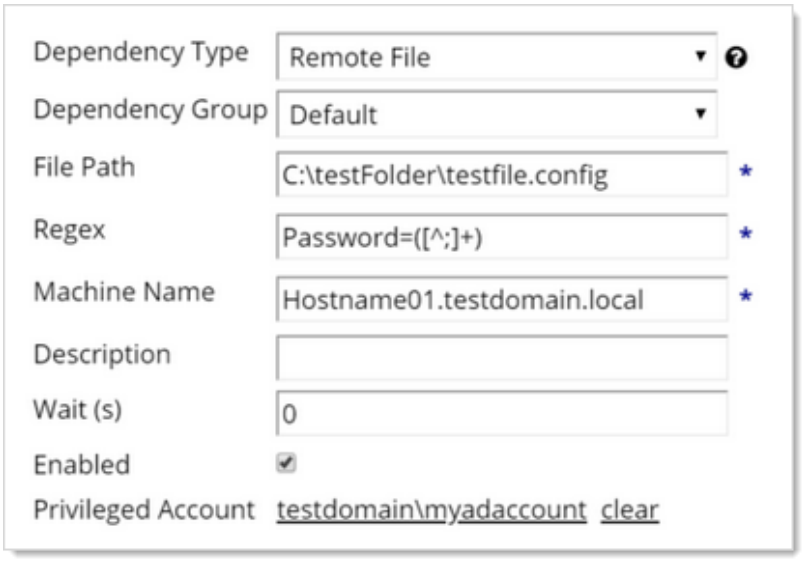
A Regular Expression (Regex) is a phrase in a language for matching text. For details on the .NET Regex language, see .NET Framework Regular Expressions.

Secret Server replaces the contents of the first group (within parentheses) within the Regex.

Setting up a remote file dependency, requires:

- **File Path:** This is the file path on the remote server where the remote password exists. UNC paths do not work here. See UNC Names.
- **Regex:** This regular expression to be used to locate the password embedded in the configuration file.
- **Machine Name:** Computer name or IP address where the dependency is located.
- **Privileged Account:** The account Secret Server will authenticate as when changing the dependency. It must have privileges on the remote machine.

A typical filled in New Dependency page looks something like this:



UNC Names

UNC names, such as:

`\\BARAKA\SHARE\test.txt` or

`\\192.168.1.154\SHARE\test.txt`

do **not** work in the file path. You can, however, put the machine name or IP address in the Machine Name text box, and put the rest of the path in the file path. For example:

In the **File Path** text box:

`\SHARE\test.txt` or

`SHARE\test.text`

In the **Machine Name** text box:

`192.168.1.154` or

`BARAKA`

Examples

The following are some examples of using Regex within file dependencies:

XML Configuration Files

Example One

Source

```
<Configuration>
  <User>
    <UserName>Bob</UserName>
    <Password>Password1</Password>
  </User>
  <User>
    <UserName>Sam</UserName>
    <Password>DontChangeThisOne</Password>
  </User>
</Configuration>
```

Regex

```
<UserName>Bob</UserName>\s*<Password>([^<]+)</Password>
```

Example Two

Source

```
<Configuration>
  <User name="Bob" password="Password1" />
  <User name="John" password="Password1" />
</Configuration>
```

Regex

```
<User name="Bob" password="([^"]+)" />
```

Windows Initialization (.ini) Files

Source

```
[owner]
name=John Doe
password=Password1
organization=Acme Widgets Inc.
```

Regex

```
name=John\sDoe\s*password=([^\r\n]+)
```

SQL Server Connection Strings

Source

```
Data
Source=myServerAddress;Initial Catalog=myDataBase;UserId=myUsername;Password=
myPassword;Server=myServerAddress;Database=myDataBase;Trusted_Connection=False;
```

Regex

```
Password=([^;]+)
```

Oracle Connection Strings

Example One

Source

```
Data Source=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=MyHost)(PORT=MyPort)))
(CONNECT_DATA=(SERVER=DEDICATED)(SERVICE_NAME=MyOracleSID)));
User Id=myUsername;Password=myPassword;
```

Regex

```
Password=([^;]+)
```

Example Two

Source

```
Data Source=username/password@//myserver:1521/[my.service.com](http://my.service.com);
```

Regex

```
username/([^@/]+)
```

YAML

Source

```
receipt: Oz-Ware Purchase Invoice
date: 2007-08-06
user:
name: Dorothy
password: Password1
```

Regex

```
name:\s*Dorothy\s*password:\s*([^\r\n]+)
```

Solution Guide: Primary Secret RPC is Changing the Passwords of Dependent Secrets

You can create multiple secrets for a single username-password combination, each with distinct templates and authorizations. Managing password changes, however, can become challenging due to the singular nature of the user account. To address this issue, you can use a linked password strategy. This approach ensures that any password modifications are made solely to the Primary Secret, with the updated password value automatically propagated to the dependent secrets.

Prerequisites

The following Delinea permissions are required for the API user's role:

- Edit Secret
- View Secret
- View Advanced Secret Options

The API user will also need edit access to the secrets to be managed.

Procedure

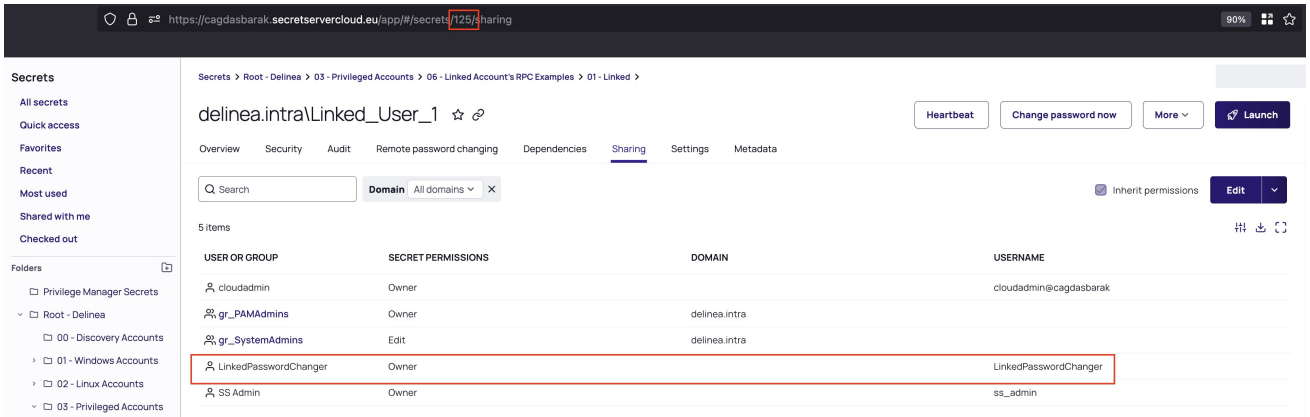
1. Upload this script to the scripts library.
   a. Settings:
      - State: **Enabled**
      - Script Type: **PowerShell**
      - Category: **Dependency**
      - Does not need to enable PowerShell Core processing.
   b. Update the top line(s) of the script to include the URL for your Vault either in the `SecretServerURL` or `DelineaPlatformURL` entry.
   c. The other URL should be left as `$null`.
2. Create an Application Account to be able to perform operations on dependent secrets.
   a. Secret Server: Application Account.
   b. Delinea Platform: Service User.
3. The Primary secret needs a way to include the secret IDs to update in a template field. You can:
   - Create a new template that is a copy of the current template and add a new text field called **Linked**.
   - Add a new text field to the existing template named **Linked**.
   - Use an existing text field on the current template (e.g. Notes).

> The last argument is this field name, so you will need to customize the argument name to match your selected field.

4. Write the secret IDs whose linked password you will change into the **Linked** field. This field is located on the Overview tab of the secret, by clicking the edit button (a pencil icon) next to it.

> The secrets should be entered as a comma-separated list with no spaces, e.g. 15,16,2692 not 15, 16, 2692.

5. Access the **Remote Password Changing** tab.
6. In the **Associated Secrets** section, click **Edit**.
7. Select **Add Secret** to add the secret, i.e. the application account you created at the beginning, and **Save**.
8. Access the Primary secret's **Dependencies** tab.
9. Add a new dependency by selecting **New Dependency**. The Create Dependency popup appears.
10. From the **Type** dropdown, select the script from the **Run PowerShell Script** section. More fields appear that you will need to fill in.
11. Select an existing dependency group or create a new group. If you create a new group:
    a. Name the group.
    b. Name the new group site from the associated dropdown.
12. Name the dependency with an informative name e.g. "Linked Secrets".
13. Optionally provide a description.
14. Make sure the **Enabled** checkbox is selected.
15. For the **Run As** option, select a secret that has Delinea permissions to run PowerShell code on the site.
16. For the **Arguments** field add the following: `$PASSWORD $[1]$USERNAME $[1]$PASSWORD $LINKED`.
17. Click **Save**.
18. In order for Linked Secrets to be updated, you need to grant edit permission for your Application Account in the **Sharing** section of each target secret:



Advanced

In some cases you may wish to initiate a password change on the target secrets rather than just updating the password field.

You can enable this by updating the arguments:

Arguments: `$PASSWORD$[1]$USERNAME $[1]$PASSWORD $LINKED "RotatePassword"`

Older versions of Secret Server may require using individual edits rather than bulk actions. You can enable this behavior by including the value **Legacy** as the 6th argument:

Arguments: `$PASSWORD$[1]$USERNAME $[1]$PASSWORD $LINKED "RotatePassword" "Legacy"`or **Arguments**: `$PASSWORD$[1]$USERNAME $[1]$PASSWORD $LINKED "UpdatePassword" "Legacy"`

Change SQL Service Account Passwords without Restarting the SQL Service

Introduction

Since Secret Server cannot restart SQL services, you can use the PowerShell script below to change SQL service account passwords without restarting the SQL service.

Requirements

This script uses a privileged account so the secret requires an associated secret added to it. No custom template is required for this changer.

> Access will only be the Windows Server and not with SQL Server itself.

Procedure

Task 1: Adding the Script

1. Search for **Scripts: PowerShell, SQL, SSH**.
2. Click **Create script**.
3. Type or select the following:
   - Name: **SQL Server Service Password Rotation**
   - Description: **Script for rotating SQL Server service account- no restart**
   - State: check **Enabled**
   - Script type: **SQL**
   - Category: **Dependency**
   - Password Changer: **SQL Server Account**
   - Script: **Copy and Paste** the provided script below.
4. Click **Save**.

Task 2: Creating the Dependency Changer

1. Search for **Remote password changing**
2. Click Options and select **Configure dependency changers** from the dropdown
3. Click **Create dependency changer**
4. Complete the form according to table below:

Field	Value
Name	SQL Server Service Dependency Changer
Description	SQL Server service rotation - no restart
State	Enabled
Dependency type	PowerShell Script
Scan Template	Windows Service
Wait(s)	Leave at 0
Create Template	Leave checked

5. In the **Scripts** section, in the **Change Script** field click the **Scripts** drop-down, and select the **PowerShell Script** dependency changer you just created.
6. Type `$MACHINE $SERVICENAME $PASSWORD`in the **Arguments** field.
7. Click **Save**.

Task 3: Adding the Dependency to a Secret

1. Navigate to the desired Secret and select the **Dependencies** tab.
2. Click **New dependency**.
3. In the Create dependency pop-up, click the **Type** dropdown list and select the dependency created in the previous step (it should be found under the **Standard** section).
4. Click the **Dependency Group** dropdown list to select a current group or create a new one. If creating a new one, provide the **New Group Name** and **New Group Site Name**.
5. Obtain the service name using following command on the SQL Server target machine:
   ```
   Get-Service *sql* | Select-Object Name
   ```
6. Type the service name in the **ServiceName** field.
7. Select a **Run As** secret if needed.
8. Type the for the target machine name in the **Machine Name** field and click **Save**.

You should now be able to rotate the password of the SQL Server service account and verify the dependency was successful.

Script: sqlservice-norestart-dependency.ps1

```
<# Utilize the Run As secret #>
$params = $args
$Target = $params[0]
$ServiceName = $params[1]
$ServicePwd = ConvertTo-SecureString -String $params[2] -AsPlainText -Force
$serviceCred = [pscredential]::new('Ignore this value',$ServicePwd)
Invoke-Command -ComputerName $Target -ScriptBlock {
    [pscredential]$cred = $using:serviceCred
    [System.Reflection.Assembly]::LoadWithPartialName
('Microsoft.SqlServer.SqlWmiManagement')> $null
    $sqlwmiLocal = New-Object 'Microsoft.SqlServer.Management.Smo.Wmi.ManagedComputer'
    $targetService = $sqlwmiLocal.Services | Where-Object Name -EQ $using:ServiceName
    if ($targetService) {
        try {
            $targetService.ChangePassword('ignore this value',$cred.GetNetworkCredential
().Password)
            $targetService.Alter()
        } catch {
            throw "Error updating the service password on $($using:Target) for service
$($targetService.Name): $($_.Exception)"
        }
    } else {
        throw "Service $($using:ServiceName) not found on $($using:Target)."
    }
}
```

Troubleshooting

`SQLWMI` is part of SMO with SQL Server.

> SMO stands for SQL Server Management Objects. It is a collection of objects designed for programmatic management of Microsoft SQL Server.

It exists on every installed SQL Server instance via the SQL Server Configuration Manager (SSCM). Newer versions of SQL Server no longer allow you to not install it. Just like WMI, there are cases where it can "break," most commonly when multiple versions of SQL Server are installed on the same machine–especially when a higher version was installed first, for example, if you installed SQL Server 2016 and then installed SQL Server 2012.

If running the dependency script you see the following error:

```
Failed to update <service name> on <target computer>. The following exception
occurred while trying to enumerate the collection: "An exception occurred in SMO
while trying to manage a service."
```

This can happen when `SQLWMI` is malfunctioning. Access that target and verify SSCM can be opened for that version of SQL Server you are trying to manage. If they have multiple versions, you need to open SSCM associated with the highest version found. If the target server is having issues, you will see WMI errors showing up when you open SSCM.

If this occurs you can solve the issue following this MS document: Error message when you open SSCM.

Pre-Run Validation for Dependencies

Customers now have the option to add RPC Pre-run validation for dependencies. This allows the user to have the system check the validity of the dependency before running the password change. If the check fails the RPC action will not take place, preventing passwords from getting out of sync with dependencies.

> This feature is currently unavailable for Secret Server On-Premises.

Configuring Dependency Pre-Run Validation for a Secret

Dependency pre-run validation is disabled by default for all secrets and must be enabled on a per-secret basis.

To enable **Dependency pre-run validation** for a secret:

1. Access Secret Server.
2. Choose a secret you want to enable this feature for.
3. Access the secret's **Remote Password Changing** tab.
4. Click **Edit** in the **RPC/Autochange** section.
5. Select the checkbox for **Enable pre-run validation on dependencies**.
6. Click the **Save** button.

Enabling Pre-Run Validation for Individual Dependencies

You can create or edit any eligible dependency. In the modal that pops up there is a drop-down for "Pre-run validation". It contains a list of the available pre-run validation types and an option for **None**. Choose any one of these and save.

To remove pre-run validation for a dependency, return to the drop-down and select **None** and save.

Types of Pre-Run Validation

- **Ping Machine**: This will attempt to make a connection to the machine listed in the **Machine** name field of the dependency.

  Available for Application Pool, Application Pool Recycle, COM+ Application, Remote File, PowerShell Script, SSH Script, SQL Script, Windows Service, and Scheduled Task dependencies.
- **Check Port**: This will attempt to make a TCP Connection to an address using the port specified in the Machine name field of the dependency.

  Available for Application Pool, Application Pool Recycle, COM+ Application, Remote File, PowerShell Script, SSH Script, SQL Script, Windows Service, and Scheduled Task dependencies.
- **Login**: This will attempt to verify that the credentials on the secret are valid for the dependency.

  Available for Application Pool, Application Pool Recycle, Remote File, PowerShell Script, SSH Script, SQL Script, Windows Service, and Scheduled Task dependencies.

- **Run PowerShell Script**: This will attempt to run a PowerShell script using the credentials on the privileged account for the secret. If there is no privileged account, the **Run As Secret** on the secret's site will be run instead.

  Available for Application Pool, Application Pool Recycle, Remote File, PowerShell Script, Custom PowerShell Script, SSH Script, SQL Script, Windows Service, and Scheduled Task dependencies.

  > As with PowerShell script dependencies, you can add arguments to pre-run validation scripts including fields from the dependency, the secret or custom values.

  > The Run PowerShell Script option only works with Windows machines. Other operating systems like UNIX/Linux are not yet supported.

Using Pre-Run Validation

Run **Remote Password Changing** on the secret you've selected as you normally would. Pre-run validation will automatically run on the secret before any other RPC steps are executed.

> Pre-run validation will run for all dependencies on a secret when it is configured and a password change is requested regardless of which site the dependencies are on.

If it succeeds RPC will continue as normal. If it fails RPC will stop and the result of the pre-run validation will be shown in the secret's RPC tab. RPC will be scheduled again for the next configured interval.

To prevent future password changing attempts from occurring, click the **Stop Password Change** button. To prevent pre-run validation from failing again either correct the condition listed in the error message that caused the failure or disable the pre-run validation on the dependency or the secret.

Running Pre-Run Validation On-Demand

To run Pre-Run validation on a dependency outside of a password change:

1. Click on the title of the dependency you want to run from the **Dependencies** tab in the secret.
2. Select the **Validate** option in the menu that comes up on the right. This will execute the Pre-Run validation type that has been selected for the secret.

   > If no type is selected, the **Login** validation type will be used, and if it is not available, the **Ping Machine** type will be used. The result of the validation will appear in the dependency's log.

RPC Errors

Remote Password Changing (RPC) errors in Secret Server can arise from various issues related to configuration, Delinea permissions, and connectivity. Common errors include user name not found, access denied, invalid password, and account locked out. These errors often stem from incorrect machine names, firewall settings, domain policy restrictions, or insufficient permissions. For instance, the "ERROR_CANT_ACCESS_DOMAIN_INFO" error may indicate a problem with machine name resolution or domain permissions, while "NERR_PasswordPolicySettings" typically points to password policy violations such as minimum password age.

Troubleshooting these errors involves verifying the configuration settings, ensuring proper network connectivity, and checking the relevant logs for detailed error messages.

Common RPC Errors

Overview

This topic lists some of the common errors experienced when setting up Remote Password Changing (RPC) for an account.

To view the errors, Search for **Remote Password Changing** in Secret Server and look for the name of the secret you are testing.

Errors

The user name cannot be found

For local Windows accounts, ensure you only have the username in the username field (do not include the machine name). The machine name should go in the Machine field only. If the RDP Launcher stops working when you remove the machine name from the username field, see "RDP Proxy Configuration" on page 817.

Change password failed: Unknown. (ERROR_CANT_ACCESS_DOMAIN_INFO)

For RPC on local Windows accounts, this error can be deceptive because the built-in Windows method used to change a password takes either a machine or domain name, so if the machine is not found, it thinks a domain was passed in and throw a domain error.

For RPC on Active Directory accounts, this error may occur if the account does not have permission to perform the password change or the domain name is wrong or abbreviated. Verify by checking the account properties in Active Directory or log in to the account and try to change the password manually or use privileged secret to perform the RPC.

> The RPC process uses information from the secret, not a central configuration for resetting the password. The Active Directory configuration settings are used for user synchronization only, so ensure the information on the secret is correct, including the Active Directory domain.

Common causes include:

- The machine name is wrong or abbreviated. For example: comp3 is entered as the machine name instead of comp3.yourdomain.com.

  Try replacing the machine name in the secret with the IP address of the machine and seeing if you still receive the domain error.
- The firewall is blocking the ports. See "Ports and IP Addresses Used by Secret Server" on page 765.

Monitor activity to see if the authentication is accepted on the machine by viewing the security log:

1. Run secpol.msc from the Run prompt.
2. Click on Local Policies, Audit Policy.

3. Turn on "Audit account logon events" and "Audit logon events" for both Successes and Failures.
4. View the logs at Administrative Tools > Event Viewer. Check the Security Logs to determine whether the requests are getting through to the computer.

   The RPC log looks different if the firewall denies the connection, and will show ERROR_ACCESS_DENIED in some cases.

   Firewall settings also apply to changing passwords on the local machine that Secret Server is running on because net authentication is used.

Change password failed: Unknown. (NERR_PasswordPolicySettings)

Cause: repeating password or a password that does not meet domain standards.

Check the minimum password age. When performing RPC on Active Directory accounts, this error may occur due to a minimum password age policy on the domain. If the minimum password age is set to 1 day or greater, and due to testing, the password has already been changed once, a follow up password change will violate the domain policy.

If you need to change the user's password more than the policy allows, change their policy so they are not subject to minimum password ages, or use the privileged account option in the Remote Password Changing tab on the secret. Privileged account will perform a password reset instead of changing the password using the accounts credentials.

Change password failed: Unknown. (ERROR_ACCESS_DENIED)

Cause: User account is set to Not Able to Change Password, firewall denial, or login incorrect. May also occur when the userWorkstations attribute on the user is set.

Change password failed: Unknown. (ERROR_INVALID_PASSWORD)

Cause: Either the user does not exist (ensure the usernames match) or the password is not correct.

Change password failed: Unknown. (ERROR_ACCOUNT_LOCKED_OUT)

Cause: User account is locked out.

ExpiredSecretMonitor - Unspecified error

Cause: Firewall issue or ports are blocked.

DirectoryEntry.Invoke SetPassword - The network path was not found.

Cause: Domain cannot be found from the computer. Check the machine can ping the domain.

Secret '[secretname]' (Id = [secretid]) returned (ArgumentError). Exception: Command requires associated Item. ($[1]$USERNAME)

Cause: the password changer for the secret template this secret is based on is looking for an "associated secret." Associated secrets are additional accounts that are needed in the password change process.

You can view the commands being used for the password change and add the associated Secret by going to the Remote Password Changing tab of the Secret in question and clicking Edit (you may also need to click Show Commands).

Error changing password - Check Out is enabled on associated Secret.

Cause: The secret has a Privileged Account Credentials option selected for performing the password change and the privileged account secret has the Require Check Out option enabled. This configuration causes an error with the remote password change process because the Required Check Out option is not intended for use by the system to avoid conflict from user's request, which is the intended usage.

RPC Error Codes

The most common RPC errors are:

- **NERR_PasswordPolicySettings**: The password Secret Server attempted to set is a repeating password or one that does not meet domain password policy standards. A common reason is minimum password age, which is often defaulted to 24 hours.
- **ERROR_ACCESS_DENIED**: The user account's "Not Able to Change Password" setting could not be set or logon was denied.
- **ERROR_INVALID_PASSWORD**: Either the user does not exist (ensure the usernames match) or the password is not correct.

For more information about common error messages for Remote Password Changing, see "Common RPC Errors" on page 949.

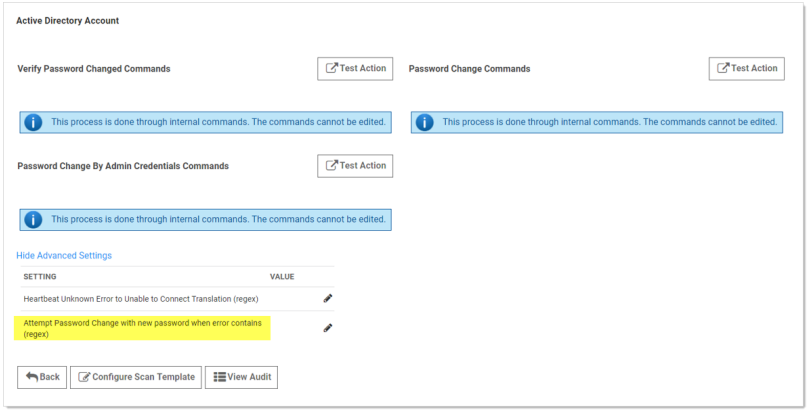
Triggering an RPC When Defined Errors Occur

Overview

When the "Attempt Password Change with new password when error contains (regex)" setting is enabled, Secret Server generates a new password to use during the next RPC attempt when the defined error is returned. Using a regular expression, which you define, Secret Server scans the error message for specific text strings. When there is a match, Secret Server generates and sets a new next password for the secret that will be used in the next RPC attempt, which will occur based on the templates RPC interval. To keep this process from generating too many next passwords, it is restricted to five attempts while failing RPC.

Only the password field is updated. Passcodes and SSH keys are left alone.

Figure: Attempt Password Change with new password when error contains (regex) setting



Logic:

(RPC Error) AND (one or more regex matches) AND (five or fewer attempts) => New password generated

Examples:

`.*UnknownError.*` (any unknown error)

`.*` (any error)

`.*minimum.*` (minimum password length requirement error)

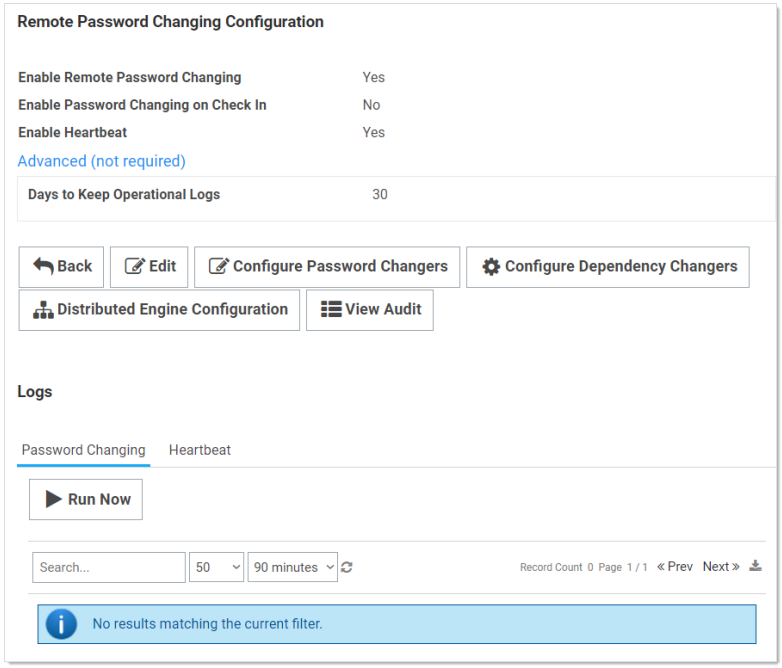
`.*0x80072035.*` (server rejects password error)

`.*0x80072035.*|.*minimum.*` (server rejects password or password length error)

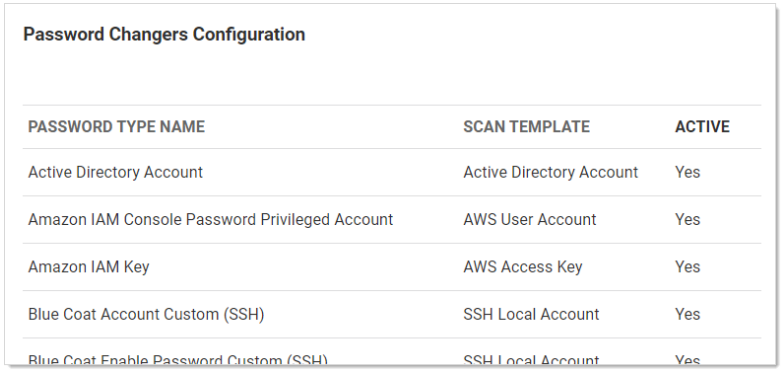
Procedure

To configure RPC in response to specific unknown errors:

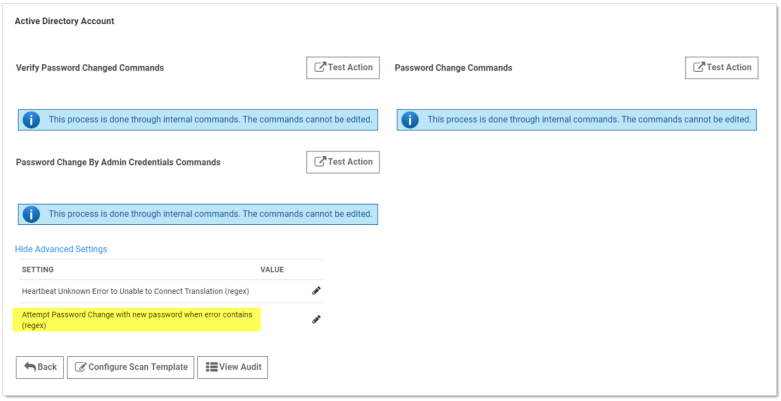
1. Search for **Remote Password Changing**. The Remote Password Changing Configuration page appears:



2. Click the **Configure Password Changers** button. The Password Changers Configuration page appears:



3. Click the link for the desired password type. Its Account page appears:



4. If necessary, click the **Advanced Settings** link.
5. Click the pencil icon next to **Attempt Password Change with new password when error contains (regex)**. The Value text box appears.
6. Determine the desired text string to search for.
7. Type the desired regex in the **Value** text box.
8. Click the **Save** icon next to the text box.

Viewing RPC Logs

The RPC logs for a specific secret can be accessed by clicking the **View Audit** button on Secret View page and ticking the check box at the bottom of the page for display password changing Log. The RPC logs for all secrets can be accessed by navigating to **Admin > Remote Password Changing**.

You can change the **Days to Keep Operational Logs** text box to set the period to keep RPC-related logs that might contain PII. Secret Server automatically deletes logs older than that (in days).

Included RPC Templates

Delinea Secret Server's out-of-the-box secret templates for remote password changing are designed to automate and secure the process of changing passwords across various systems and accounts. These templates provide a customizable framework, enabling organizations to define specific criteria and procedures for password updates, ensuring that password changes are executed consistently and securely, without manual intervention, thereby enhancing overall security and compliance.

> This section of topics is about using the provided templates, not about configuring RPC to support a given template. For that, see "RPC for Specific Vendors and Technologies" on page 1006.

> Please see Delinea SaaS Apps Integrations for details on integrations available for Secret Server Cloud, Secret Server On-Premises, and the Delinea Platform.

Amazon IAM Console Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Amazon IAM Console accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Configuring Amazon IAM

Secret Server can scan Amazon Web Services (AWS) for accounts that can access the cloud resource. Secrets based on the "AWS Console Account" secret template can be discovered and managed through the Secret Server.

The Secret Server heartbeat feature is not available with this template due to AWS IAM limitations.

You can change passwords and access unique passwords for the password secrets in the Amazon IAM console. An Amazon IAM Key should be connected to an "Amazon IAM Console Password" secret to enable password modification. For details, see "Password Management in AWS" on page 613.

Assigning a Password Changer to a Secret Template

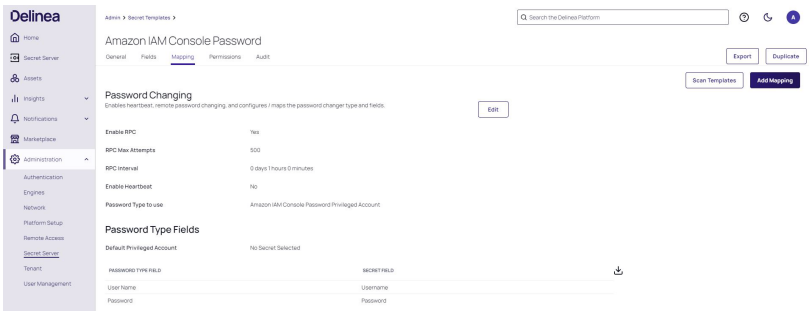
Remote Password Changing (RPC) provides pre-configured password changers assigned to specific secret templates available out of the box. You can view and modify secret templates in the Secret Server administration panel. All possible modification options for secret templates are described in "Creating or Editing Secret Templates" on page 1194. Ensure that the secret template is active. For details, see "Activating and Deactivating Templates" on page 1183.

To navigate to an Amazon IAM Console secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an Amazon IAM Console secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Amazon IAM Console Password Privileged Account RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Amazon IAM Console template on a secret, see "Managing Secrets" on page 1365.



Amazon IAM Key Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Amazon IAM Key accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Secret Server can scan Amazon Web Services (AWS) for accounts that can access the cloud resource. The secrets based on the "Amazon IAM Key" templates can be discovered and managed through the Secret Server.

An Amazon IAM key secret should be connected to an Amazon IAM console password secret to enable password modification. For details, see "Password Management in AWS" on page 613.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Amazon IAM Key, we want the Amazon IAM Key template.

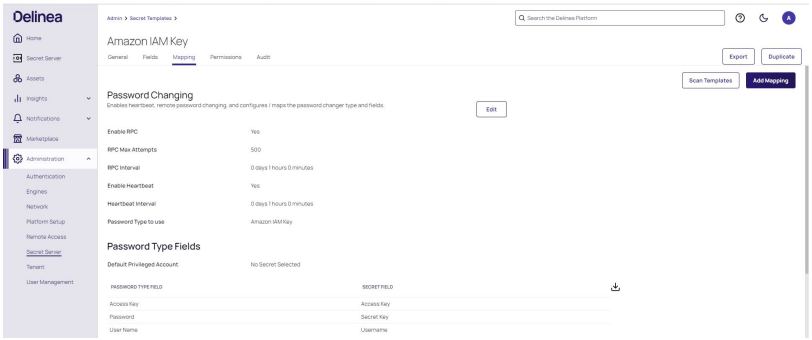
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an Amazon IAM secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an Amazon AIM secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Amazon IAM Key RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the Amazon IAM Key template on a secret, see "Managing Secrets" on page 1365.



Entra ID Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Entra ID accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Configuring Entra ID

To use Secret Server for Entra ID account scanning, we currently rely on an Active Directory scan. For details, see "Setting Permissions for Active Directory Scans" on page 606.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Entra ID, we want the Entra ID template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an Azure Active Directory secret template:

1. Go to the **Administration** page in Secret Server.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an Entra ID secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The Entra ID RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Entra ID template on a secret, see "Managing Secrets" on page 1365 documentation.

Cisco Account (SSH) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Cisco Account (SSH) and Cisco Account (Telnet) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Secret Server can use scripted password changers for devices that support SSH or Telnet (this allows for flexibility in changing passwords on less common devices). You can also run custom RPC PowerShell scripts to conduct password changes to other platforms.

With the help of the Secret Server, admins can use private SSH keys for PuTTY launcher sessions and RPC tasks–configurable through password changer settings. Secret Server supports SSH key rotation on secrets. For more details, see "Secret Key Rotation" on page 1475.

Assigning a Password Changer to a Secret Template

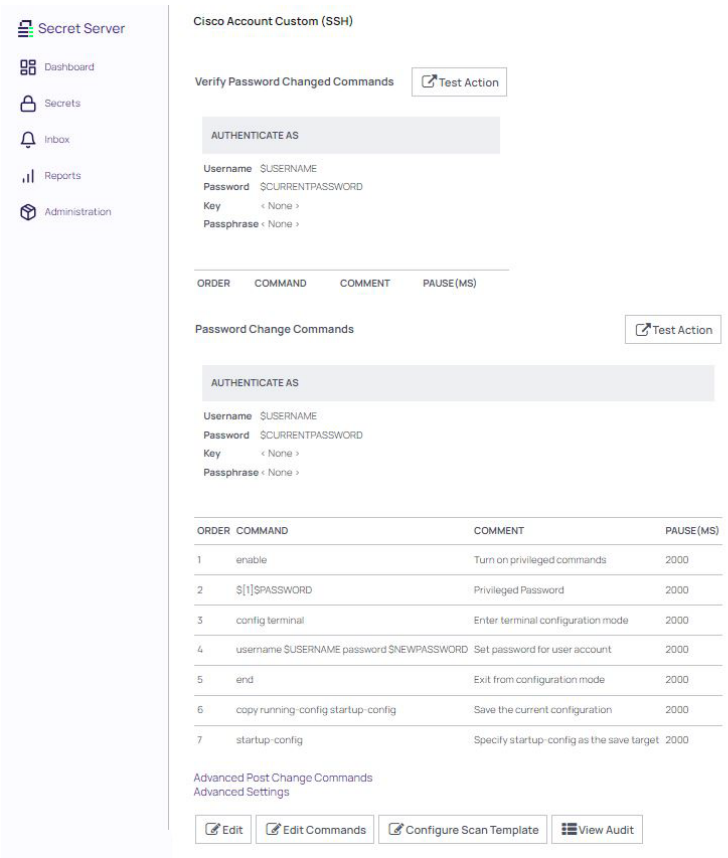
After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Cisco Account, we want the Cisco Account template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Cisco Account secret template:

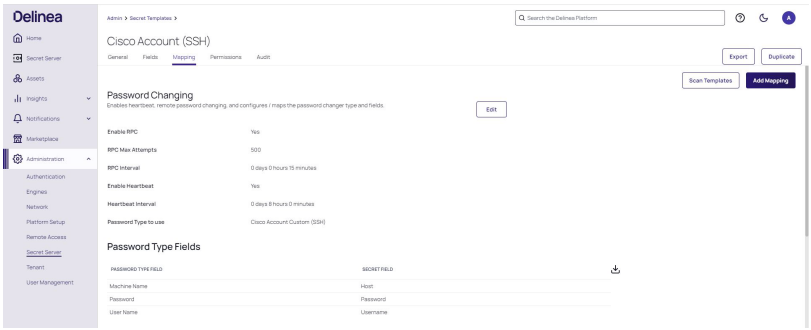
1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Cisco Account secret template and then click the **Mapping** tab.

It is available to edit custom password changer commands. For more details, see "Editing Custom Commands" on page 1045.



You can check what secret template applies to the selected RPC. The screenshot below shows that a Cisco Account Custom (SSH) RPC is based on the Cisco Account (SSH) secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret Templates determine the fields, launchers, and the remote password changer for secrets. To utilize the Cisco Account template on a secret, see "Managing Secrets" on page 1365 documentation.



Cisco Enable Secret (Telnet) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Cisco Enable Secret (SSH) and Cisco Enable Secret (Telnet) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Secret Server can use scripted password changers for devices that support SSH or Telnet (this allows for flexibility in changing passwords on less common devices). You can also run custom RPC PowerShell scripts to conduct password changes to other platforms.

With the help of the Secret Server, admins can use private SSH keys for PuTTY launcher sessions and RPC tasks–configurable through password changer settings. Secret Server supports SSH key rotation on secrets. For more details, see "Secret Key Rotation" on page 1475.

Assigning a Password Changer to a Secret Template

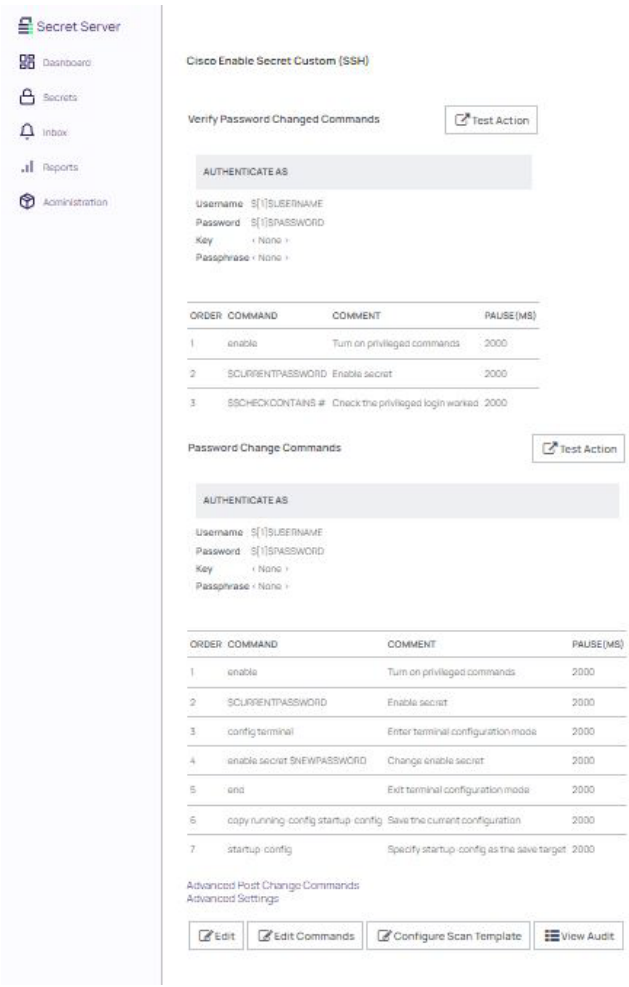
After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Cisco Enable Secret (SSH), we want the Cisco Enable Secret (SSH) template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Cisco Enable secret template:

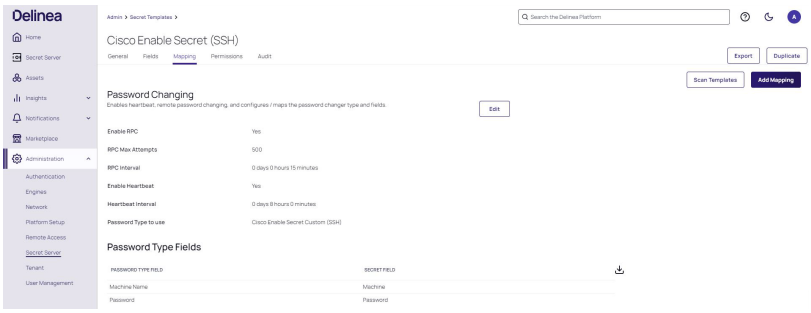
1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Cisco Enable secret template and then click the **Mapping** tab.

It is available to edit custom password changer commands. For more details, see "Editing Custom Commands" on page 1045.



You can check what secret template conforms to the selected RPC. The screenshot below shows that a Cisco Enable Secret Custom (SSH) RPC refers to a Cisco Enable Secret (SSH) template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Cisco Enable Directory template on a secret, see "Managing Secrets" on page 1365.



Entra ID Secret Template for RPC

Overview

> For setting up the password changer itself, see "Configuring an Azure AD or Entra ID Password Changer" on page 1017

Introduction

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Entra ID accounts. With RPC secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the Password Changer List for a complete list of available password changers.

Secret Server has supported Azure AD remote password changing for several years, this overhaul creates a new password changer and template which use Oauth application credentials as a privileged account, to change a user password.

> In July 2023, Microsoft rebranded Azure AD to Microsoft Entra ID to improve consistency with its other Entra cloud products.

Entra ID

Entra ID is Microsoft's cloud-based identity and access management (IAM) solution. Key points about Entra ID:

- It is a directory and identity management service that operates in the cloud. It provides authentication and authorization services for various Microsoft services like Microsoft 365, Dynamics 365, and Microsoft Azure.
- Entra ID enables a single sign-on experience for users, regardless of whether their applications are cloud-based or on-premises.
- It offers multiple authentication methods including password-based, multi-factor, smart card, and certificate-based authentication.
- Entra ID includes security features like Conditional Access policies, risk-based authentication, and identity protection.
- Entra ID provides benefits to different members of an organization based on their roles. This can include giving IT admins control over app access, enabling developers to easily integrate single sign-on, and providing a unified identity management solution for Microsoft 365, Azure, and Dynamics 365 subscribers.

In summary, Entra ID is Microsoft's comprehensive cloud-based identity and access management solution that helps organizations securely manage identities and access across their Microsoft services and applications.

Template Benefits

- Supports MFA
- Does not require PowerShell

Creating an Entra ID Secret and Assigning it to Individual-Account Secrets

> The following steps are meant for users who either utilize an App Registration created during Discovery or already know how to create a separate App Registration in Entra ID. This is a prerequisite to proceed and If you do not have this set up, see "Entra ID Discovery" on page 615 to create and configure an App Registration in Entra ID.

To create a privileged secret and assign it to individual account secrets:

1. Access **Secrets > All secrets** and create a secret of the **Azure Application Registration** type.
2. Type in values for these fields:
   - Secret name
   - Client ID
   - Client Secret
   - Tenant ID
3. Click **Create secret**.
4. For each Entra ID user that corresponds to the above credentials, create a secret of the **Entra ID User Account** type.
5. Type in values for the following fields:
   - Secret name
   - Username
   - Password
   - Domain and Notes are optional fields
6. For Entra ID user accounts, heartbeat and password changing will only work if a privileged account of the **Azure Application Registration Account** type is set:
   a. Click the **Remote Password Changing** tab for the secret you just created.
   b. Click **Edit** under **RPC / Autochange**.
   c. Select the **Privileged Account Credentials** radio button for the **Change Password Using** option.
   d. Click **No Secret Selected**. A list of eligible Secrets appears.
   e. Select a secret with credentials that would have Entra ID permissions over the user account. If no secrets appear, check that there are secrets of the **Azure Application Registration** type that are visible to the logged in user.

> Until a privileged account is set, heartbeat and RPC options are unavailable and will fail if running automatically.

Generic Discovery Credentials Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Generic Discovery Credentials accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Generic, we want the Generic Discovery Credentials template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Generic Discovery Credentials secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Generic Discovery Credentials secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows the Generic Discovery-Only Credentials RPC refers to the Generic Discovery Credentials secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Generic Discovery Credentials template on a secret, see "Managing Secrets" on page 1365.
