
Google IAM Service Account Key Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Google IAM accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a

secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Secret Server can manage Google Cloud Platform (GCP) service accounts and VM instances. For more details, see "Google Cloud Platform Discovery" on page 621.

Assigning a Password Changer to a Secret Template

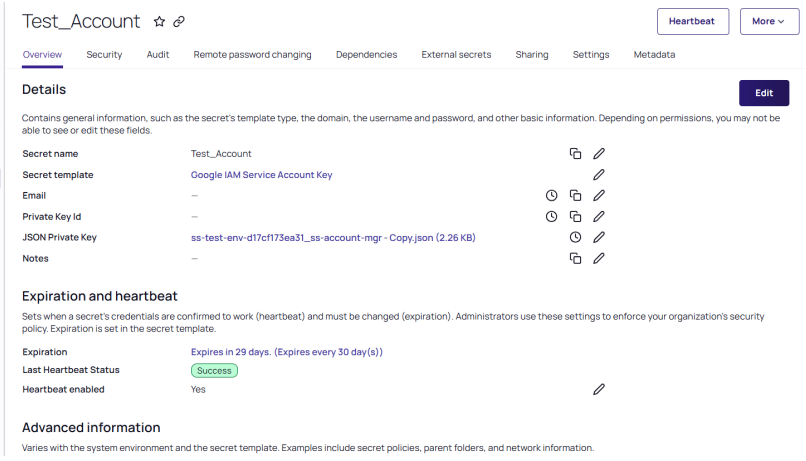
After completing the RPC setup, you can manage the built-in secret templates. Each secret template is a specific application and is preconfigured with the password changer best suited to that. For the Google Cloud Platform, we want the Google IAM Service Account Key template.

You can view and modify secret Templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

Search for **Secret Templates**, and select Google IAM Service Account Key template from the list (or use the search box if you don't see it). On the template page select the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows the Google IAM Service Account Key RPC refers to the selected Google IAM secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Google IAM Directory template on a secret, see "Managing Secrets" on page 1365.



Note that for the Google IAM Service Account Key secret template, the Email and Private Key ID fields are not required, as the JSON private key file contains all the necessary information.

HP iLO Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for HP Integrated Lights-Out (iLO) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

HP Integrated Lights-Out (iLO) is an embedded server management technology exclusive to Hewlett Packard Enterprise (HPE) servers, providing a comprehensive suite of tools to ensure seamless server setup, health monitoring, power and thermal control, and remote server administration.

Secret Server can set up scripted password changers for devices that support SSH or Telnet (this allows for flexibility in changing passwords on less common devices). You can also run custom RPC PowerShell scripts to conduct password changes to other platforms.

With the help of the Secret Server, admins can use private SSH keys for PuTTY launcher sessions and RPC tasks—configurable through password changer settings. Starting with version 10.1.000000, the Secret Server supports SSH key rotation on secrets. For more details, see "Secret Key Rotation" on page 1475.

Assigning a Password Changer to a Secret Template

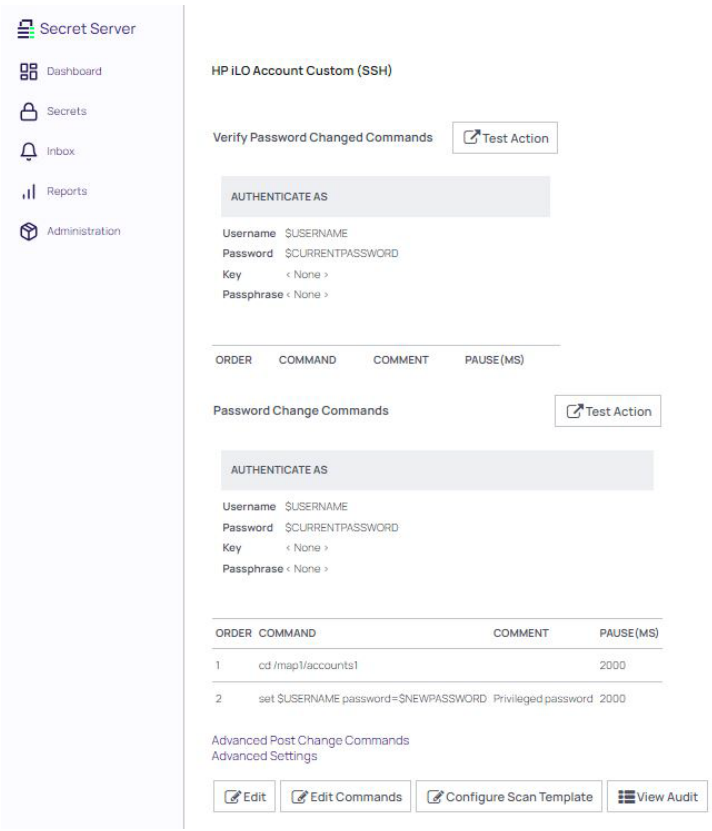
After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the HP iLO, we want the HP iLO template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an HP iLO secret template:

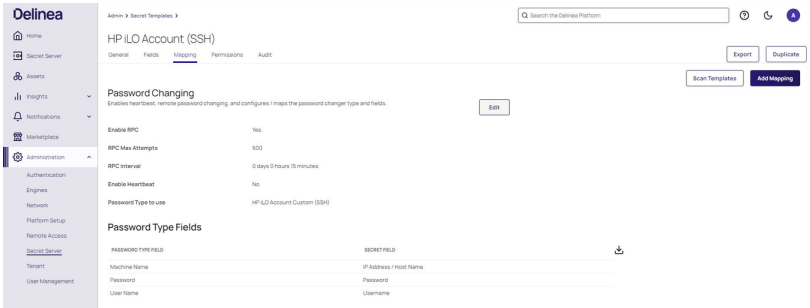
1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an HP iLO secret template and then click the **Mapping** tab.

It is available to edit custom password changer commands. For more details, see "Editing Custom Commands" on page 1045.



You can check what secret template conforms to the selected RPC. The screenshot below shows that the HP iLO Account Custom (SSH) RPC refers to an HP iLO Account (SSH) secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the HP iLO template on a secret, see "Managing Secrets" on page 1365.



IBM iSeries (AS/400) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for IBM iSeries (AS/400) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords

when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

The IBM iSeries (AS/400) Terminal password changer uses the same principles as the z/OS Mainframe password changer. The password change and heartbeat execute the 5250 terminal connection and scripting. You can modify the script for any advanced configuration requirements. For more details, see "Create and Customize an IBM iSystem (AS/400) Template to use the new IBM iSeries (AS/400) Password Changer" on page 1220 .

Assigning a Password Changer to a Secret Template

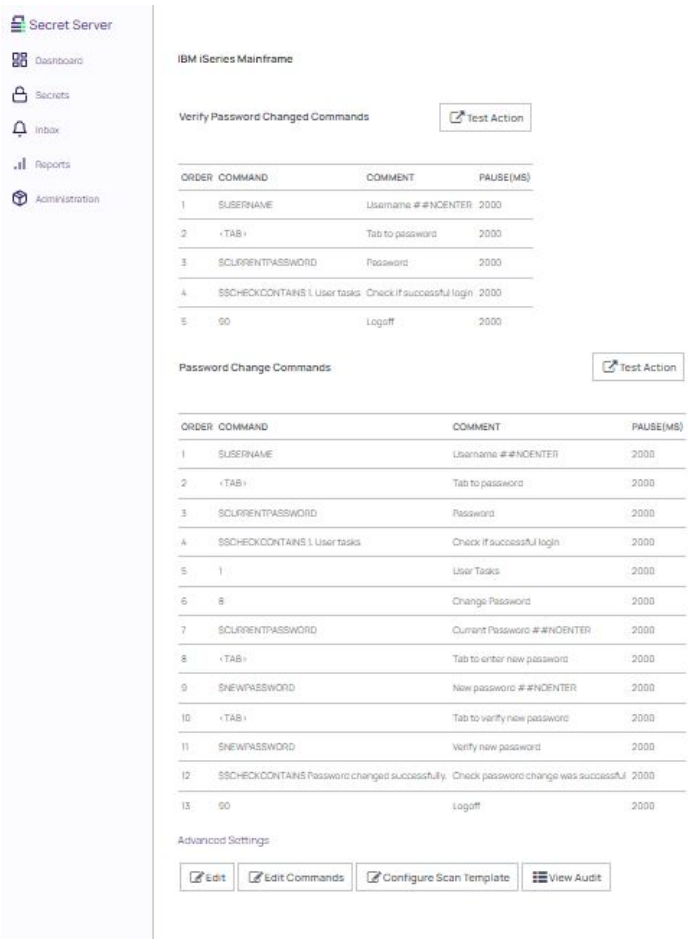
After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the IBM Series (AS/400), we want the IBM Series (AS/400) template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an IBM Series (AS/400) secret template:

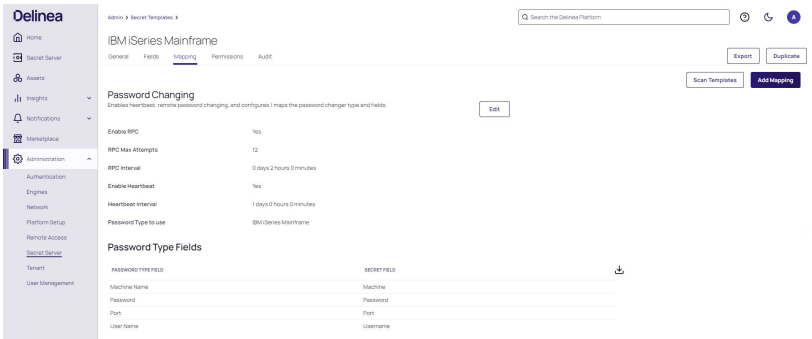
1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an IBM Series (AS/400) secret template and then click the **Mapping** tab.

It is available to edit custom password changer commands. For more details, see Editing Custom Commands.



You can check what secret template conforms to the selected RPC. The screenshot below shows the IBM Series Mainframe RPC refers to the selected IBM Series (AS/400) secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the IBM Series (AS/400) template on a secret, see "Managing Secrets" on page 1365.



Microsoft AD Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Microsoft Active Directory (AD) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Prerequisites

RPC setup for AD requires the following:

- Use a privileged account with the correct Active Directory permissions. Select the Privileged Account Credentials option on an AD secret with permission to change the account's password.
- Ensure the appropriate Active Directory permissions are enabled. For details, see "Configuring Delegation Control for the Administrative Account" on page 1015.

The Active Directory password changer has an RPC "timeout minutes" advanced setting. This setting only applies when using the "Password Change By Admin Credentials" option.

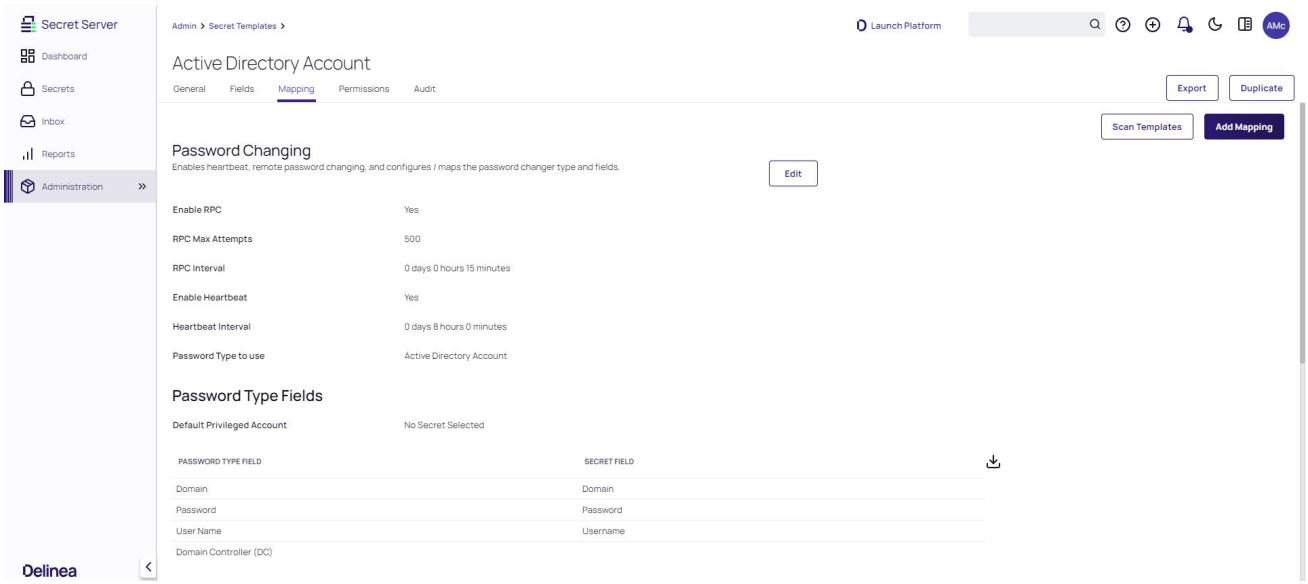
Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For AD, we want the Active Directory Account template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Microsoft AD secret template:

1. Search for **Secret Templates**. The Secrets Administration page appears.
2. In the **Core Actions** section, click **Secret Templates**. The Secret Templates page appears with a list of available templates.
3. Click the **Active Directory Account** template name. That template's page appears.
4. Click the **Mapping** tab.
5. You can now view or edit the RPC for the secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.



MySQL Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for MySQL Accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

MySQL is a widely-used open-source relational database management system (RDBMS) known for its speed, reliability, and ease of use. It is a central component of the LAMP web application software stack, along with Linux, Apache, and PHP/Perl/Python.

To configure secret templates for MySQL, see .

Distributed Engine Considerations

For MySQL RPC to work, a MySQL connector is required on the distributed engine (DE), and the MySQL.data.dll file needs to be added in the DE files. See "Distributed Engine Overview" on page 718 for details.

When DEs auto update, they remove the MySQL, Oracle, and other DLLs that were manually placed there. To forestall this, we recommend creating an ignore file for DE upgrades.

How to Create an Ignore File for Distributed Engine Upgrades

Create and configure an ignore file for Distributed Engine upgrades to allow Distributed Engine ignoring specific DLLs and not replacing them during upgrades.

1. Open a text editor like Notepad or Notepad++.

2. In the content of the file, add the filename of any DLLs that you'd like to ignore during upgrades. If there is more than one file, add each additional filename on a new line.

3. Save this file to the data folder on the Distributed Engine machine. By default, it is: C:\Program Files\Thycotic Software Ltd\Distributed Engine\data.

- Filename must be "ignore" without quotes.
- Uncheck "Append Extension" as this file must not contain an extension.

4. Once complete, any further upgrades will ignore any file listed in the ignore file.

Additionally see video demo for details.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the MySQL Account, we want the MySQL Account template.

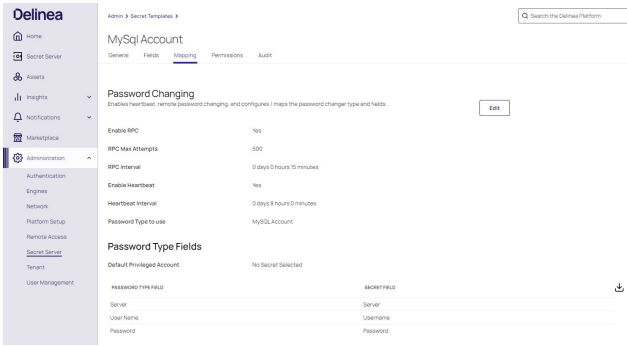
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a MySQL Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a MySQL Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the MySQL Account RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the MySQL Account template on a secret, see "Managing Secrets" on page 1365 documentation.



Okta Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for an Okta Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret

expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Okta is a leading identity management platform that enables organizations to securely connect their employees, partners, and customers with the right technology resources. For instructions on how to set up an Okta Account and arrange its secret template, see Remote Password Changing for Okta.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is application specific and is preconfigured with the password changer best suited to it. For Okta, we want the **Okta Account template**.

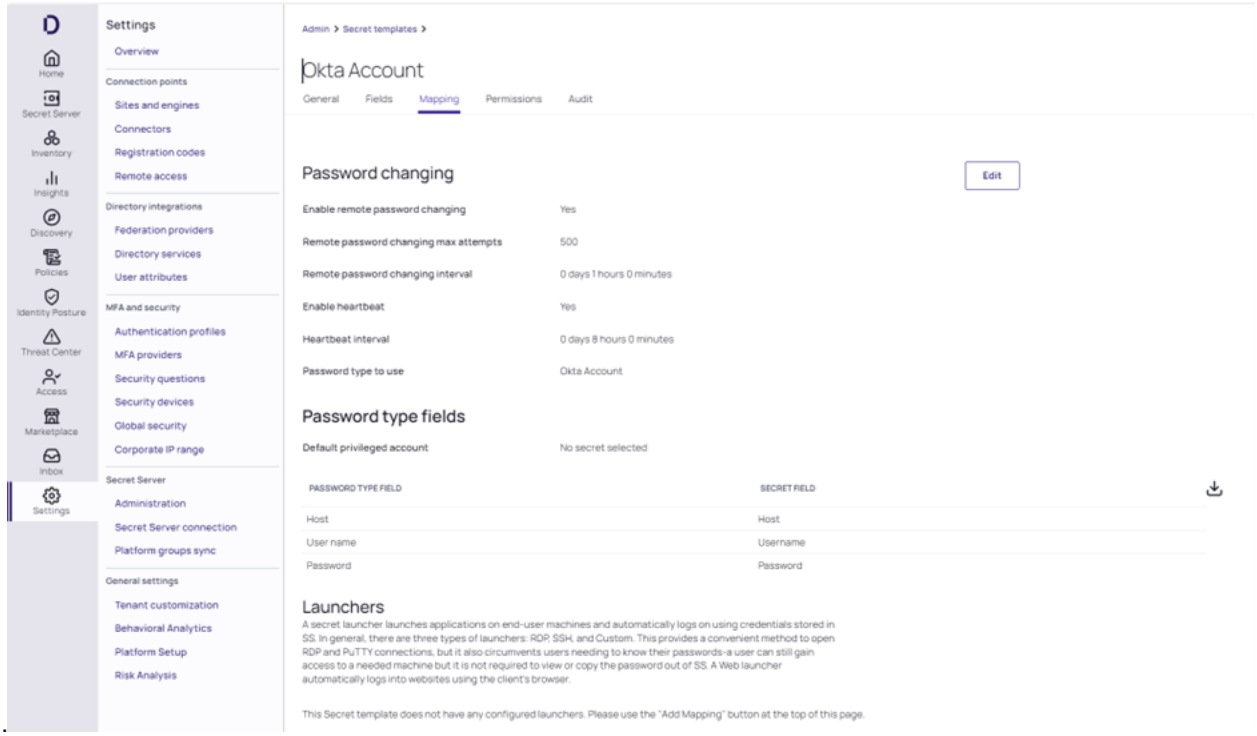
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in the **Active** status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an Okta Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page will be displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates will be displayed.
3. Select an **Okta Account** secret template and then access the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Okta Account RPC conforms to the selected secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the Okta Account template on a secret, see "Managing Secrets" on page 1365



OpenLDAP Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for OpenLDAP Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

OpenLDAP is an open-source implementation of the Lightweight Directory Access Protocol (LDAP), widely used for directory services in network environments. It enables the management and access of information about network resources and users, facilitating centralized authentication and authorization.

To use Secret Server for OpenLDAP Account scanning, you should set the integration process. For more details, see"Syncing with OpenLDAP Directory Service" on page 530.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the OpenLDAP, we want the OpenLDAP Account template.

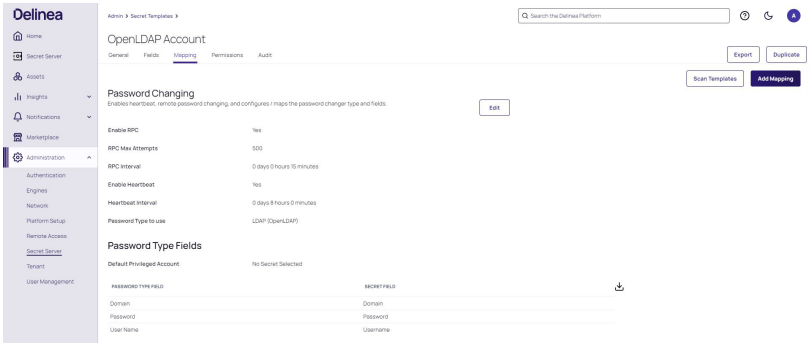
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an OpenLDAP Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an OpenLDAP Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the LDAP (OpenLDAP) RPC conforms to the OpenLDAP Account secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the OpenLDAP Account template on a secret, see "Managing Secrets" on page 1365 documentation.



Oracle Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Oracle Account and Oracle Account (Template Ver 2) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

To configure secret templates for Oracle, see "Configuring Oracle Secret Templates" on page 1230.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Oracle, we want the Oracle Account template.

You can view and modify secret Templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

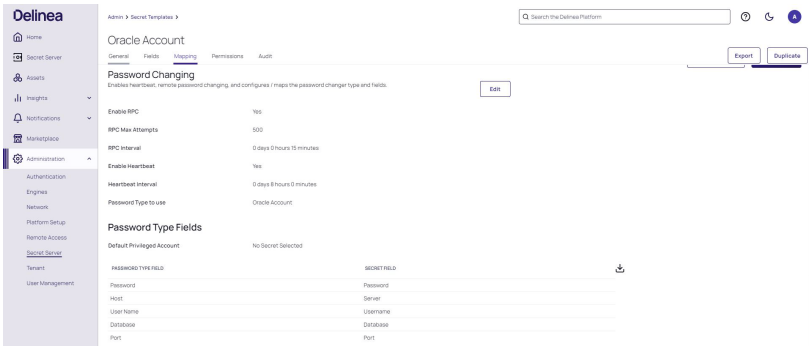
To navigate to an Oracle Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.

3. Select an Oracle Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Oracle Account RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Oracle Account template on a secret, see "Managing Secrets" on page 1365.



Oracle Account (TCPS) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Oracle Account (TCPS) and Oracle Account (Walletless) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Oracle TCPS (Transparent Network Substrate over SSL/TLS) is a technology used in Oracle Database environments to provide secure, encrypted communication between clients and servers. It operates as an extension of Oracle's Transparent Network Substrate (TNS), a fundamental part of the Oracle Net Services, facilitating network sessions from clients to Oracle databases.

To configure secret templates for Oracle, see "Configuring Oracle Secret Templates" on page 1230.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Oracle Account (TCPS), we want the Oracle Account (TCPS) template.

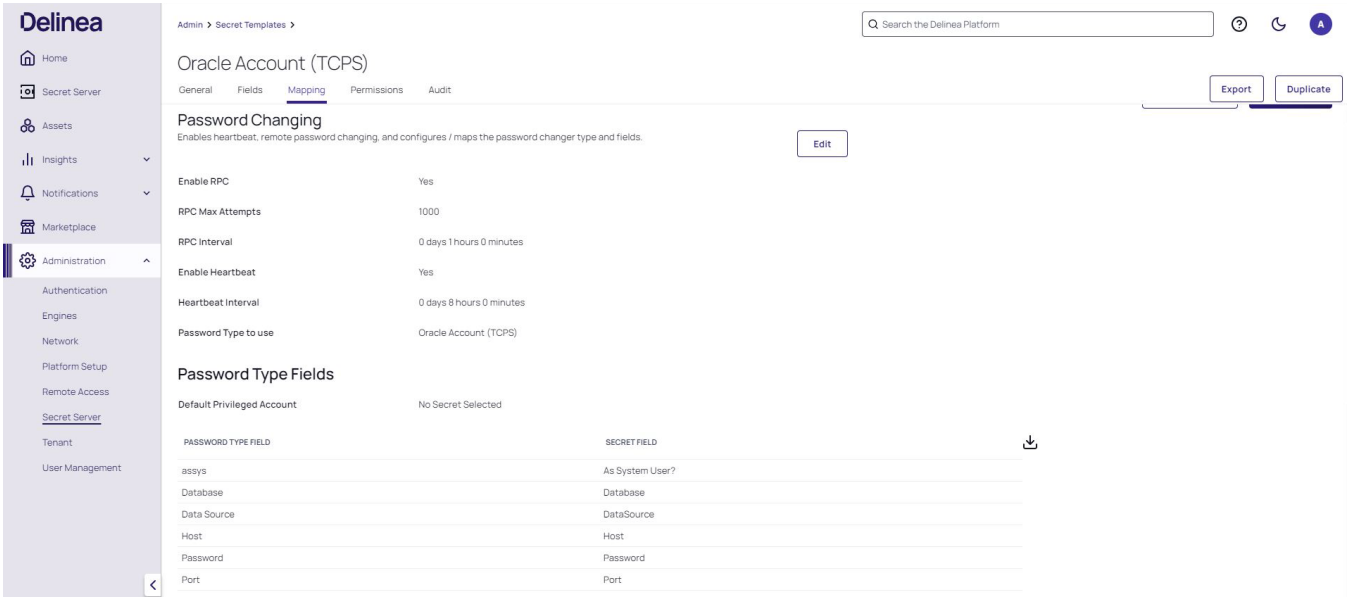
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an Oracle Account (TCPS) secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an Oracle Account (TCPS) secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Oracle Account (TCPS) RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Oracle Account (TCPS) template on a secret, see "Managing Secrets" on page 1365.



SAP Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for SAP Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

SAP, an acronym for Systems, Applications, and Products in Data Processing, is a global leader in enterprise resource planning (ERP) software and related enterprise applications. For instructions on how to set up the SAP Account and arrange its secret template, see "Configuring SAP SNC Account Secret Templates" on page 1209.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the SAP, we want the SAP Account template.

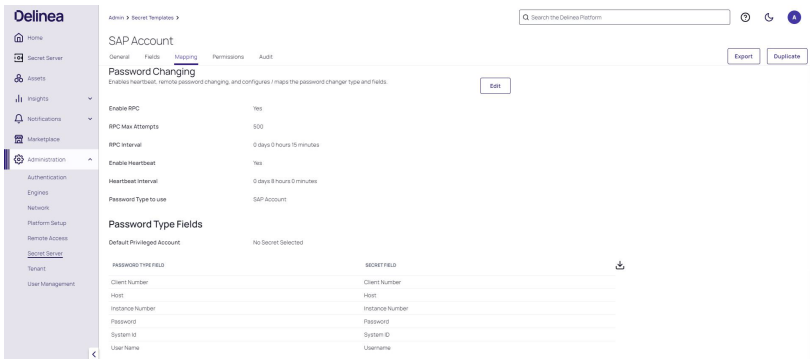
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a SAP Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a SAP Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the SAP Account RPC conforms to the selected secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the SAP Account template on a secret, see "Managing Secrets" on page 1365.



ServiceNow Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for the ServiceNow Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

ServiceNow is a software-as-a-service supplier that provides technical management support, such as IT service management, to the IT operations of large corporations, including help desk functionality. For instructions on how to set up the ServiceNow Account and arrange its secret template, see Integrating ServiceNow RPC with Secret Server.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is application specific and is preconfigured with the password changer best suited to it. For ServiceNow, please use the **ServiceNow Account template**.

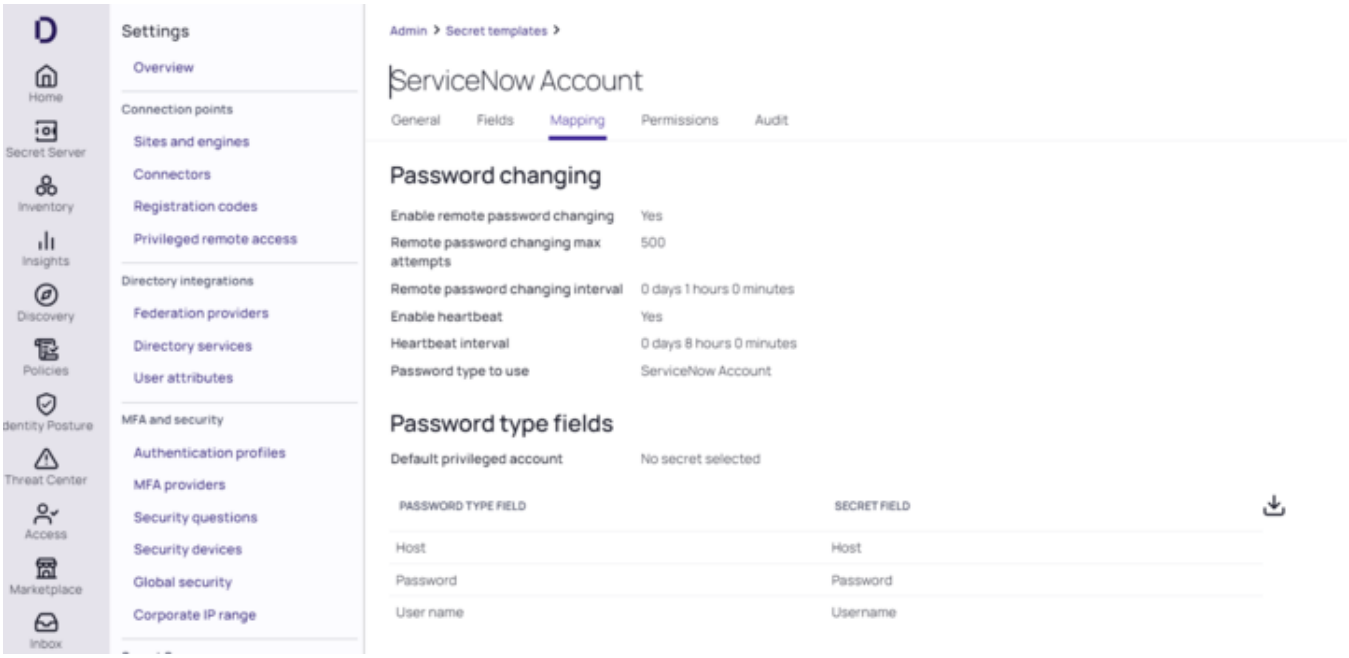
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more details on the available options. Ensure that the secret template is in the **Active** status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a ServiceNow Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page will be displayed.
2. In the **Secrets** section, select **Secret Templates**. The list of available templates will be displayed.
3. Select a **ServiceNow Account** secret template and then access the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the ServiceNow Account RPC conforms to the selected secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the ServiceNow Account template on a secret, see "Managing Secrets" on page 1365.



RPC for Snowflake in Secret Server

RPC for Snowflake in Secret Server applies to Snowflake SQL database user accounts, including both admin and non-admin user accounts.

Prerequisites

Make sure you have:

- Two active Snowflake accounts. One of these accounts must be a privileged admin account which will be used for password changing.

- A Secret Server user who can create two Snowflake secrets.
  - Optionally, admin credentials for Secret Server (the **Limited_User_Admin** role) must be assigned to the admin account.
- The RPC feature enabled in Secret Server.
- Permission to create and configure secrets.
- Heartbeat monitoring and remote password-changing features enabled in Secret Server.
- A site with a distributed engine that has access to the internet.

> The creation of custom roles and the setup of user-role relationships are not part of the password changer implementation itself. These steps are a prerequisite that you must perform in order to use the password changer securely and correctly.

Role Usage Scenarios

- The user can define a custom role for managing multiple users and their passwords. Essentially, this role would function like a group while still being a role.

  Example: A user can create a user-defined role named `Custom_Role`. `User1, User2, User3, User4`, and `User5` are users, owned by `Custom_Role`. `User1` has been assigned to `Custom_Role`, allowing this user to manage the passwords of the other users who also belong to `Custom_Role` as well.

- Two roles can be created, each managing their own set of users.

  Example: Two roles are created: `AccountAdmin` and `Limited_User_Admin`, each have multiple separate user accounts assigned to them. One of these accounts is `AccountUser1`, which has both roles assigned to it. This allows `AccountUser1` to rotate the passwords of users belonging to both roles.

  `AccountUser1` needs to use the following commands:

  - `USE ROLE AccountAdmin` before doing password rotation for any of the users assigned to that role.
  - `USE ROLE Limited_User_Admin` before doing password rotation for users assigned to this second role, respectively.

Configuration

1. Log into Secret Server.
2. Navigate to **All Secrets** and click the **Create secret** button, the **Create new secret** popup appears.
3. Search for the **Snowflake account** template and select it. The popup refreshes automatically to reflect the fields you must fill in.
4. Complete the following fields:
   a. **Secret name**: give the secret an appropriate name.
   b. **AccountId**: you will find this as a part of your Snowflake URL (starts with lsb followed by several numbers).
   c. **Username**: the username used to sign into the Snowflake account.
   d. **Password**: the password used to sign into the Snowflake account.

e. **Site**: set a site with a distributed engine that can access Snowflake services.

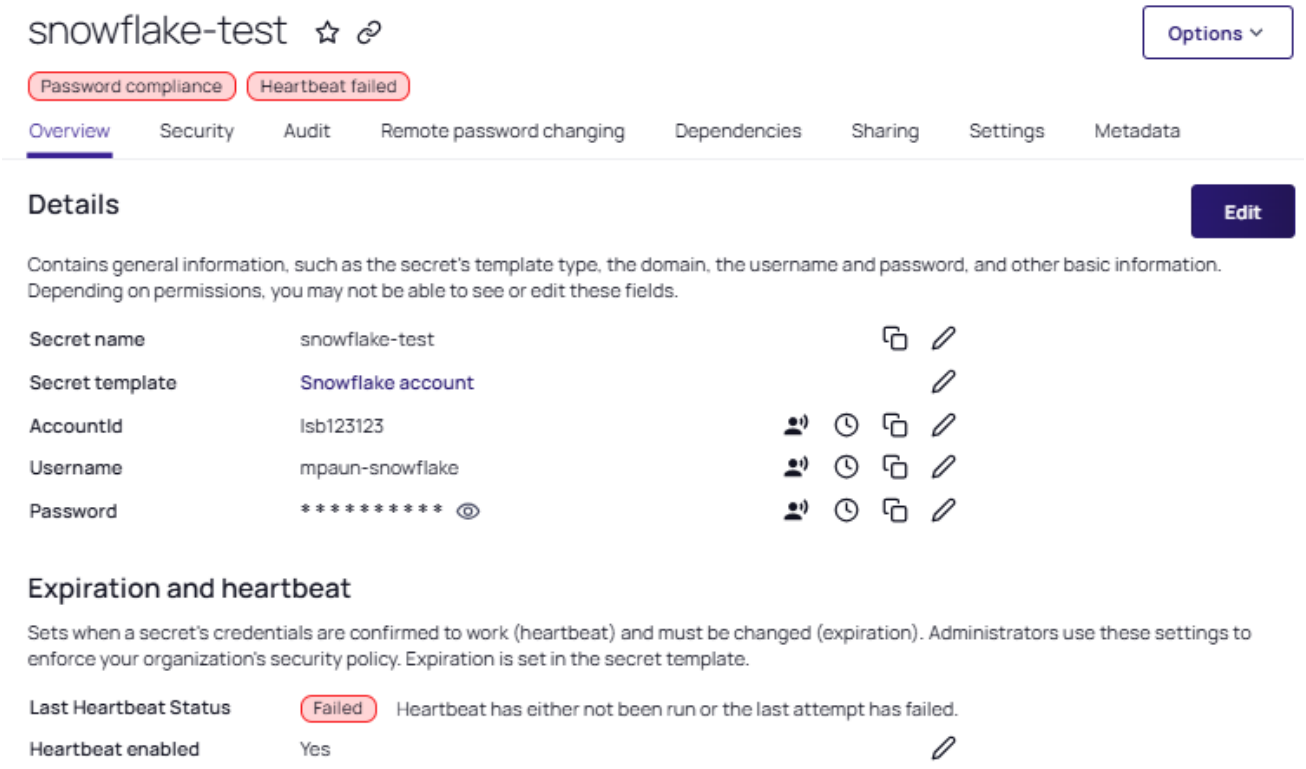
f. Leave **Auto Change Enabled** unchecked and click **Create secret**. The newly created secret loads automatically for viewing.

5. The **Heartbeat** operation runs automatically to check if the entered credentials are valid. If the credentials are valid the status will change from **Pending** to **Success**.

   If the credentials are not valid the status will change from **Pending** to **Failed**.

   > The distributed engine checks for RPC every 300 seconds. If the heartbeat state remains in **Pending** for longer than 300 seconds, confirm that the site has an operational distributed engine by accessing **Settings > Sites and engines**.

   > To verify the status of the heartbeat processes, Search for **Heartbeat Log**.



6. Navigate to the **Remote password changing** tab and select **Edit** for the **RPC/Autochange** section.
7. For **Change password using**, select the **Privileged account credentials** option.

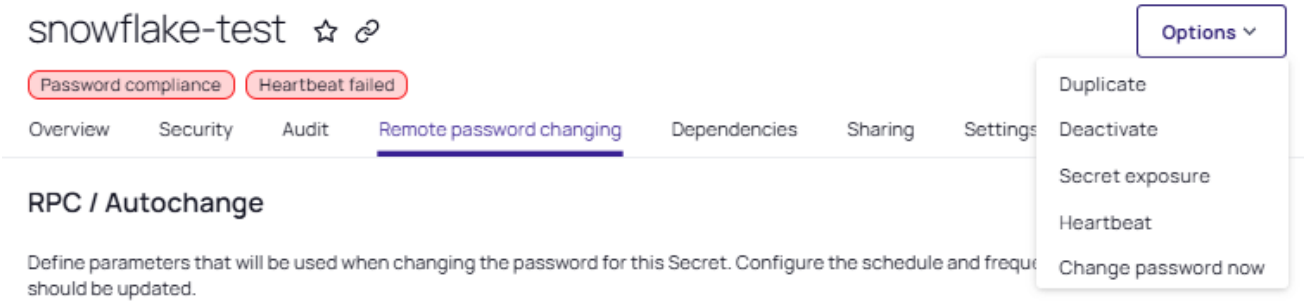
   a. If you chose the option above, the **Change password using** option appears, and you must select a secret by clicking on the **No secret selected** link.

   b. A popup will appear where you can search for the secret you want to associate.

c. Select a Snowflake user with the **Limited_User_Admin** role used to process the password change.

d. Click **Save**.

8. (Optional) Access the **Change password now** option button from the top right corner if you want to change the secret password. Alternatively, it can be found under the **Options** dropdown list:



SonicWall NSA Web Admin Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for SonicWall NSA Web Admin Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

SonicWall is a well-established company specializing in network security and data protection solutions. It offers a wide array of products and services designed to safeguard businesses from a variety of cyber threats, including firewalls, VPNs (Virtual Private Networks), anti-spam, and content filtering systems.

The SonicWall Network Security Appliance (NSA) series is a line of advanced firewalls designed by SonicWall, targeted primarily at medium to large-sized businesses and distributed enterprise environments. These appliances provide comprehensive network security through intrusion prevention, anti-malware, content/URL filtering capabilities, and VPN support for secure remote access.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the SonicWall NSA Web Admin Account, we want the SonicWall NSA Web Admin Account template.

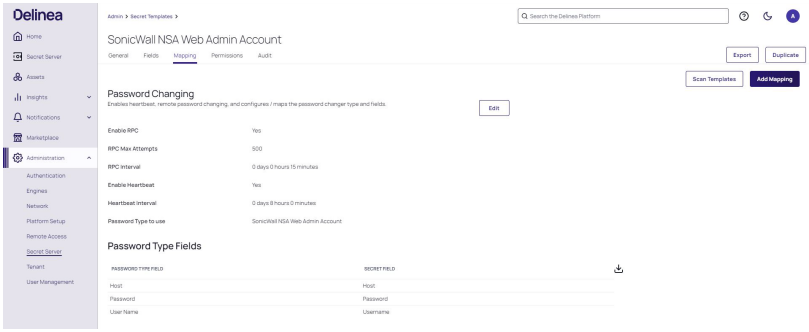
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a SonicWall NSA Web Admin Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a SonicWall NSA Web Admin Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows the SonicWall NSA Web Admin Account RPC is based on the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the SonicWall NSA Web Admin Account template on a secret, see "Managing Secrets" on page 1365 documentation.



SonicWall NSA Web Local User Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for SonicWall NSA Web Local User Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the SonicWall NSA Web Local User Account, we want the SonicWall NSA Web Local User Account template.

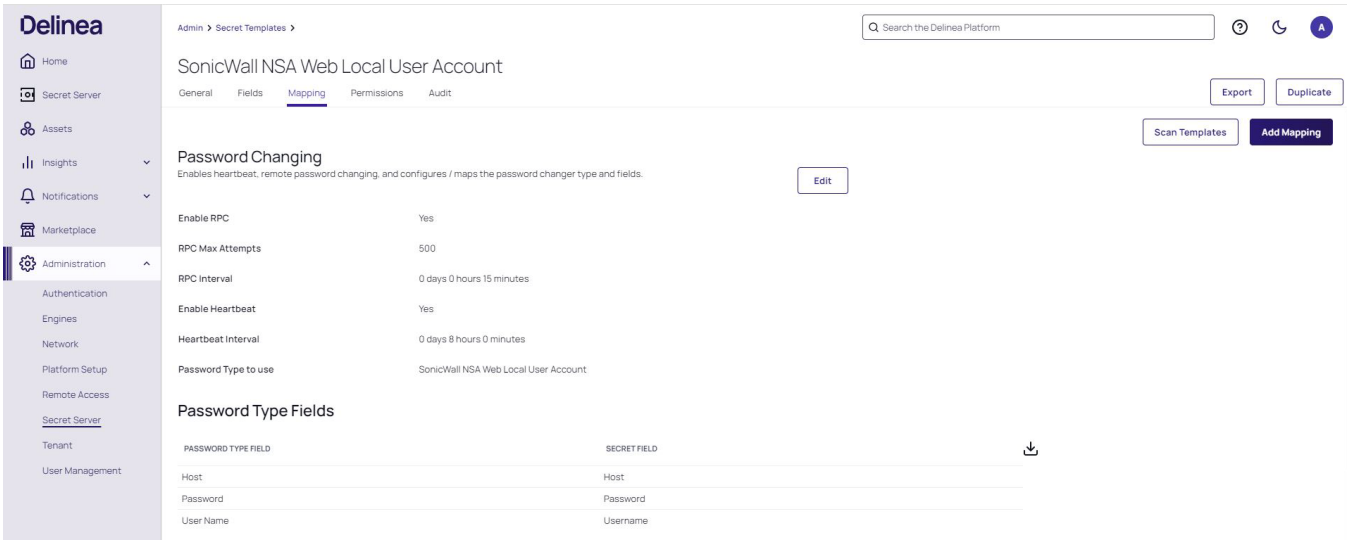
You can view and modify secret Templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a SonicWall NSA Web Local User Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a SonicWall NSA Web Local User Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows the SonicWall NSA Web Local User Account RPC is based on the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the SonicWall NSA Web Local User Account template on a secret, see "Managing Secrets" on page 1365.



Sybase Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Sybase accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Sybase SQL Server, was a high-performance relational database management system (RDBMS), which gained significant popularity in the financial industry for its robustness and efficiency in handling large transactions. For more details on Secret Server and Sybase integration, see"Ports and IP Addresses Used by Secret Server" on page 765.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Sybase Account, we want the Sybase Account template.

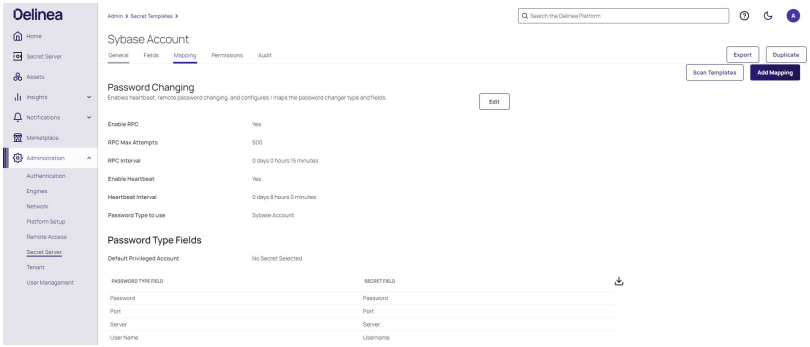
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Sybase Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Sybase Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows the Sybase Account RPC is based on the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Sybase Account template on a secret, see "Managing Secrets" on page 1365.



Unix Account (SSH Key Rotation) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) Unix Account (SSH Key Rotation) and Unix Account (Privileged Account SSH Key Rotation) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

SSH Key Rotation manages a Unix account's private keys, passphrases, and passwords. The public/private key pair is regenerated, and the private key is encrypted with a new passphrase any time a secret's password changes, manually or automatically. The public key is then updated on the Unix machine referenced on the secret. For details, see "Custom SSH Key Rotation" on page 1069.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Unix Account SSH Key Rotation, we want the Unix Account SSH Key Rotation template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

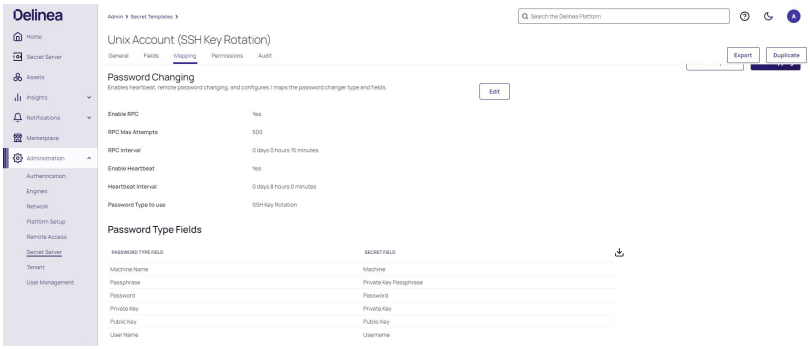
To navigate to a Unix Account SSH Key Rotation or Privileged Account SSH Key Rotation secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.

3. Select a Unix SSH Key Rotation or Privileged Account SSH Key Rotation secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a Unix SSH Key Rotation RPC refers to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Unix SSH Key Rotation or Privileged Account SSH Key Rotation template on a secret, see "Managing Secrets" on page 1365 documentation.



Unix Account (SSH Key Rotation - No Password) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Unix Account (SSH Key Rotation - No Password) and Unix Account (Privileged Account SSH Key Rotation - No Password) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

SSH Key Rotation manages a Unix account's private keys, passphrases, and passwords. The public/private key pair is regenerated, and the private key is encrypted with a new passphrase any time a secret's password changes, manually or automatically. The public key is then updated on the Unix machine referenced on the secret. For more details, see "SSH Key Rotation" on page 1065.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Unix Account (SSH Key Rotation - No Password), we want the Unix Account (SSH Key Rotation - No Password) template.

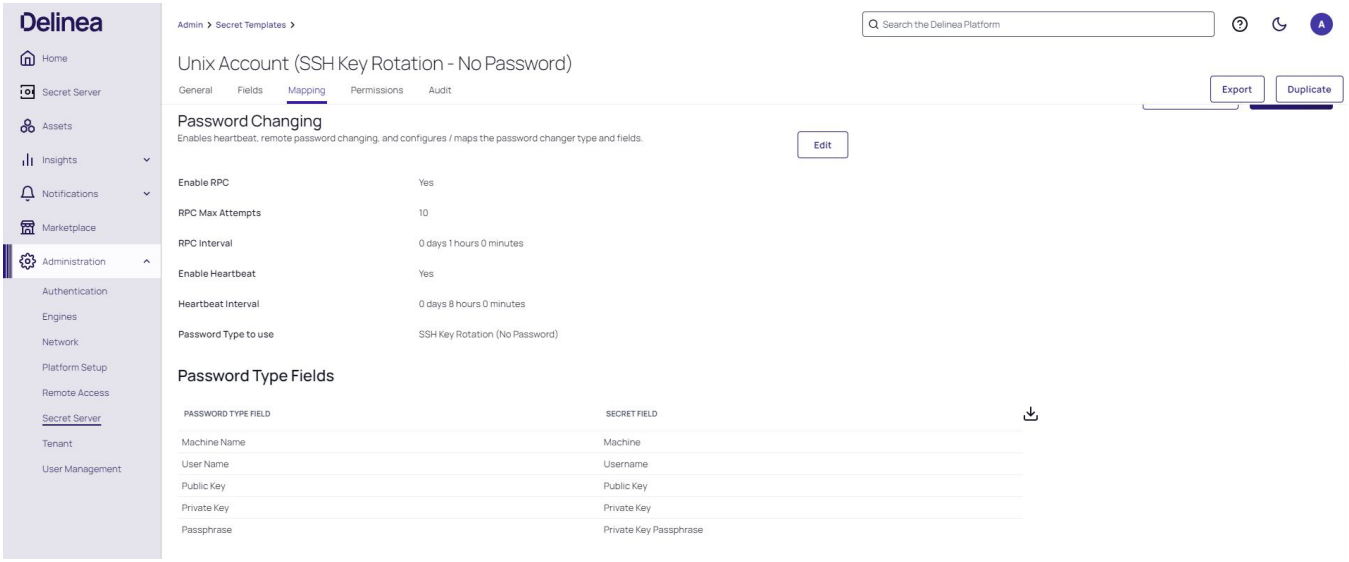
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Unix Account (SSH Key Rotation - No Password) or Unix Account (Privileged Account SSH Key Rotation - No Password) secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Unix Account (SSH Key Rotation - No Password) or Unix Account (Privileged Account SSH Key Rotation - No Password) secret template, then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a Unix Account (SSH Key Rotation - No Password) RPC refers to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the Unix Account (SSH Key Rotation - No Password) or Unix Account (Privileged Account SSH Key Rotation - No Password) template on a secret, see "Managing Secrets" on page 1365.



Unix Account (SSH) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Unix Account (SSH) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

With this feature, admins can use private SSH keys for PuTTY launcher sessions, RPC tasks (configurable through password changer settings), and Unix along with Linux discovery. Passphrases can be stored, if necessary, to decrypt the private keys for additional security. The Unix Account (SSH) secret template includes text-entry fields for the private key and passphrase by default.

The SSH Key template is included by default and can be used to store SSH keys that can later be selected for RPC, discovery, or launcher authentication for other secrets.

The **Unix Account (SSH)** secret template uses password changers that change the public key in the account's `authorized_keys` file and the account password. Secret Server ships with a password changer and custom command sets that allow an account to change its public key and password, as well as a password changer and custom command sets that change a user's public key and password using a privileged account. These scripts can be customized for different Unix environments.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage built-in secret templates. Each secret template is application-specific and is preconfigured with the password changer best suited to that application. For this example you will use the Unix Account (SSH) template.

You can view and modify secret templates in the Secret Server by searching for "secret templates". See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Unix Account (SSH) secret template:

1. Search for **Secret Templates** and select it. The list of available templates is displayed.
2. Select the **Unix Account (SSH)** secret template.
3. Access the **Mapping** tab.

Secret templates determine the fields, launchers, and the remote password changer for secrets using that template. To use the Unix Account (SSH) template on a secret, see "Managing Secrets" on page 1365. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Unix Account (Telnet) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Unix Account (Telnet). With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Secret Server can use scripted password changers for devices that support SSH or Telnet (this allows for flexibility in changing passwords on less common devices). You can also run custom RPC PowerShell scripts to change other platforms' passwords.

With the help of the Secret Server, admins can use private SSH keys for PuTTY launcher sessions and RPC tasks—configurable through password changer settings. Secret Server supports SSH key rotation on secrets.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Unix Account (Telnet), we want the Unix Account (Telnet) template.

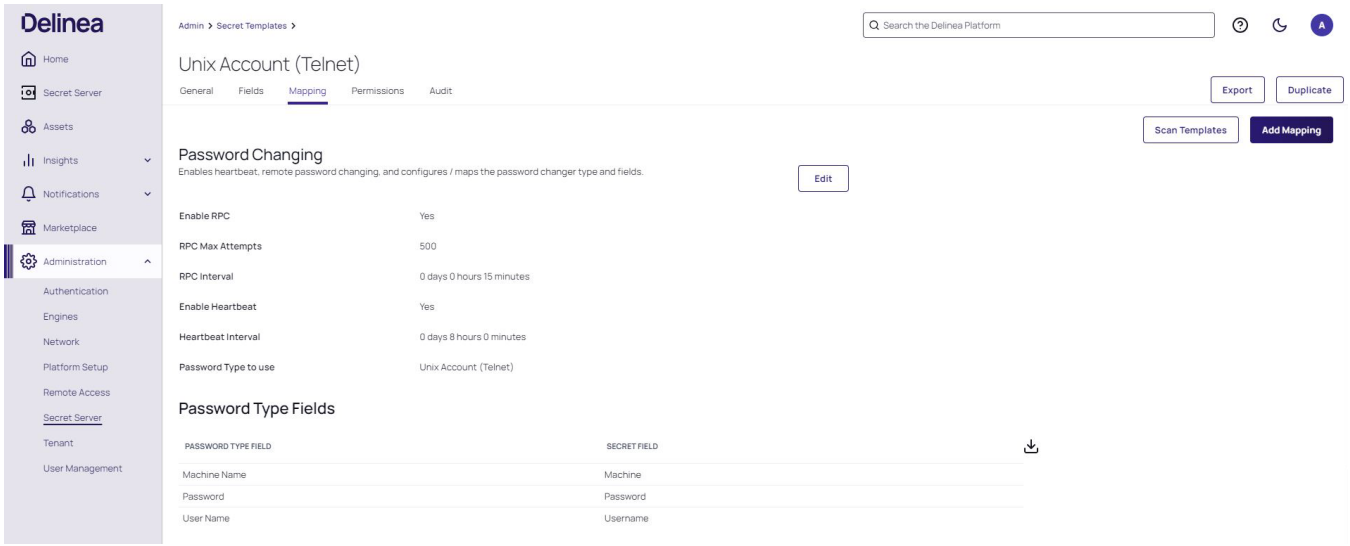
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Unix Account (Telnet) secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Unix Account (Telnet) secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a Unix Account (Telnet) RPC refers to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To utilize the Unix Account (Telnet) template on a secret, see "Managing Secrets" on page 1365.



Unix Root Account (SSH) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for the Unix Root Account (SSH). With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

With this Secret Server feature, admins can use private SSH keys for PuTTY launcher sessions, RPC tasks (configurable through password changer settings), and Unix and Linux discovery. Passphrases can additionally be stored, if necessary, to decrypt the private keys for additional security. The Unix Account (SSH) secret template includes text-entry fields for the private key and passphrase by default.

The SSH Key template is included by default and can be used to store SSH keys that can later be selected for RPC, discovery, or launcher authentication for other secrets.

The **Unix Root Account (SSH)** secret template uses password changers that change the public key in the account's `authorized_keys` file and the account password. Secret Server ships with a password changer and custom command sets that allow an account to change its public key and password and a password changer and custom command sets that change a user's public key and password using a privileged account. These scripts can be customized for different Unix environments.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Unix Root Account (SSH), we want the Unix Root Account (SSH) template.

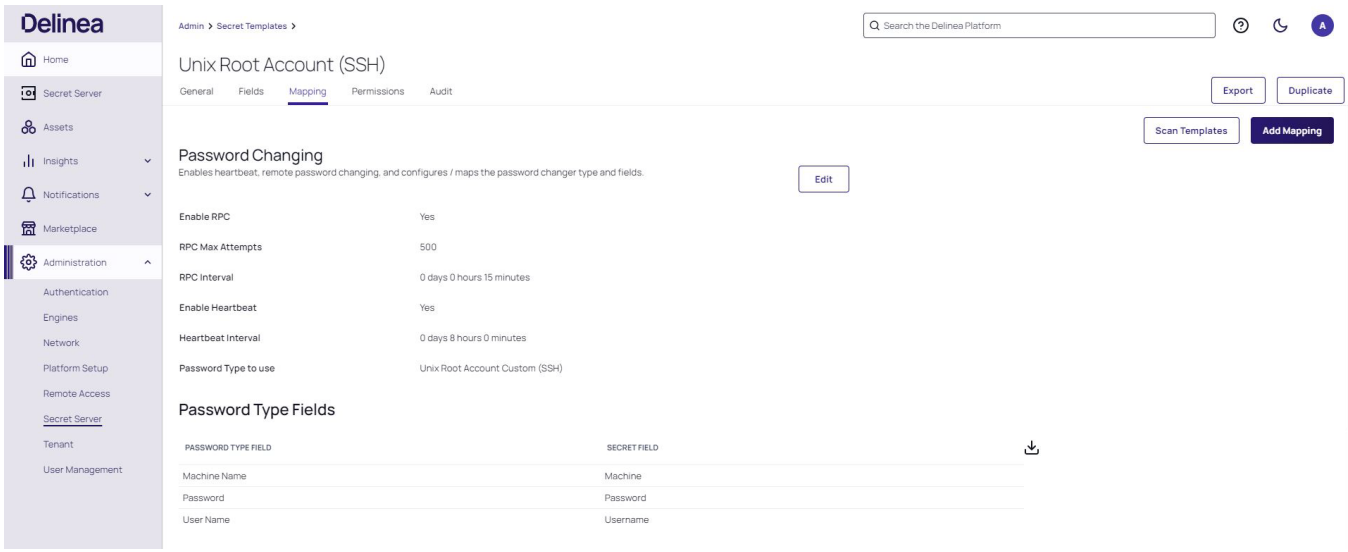
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Unix Root Account (SSH) secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Unix Root Account (SSH) secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a Unix Root Account Custom (SSH) RPC refers to the Unix Root Account (SSH) secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Unix Root Account (SSH) template on a secret, see "Managing Secrets" on page 1365.



VMware Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for the VMware ESX/ESXi (API) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

During configuration, Secret Server is given a list of IP addresses or computer names that correspond to ESX or ESXi servers. Secret Server then connects to each server using the provided credentials to query for a list of user accounts on the target system. For details, see "VMware ESX/ESXi Account Discovery" on page 648.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the VMware ESX/ESXi (API), we want the VMware ESX/ESXi (API) template.

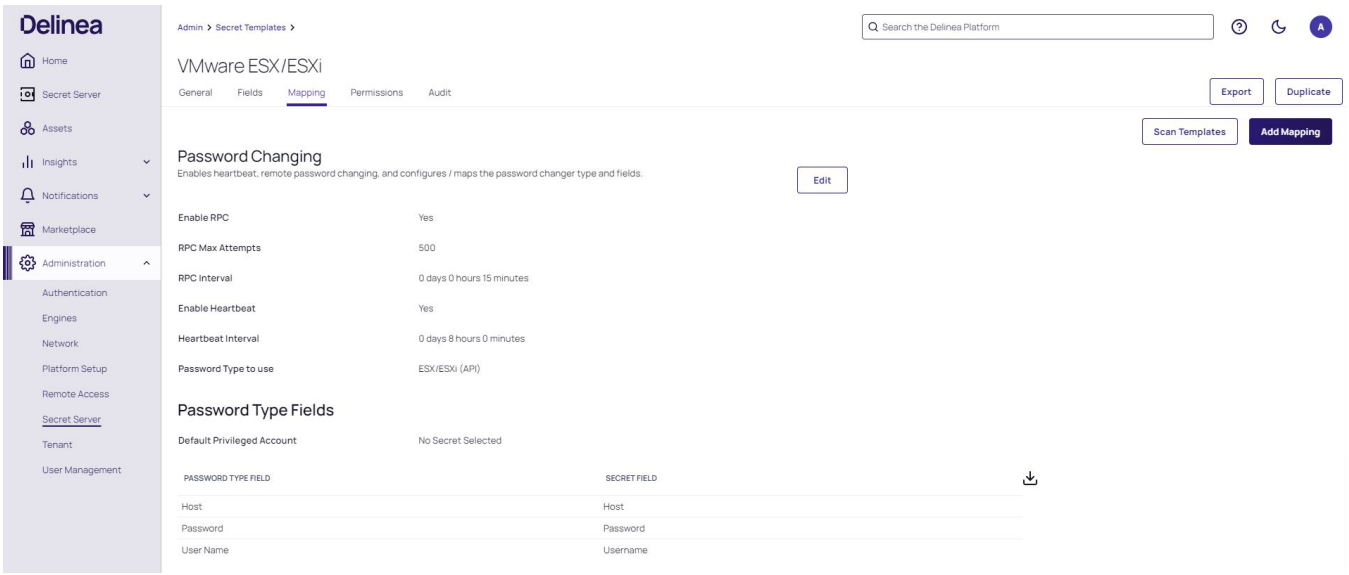
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a VMware ESX/ESXi (API) secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a VMware ESX/ESXi secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a VMware ESX/ESXi (API) RPC refers to the ESX/ESXi secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the VMware ESX/ESXi template on a secret, see "Managing Secrets" on page 1365.



WatchGuard Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for the WatchGuard accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

WatchGuard is a technology company that specializes in network security products and services, including firewalls, secure Wi-Fi, multi-factor authentication, and network intelligence solutions for small to medium-sized businesses and organizations.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the WatchGuard, we want the WatchGuard template.

You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

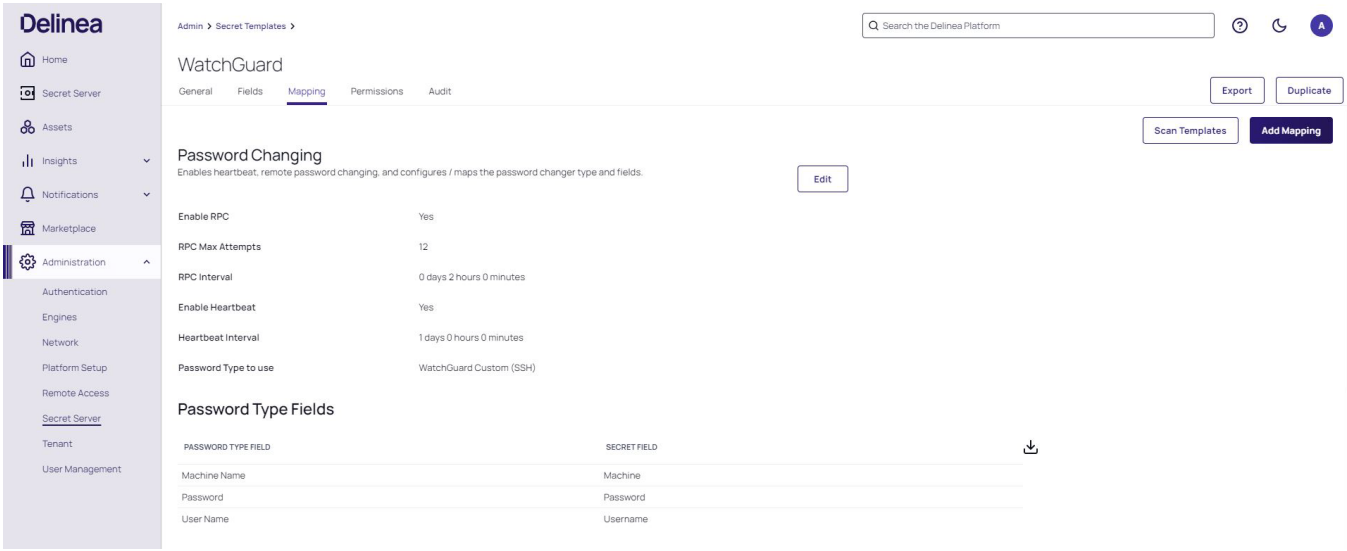
To navigate to a WatchGuard secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a WatchGuard secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a

WatchGuard Custom (SSH) RPC refers to the WatchGuard secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the WatchGuard template on a secret, see "Managing Secrets" on page 1365.



Web Password Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for the Web Password accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Web Password, we want the Web Password template.

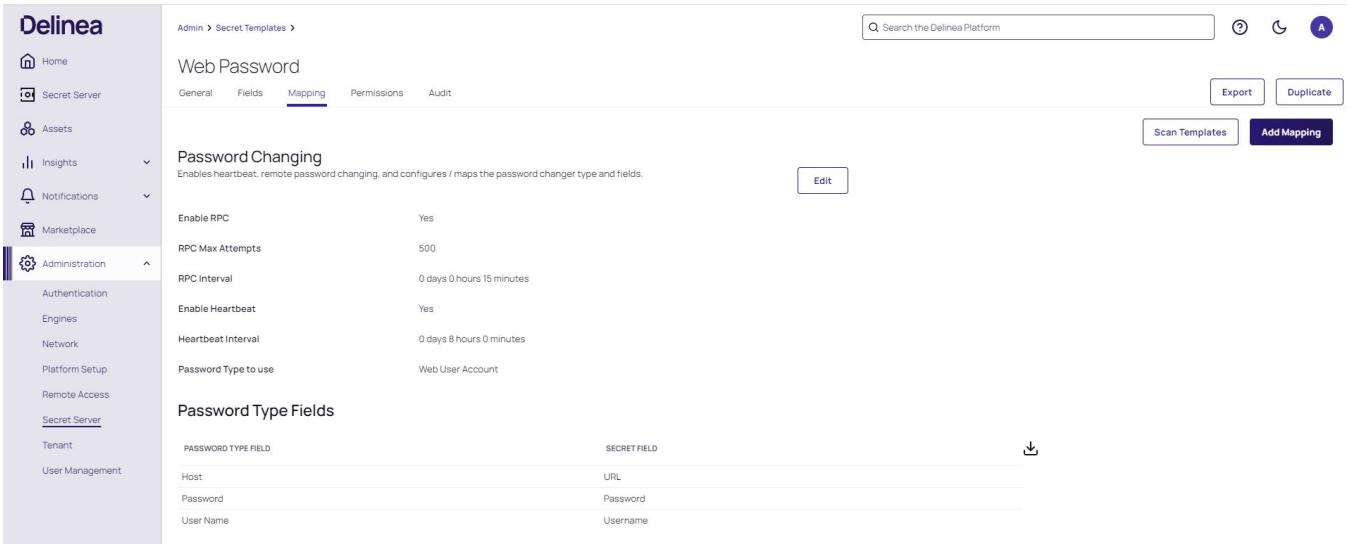
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Web Password secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Web Password secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a Web User Account RPC refers to the Web Password secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Web Password template on a secret, see "Managing Secrets" on page 1365.



Windows Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for the Windows Account. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Windows Account, we want the Windows Account template.

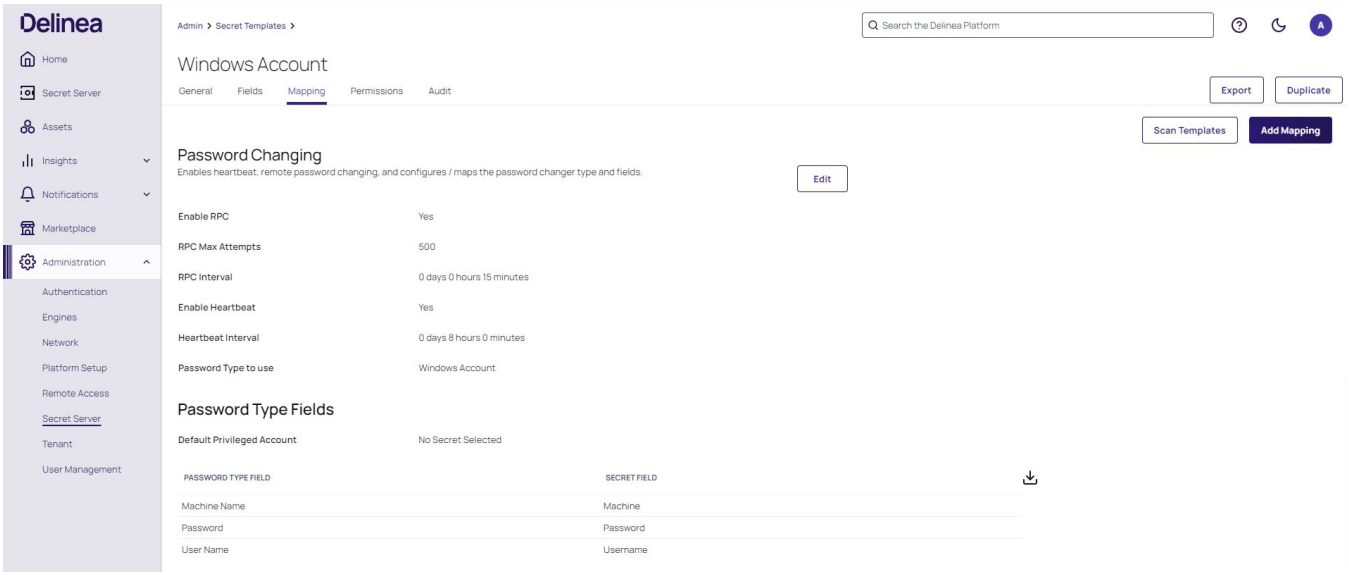
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to a Windows Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select a Windows Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that a Windows Account RPC refers to the Windows Account secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Windows template on a secret, see "Managing Secrets" on page 1365.



Remote Password Changing for Teradata

With Remote Password Changing (RPC), secrets can automatically change remote account passwords on a schedule, upon check-in, or explicit user request. The complexity requirements for the password are user-configurable.

Teradata is a performance scaling RDBMS. Teradata Vantage is the on-prem offering (supplied as VMware VMI). Teradata Clearscape is the cloud SaaS offering. Secret Server uses a Teradata-supplied NuGet client, compatible with Teradata v15-v20.

In Teradata RPC, accounts can change their own password, or the password can be changed using privileged credentials.

Prerequisites

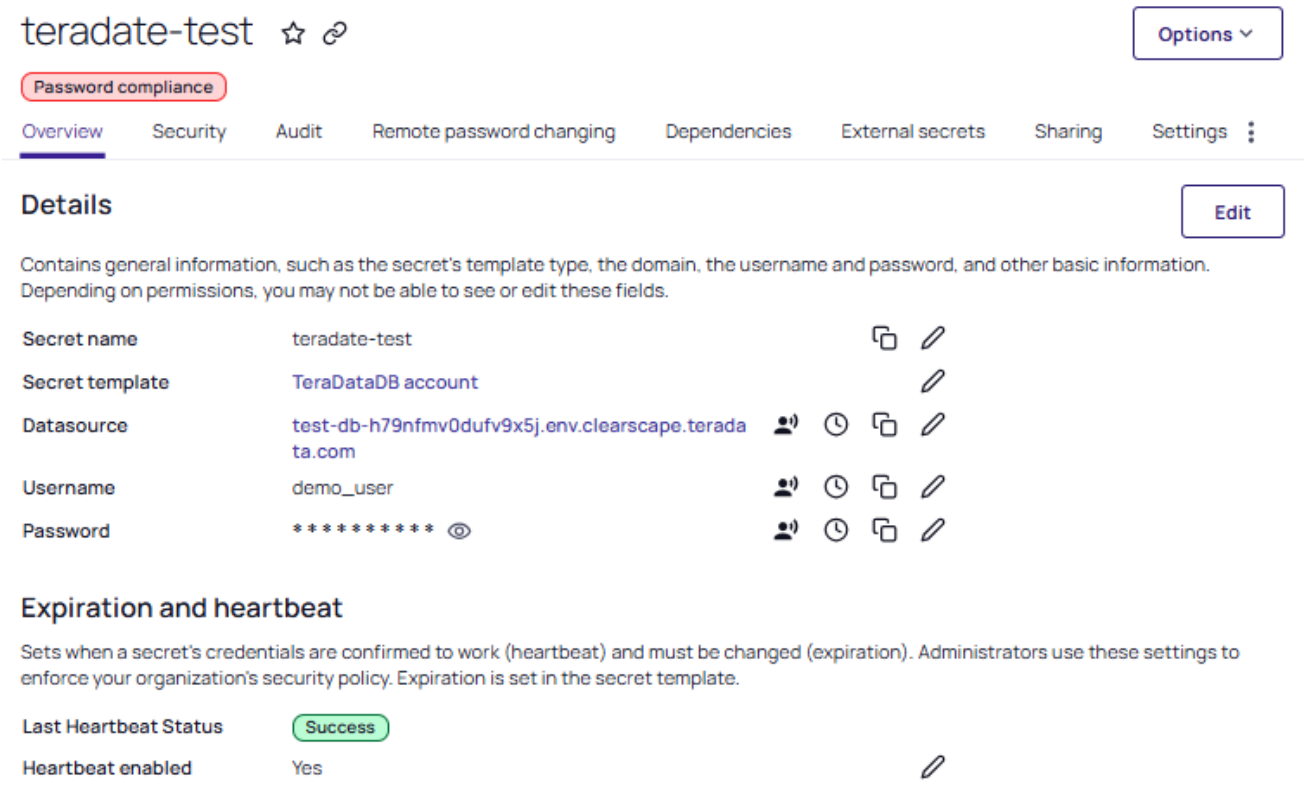
Make sure you have:

- Access to a Teradata database service (Vantage or Clearscape).
- User credentials to access Secret Server.
- Heartbeat monitoring and remote password changing enabled in Secret Server.
- A distributed engine from which to make the connection.

Configuration

1. Log into Secret Server.
2. Install a distributed engine onto a site (“Default” for this procedure).
3. Navigate to **Secret Server > All secrets**.
4. Select the **Create secret** button. The Create new secret popup appears.
5. Select the **TeradataDb account** template.
6. Complete the mandatory fields:
   - **Secret name**: Give the secret an appropriate name.
   - **Datasource** Specify the DNS name or the IP address of the Teradata connection.
   - **Username**: The username of the TeradataDB account.
   - **Password**: The password of the TeradataDB account.
   - **Site**: Leave it set to Default for this tutorial.
7. Select **Create Secret**. The newly created secret appears automatically, with **Last Heartbeat Status** set to Pending.

> After a few minutes if the DE is working correctly it will attempt to run a heartbeat and **Last Heartbeat Status** will change to either **Success** or **Failure**.



> In the event of a failure the cause can be searched for in the **Heartbeat Log** entries. After selecting the correct log entry the error will appear in the popup pane on the right.

8. A heartbeat has now been performed.

Heartbeats are queued whenever:

- The secret's password value is changed manually (to determine if the new password value is valid).
- An RPC is performed.
- A user manually clicks the **Heartbeat** button on the secret's overview page.

The distributed engine processes a heartbeat on a short schedule (<5 min) unless the heartbeat button is selected, causing it to run immediately (within 15 seconds).

Remote Password Changing

Teradata account passwords can be changed through the Remote Password Changing feature in Secret Server. When this feature is enabled and activated the command executes, then a heartbeat is automatically performed. If the heartbeat returns with a successful result the secret is valid.

> There are various reasons why a failure might result instead, such as the new password not being accepted due to complexity requirements, or the Teradata database server might be down. In these cases, the cause will show up in the heartbeat log.

1. Access the secret you created above.
2. Select the **Remote Password Changing** tab.
3. For the **RPC / Autochange** section, select **Edit**.
4. For **Change password using** set **Privileged account credentials**.

> If a secret's password is valid, it can use itself to change its own password. If a secret's password is not valid, then the secret cannot be used to authenticate in order to perform the password change. Teradata supports changing passwords with a secret that represents a privileged (superuser) Teradata account.

5. Click **no secret selected**.
6. Choose the secret you created previously. The password change command will be run as the privileged user listed here. This allows the RPC to succeed even if the account's password in the secret is invalid.
7. Select **Save**. On the Overview tab, the last heartbeat status becomes Pending again until the RPC completes.
   a. You can skip the wait time by navigating to **Settings > Password Change Log**.
   b. Select **Run RPC Now** to launch the process immediately.

      When RPC is complete a banner will briefly appear at the bottom of the page indicating success or failure. If you miss it the result can be seen in the password change log list.

Remote Password Changing for WebSphere

With Remote Password Changing (RPC), secrets can automatically change remote account passwords on a schedule, upon check-in, or explicit user request. The complexity requirements for the password are user-configurable.

IBM WebSphere is a suite of enterprise application and integration middleware, with WebSphere Application Server (WAS) as its core offering. It provides a runtime environment for deploying and managing Java-based applications and services. WebSphere can be run on-premises or in cloud environments, supporting scalability, clustering, and centralized administration.

In WebSphere RPC, accounts can change their own password, or the password can be changed using privileged credentials. See the Password Changer List for a complete list of available password changers.

Prerequisites

WebSphere can run in two main deployment models:

- **On-premises (local install)**
  - Traditionally, the IBM WebSphere Application Server (WAS) is installed on local servers (Windows, Linux, AIX, z/OS, etc.).
  - Secret Server connects to those servers (directly or via a distributed engine) to perform remote password changes against service accounts, application users, or underlying OS/LDAP accounts.
- **Cloud-based offerings**
  - IBM also provides the WebSphere Hybrid Edition and WebSphere Liberty on IBM Cloud.
  - In such cases, the WebSphere runtime is provisioned in the cloud but can still integrate with the distributed engine in Secret Server, provided network connectivity exists between them. Additionally, always ensure that the machine hosting WebSphere can communicate with the distributed engine:
    - For Linux, SSH connectivity is required.
    - For Windows, a PowerShell setup and connectivity is required.

    Without proper connectivity, secret integration between WebSphere and the distributed engine will fail.
  - If the cloud WebSphere instance sits behind restricted access, you may still need a distributed engine deployed in a cloud VPC/subnet to handle RPC.
- User credentials to access Secret Server.
- Heartbeat monitoring and Remote Password Changing enabled in Secret Server.
- A distributed engine from which to make the connection.

> This is always required in cloud, but for on-prem Secret Server, a DE is one of two options available. The other is connecting directly, appropriate for small networks, using **Local** site.

Configuration for Remote Password Changing

When a password is changed manually or by RPC, a Heartbeat is queued to determine if the credentials in the secret are valid. The heartbeat status shows **Pending** while the process executes. When the heartbeat completes

the status will change to either Success or Failure. Success means the credentials in the secret are valid.

> If a failure results instead, the cause will show up in the heartbeat log.

1. Log into Secret Server.
2. Install a distributed engine onto a site (“Default” for this procedure).
3. Navigate to **All secrets**.
4. Select the **Create secret** button. The Create new secret popup appears.
5. Search for one of the two WebSphere secret templates.
   a. If you select the **Websphere Account** template, the popup refreshes automatically to reflect the following fields:
      - **Secret name**: give the secret an appropriate name.
      - **MachineName**: The name of the WebSphere Machine.
      - **Username**: The username of the WebSphere account.
      - **Password**: The password of the WebSphere account.
      - **Site**: The container in which heartbeat, RPC, and other secret activities occur.
      - **Auto Change Enabled**: When enabled, this secret will be set to expire on a schedule and change the password. After creation view the RPC tab for details.
      - Click **Create Secret** to save your changes.

        > If you only require a non-privileged secret, configuration is complete after creating the secret as shown in step 5a. HB and RPC will run using the secret’s own credentials.

   b. If you select the **WebSphere Privileged Account** template, the popup refreshes automatically to reflect the following fields:
      - **Secret name**: give the secret an appropriate name.
      - **MachineName**: The name of the WebSphere Machine.
      - **Username**: The privileged username of the WebSphere account.
      - **Password**: The privileged password of the WebSphere account.
      - **Remote Machine Username**: The username of the WebSphere machine.
      - **Remote Machine Password**: The password of the WebSphere machine.
      - **WsAdminToolPath**: The path of the WebSphere ws admin.
      - **Port**: The port of the WebSphere ws machine.
      - **Is Linux Server**: RPC running on the Linux Server. Requires a yes or a no.
      - **Site**: The container in which heartbeat, RPC, and other secret activities occur.
      - Click **Create Secret** to save your changes.

> Be sure to add default port number 22 for Linux (SSH) and 5985 for Windows (PowerShell).

For this example, we'll be using the second template.

6. Access of the secret you created using the **WebSphere Privileged Account** template.
7. Select the **Remote Password Changing** tab.
8. For the **RPC / Autochange** section, select **Edit**.
9. For **Change password using** set **Privileged account credentials**.

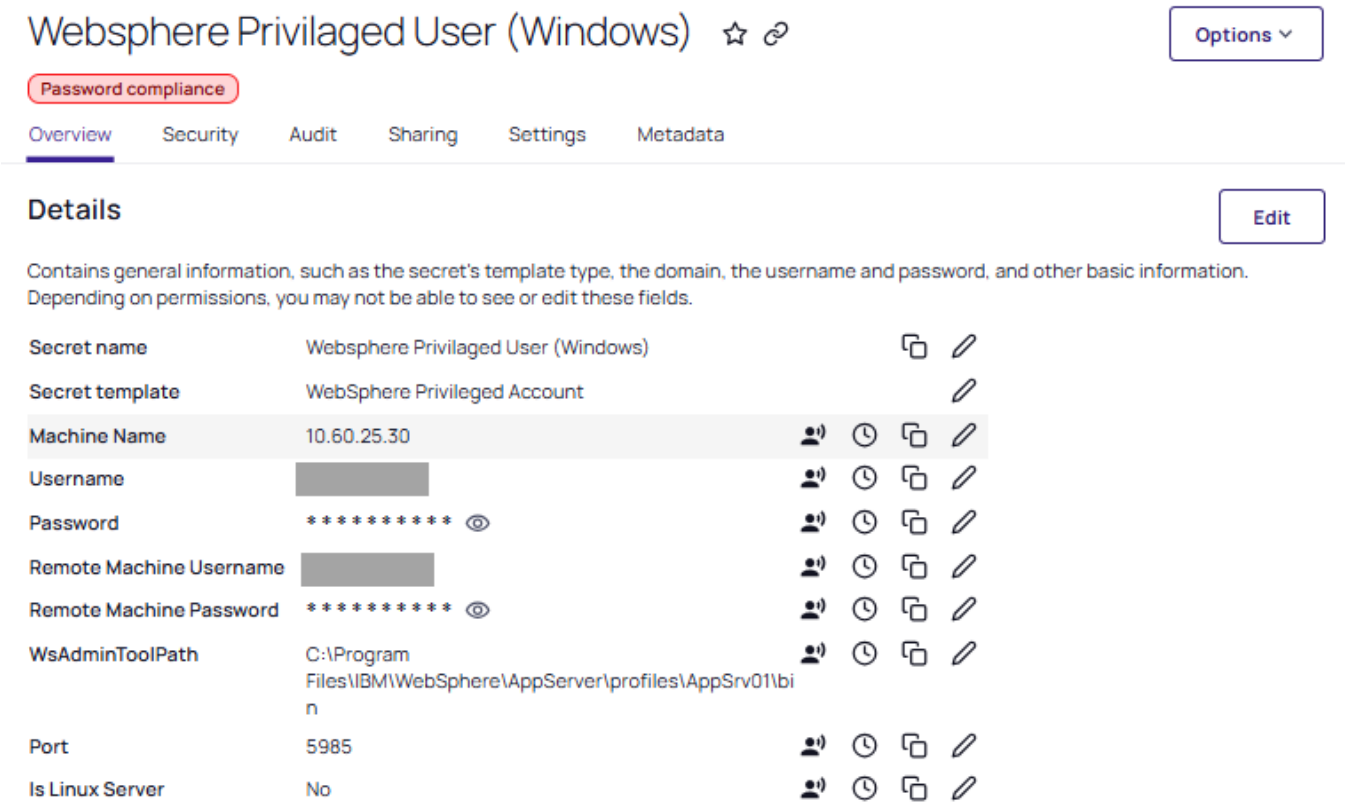
> If a secret's password is valid, it can use itself to change its own password. If a secret's password is not valid, then the secret cannot be used to authenticate in order to perform the password change.

10. Click **no secret selected**.
11. Choose the secret you created previously. The password change command will be run as the privileged user listed here.

> This allows the password change to run as the privileged user, ensuring RPC succeeds even if the secret's password is invalid. This configuration allows for **takeover**, where Secret Server enforces the authoritative password, similar to the how a super user functions.

12. Select **Save**.
13. On the **Overview** tab, the last heartbeat status becomes Pending again until the RPC completes.
    a. You can skip the wait time by navigating to **Settings > Password Change Log**.
    b. Select **Run RPC Now** to launch the process immediately.

    When RPC is complete a banner will briefly appear at the bottom of the page indicating success or failure. If you miss it the result can be seen in the password change log list.



Remote Password Changing for Windows Account (PowerShell)

With Remote Password Changing (RPC), secrets can automatically change remote account passwords on a schedule, upon check-in, or explicit user request. The complexity requirements for the password are user-configurable.

Windows PowerShell is Microsoft's console. It provides a command-line shell and a scripting language built on .NET, allowing administrators to automate system management tasks and integrate with various services. PowerShell scripts and modules can be run locally or remotely (called WinRM), making it a flexible tool for managing accounts, systems, and applications. Windows Account (Powershell) performs heartbeat and RPC by running PowerShell remotely using WinRM.

Windows Account (PowerShell) secrets require a privileged takeover secret to operate, and to perform heartbeats and RPC. See the Password Changer List for a complete list of available password changers.

Prerequisites

Make sure you have the following set up:

- PowerShell installed and properly configured on the Windows machine hosting Secret Server.
- WinRM (Windows Remote Management) enabled and set up correctly.
- Admin user credentials to access Secret Server.

- Heartbeat monitoring and Remote Password Changing enabled in Secret Server.
- A Distributed Engine from which to make the connection.

Configuration for Remote Password Changing

When a password is changed manually or by RPC, a Heartbeat is queued to determine if the credentials in the secret are valid. The heartbeat status shows **Pending** while the process executes. When the heartbeat completes the status will change to either Success or Failure. Success means the credentials in the secret are valid.

> If a failure results instead, the cause will show up in the heartbeat log.

Task 1: Installing the DE

1. Log into Secret Server.
2. Install a Distributed Engine (DE) onto a site.

Task 2: Creating a Windows Account (PowerShell) Secret for RPC

1. Navigate to **All secrets**.
2. Select the **Create secret** button. The Create new secret popup appears.
3. Search for the **Windows Account (PowerShell)** secret template.

   > This will function as the secret which will be tested for heartbeat or changed by RPC.

4. The popup refreshes automatically to reflect the following fields:
   - **Secret name**: give the secret an appropriate name.
   - **Machine**: The (URL) host name of the Windows machine this secret resides on.
   - **Username**: The username of the windows local account.
   - **Password**: The password of the windows local account.
   - **Site**: Select the site that has the Distributed Engine you setup earlier. It must have network access to the necessary Windows hosts.
   - **Auto Change Enabled**: When enabled, this secret will be set to expire on a schedule and change the password. After creation view the RPC tab for details.
   - Click **Create Secret** to save your changes.
5. The secret you just created loads automatically, landing on the **Overview** tab.
6. You will see a warning below the name of the secret, at the top: **A Windows Account (PowerShell) takeover secret is required to change or verify the password on this account**.

Task 3: Creating the Takeover Secret

1. Navigate to **All secrets**.
2. Select the **Create secret** button. The Create new secret popup appears.

3. Search for the **Windows Account (PowerShell) takeover** secret template.

   The takeover secret contains the credentials of an administrative user. This account's privilege will be used to change or verify the password on the (main) secret created in Task 2.
4. The popup refreshes automatically to reflect the following fields:
   - **Secret name**: give the secret an appropriate name.
   - **Endpoint**: Remote machine WinRM endpoint: `https://hostname:5986/wsman`
   - **Username**: The username of the privileged account.
   - **Password**: The password of the privileged account.
   - **Site**: Set to the site which has the Distributed Engine with network access to the WinRM host.
   - Click **Create Secret** to save your changes.
5. Your secret automatically loads on the **Overview** tab.

   This secret cannot perform heartbeats.

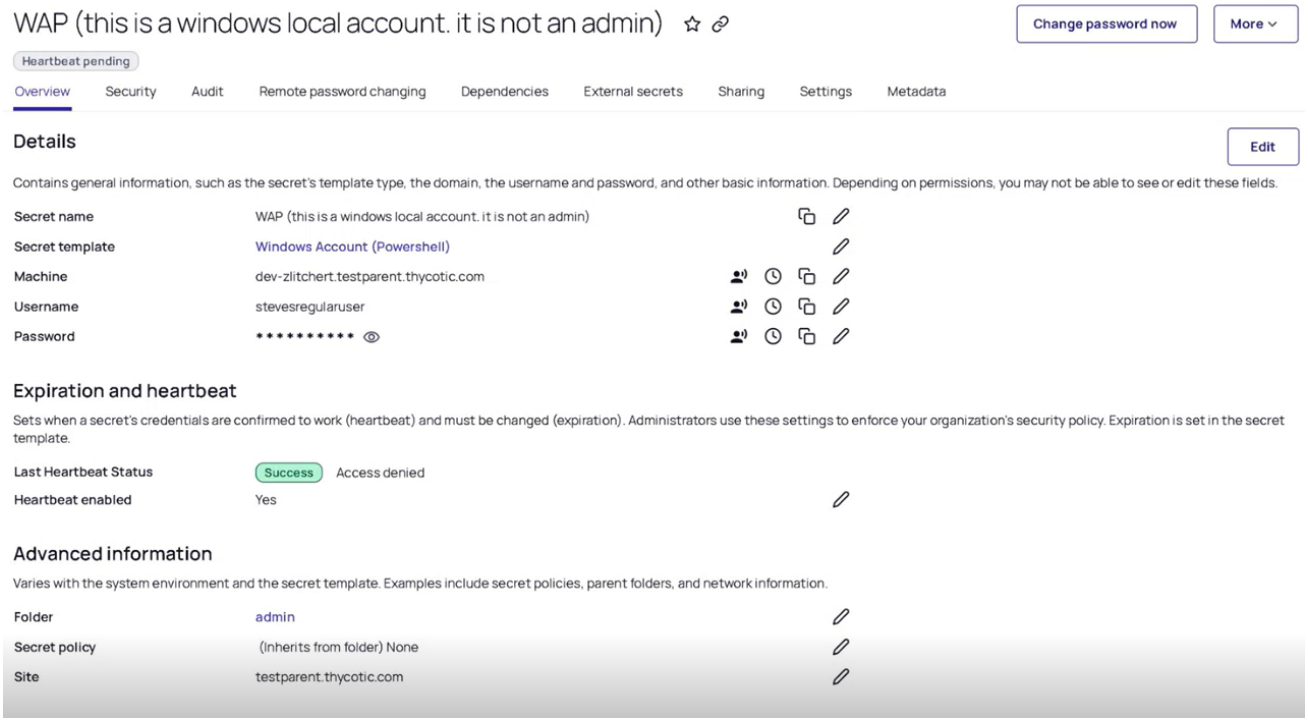
Task 4: Performing Heartbeats and RPC

1. Access the main secret you created in Task 2, the Windows Account (PowerShell) secret.
2. Select the **Remote Password Changing** tab. The previous warning still appears.
3. For the **RPC / Autochange** section, select **Edit**.
4. For **Change password using** set **Privileged account credentials**.
5. Click **no secret selected**.
6. Select the Windows Account (PowerShell) takeover secret created in task 3.

   This causes the heartbeat and remote password change to run as the privileged credentials in the takeover secret.
7. Select **Save**. The heartbeat will run automatically.
8. On the **Overview** tab, the **Last Heartbeat Status** becomes **Pending** again until the heartbeat completes.
   a. You can skip the wait time by navigating to **Settings > Heartbeat Log**.
   b. Select **Run heartbeat Now** to launch the process immediately.
9. You can now also perform RPC by selecting **Change Password Now** from the main secret. The takeover secret will be used.
   a. You can skip the wait time by navigating to **Settings > Password Change Log**.
   b. Select **Run RPC Now** to launch the process immediately.

      When RPC is complete a banner will briefly appear at the bottom of the page indicating success or failure. If you miss it the result can be seen in the password change log list.

c. Once the RPC completes a Heartbeat is performed. Success indicates the password has changed and the new password has been validated.



Procedure: Enable CredSSP Between Machine A (Client) and Machine B (Server)

This procedure configures CredSSP authentication between two Windows machines to allow secure credential delegation for remote PowerShell commands.

> The site must be configured with the WinRM Endpoint URL of the target host, with the **Enable CredSSP Authentication for WinRM** option set to true.

- Machine A = Client.
- Machine B = Server.

Step 1: Configure Machine A (Client)

1. Create a power user on Machine A:

```
#configuration on Machine A (client):
#create power user on client
net user poweruser "Your strong passphrase" /add
net localgroup Administrators poweruser /add
```

2. Validate connectivity to Machine B:

```
ping MachineB.fqdn.com
```

3. Enable CredSSP on Machine A:

```
Enable-WSManCredSSP -Role Server -Force
Enable-WSManCredSSP -Role Client -DelegateComputer MachineB.fqdn.com
```

Step 2: Configure Machine B (Server)

1. Create a power user on Machine B:

```
#Machine B is the server.
#configuration on Machine B (server):
net user poweruser "Your strong passphrase" /add
net localgroup Administrators poweruser /add
```

2. Validate connectivity to Machine A:

```
ping MachineA.fqdn.com
```

3. Enable WinRM and CredSSP:

```
winrm quickconfig
Enable-WSManCredSSP -Role Server -Force
```

Step 3: Test CredSSP Access

Run the following test script from Machine A:

```
# to test
$scriptblock = {
Write-Host Success
}
$credentialUsername = "poweruser"
$credentialPasswordPlainText = "Your strong passphrase"
$securePassword = ConvertTo-SecureString -String $credentialPasswordPlainText -
AsPlainText -Force
$creds = New-Object System.Management.Automation.PSCredential($credentialUsername,
$securePassword)
Invoke-Command machineb.fqdn.com -Credential $creds -ScriptBlock $scriptblock -
Authentication CredSSP
# you should see "success"
```

You should see the message: Success, indicating that CredSSP authentication and remote execution are functioning correctly.

RPC for Specific Vendors and Technologies

Remote Password Changing (RPC) in Secret Server supports a wide range of specific vendors and technologies, enabling automated password management across diverse systems. Each vendor or technology, such as ServiceNow, WatchGuard, HP iLO, Sybase, Okta, IBM iSeries (AS/400), VMware ESX/ESXi, and SonicWall NSA, has a dedicated secret template preconfigured with the appropriate password changer. These templates ensure that passwords can be automatically updated when they expire or on a defined schedule, maintaining synchronization with Secret Server. Administrators can also customize these templates and password changers to fit specific requirements, leveraging SSH, Telnet, or PowerShell scripts for more complex environments. This flexibility allows organizations to securely manage credentials across various platforms, enhancing overall security and operational efficiency.

See the Delinea Integrations site for more about vendors and technologies.

This section of topics is about configuring RPC for specific technologies, not about using templates to create secrets. For that, see "Included RPC Templates" on page 954.

RPC for Entra ID and Active Directory

Remote Password Changing (RPC) is a core Secret Server feature that automates credential rotation for privileged accounts, ensuring passwords remain synchronized with organizational security policies. Secret Server supports RPC for both traditional Active Directory environments and modern Microsoft Entra ID (formerly Azure AD) cloud directories. While both of these implementations of RPC achieve the same goal—automated password management—they employ fundamentally different architectures, authentication mechanisms, and permission models. Understanding these differences is essential for organizations planning their privileged access management strategy, particularly those operating in hybrid environments.

Active Directory RPC uses native Windows protocols (LDAP and ADSI) to communicate directly with domain controllers for password operations. This approach requires a dedicated service account with delegated permissions configured through Active Directory Users and Computers and ADSI Edit, including rights to change passwords, reset passwords, and modify account properties. The service account permission model is object-based, allowing granular control over which organizational units or specific accounts the service account can manage. For on-premises Secret Server deployments, AD RPC can execute directly from the web server without requiring Distributed Engines.

Entra ID RPC, introduced in Secret Server 11.7.000015, takes a cloud-native approach using OAuth 2.0 authentication and the Microsoft Graph API over HTTPS. Instead of a service account, this implementation requires an Azure App Registration configured with appropriate API permissions and assigned either the User Administrator or Privileged Authentication Administrator role. Entra ID RPC supports managing MFA-protected accounts through the Resource Owner Password Credential (ROPC) grant flow without requiring PowerShell scripts. All Entra ID RPC operations require a Distributed Engine, even for on-premises Secret Server installations.

Organizations with hybrid identity environments must understand that these two RPC methods serve different account populations and cannot be used interchangeably. Entra ID RPC only supports cloud-native accounts created directly in Entra ID; accounts synchronized from on-premises Active Directory must continue using AD RPC even if they appear in the Azure portal. This means hybrid organizations typically need both configurations operating simultaneously—AD RPC for synchronized accounts and domain controllers, and Entra ID RPC for cloud-

only identities. Proper planning ensures complete coverage of privileged accounts across the entire identity infrastructure.

Setting Minimum Permissions for AD RPC Service Accounts

Overview

> We have identified a root-cause issue in certain environments. The RPC service account must also have the Active Directory **Unexpire Password** permission assigned at the domain root level. Without this permission, delegated password reset functionality may fail, even if all other standard RPC permissions are configured. Assigning this permission only at an OU level (including on **AdminSDHolder**) has no effect – **the permission must be applied at the domain root level**.

Secret Server requires proper Active Directory permissions to perform Remote Password Changing (RPC). The privileged Delinea Secret Server RPC service account used for RPC of an Active Directory (AD) account secret, must have granular Active Directory permissions applied to it.

You will be using two Active Directory tools to make these modifications to the RPC account:

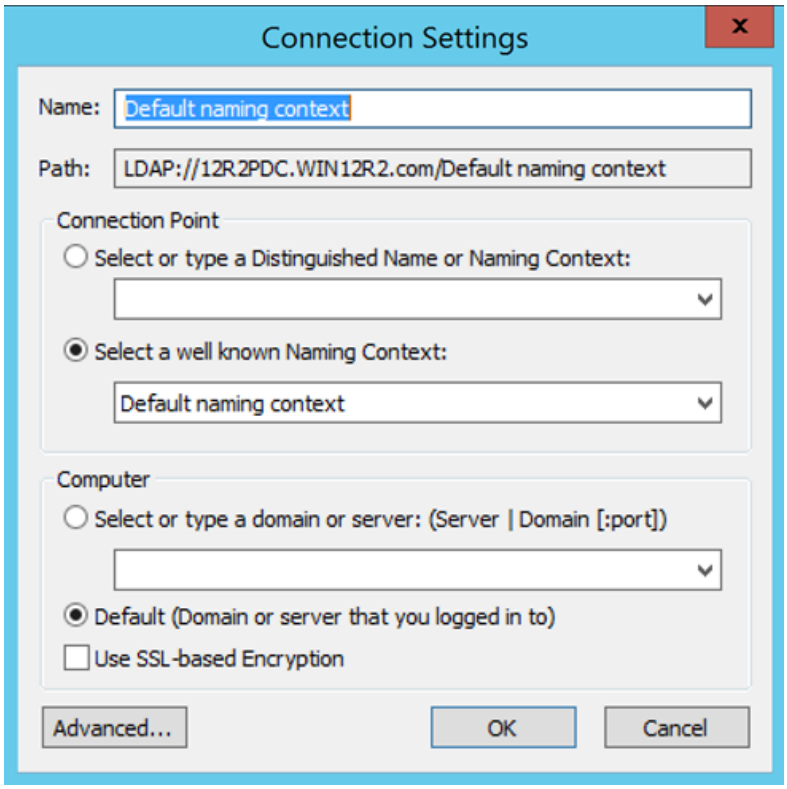
- ADSI Edit
- Active Directory Users and Computers.

> ADSI stands for *Active Directory Service Interfaces*. It is a set of COM interfaces used to access the features of directory services from different network providers.

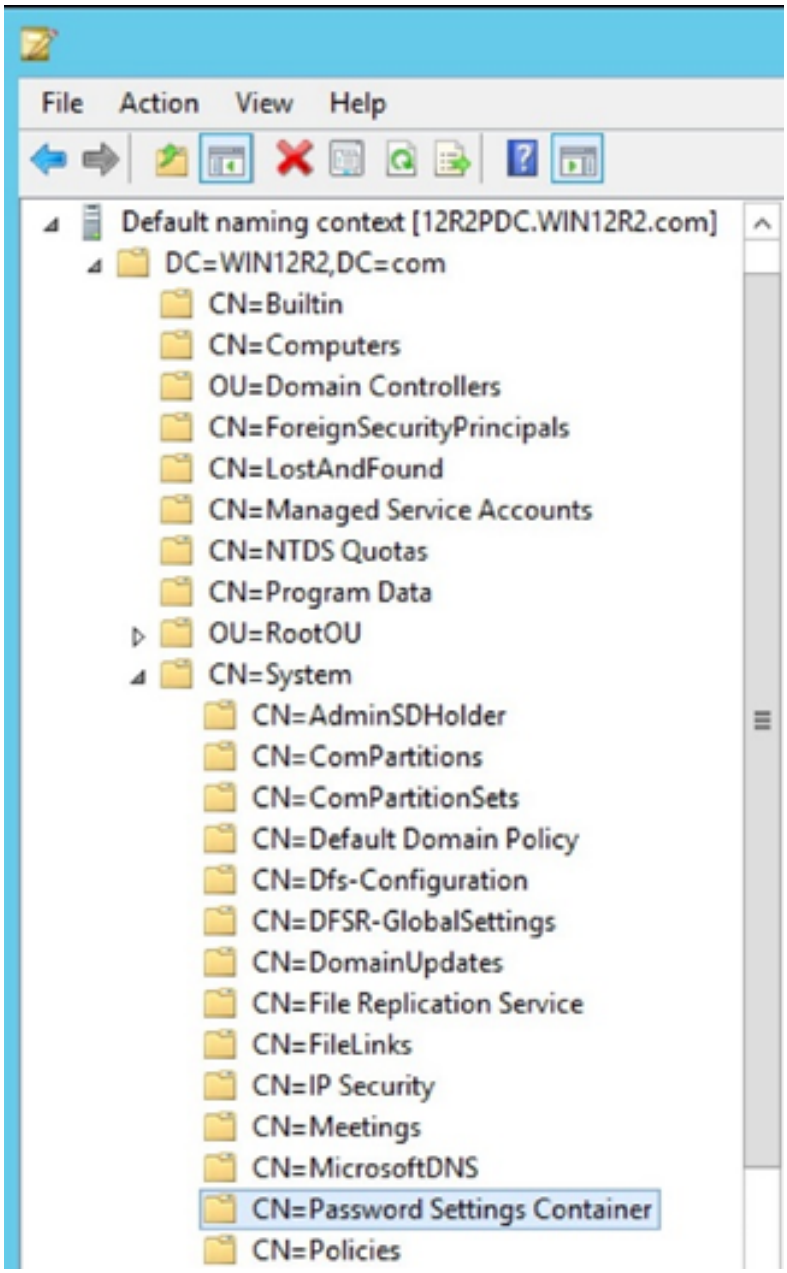
> The AD password changer has an RPC **timeout minutes** advanced setting. This setting only applies when using **Password Change By Admin Credentials**.

Setting ADSI Permissions

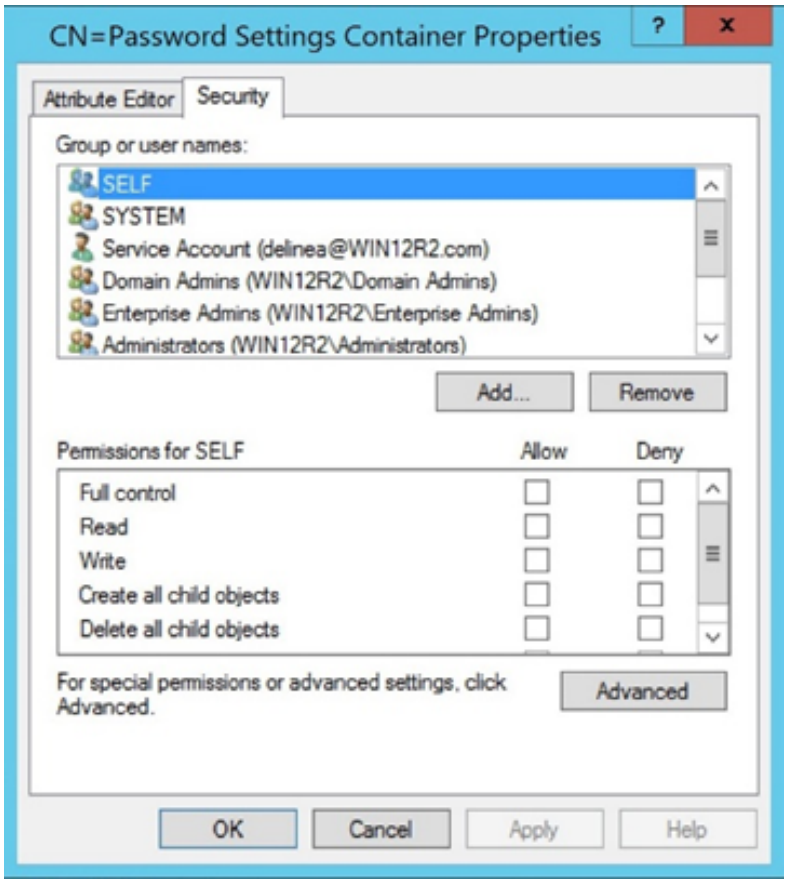
1. Open ADSI Edit (found on Domain Controllers as part of the Active Directory Administration Tools).
2. From the **Action** drop down menu select **Connect to...**. The "Connection Settings" window appears:



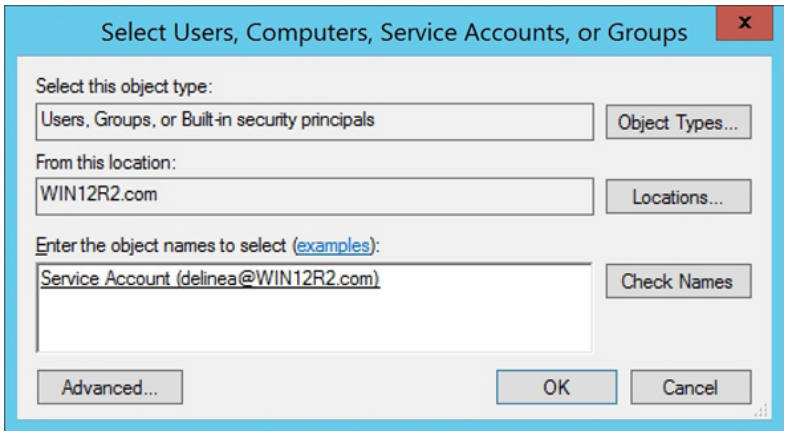
3. Make any necessary adjustments.
4. Click the **OK** button to connect to the domain you are logged into. The ADSI Edit window appears.
5. Click on the **Default naming context** node (the root of the domain).
6. Expand the domain name root and scroll down until you reach **CN=System > CN=Password Settings Container** as noted in the image below:



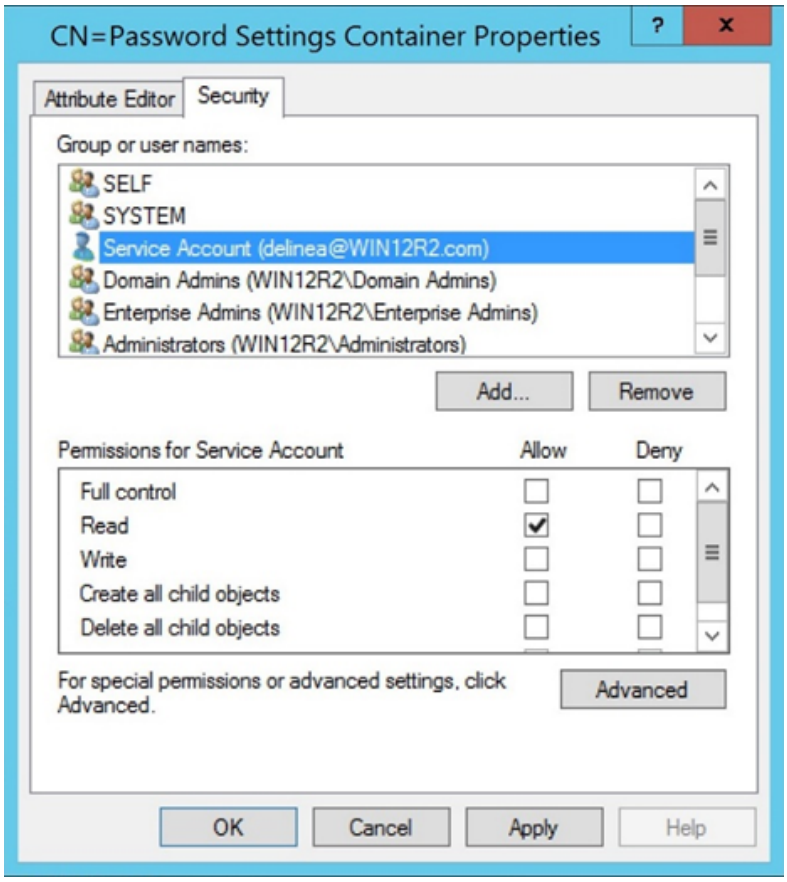
7. Right-click **CN=Password Settings Container** and select **Properties**. A properties dialog box appears:



8. Click the **Add...** button. The "Select Users, Computers, Service Accounts, or Groups" dialog box appears:



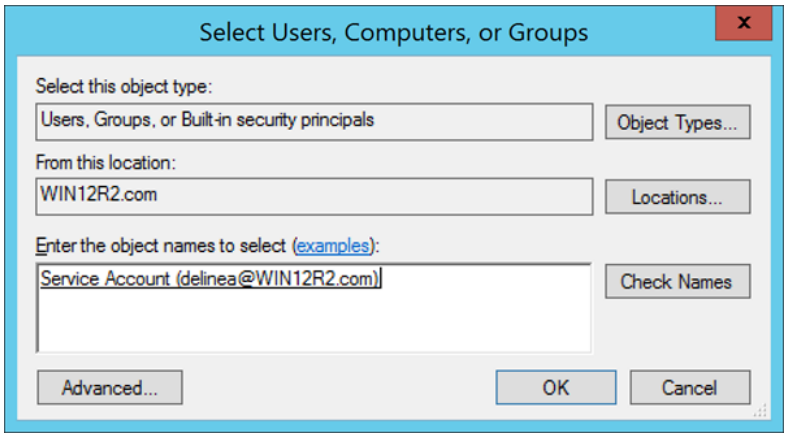
9. Type the information for the Delinea Secret Server RPC account.
10. Select **OK**. The previous dialog box reappears with the "delinea" service account appearing in the "Group or user names" list.
11. Click on the new account, its permissions appear:



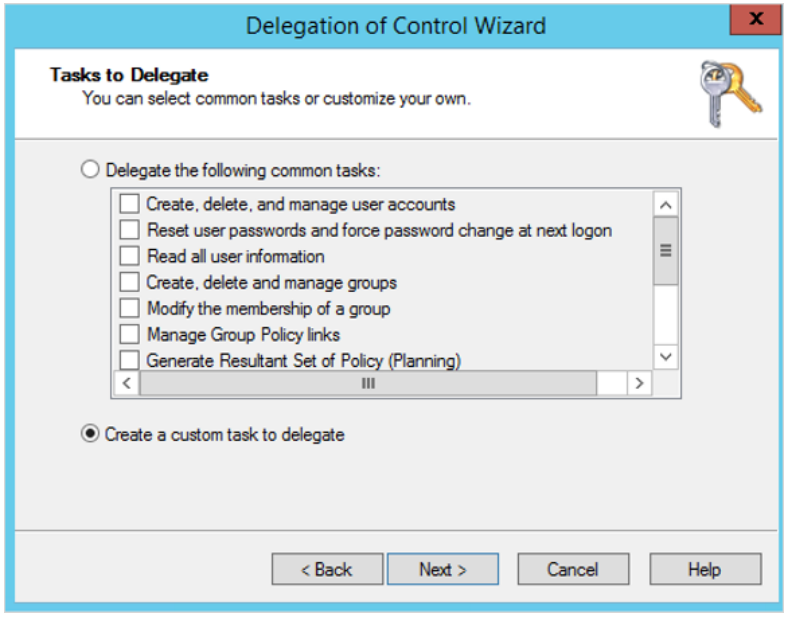
12. Select the **Read** checkbox in the **Allow** column.
13. Click **OK** to save your changes.

Setting Active Directory Delegate Control Permissions

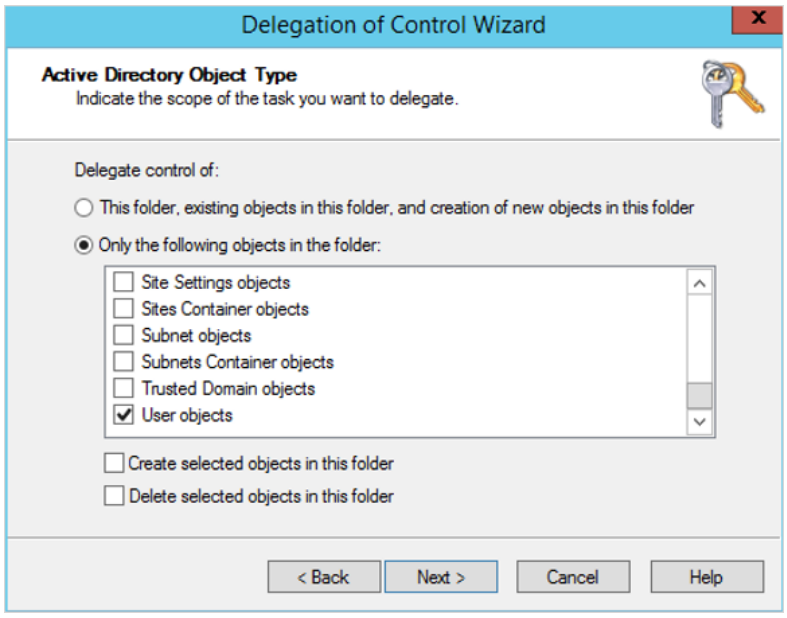
1. Open the **Active Directory Users and Computers** administrative console.
2. Right-click the Organizational Unit (OU) or the top-level domain you want to configure.
3. Select **Delegate Control...** as noted in the image below. The Delegation of Control Wizard appears.
4. Click the **Next** button. The **Users or Groups** dialog appears.
5. Click the **Add...** button in the **Users or Groups** section.
6. Click the **Add...** button. The "Select Users, Computers, Service Accounts, or Groups" dialog box appears:



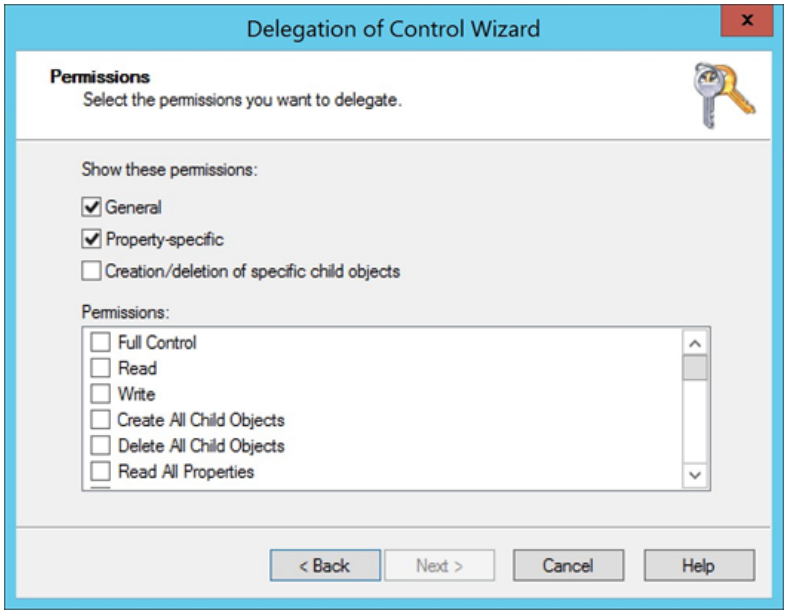
7. Type the information for the Delinea Secret Server RPC account.
8. Click the **OK** button. The Wizard reappears.
9. Click the **Next** button. The Tasks to Delegate page of the wizard appears:



10. Select the **Create a custom task to delegate** radio button.
11. Click the **Next** button. The Active Directory Object Type page of the wizard appears:



12. Click to select the **Only the following objects in the folder** selection button.
13. Scroll to bottom of the list.
14. Select the **User objects** checkbox.
15. Click **Next**. The Delegate Control Permissions page of the wizard appears:



16. Click to select the **General** and **Property-specifics** check boxes.
17. In the **Permissions** list, ensure none of the check boxes are selected.
18. Locate and click to select the following check boxes in the **Permissions** list:

- Change Password
- Reset Password
- Read lockoutTime
- Write lockoutTime
- Read pwdLastSet
- Write pwdLastSet
- Read UserAccountControl
- Write UserAccountControl

19. Click the **Next** button.
20. Click the **Finish** button.

Setting Delegate Control Permissions for Protected Group Accounts

> See the Protected Accounts and Groups in Active Directory page for details about protected groups.

Configure delegation control in the domain controller for protected group accounts:

1. At a command prompt on the domain controller, type the following command to grant the domain account permission to unlock the account:

> `dc=cps` and `dc=com` in the following commands should be changed to your domain name.

```
dsacls "dc=cps,dc=com" /G "<yourDomainName>\<yourAccountName>:RP;msDS-User-Account-
Control-Computed;user" /I:S
dsacls "dc=cps,dc=com" /G "<yourDomainName>\yourAccountName>:RPWP;lockoutTime;user" /I:S
dsacls "CN=AdminSDHolder, CN=System, DC=cps, DC=com"  /G
"<yourDomainName>\<yourAccountName>:RPWP;lockoutTime"
```

2. At a command prompt on the domain controller, type the following command to grant the domain account permission to reset the password:

> `dc=cps` and `dc=com` in the following commands should be changed to your domain name.

```
dsacls "dc=cps,dc=com" /G "<yourDomainName>\<yourAccountName>:CA;Reset Password;user"
/I:S
dsacls "CN=AdminSDHolder, CN=System, DC=cps, DC=com" /G
"<yourDomainName>\<yourAccountName>:CA;Reset Password"
```

> It can take a while for the Security Descriptor Propagator Update (SDProp) process to pick up the new settings from AdminSDHolder.

To initiate the SDProp process immediately, complete the following steps:

1. Click **Run**, and type `ldp.exe` in the domain controller desktop Start menu.
2. Select **Connection > Connect...** from the LDP window.
3. In the Connect window, make sure **389** is listed in the **Port** field, and then click **OK**.
4. Select **Connection > Bind...** from the LDP window.
5. Select **Bind as currently logged on user** and click **OK**.
6. Select **Browse > Modify** from the LDP window.
7. Configure the following fields in the Modify window:
   - **DN**: empty
   - **Attribute**: `RunProtectAdminGroupsTask`
   - **Values**: 1
   - **Operation**: click **Add** and then click **Enter**.
8. Click **Run**.

If you have a large environment, it may take some time for SDProp to update the protected admin group permissions.

Configuring Delegation Control for Administrative Accounts

If you use a regular domain account (not part of the Domain Admins group) for the administrative account, you need to configure the domain account delegation in the domain controller.

> The delegated permissions configured for the administrative account are not available for some protected groups. See Delegated permissions are not available and inheritance is automatically disabled, for details.

> To enable delegated permissions on the administrative account in order to manage protected groups, see the additional configuration steps in "Configuring Delegation Control for Administrative Accounts" above.

Configuring Delegation Control for the Administrative Account

To configure delegation control in the domain controller for the administrative account, do the following:

1. In the domain controller of the domain, select **Administrative Tools > Active Directory Users and Computers**.
2. Right-click the domain with the accounts that will be managed. Select **Delegate Control**, then click **Next** at the Welcome window.
3. In **Users and Groups**, click **Add** and enter the name of the user you want to configure with the administrative account (with unlock and password reset permissions) and click **OK**.
4. In **Task to Delegate**, select **Create a custom task to delegate** and click **Next**.

5. In **Active Directory Object Type**, select **Only the following objects in the folder**, as well as **User objects**, then click **Next**.
6. In **Permissions**, select the following:
   a. **General** and **Reset password** to delegate password reset rights.
   b. **Property-specific, Read msDS-User-Account-Control-Computed, Read lockout Time**, and **Write lockout Time** to delegate account unlock rights.
7. Click **Next** and then **Finish**.

The domain account with delegated permissions can now be configured as the domain administrative account for the account unlock and automatic account maintenance features.

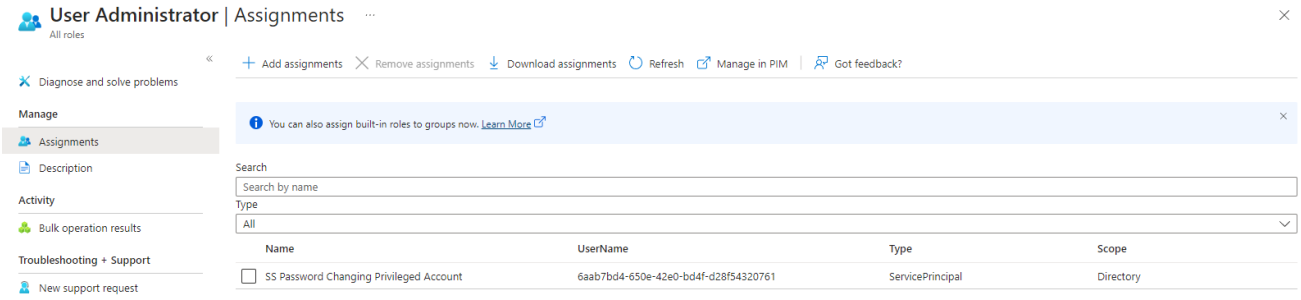
Minimum Permissions for Entra ID RPC

> For the complete setup for Entra ID RPC, see "Configuring an Azure AD or Entra ID Password Changer" on the next page.

Secret Server requires proper Entra ID permissions to perform remote password changing (RPC). The privileged Secret Server RPC service principal used for RPC of an Entra ID user account secret must be assigned to the **User Administrator** role.

Assigning a Secret to the User Administrator Role

1. Log into the Navigate to the Microsoft Entra Admin Center or Azure AD Portal.
2. Go to **Microsoft Entra ID > Roles and Administrators**.
3. Select the **User Administrator** role.
4. Click **Add Assignments**.



5. Search for the desired service principal. This is the account to give permissions to, in this case, the registered application.
6. Click **Add**.

> These Entra ID permissions will only work for non-administrator accounts. For administrator accounts, users need to have at least *Privileged Authentication Administrator* permissions. For more information about the Entra ID secret template, see "Entra ID Secret Template for RPC" on page 962.

Assigning the Privileged Authentication Administrator Role for Administrator Accounts

To perform remote password changing for Entra ID administrator accounts, the service principal must be assigned the **Privileged Authentication Administrator** role.

1. Locate the service principal:
   a. In the Microsoft Entra admin center, go to **Azure Active Directory > App registrations**.
   b. Find the app registration you want to manage and note its **Application (client) ID**.
2. Find the corresponding service principal:
   a. Go to **Azure Active Directory > Enterprise applications**.
   b. Search for the application name or filter by the **Application (client) ID**.
3. Assign the role:
   a. Select the service principal.
   b. Navigate to **Roles and administrators**, then click **Add assignments**.
   c. Search for and select the **Privileged Authentication Administrator** role.
   d. Choose the user, group, or service principal.
   e. Click **Add** to finalize the assignment.

See Entra ID service principal for more details.

Configuring an Azure AD or Entra ID Password Changer

The built-in templates use Microsoft Graph in Entra ID (Azure AD). The password changer works based on a combination of items including:

- Entra ID tenant ID.
- Client ID (originates from an app registration in Azure AD or Entra ID).
- Client secret (originates from an app registration in Azure AD or Entra ID).
- Username of the managed user in UPN format (username@domain).
- Password of the managed user.
- New password of the managed user generated by the Secret Server password changer.

The built-in templates are designed to perform the password change as the application registration itself, in order to facilitate managing MFA-protected accounts. The heartbeat functionality is designed for both MFA and non-MFA protected accounts using error-handling logic.

The authentication flow is based on the resource owner password credentials grant flow. This flow is **not** recommended for regular use but is being used in this case because the script is designed to run as a service account, and the user account being interacted with is managed by Secret Server. For password changing and validation, the actual account credentials are acquired without human interaction. This enables the script to manage accounts that are also protected with MFA.

Requirements

> See "Minimum Permissions for Entra ID RPC" on page 1016 for information on the required Entra ID permissions.

- A valid Entra ID tenant.
- A dedicated app registration for the password changer:
  - See Register an application with the Microsoft identity platform for more information on creating an app registration. See "Task 1: Creating an App Registration" below for details.
  - The Azure Application Registration template to store application registration information in Secret Server. This comes with the out-of-the-box integration.
  - The Entra ID User Account template to store Entra ID secrets. This also comes with the out-of-the-box integration.
- The username should be stored in UPN format (username@domain.com) for the password changer to function.
- Entra ID User Administrator permissions are needed to configure Entra ID RPC in Secret Server.

> Entra ID password changer only supports cloud accounts. Hybrid accounts are not supported.

- Communication with Secret Server Cloud also requires a distributed engine (DE) to be installed. See Downloading and Installing a Distributed Engine for details on how to proceed.

> You should not install a DE on the same machine running Secret Server.

Task 1: Creating an App Registration

The application registration provides the password changer with the Entra ID permissions to perform the password change. The following steps are required to create the application registration:

1. Log into the Entra ID or Azure AD Portal (https://portal.azure.com).
2. Navigate to **Microsoft Entra ID**.
3. Navigate to **Manage > App Registrations**.
4. Click **New Registration**.
5. Provide a name for the application registration. You will need this name later in the procedure.
6. Select the account type (single tenant or multi-tenant).
7. Click **Register**. Make note of the application (client) ID, which is required when creating the corresponding secret in Secret Server.
8. While still on the **App Registration** page, navigate to **Manage > Certificates & Secrets**.
9. Click **New Client Secret**.
10. Provide a description for the client secret.

11. Select an expiration date.
12. Click **Add**. Make note of the client secret value, which is required when creating the corresponding secret in Secret Server.
13. Navigate to **Manage > API Permissions**.
14. Check if the following API permission is assigned: **User.Read**. If not assigned, add the permission by:
    a. Clicking **Add a Permission**.
    b. Selecting **Microsoft Graph**.
    c. Selecting **Delegated Permissions**.
    d. Choosing the **User.Read** permission.
15. Click on **Grant Admin Consent** for the respective tenant button. This completes the creation of the application registration.

Task 2: Providing the Password Changer App the Permissions to Manage Users

See "Minimum Permissions for Entra ID RPC" on page 1016 for more on this topic.

1. Log into the Azure Portal (https://portal.azure.com).
2. Navigate to **Microsoft Entra ID**.
3. Navigate to **Manage > Roles and Administrators**.
4. In the search bar, search for the role (such as Global Administrator). We recommend the **Privileged Authentication Administrator** role.
5. Click the role name in the resulting list.
6. Click **Add Assignments**.
7. Search for and select the previously created application registration.
8. Click **Add**.

Task 3: Creating an Entra ID App Registration Secret in Secret Server

1. Log into Secret Server or Delinea Platform.
2. Navigate to **Secrets**.
3. Click **Create Secret**.
4. Select the template to store the application registration information (**Azure Application Registration**).
5. Fill out the required fields with the information from the application registration:
   - **Secret Name**: Provide a descriptive name (for example, Delinea Entra ID Password Changer).
   - **Client ID**: Enter the **Application (client) ID** from the app registration's **Overview** page. This is the value you noted in Task 1, Step 8.
   - **Client Secret**: Enter the client secret value you created and noted in Task 1, Step 13.

- **Tenant ID**: Enter the **Directory (tenant) ID**. To find this value, navigate to **Microsoft Entra ID > Overview** in the Azure portal. The Directory (tenant) ID appears in the **Basic information** section.

6. Click **Create Secret**.

Task 4: Associating the Privileged Account with the Entra ID Account Secret

To correctly use the password changer, the privileged account must be associated with the Entra ID User Account secret:

1. Log into Secret Server or Delinea Platform.
2. Navigate to **Secrets**.
3. Locate your secret(s) based on the **Entra ID User Account** template.
4. Click on the secret.
5. Select the **Remote Password Changing** tab.
6. Click **Edit** for the **RPC / Autochange** section on the page.
7. For **Change Password Using**, select **Privileged Account Credentials**.
8. Click **No Secret Selected**. A list of eligible secrets appears.
9. Search for and select the earlier-created **Azure Application Registration** secret.
10. Click **Save**.

Task 5: Testing the Configuration

If all went well, you now should have:

- A secret in Secret Server for the application registration.
- An Entra ID User Account secret (not covered in this guide).
- The application registration secret associated with the Entra ID User Account secret.

To test the configuration, you can start with performing a heartbeat on the Entra ID User Account secret:

1. Log into Secret Server.
2. Navigate to **Secrets**.
3. Locate your secret based on the **Entra ID** template.
4. Click the secret.
5. Click **Heartbeat**. After a few moments the heartbeat should complete successfully.

To further test the configuration, you can change the password of the Entra ID User Account secret:

1. Log into Secret Server.
2. Navigate to **Secrets**.
3. Locate your secret based on the **Entra ID User Account** template.
4. Click the secret.

5. Click **Change Password Now**.
6. Select **Randomly Generated** or **Manual** (and enter a password).
7. Click **Change Password**.

Creating a Custom Password Changer for Cisco ASA

To create a custom password changer using SSH for Cisco ASA 5505, 5515 and other models with IOS 12.2 and earlier that cannot use the copy command, follow the procedure for "Creating a Custom Password Changer" on page 901. Make sure you choose a base password changer that ends with (SSH) with a command set similar to the one you are adding, and use the following settings:

Authenticate As

1. `$[1]$USERNAME`
2. `$[1]$PASSWORD`

Commands

1. Enter `enable`
2. Enter `$CURRENTPASSWORD`
3. Enter `config terminal`
4. Enter `enable password $NEWPASSWORD`
5. Enter `end`
6. Enter `wr mem`
7. Enter `exit`

Creating a Custom Password Changer for IBM AS/400

> Password changing on the IBM AS/400 can be performed through SSH, which is installed by default. If you are using an earlier version, you will need to install SSH.

To create a custom password changer for IBM AS/400 on newer systems such as i7, use the procedure for "Creating a Custom Password Changer" on page 901 but be sure to use the following SSH command:

- Command: system `CHGUSRPRF $USERNAME PASSWORD($NEWPASSWORD)`
- Comment: Set Password on account
- Pause(ms): 2000

> For additional information, see Securing Communications with OpenSSH on IBM i5/OS.

Creating a Custom Password Changer for IBM AS/400 in Secret Server 10.5.

The procedure for creating password changers in Secret Server 10.5 for the IBM AS/400 terminal includes using the 5250 terminal connection and scripting to perform the password change and heartbeat.

To create this IBM AS/400 password changer, start with an existing z/OS Mainframe password changer as a baseline, then modify the changer commands. You also need to create an AS/400 secret template using the z/OS secret template as a baseline, then modify the template to use the new password changer.

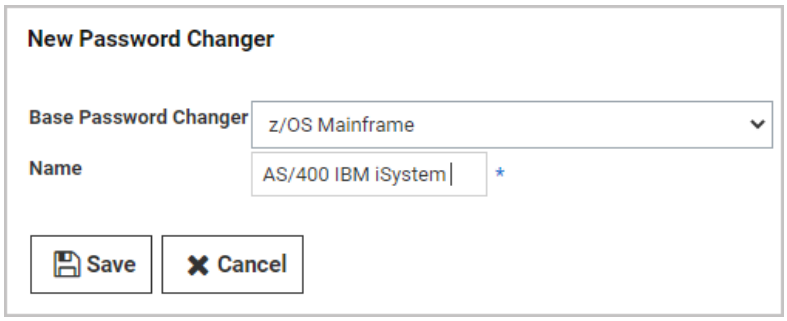
> Support for this feature, including script customization for advanced requirements, is available only through professional services.

Configuration

Follow the procedure below, in the sequence presented.

Create an AS/400 password changer from an existing z/OS Mainframe password changer:

1. Browse to **Admin > Remote Password Changing > Configure Password Changers**.
2. Scroll to the bottom and select **New**.
3. For the **Base Password Changer**, select the **z/OS Mainframe**.
4. In the **Name** field, enter `AS/400 IBM iSystem`

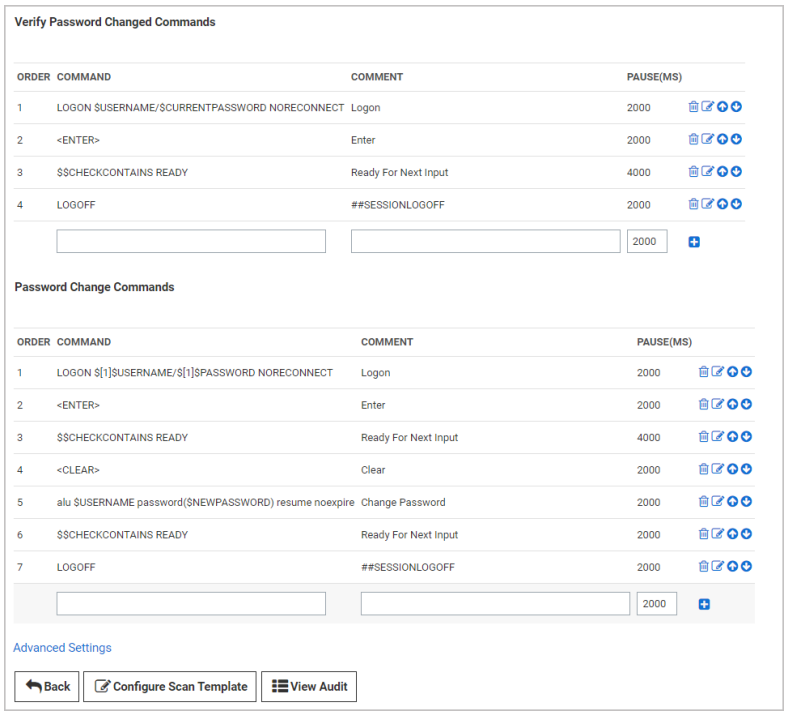


5. Click **Save**.

Modify the AS/400 IBM iSystem password changer commands:

To add custom password changer commands to the AS/400, you must replace the existing standard z/OS mainframe command set.

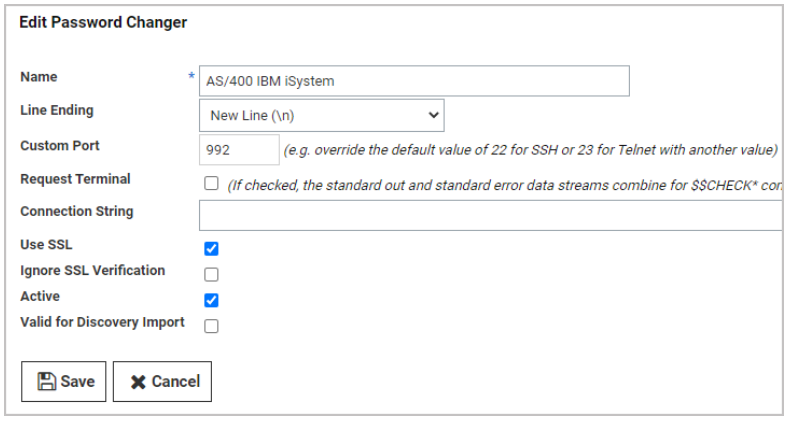
1. Browse to **Admin > Remote Password Changing > Configure Password Changers**.
2. Click the **AS/400 IBM iSystem** password changer you just created.
3. On the **AS/400 IBM iSystem** page, scroll to the bottom and click the **Edit Commands** button. The commands that appear initially on the **Verify Password Changed Commands** page represent the standard z/OS Mainframe command set. You can use these commands as a baseline but you must customize them to suit your environment.



4. Click the **Back** button when you have finished customizing your password changer commands, to return to the **AS/400 IBM iSystem** password changer page.

Modify the AS/400 password changer for 5250 emulation and commands:

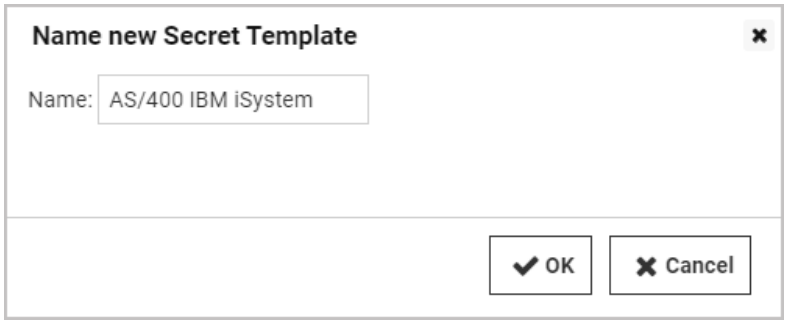
1. On the **AS/400 IBM iSystem** page, scroll to the bottom and click the **Edit** button.
2. On the **Edit Password Changer** page, check the box next to **Use SSL** (recommended).
3. Set the **Custom Port** to 992.



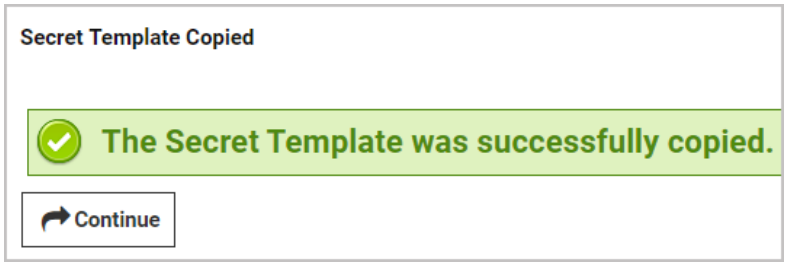
For extra troubleshooting assistance, you can add TRACE to the connection string to have a trace file written to the Secret Server website or engine.

Create an AS/400 template from the z/OS Secret Template:

1. Browse to **Admin > Secret Templates**.
2. On the **Manage Secret Templates** page, select **z/OS Mainframe** from the drop-down menu and click **Edit**.
3. On the **Secret Template Designer** page, scroll to the bottom and click **Copy Secret Template**.
4. On the **Name New Secret Template** page, enter `AS/400 IBM iSystem` in the **Name** field.

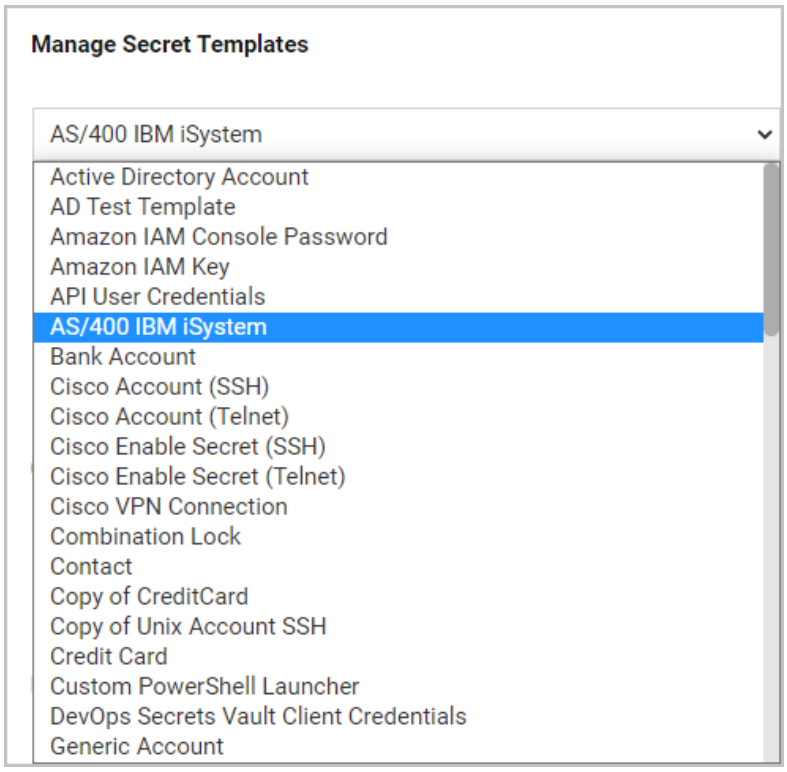


5. Click **OK**.
6. On the confirmation screen, click **Continue**.

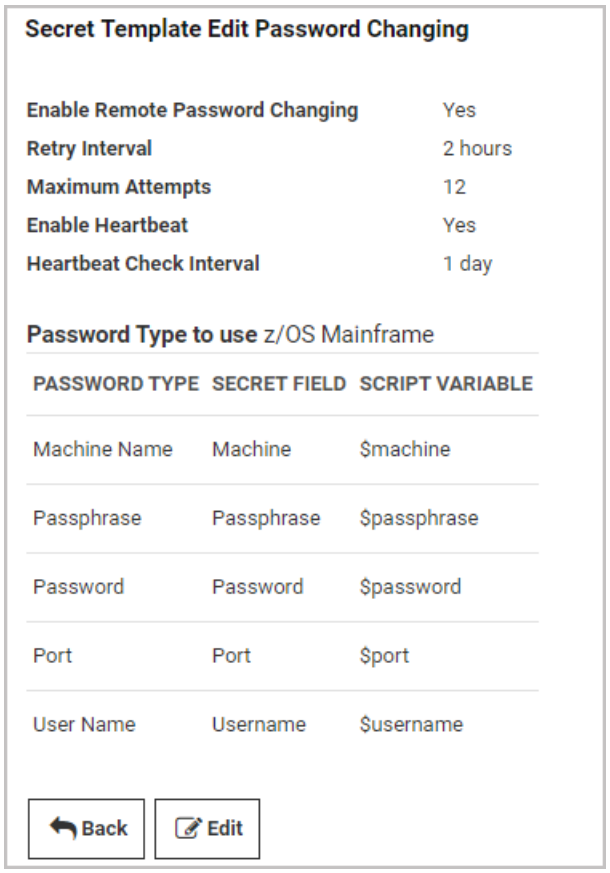


Modify the AS/400 Secret Template to use the AS/400 Password Changer:

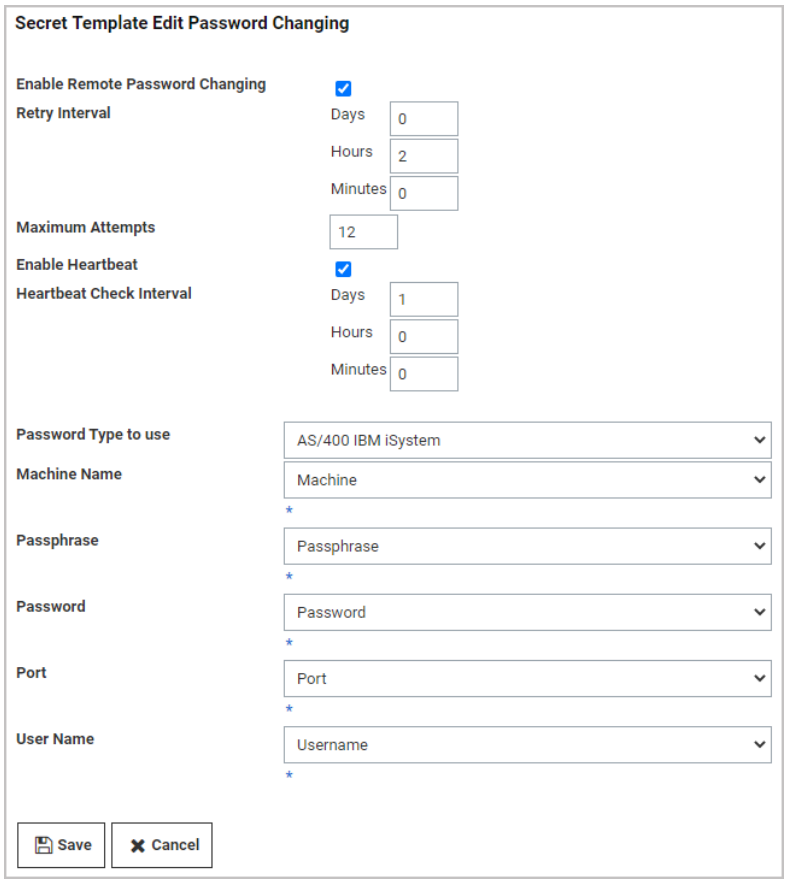
1. Browse to **Admin > Secret Templates**.
2. On the **Manage Secret Templates** page, click the drop-down menu and select the new **AS/400 IBM iSystem** secret template you just created.



3. Click **Edit**.
4. On the **Secret Template Designer** page, scroll to the bottom and click **Configure Password Changing**.
5. On the **Secret Template Edit Password Changing** page, click **Edit**.



6. On the second **Secret Template Edit Password Changing** page, select **AS/400 IBM iSystem** from the **Password Type to Use** drop-down menu.



7. Click **Save**.

Your can now create secrets using your new template and password changer in Secret Server 10.5.

If you would like to test your template and password changer but you do not have access to an AS/400 IBM iSystem, you can use the website PUB400.com.

Running Heartbeat and RPC for Office 365 and Azure Accounts with PowerShell

This page is deprecated. Please refer to additional documentation from Microsoft for more information.

This feature does not require the advanced scripting add-on license. To perform heartbeat checks and remote password changes on secrets using the Office 365 and Azure password changer for user accounts, follow the steps below:

Procedure

This applies to both the Secret Server Web server or distributed engines.

1. Run Windows PowerShell as an admin. This opens an elevated Windows PowerShell command prompt.
2. Run this command: `Install-Module -Name AzureAD`.

3. Recycle the application pool.

> These steps are required once on the subject computer, not every time you connect. However, you may want to update the module periodically as a security best practice using the command: `Update-Module -Name AzureAD`

Troubleshooting

1. Uninstall AzureAD using command `remove-module AzureAD`.
2. Reinstall using the above procedure.
3. Ensure the Secret Server application pool setting *Load User Profile* is set to "True".
4. Recycle the application pool.

Configuring Oracle Secret Templates

Secret Server now has four Oracle templates, three current and one legacy:

- Oracle Account
- Oracle Account (TCPS)
- Oracle Account (Template Ver 2)
- Oracle Account (Walletless)

Introduction

Overview

Secret Server now has three secret templates based off the Oracle Managed Data Access NuGet library. Unlike earlier Oracle secret templates, templates, using the NuGet library does not require `Oracle.ManagedDataAccess.dll` to be installed alongside Secret Server or its engines. Additionally, two of these templates support Oracle's TCPS connection protocol. You can run the new templates alongside the earlier Oracle secret templates, but we recommend using the new templates when creating new Oracle secrets.

DataSource Field

All three new templates include an optional DataSource field. The DataSource field acts like a connection string to the Oracle database. When used, it is not necessary to fill out the Host, Database, Port, or SSL Server Cert DN fields. On the secret template's page, "none" appears in each of those fields.

Without DataSource:

Secret Name *	Oracle Walletless without DataSource
Secret Template	Oracle Account (Walletless)
Host	adb.us-ashburn-1.oraclecloud.com
Username *	walletless_local
Password *	**********
Database	g62a2e091eede11_jjtest2_high.adb.oraclecloud.com
Port	1521
As System User? *	0
DataSource	None
SSL Server Cert DN	CN=adwc.uscom-east-1.oraclecloud.com, OU=Oracle BMCS US, O=Oracle Corporation, L=Redwood City, ST=California, C=US
Notes	None

With DataSource:

Secret Name *	Walletless with DataSource
Secret Template	Oracle Account (Walletless)
Host	None
Username *	walletless_with_datasource
Password *	**********
Database	None
Port	None
As System User? *	0
DataSource	(description= (retry_count=20)(retry_delay=3)(address=(protocol=tcps)(port=1521)(host=adb.us-ashburn-1.oraclecloud.com))(connect_data=(service_name=g62a2e091eede11_jjtest2_high.adb.oraclecloud.com))(security=(ssl_server_dn_match=yes)(ssl_server_cert_dn="CN=adwc.uscom-east-1.oraclecloud.com, OU=Oracle BMCS US, O=Oracle Corporation, L=Redwood City, ST=California, C=US")))
SSL Server Cert DN	None
Notes	None

As System User Field

All new templates also have the “As System User” field. It allows connections to the database as the system user. Setting this to “1” allows database connections with the SYSDBA privilege. Setting this to “0” connects with the default role.

Templates

Oracle Account

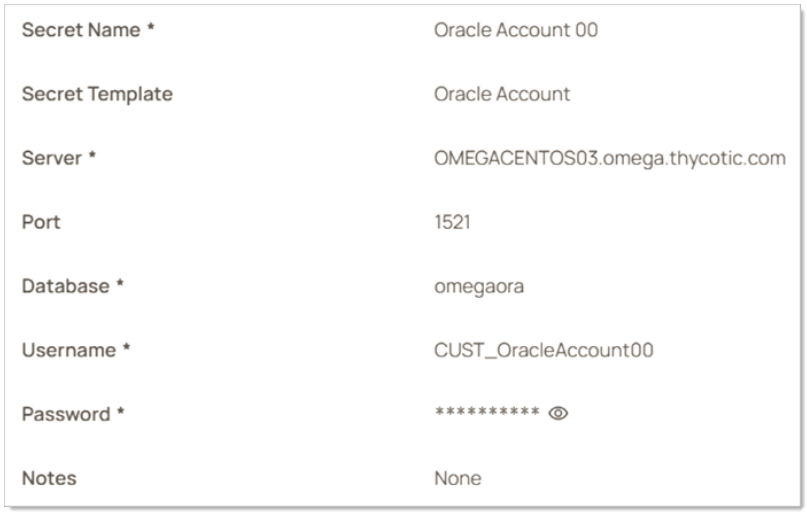
This is the deprecated original template that maintained for legacy implementations. I requires that `Oracle.ManagedDataAccess.dll` is installed alongside Secret Server or its engines.

Oracle Account (Template Ver 2)

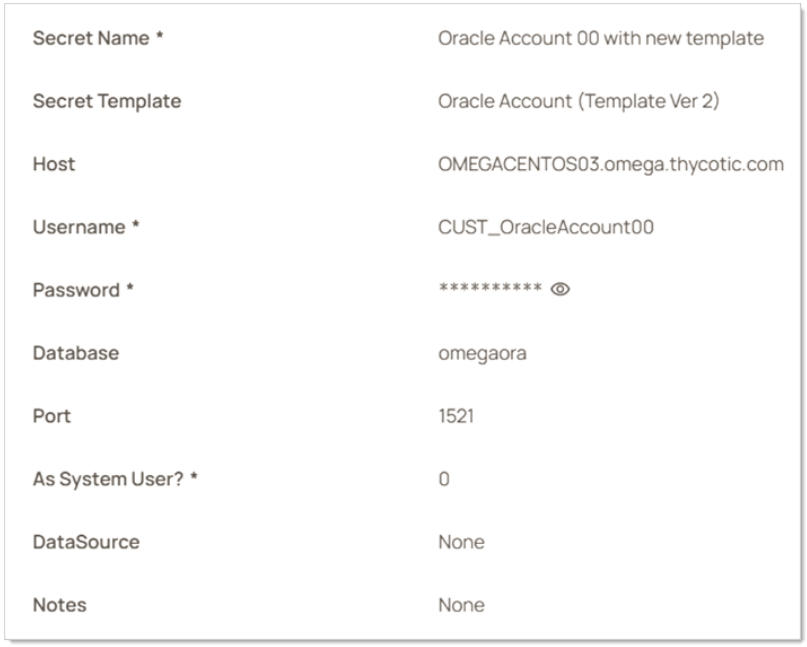
Oracle Account (Template Ver 2) is the closest equivalent to the original Oracle Account template. It does not support Oracle TCPS, but it does use the Oracle Managed Data Access NuGet library. The fields on this secret

template are the same as in the original Oracle Account template with a few exceptions. We added two new fields, the DataSource and “As System User” fields described above. Additionally, the “Server” field is called “Host” in the new template to more closely match the terminology in Oracle’s connection string.

Original template:



New template:



See "Oracle Account Secret Template for RPC" on page 1034 for more using this template.

Oracle Account (TCPS)

Overview

You can make TCPS connections using the "Oracle Account (TCPS)" secret template and an Oracle Wallet. As described by Oracle, “Oracle Wallet is a container that stores authentication and signing credentials.”

> See Understanding Oracle Wallet for more information, and refer to the documentation on your specific Oracle database for detains on obtaining and using your wallet.

Wallet Location

Prior to setting up Oracle Account (TCPS) secrets, you will need to place copies of your Wallet files on the same server(s) as your Secret Server site(s) where you will have Oracle Account (TCPS) secrets. Afterwards, use the “Wallet Location” field to note the location of your wallet files on your newly created secret. Note that you will need to ensure that the user running Secret Server’s app pool (or engine when applicable) is granted Delinea permissions to access the directory where the wallet is located.

TNS Admin

The “TNS Admin” field is optional. If you have a `tnsnames.ora` file, specify its containing directory in this field.

As with wallets, you should consult documentation specific to your Oracle database for information on using `tnsnames.ora`. However, in general, `tnsnames.ora` file is a configuration file containing network service names mapped to connect descriptors (for local naming method) or net service names mapped to listener protocol addresses.

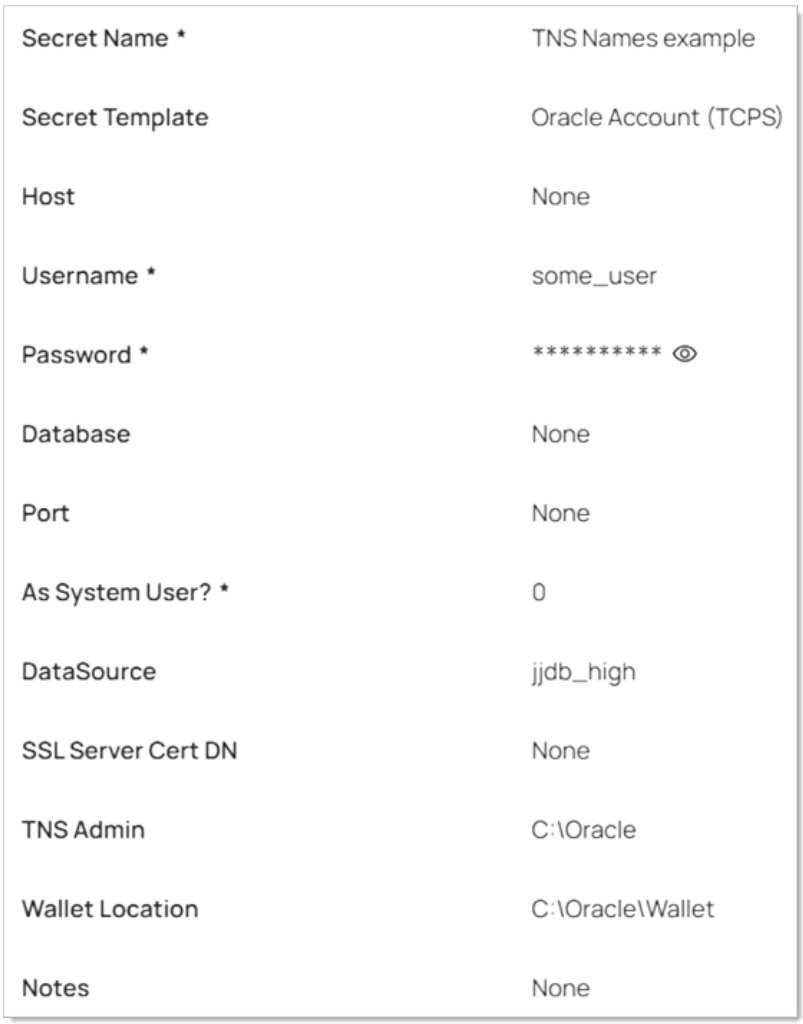
> See Local Naming Parameters in the tnsnames.ora File for more information.

Thus, you can use the `tnsnames.ora` file as an alternative way to specify a connection string. First, put the directory of the `tnsnames.ora` file in the “TNS Admin” field. Second, format the contents of `tnsnames.ora` as `<ALIAS> = <CONNECTION STRING>`. Paste the desired alias from inside the `tnsnames.ora` files in the DataSource field of the secret. For example, if we had a file at `C:\Oracle\tnsnames.ora`, the contents might be as follows:

```
jjdb_high = (description= (retry_count=20)(retry_delay=3)(address=(protocol=tcps)(port=1522)
(host=adb.us-ashburn-1.oraclecloud.com))(connect_data=(service_name=g62a2e091eede11_jjdb_
high.adb.oraclecloud.com))(security=(ssl_server_cert_dn="CN=adwc.uscom-east-
1.oraclecloud.com, OU=Oracle BMCS US, O=Oracle Corporation, L=Redwood City, ST=California,
C=US")))

jjdb_low = (description= (retry_count=20)(retry_delay=3)(address=(protocol=tcps)(port=1522)
(host=adb.us-ashburn-1.oraclecloud.com))(connect_data=(service_name=g62a2e091eede11_jjdb_
low.adb.oraclecloud.com))(security=(ssl_server_cert_dn="CN=adwc.uscom-east-1.oraclecloud.com,
OU=Oracle BMCS US, O=Oracle Corporation, L=Redwood City, ST=California, C=US")))
```

In this example, `jjdb_high` or `jjdb_low` are both aliases. We would choose one, say `jjdb_high`, and paste it into the DataSource field on my secret. I would include `C:\Oracle` in the TNS Admin field. My secret would appear as in the following screenshot:



Oracle Account (Walletless)

Oracle has recently announced its support of TCPS without requiring the use of wallets. See Securely Connecting to Autonomous DB Without a Wallet (Using TLS) for details.

Because walletless connections utilize TLS instead of "mutual TLS," this is potentially less secure than a wallet-based authentication, so you should do your own research before deciding if this is the right approach for you. The advantage of the walletless template is that it allows a secure TCPS connection with the simplicity of the "Oracle Account (Template Ver 2)" template. No wallet files need to be deployed to a server.

The fields on this template are the same as Oracle Account (Template Ver 2) with the addition of the "SSL Server Cert DN" field, which can be found in the TLS connection string. Refer to documentation on your specific Oracle database about how to enable walletless connections, as well as how to obtain the TLS connection string to fill in fields on this secret template.

Oracle RPC Templates

Secret Server now has four Oracle templates, three current and one legacy:

- Oracle Account
- Oracle Account (TCPS)
- Oracle Account (Template Ver 2)
- Oracle Account (Walletless)

See "Configuring Oracle Secret Templates" on page 1230 for details.

Oracle Account (TCPS) Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Oracle Account (TCPS) and Oracle Account (Walletless) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

Oracle TCPS (Transparent Network Substrate over SSL/TLS) is a technology used in Oracle Database environments to provide secure, encrypted communication between clients and servers. It operates as an extension of Oracle's Transparent Network Substrate (TNS), a fundamental part of the Oracle Net Services, facilitating network sessions from clients to Oracle databases.

To configure secret templates for Oracle, see "Configuring Oracle Secret Templates" on page 1230.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Oracle Account (TCPS), we want the Oracle Account (TCPS) template.

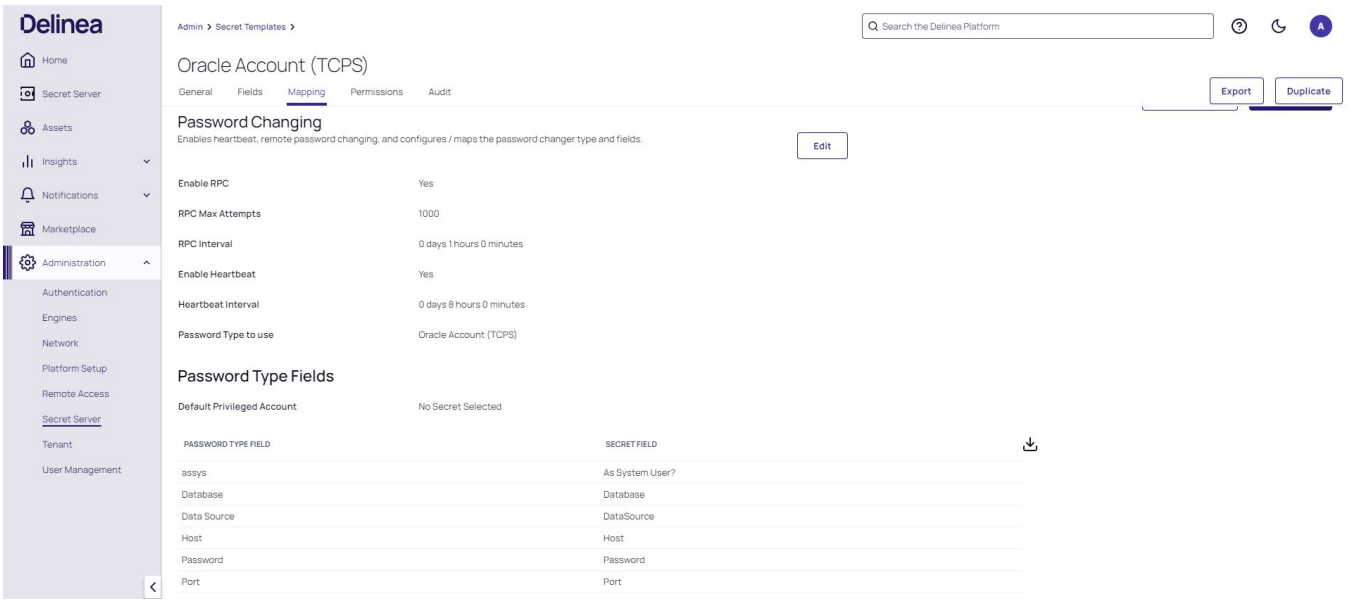
You can view and modify secret templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an Oracle Account (TCPS) secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an Oracle Account (TCPS) secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Oracle Account (TCPS) RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Oracle Account (TCPS) template on a secret, see "Managing Secrets" on page 1365.



Oracle Account Secret Template for RPC

Overview

This document briefly discusses using Secret Server Remote Password Changing (RPC) for Oracle Account and Oracle Account (Template Ver 2) accounts. With Remote Password Changing (RPC), secrets can automatically change remote account passwords when a secret expires, either immediately or on a defined schedule. In addition, the new passwords' strengths and other qualities are completely configurable. See the "Password Changer List" on page 904 for a complete list of available password changers.

To configure secret templates for Oracle, see "Configuring Oracle Secret Templates" on page 1230.

Assigning a Password Changer to a Secret Template

After completing the RPC setup, you can manage the built-in secret templates. Each secret template is specific application and is preconfigured with the password changer best suited to that. For the Oracle, we want the Oracle Account template.

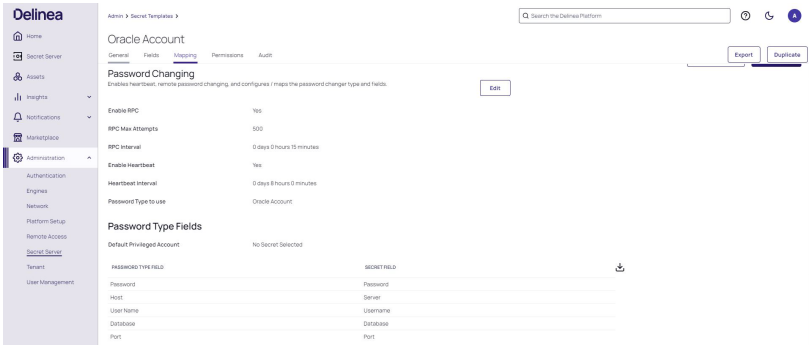
You can view and modify secret Templates in the Secret Server administration panel. See "Creating or Editing Secret Templates" on page 1194 for more on the available options. Ensure that the secret template is in active status. See "Activating and Deactivating Templates" on page 1183 for details.

To navigate to an Oracle Account secret template:

1. Search for **Secret Templates**. The Secrets Administration page is displayed.
2. In the **Core Actions** section, click **Secret Templates**. The list of available templates is displayed.
3. Select an Oracle Account secret template and then click the **Mapping** tab.

You can check what secret template conforms to the selected RPC. The screenshot below shows that the Oracle Account RPC conforms to the identically titled secret template. It is possible to assign several password changers to one secret template. For more information, see "Assigning a Password Changer to a Secret Template" on page 910.

Secret templates determine the fields, launchers, and the remote password changer for secrets. To use the Oracle Account template on a secret, see "Managing Secrets" on page 1365.



Configuring Oracle DB 19c for Heartbeat and RPC

This document explains how to configure Oracle Database 19c for heartbeat and remote password changing (RPC) with Secret Server. It consists of installing the Oracle Database Access Components (ODAC), configuring Secret Server, and configuring one or more distributed engines.

> This document is not updated with every release—many releases do not affect the guide's contents and thus do not warrant a document update.

This Delinea technical configuration knowledge base article is relevant to and has been tested on:

- Secret Server 10.7 on Windows Server 2016 Standard (64-bit)
- Distributed engine 10.7 on Windows Server 2016 Standard (64-bit)
- Oracle Database 19c on Windows Server 2019 Standard (64-bit)

Introduction

This document explains how to configure Oracle Database 19c for heartbeat and remote password changing (RPC) with Secret Server. The process consists of installing the Oracle Database Access Components (ODAC) and configuring Secret Server and one or more distributed engines.

Procedure

Task One: Installing the Oracle Database Access Components

1. Navigate to ODAC Runtime Downloads in your browser.

   > **Note:** Oracle Account (Template Ver 2) does not actually require this extension to be installed

2. Download the latest version of the ODAC OUI file with the same major number as your database version.
3. Unzip the file.
4. Right click and run setup.exe as a Windows administrator. The setup wizard appears.

5. Click to select **Use Windows Built-in Account**.
6. Click the **Next** button.
7. Type the desired installation path, such as `c:\oracle`.
8. Click the **Next** button.
9. Confirm the default product components are selected. If not, click to select **Reset Defaults**.
10. Click the **Next** button.
11. Leave the **DB Connection Configuration** fields as they are (empty).
12. Click the **Next** button. The setup runs some pre-installation configuration tests.
13. When the tests are completed, click the **Install** button.
14. Reboot your machine.

Task Two: Configuring Secret Server

1. Navigate to the ODAC directory, such as c:\oracle.
2. Copy the `C:\oracle\product\19.x.x\client_1\odp.net\bin\4\Oracle.DataAccess.dll` file to the bin directory of your Secret Server directory, for instance, `c:\inetpub\wwwroot\SecretServer\bin`.
3. Navigate to the `C:\Windows\Microsoft.NET\Framework64\v4.0.30319\Config` directory.
4. Open the `machine.config` file.
5. Copy and paste the line below into the `DbProviderFactories` section:

```
<add name="Oracle.DataAccess" invariant="Oracle.DataAccess.Client" description="Oracle Data Provider for .NET, Unmanaged Driver" type="Oracle.DataAccess.Client.OracleClientFactory, Oracle.DataAccess, Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
```

The section should look like this:

```
<system.data>   <DbProviderFactories>      <add name="Oracle.DataAccess" invariant="Oracle.DataAccess.Client" description="Oracle Data Provider for .NET, Unmanaged Driver" type="Oracle.DataAccess.Client.OracleClientFactory, Oracle.DataAccess, Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342"/>
</DbProviderFactories></system.data>
```

There may be additional `<Add>` sections, such as for Microsoft SQL Server. Leave them as is.

Task Three: Configuring a Secret Server Distributed Engine

1. Install ODAC on the machine hosting the distributed engine using the same procedure as Task One.
2. Navigate to the ODAC directory on the distributed engine machine, such as `c:\oracle`.
3. Copy the `C:\<ODAC_Directory>\odp.net\bin\4\Oracle.DataAccess.dll` file to the Distributed Engine directory, for instance, `C:\Program Files\Thycotic Software Ltd\Distributed Engine`.
4. Navigate to the `C:\Windows\Microsoft.NET\Framework64\v4.0.30319\Config` directory.
5. Open the `machine.config` file.

6. If necessary, create a `<DbProviderFactories>` section within the <system.data> section.
7. Copy and paste the line below into the `<DbProviderFactories>` section:

```
<add name="Oracle.DataAccess" invariant="Oracle.DataAccess.Client" description="Oracle Data
Provider for .NET, Unmanaged Driver" type="Oracle.DataAccess.Client.OracleClientFactory,
Oracle.DataAccess, Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342"/>
```

The section should look like this:

```
<system.data>   <DbProviderFactories>      <add name="Oracle.DataAccess"
invariant="Oracle.DataAccess.Client" description="Oracle Data Provider for .NET, Unmanaged
Driver" type="Oracle.DataAccess.Client.OracleClientFactory, Oracle.DataAccess,
Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342"/>
</DbProviderFactories></system.data>
```

How to Create an Ignore File for Distributed Engine Upgrades

Create and configure an ignore file for Distributed Engine upgrades to allow Distributed Engine ignoring specific DLLs and not replacing them during upgrades.

1. Open a text editor like Notepad or Notepad++.

2. In the content of the file, add the filename of any DLLs that you'd like to ignore during upgrades. If there is more than one file, add each additional filename on a new line.

3. Save this file to the data folder on the Distributed Engine machine. By default, it is: C:\Program Files\Thycotic Software Ltd\Distributed Engine\data.

- Filename must be "ignore" without quotes.
- Uncheck "Append Extension" as this file must not contain an extension.

4. Once complete, any further upgrades will ignore any file listed in the ignore file.

Additionally see video demo for details.

Troubleshooting

Log Files

The errors below may appear in these files:

- `SS-BWSR.log` (Secret Server)
- `SSDE.log` (distributed engine)

These files are located within the log subdirectory of the application's directory. Typically, these are:

- Secret Server: `c:\inetpub\wwwroot\secretserver\log\SS-BWSR.log`
- Distributed engines: `c:\program files\thycotic software ltd\distributed engine\log\SSDE.log`

Errors

Oracle.DataAccess.Client.OracleException: The provider is not compatible with the version of Oracle client

This error occurs when the Oracle ODAC driver does not match the Oracle database version.

Uninstall the ODAC, and then re-install the correct version. You can uninstall ODAC using the universal installer that is included with the ODAC installation that resides in the ODAC directory.

Oracle.DataAccess.Client.OracleException (0x80004005): ORA-12514: TNS:listener does not currently know of service requested in connect descriptor

This error occurs when the secret's database field does not match the Oracle SERVICE_NAME database.

> The default "Oracle Account" secret template's database field is looking for the Oracle SERVICE_NAME database. You can find that database's location by reading the tnsnames.ora configuration file on your Oracle database server.

System.ArgumentException: Unable to find the requested .Net Framework Data Provider. It may not be installed.

This error occurs when Oracle parameters are missing from the section in the machine.config file.

System.Configuration.ConfigurationErrorsException: Unrecognized element

This error occurs when the section, located in the machine.config file, is not properly formatted.

Oracle RPC Templates

Secret Server now has four Oracle templates, three current and one legacy:

- Oracle Account
- Oracle Account (TCPS)
- Oracle Account (Template Ver 2)
- Oracle Account (Walletless)

See "Configuring Oracle Secret Templates" on page 1230 for details.

RPC for Postgres SQL

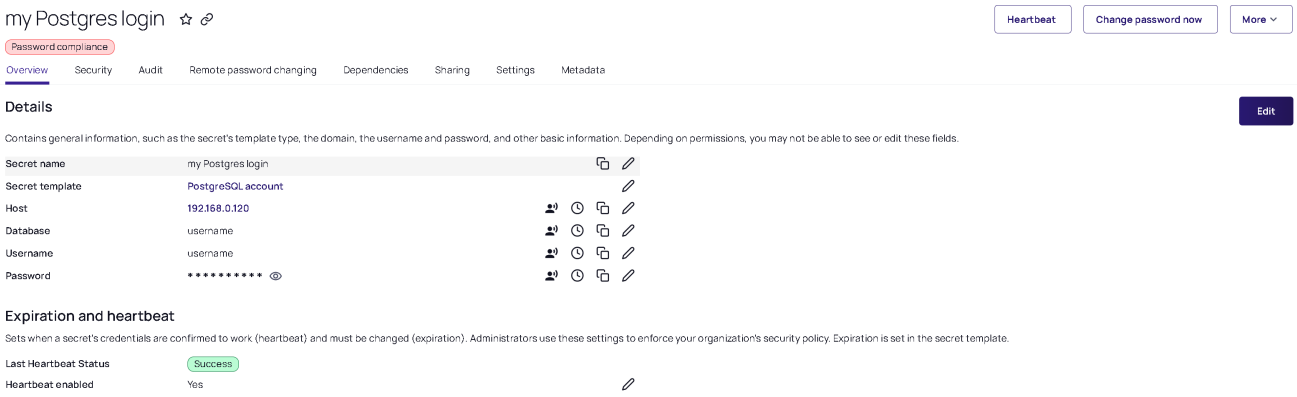
> This guide is for users familiar with PostgreSQL software who have it already installed and configured. If that is not the case, see PostgreSQL Downloads - Packages and installers for details on installing and configuring PostgreSQL.

Prerequisites

- A distributed engine.
  - Search for **Sites and engines**. You will see sites and their installed distributed engines here, along with any engines that are pending.
  - If you do not have a site with a distributed engine, see "Downloading and Installing a Distributed Engine " on page 759

Configuration

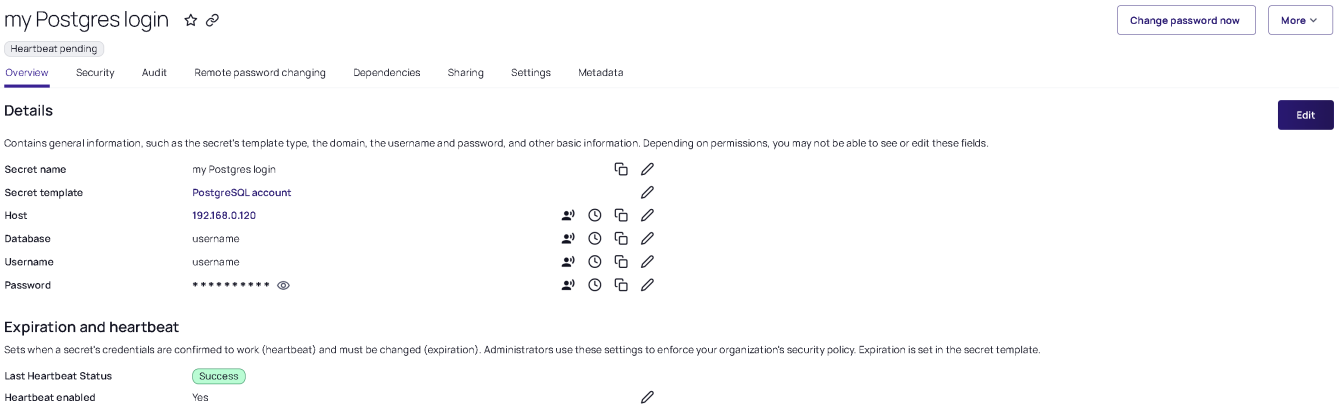
1. Log into Secret Server.
2. Navigate to **Secrets > All secrets**.
3. Select the **Create secret** button. The **Create new secret** page opens.
4. Search for and select the **PostgreSQL account** template. The popup refreshes automatically to reflect the necessary fields.
5. Complete the following fields:
   - **Secret name**: give the secret an appropriate name.
   - **Host**: the URL of the PostgreSQL tenant.
   - **Database**: specify the database on the PostgreSQL server to connect to.
   - **Username**: the username of the PostgreSQL account.
   - **Password**: the password of the PostgreSQL account.
   - **Site**: set a site with a distributed engine, as mentioned in the prerequisites.
   - **Auto Change Enabled**: leave unchecked.
6. Click **Create secret**. The newly created secret loads automatically for viewing:



Secret Server automatically runs a **Heartbeat** to verify if the credentials are valid, causing the status to change from **Pending** to **Success**. If the credentials are not valid the status will change from **Pending** to **Failed**.

> To verify the status of the heartbeat process immediately, Search for **Heartbeat Log**.

You can change the password by selecting the **Change password now** option from the top right. This causes Secret Server to connect to the PostgreSQL instance specified in the secret and change the password in PostgreSQL, while simultaneously updating the password in the Secret as well.



RPC for Service Accounts

RPC can be performed on service accounts where the dependent services is automatically updated and restarted as the service account password is changed. Administrators are notified if a dependency fails to restart. The supported dependency types are IIS application pools, IIS application pool recycle, scheduled tasks, windows services, passwords embedded in .ini, .config, and other text files. Custom dependencies can be created using SSH, PowerShell, or SQL scripts. The application pool recycle only recycles the specified application pool, it does not update the password of the service account running the application pool. Secret Server attempts to unlock the service account should the account become locked during the dependency password change if there is a privileged account assigned to the secret.

Minimum Requirements for Windows Local Accounts

Due to a security issue (MS KB3178465), we do not allow Windows local accounts to change their own passwords unless the local admin account comes with the operating system. Other local admin accounts can also change their own passwords if the local security policy allows this. We recommend using the discovery privileged account to change these passwords. Each privileged account should meet the following requirements:

- Must be a domain user
- Must be a member of the local administrator group on all target end points

> The discovery account for Secret Server can also be used for RPC.

To use RPC, a specific registry setting is required:

- **Key:** HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System
- **Value:** LocalAccountTokenFilterPolicy = 1

This setting is required to bypass Remote UAC restrictions.

Salesforce.com Password Changer

As of version 8.6, Secret Server supports password changing for Salesforce.com accounts under the Web User Account secret Template, by selecting the Salesforce Password Type under Remote Password Changing. In

version 11.7.3, and Distributed Engine version 8.4.27.0, the standalone Salesforce secret template was added.

The Secret Server Web server's outbound IP Address must be added to the IP Address white list for your Saleforce.com organization. Please refer to the Salesforce.com documentation for instructions on how to set this up. See Restricting Login IP Ranges for Your Organization.

In cases where this is not set up correctly, you may see the follow error in the Remote Password Changing logs:

`Login failed: LOGIN_MUST_USE_SECURITY_TOKEN: Invalid username, password, security token; or user locked out.`

Please note:

- Secret Server can only communicate to the following Salesforce default Login URLs: https://test.salesforce.com and https://login.salesforce.com.
- Having the domain URL in the secret will not work and will throw this exception: `Login failed: INVALID_LOGIN: Invalid username, password, security token; or user locked out.` Only those two URLs work.
- There are three required Salesforce configurations:
  - Go to **Setup > Administration > Users > Profile**. Choose the user profile. Make sure that **Enabled API** is checked. This option is not available in all versions of Salesforce. Other versions will not have this enabled by default. Please see this "Enable API" not available article. If this setting is not enabled in Salesforce you will get one of these errors: `ERROR: Secret 'Salesforce Test' (Id = 1063) on Site 'EARTH' returned (LoginFailed). Exception: Login failed: API_DISABLED_FOR_ORG: API is not enabled for this Organization` or `Partner,System.Web.Services.Protocols.SoapException: API_DISABLED_FOR_ORG: API is not enabled for this Organization or Partner.`
  - Configure network access and allowlist the distribute engine or Secret Server IP address. If this is internal, use the public IP address.
  - Go to **Setup > Company Settings > My Domain**. Edit my domain settings and make sure that **Prevent login from https://login.salesforce.com** is unchecked.

SAP Heartbeat and Password Changing

You can enable Secret Server to perform heartbeats and change passwords on SAP accounts by doing the following:

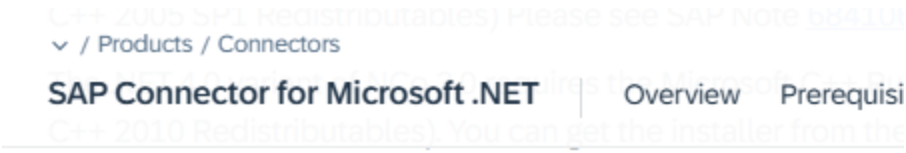
1. Create a new privileged SAP account administrator secret, typically for the SAP or DDIC account which is used to log into SAP for administrative tasks.
2. Select the **SAP Account** template and enter all required information to create the new SAP account administrator secret. By default, the **Instance Number** will be 00 and the **Client Number** will be 001.

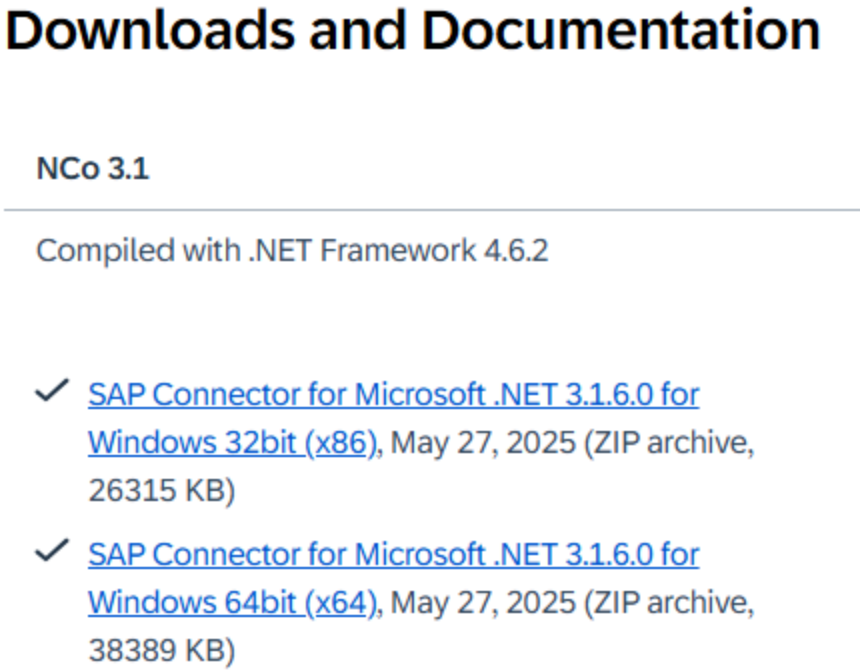
   The default **System ID** for SAP is NSP.
3. Create the account you are planning to change. Follow the same method as before and enter the current account password in the **Password** field.
4. In your new SAP account administrator secret, set the privileged account in the **Remote Password Changing** tab.

For an account to have its password changed, even a privileged account changing its own password, it requires permissions in SAP.

Installing SAP .Net Connector

1. Navigate to `service.sap.com/connectors`.
2. Type your credentials for the SAP Marketplace.
3. Select **SAP Connector for Microsoft .NET**.
4. Download SAP .Net Connector 3.1 (located under **NCo 3.1**), choosing the appropriate bit mode for your application pool (64-bit mode for most customers):





5. Install the downloaded file.
6. Copy the `sapnco.dll` and `sapnco_utils.dll` files into the `bin` folder of your web application.

For a distributed engine, add these files to the installation folder. Please see How to create an

> ignore file for Distributed Engine upgrades for details.

7. Recycle the application pool. Once these steps are complete, heartbeats and password changing should work.

> Accounts can change their own SAP passwords just once per day. This is a restriction in the SAP software that cannot be changed. If an account needs its password to change more than once a day, use a privileged account to perform the reset.

If performing a heartbeat on a SAP secret fails, throwing the `Exception: PASSWORD_EXPIRED` error, it likely means an administrator has reset the SAP account's password, and the account must log in and change its own password in SAP.

> If issues arise, please verify the secret template is set up properly. See Configuring SAP SNC Account Secret Templates for more details.

SQL Server RPC

Remote Password Changing (RPC) for SQL Server accounts in Secret Server allows administrators to automate the management of SQL Server account passwords, ensuring they remain synchronized with Secret Server policies. This feature supports the use of privileged accounts to change SQL Server passwords without knowing the current password, enhancing security and efficiency. Administrators can create SQL Server accounts, assign the necessary SQL permissions, and configure Secret Server to use these privileged accounts for password changes. The SQL Server Account template in Secret Server is preconfigured to facilitate this process, and administrators can customize it as needed. This functionality ensures that SQL Server account passwords are automatically updated according to defined schedules or upon expiration, maintaining compliance with security policies and reducing the risk of unauthorized access.

Using an SQL Privileged Account for RPC

This procedure enables you to password change SQL accounts using a privileged account. This allows you to take over accounts without knowing their password.

> Make sure your server authentication is set to **SQL server and windows authentication** mode for the RPC / HB to succeed.

Task 1: Creating an Account

> This task may not be needed if you already have an account setup.

1. Open the SQL Server Management Studio.
2. Connect to your database server.
3. Expand the root-level security folder.
4. Right click the **Logins** folder.
5. Click **New login**.

6. Name the account.
7. Click **SQL Authentication**.
8. Go to Secret Server.
9. Create a secret using the **SQL Server Account** template. Give it the same username as the "New Login" you are trying to create in the SQL Server Management Studio.
10. Click the **Generate** button on the secret password field enhanced security.
11. Copy the generated password to the account creation wizard in the SQL Server Management Studio.
12. Click **Create Secret** to save your secret.

Task 2: Assigning SQL Permissions

1. Return to the SQL Server Management Studio and connect to your database server.
2. Right-click on the SQL login you created in task 1 and click **Properties**.
3. Select **Securables** in the left column.
4. Select **Grant** for **Alter any login**.

Task 3: Using the Account

1. In Secret Server, select the SQL account secret you are going to have represent your new privileged account.
2. Select the **Remote Password Changing** tab.
3. Click **Edit** in the **RPC / AutoChange** section.
4. Change from the **Change Password Using** default selection to **Privilege Account Credentials** option.
5. Click the **No Selected Secret** link that appears.
6. Find and select the secret created for the privileged account in the first task.
7. Click the **Save** button.
8. Click the **Change password now** button.
9. In the **Next Password** dropdown select either **Manual** or **Randomly generated**.
   a. If you selected Manual, provide a new password and click **Change Password**.
   b. If you selected Randomly generated, the default option, just click the **Change Password** button.
10. You have now successfully changed a SQL account password using a privileged account.

You can also assign the account for use by multiple secrets by creating a secret policy and applying that policy to a folder.

RPC for SSH

Secret Server's Remote Password Changing (RPC) feature for SSH allows administrators to automatically update passwords for remote accounts using SSH protocols. This functionality ensures that passwords are rotated according to defined schedules or upon expiration, enhancing security by maintaining strong, up-to-date credentials. Secret Server supports SSH key rotation, enabling the management of private SSH keys for tasks such

as PuTTY launcher sessions and Unix/Linux discovery. Using SSH RPC, organizations can automate password changes, enforce password policies, and reduce the risk of credential-based attacks.

Creating a Custom SSH Password Changer

To create a custom SSH password changer for a device that supports changing passwords via SSH, follow the procedure for "Creating a Custom Password Changer" on page 901. Be sure to choose a base password changer with a name that ends in `(SSH)`.

Editing Custom Commands

The SSH type changers use the SSH protocol to access the machine. This type contains custom commands for password reset and can contain commands for the verify password functionality but most SSH type changers simply verify that a connection can be established with the username and password. The Telnet type changers use the Telnet protocol in order to access the machine and contain custom commands for both the password reset and the verify password functionality. The verify functionality is used in the heartbeat, as well as verifying that the password was changed successfully.

SSH key rotation type changers also include post-reset success and failure custom commands. These extra command sets are run after both the reset and verify functions are run and are used to either finalize the key rotation and password change (success) or clean up after a failure. If both the reset and verify functions are successful, the post-reset success command set is run. If either the reset or the verify fail, the post-reset failure command set is run.

To edit the custom commands, click on the **Edit** Commands button. This sets the command grids into Edit mode where you can add, update, or delete the commands in order to suit their purpose.

RPC-Mapped Text-Entry Fields

Prepend a `$` to any text-entry field name to access that field. For example, to echo the notes value for a secret, you would use this command: `echo $Notes`. Commonly accessed fields include:

- `$USERNAME` The username text-entry field mapped in RPC on the secret template.
- `$CURRENTPASSWORD` The password text-entry field mapped in RPC on the secret template.
- `$NEWPASSWORD` The next password (filled in Next Password textbox or auto-generated).
- `$PRIVATEKEY` The private key text-entry field mapped in RPC on the secret template.
- `$NEWPRIVATEKEY` The next private key (filled in Next Private Key text box or auto-generated).
- `$CURRENTPUBLICKEY` The public key text-entry field mapped in RPC on the secret template.
- `$NEWPUBLICKEY` The next public key (generated from the next private key).
- `$PASSPHRASE` The passphrase text-entry field mapped in RPC on the secret template.
- `$NEWPASSPHRASE` The next passphrase (filled in Next Private Key Passphrase text box or auto-generated).

Associated Reset Secrets

- `$[1]$` Adding this prefix to any text-entry field targets the associated reset secret with order 1.
- `$[1]$USERNAME` The mapped username of the associated secret, identified by order. Can also reference any other property on the associated secret. Common examples include:
- `$[1]$PASSWORD`
- `$[1]$CURRENTPASSWORD`
- `$[1]$PRIVATE KEY`
- `$[1]$PRIVATE KEY PASSPHRASE`
- `$[SID:105]` Adding this prefix to any text-entry field targets the associated reset secret with a secret Id of 105.
- `$[SID:105]$USERNAME` The mapped username of the associated secret, identified by secret id. Like referencing an associated secret by order, referencing by secret id can also access any text-entry field on the secret by name.

Both the mapped text-entry fields and secret text-entry field names can be used.

Check-Result Commands

- `$$CHECKCONTAINS <text>` Checks that the response from last command contains `<text>`.
- `$$CHECKFOR <text>` Checks that the response from the last command equals `<text>`.
- `$$CHECKNOTCONTAINS <text>` Checks that the response from last command does not contain `<text>`.

If these conditions are not met the process fails and immediately returns a result.

If you want to exit out of the command set early without triggering a failure, echo an "OK" on the line immediately preceding the `exit 0;` statement. "OK" must be the only text in the response from the server for this to work.

You can test out your password reset and verify password command sets by clicking on the **Test Action** buttons next to the relevant sections. All communication between Secret Server and the target machine is displayed when using these test buttons.

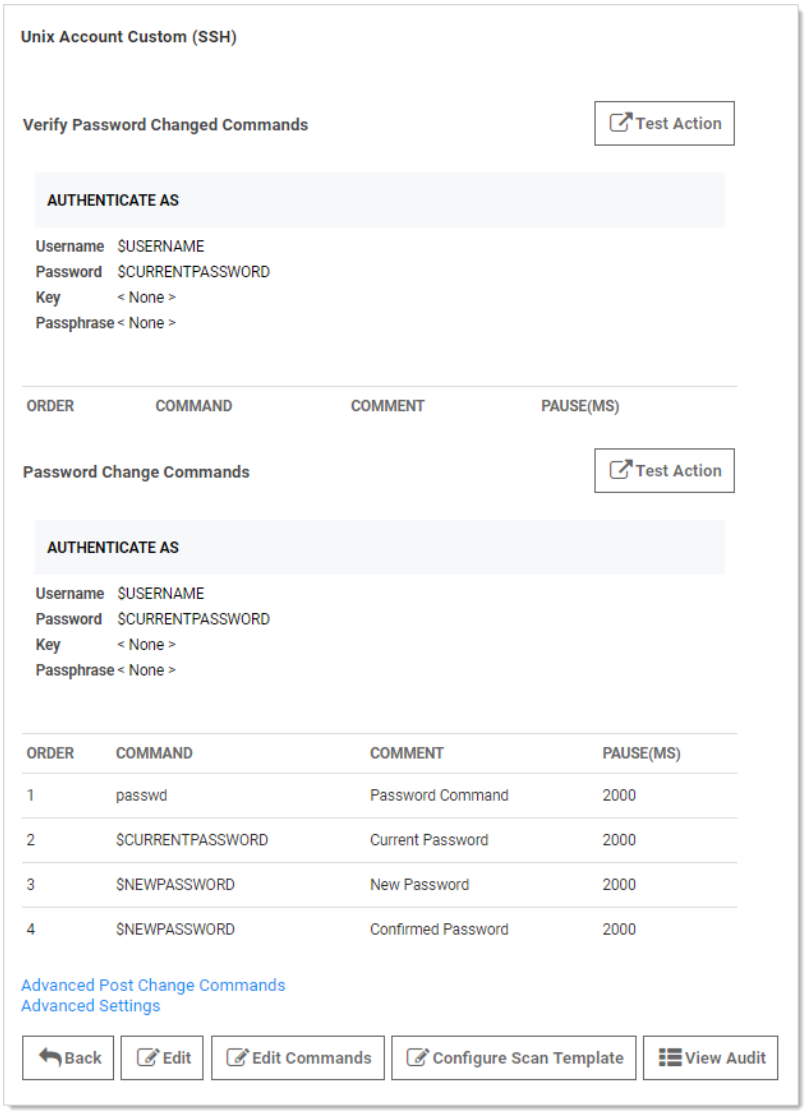
ConditionalTab Command

The script now includes the command `<ConditionalTab_TAB_SIZE_VAL_>`, where `_TAB_SIZE_VAL_` is replaced by an integer value (e.g., `<ConditionalTab10>`). The behavior of this command is as follows:

- If the prior specified size is 10 and the previous input is 10 or greater characters, the command does nothing, or the Tab command is skipped.
- If the previous input is less than the specified value but greater than zero, the tab will be executed.
- A zero value will disable the command.

Mapping an SSH Key or Private Key Passphrase for Authentication

Some password changers may be customized to use SSH key authentication. Secret Server needs to know which text-entry fields contain the key and the passphrase. These text-entry fields can be specified after clicking **Edit** from the password changer page.



The key and passphrase must be identified by a $ sign and the secret text-entry field name, which can be obtained from the secret template.

To set which text-entry fields are your key and passphrase, go to the extended mappings for a secret template by clicking **Extended Mappings** from the **Secret Template Edit** page. Select the text-entry fields that correspond to the SSH private key and passphrase if applicable. No matter what you name your key text-entry field, Secret Server knows what it is. This is set up by default, so you should not need to do this unless you've created custom Unix templates you want to use keys with.

Once Secret Server knows which text-entry fields contain the private key and private key passphrases, it can automatically use them as a part of launchers.

Remote Password Changing for Okta

When using Remote Password Changing (RPC), Secrets automatically change remote account passwords when they expire, either immediately or on a defined schedule. You can also configure password strength and other attributes.

If you need information on configuring Okta for SAML or assigning a password changer to an Okta secret template see "Configuring SAML Okta" on page 424 and "Okta Secret Template for RPC" on page 972.

Prerequisites

Before configuring the integration, ensure the following requirements are met:

- Download the **Okta Verify** app from the App Store or Google Play. See Configure Okta Verify for setup details.
- If using **Okta password changers with a distributed engine**, ensure the version is 8.4.32.0 or newer.

Setup and Configuration

To set up RPC in Okta, you must complete the following tasks:

- Create a custom role for the minimum required permissions for RPC.
- Create each user account whose credentials you want to automatically update (RPC) or verify (heartbeat).
- Generate an API key to authenticate with the Okta API during remote password changes.

The following sections describe how to perform these tasks.

Creating a Custom Role with the Minimum Permissions for RPC

Configuring RPC in Okta requires a dedicated account called *privileged user*. You need to use the privileged user to create an API key, which is required to access the Okta APIs for remote password changes. You can choose any user account in Okta as the privileged user for RPC purposes. For information about creating user accounts in Okta, see Okta - How to add users manually.

The privileged user must have specific minimum role permissions to enable RPC. You must create a role with the required permissions in Okta. You also need to create a resource set (a collection of resources) to define the scope of the role by constraining it to the resources in the resource set. After you create a custom role and a resource set, you must associate them with your privileged user by assigning them to the user.

This section describes how to create a custom role with the minimum required permissions for RPC in Okta, create a resource set, and assign the role and resource set to the privileged account.

To create a custom role with the minimum permissions for RPC:

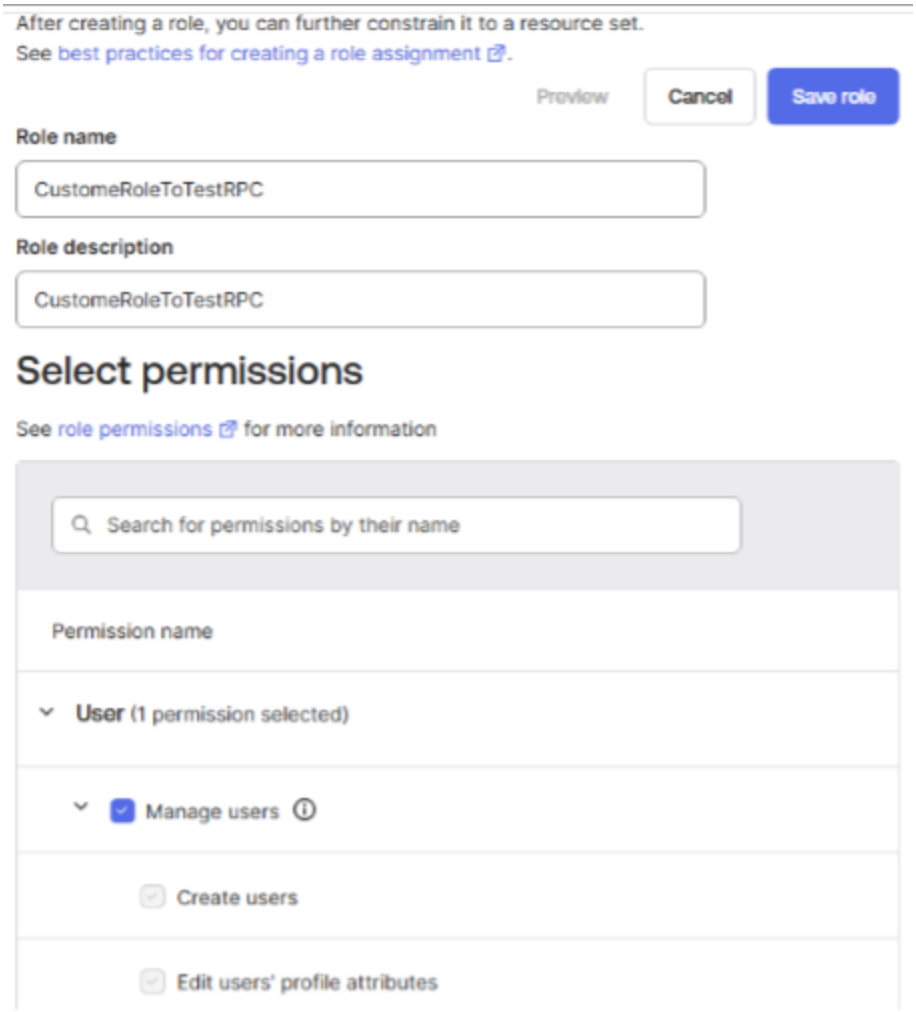
1. Log in to Okta as a super admin.
2. To create a custom role:

a. Navigate to **Security** > **Administrators**.

b. Go the **Roles** tab and select **Create new role**.

c. Provide a name and an optional description for the new role.

d. Under **Select Permissions**, expand **User** and select **Manage users**:

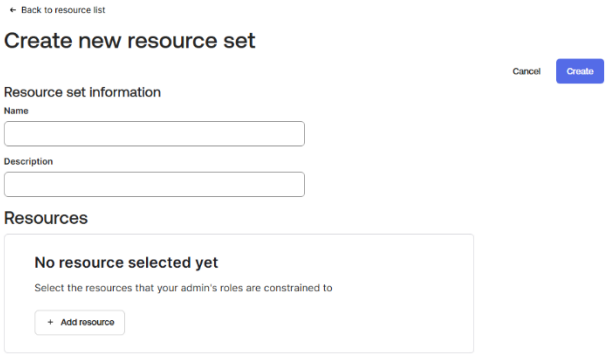


e. Select **Save role**.

3. To create a resource set for the role:

a. Navigate to **Security > Administration** and go to the **Resources** tab.

b. Select **Create new resource set**:



c. Provide a name and an optional description for the resource set.

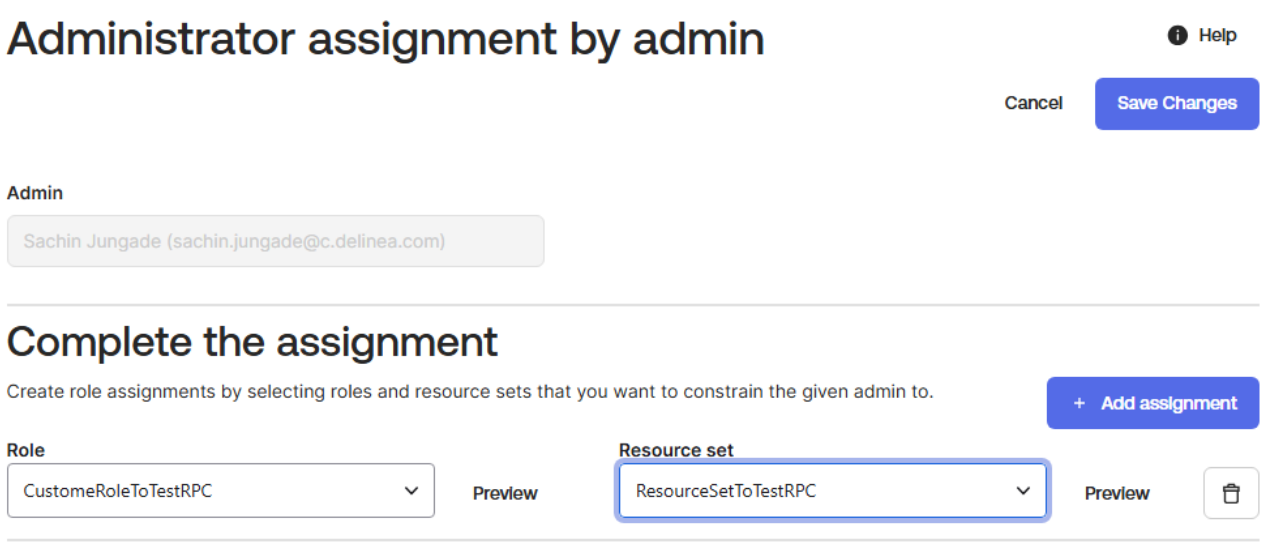
d. Select **Add resource**, the **Add Resource** dialog appears.

e. Select a resource type and then add appropriate resources to the resource set.

   For example, you can select the **Users** resource type and then choose **All users**, to add all users to the resource set.

f. Select **Save selection** and then **Create**.

4. Navigate to **Directory > People**.
5. On the **People** page, search for and select your privileged user account.
6. On the user's page, go to the **Admin roles** tab and select **Edit individual admin privileges**.
7. Under **Complete the assignment**, select the custom role and role set that you created, and assign them to the user:



8. Select **Save Changes**.

Creating a User Account

You must create an Okta user account whose credentials will be verified (heartbeat) or changed (RPC).

To create a user account in Okta:

1. Log into the **Okta Administrator Dashboard** using your administrator credentials.
2. Navigate to **Directory > People**.
3. Select **Add Person** and complete the following fields in the popup dialog:
   - First name
   - Last name
   - Primary e-mail
   - Username
4. Select **Save** to create the new user account.

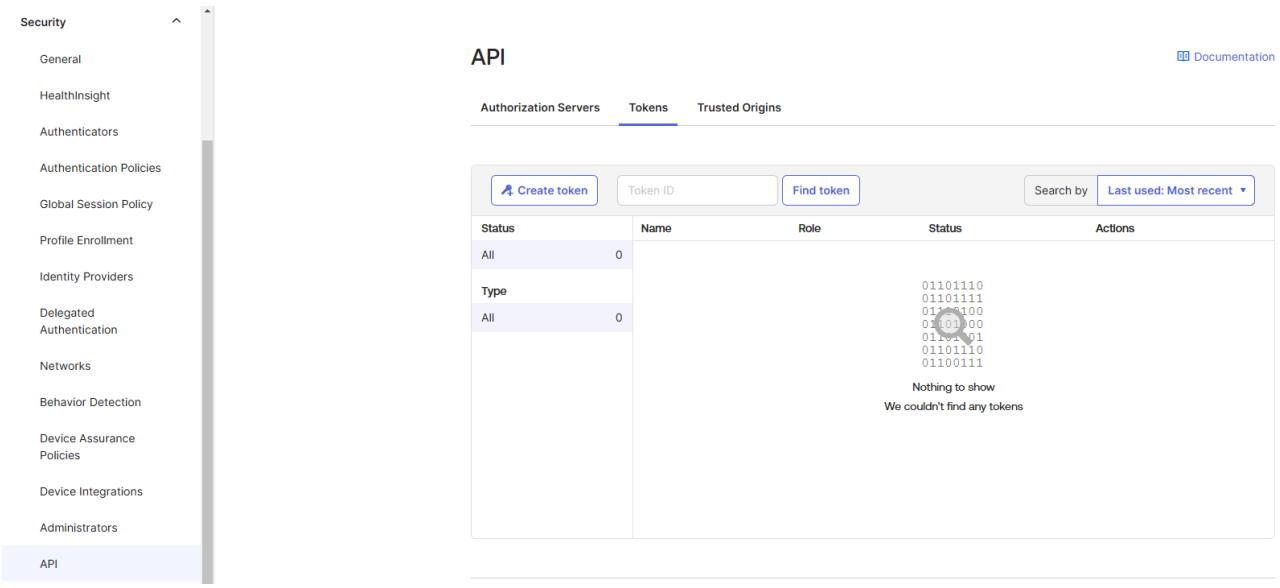
Generating an API Key

Heartbeat and RPC operations on accounts in Okta are performed through calls to the Okta APIs. You must generate an API key to provide the necessary API credentials for authentication with the Okta APIs.

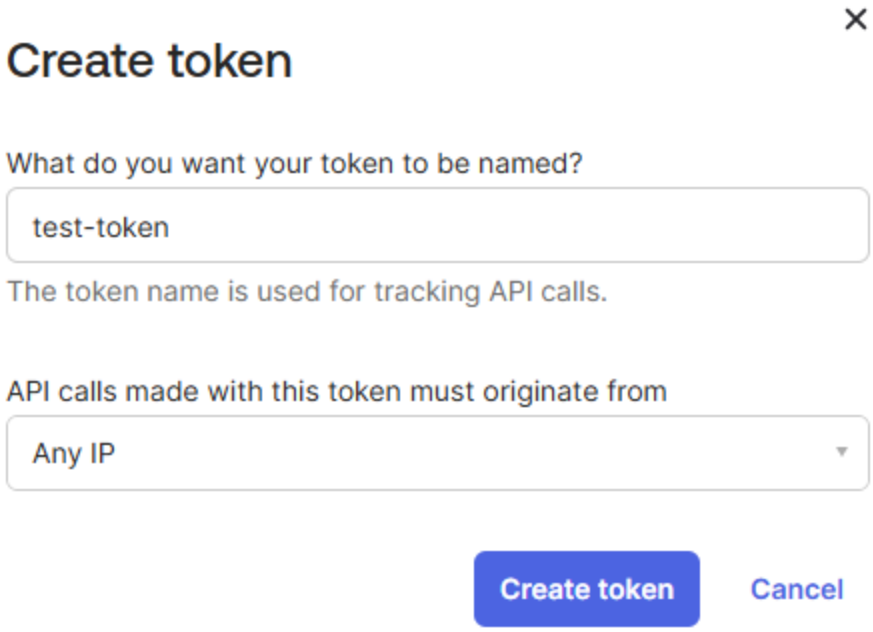
> To maintain security, rotate the API key regularly. Okta recommends rotating API keys at least every 90 days or according to your organization's security policies.

To generate an API key:

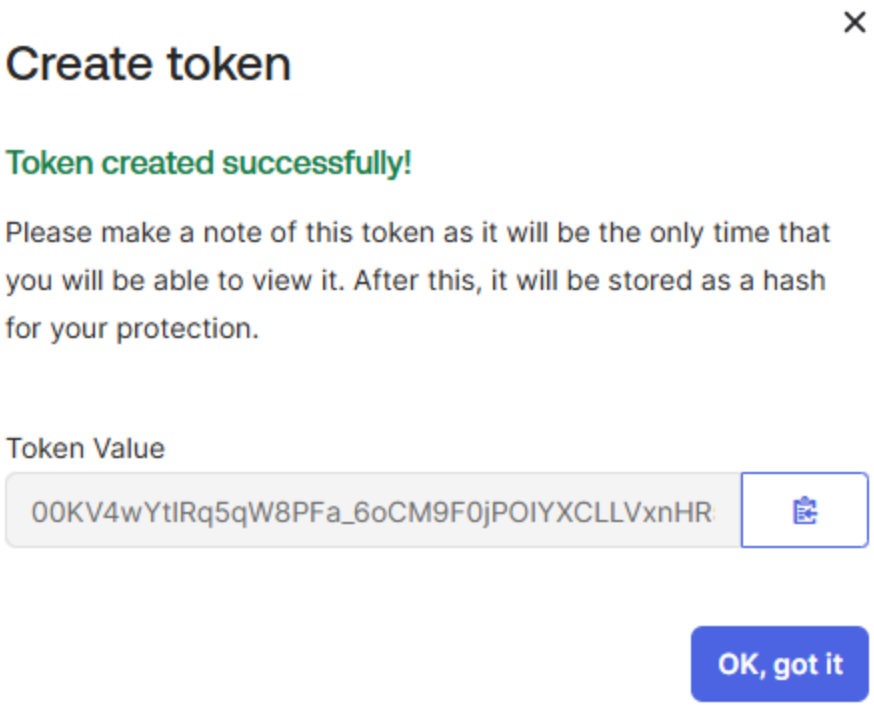
1. Log into Okta as the privileged user.
2. Navigate to **Security > API**.
3. In the **Tokens** tab, select the **Create Token** button. The Create token popup appears:



4. Provide a name for the token, select **Any IP** from the dropdown, and select **Create Token**:



5. A success message for the created token appears. Copy the generated API key (Token Value) to a secure location:



Configuring Okta RPC in Secret Server

To configure Secret Server for Okta RPC, you must complete the following tasks:

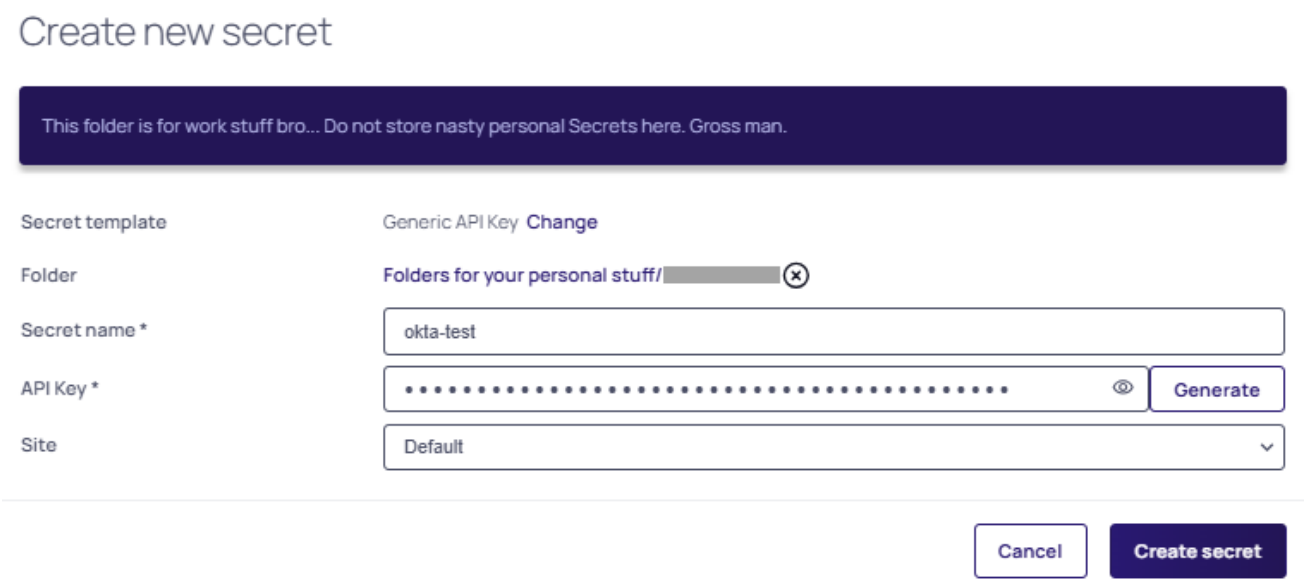
- Create a secret to hold the Okta API key.
- Create a secret for the Okta user account whose credentials you want to be changed or verified.

Creating a Secret to Hold the Okta API token

You must create a secret in Secret Server to hold the Okta API key that you created in the Okta UI.

To create a secret to hold the Okta API key:

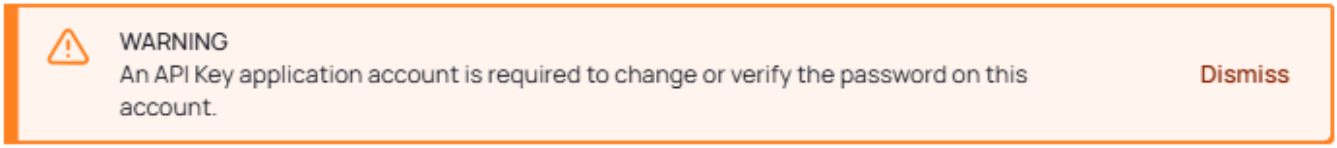
1. Log into Secret Server.
2. Navigate to **Secret Server > All secrets**.
3. Select the **Create secret** button. The **Create new secret** popup appears.
4. Search for and select the **Generic API Key** template.
5. Create a Secret using the **Generic API Key** type to hold the Okta token value:



6. In the **API key** field, paste the Token Value (API Key) copied from the Okta interface.
7. Select the **Create secret** button to save the secret. The newly created secret opens by default.

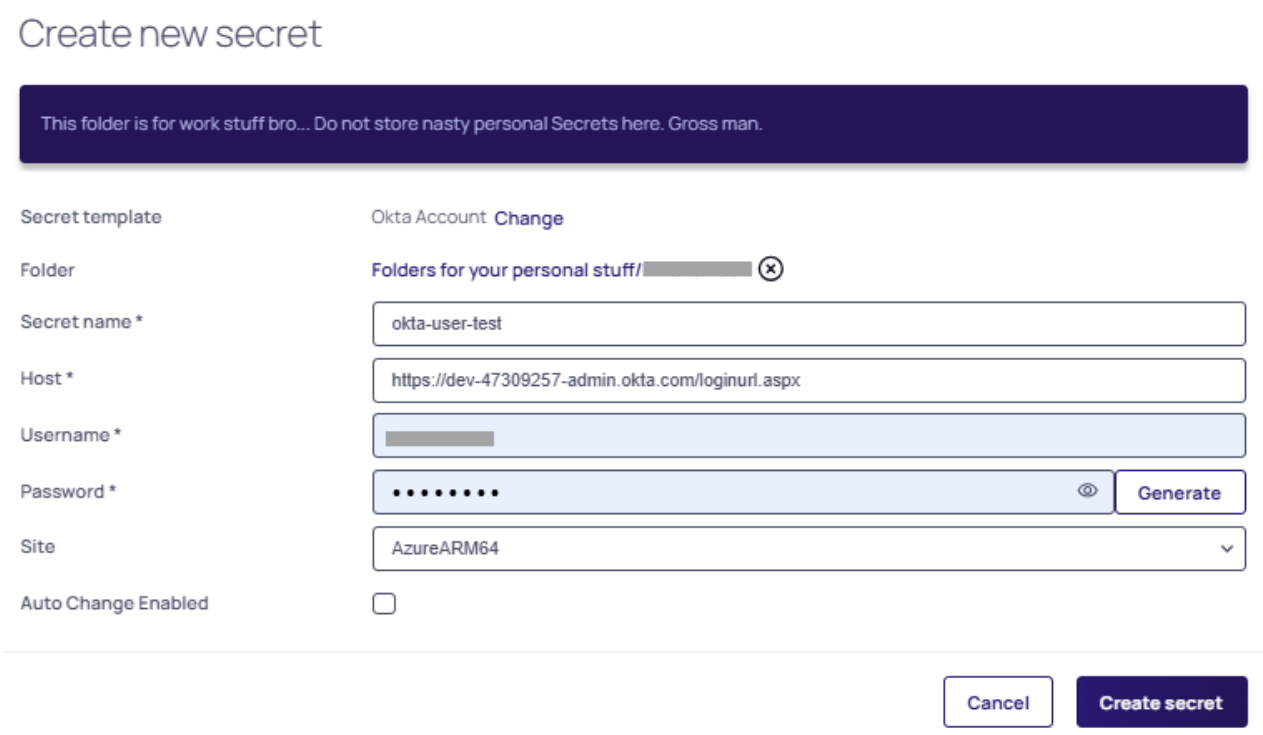
Creating a Secret for the Okta User Account

You must create a secret to hold the Okta user account whose credentials you want to be verified or password changed. All Okta accounts require an API key in the privileged account field under the **Remote Password Changing** tab to change or verify passwords. If no API key is assigned, a warning notification appears:



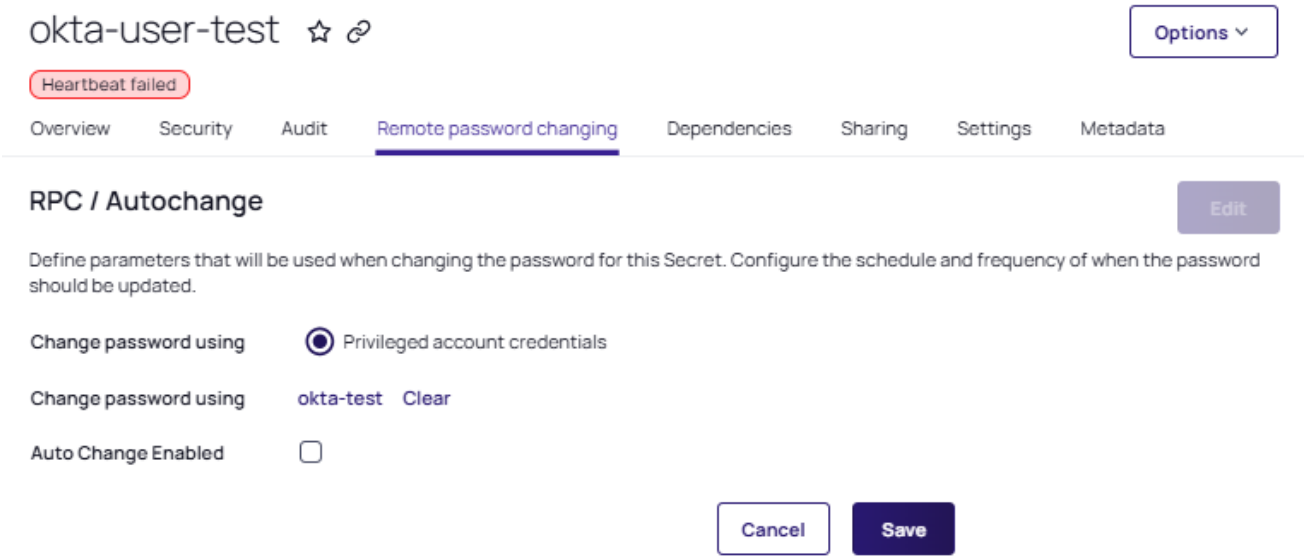
To create a secret for the Okta user account:

1. Log into Secret Server.
2. Navigate to **Secret Server > All secrets**.
3. Select the **Create secret** button. The **Create new secret** page opens.
4. Search for and select the **Okta Account** template.
5. Complete the following fields:
   - **Secret name**: Provide a name for your secret.
   - **Host**: Use your tenant URL (e.g. https://yourcompany.okta.com).
   - **Username**: Enter the username of your Okta account.
   - **Password**: Enter the password of your Okta account.
   - **Site**: Select a site with a distributed engine connected to the internet:



6. Select the **Create secret** button to save the secret. The newly created secret opens by default.
7. Access the **Remote password changing** tab.
8. Select **Edit** in the **RPC / Autochange** section.

9. Select the option for **Change password using** titled **Privileged account credentials**.
10. A second option for **Change password using** appears, click on **No secret selected**.
11. Search for the secret you created previously that holds the API key of your Okta account:



12. Click **Save** to implement your changes, and return to the **Overview** tab.
13. Select the **Heartbeat** button in the top right corner, to verify the credentials. If the credentials are valid the status will change from **Pending** to **Success**.

> To check the heartbeat status immediately, Search for **Heartbeat Log**.

Verification

To monitor heartbeat status, Search for **Heartbeat Log**. To change the password immediately, select **Change password now**.

RPC for Snowflake in Secret Server

RPC for Snowflake in Secret Server applies to Snowflake SQL database user accounts, including both admin and non-admin user accounts.

Prerequisites

Make sure you have:

- Two active Snowflake accounts. One of these accounts must be a privileged admin account which will be used for password changing.
- A Secret Server user who can create two Snowflake secrets.

  - Optionally, admin credentials for Secret Server (the **Limited_User_Admin** role) must be assigned to the admin account.
- The RPC feature enabled in Secret Server.
- Permission to create and configure secrets.
- Heartbeat monitoring and remote password-changing features enabled in Secret Server.
- A site with a distributed engine that has access to the internet.

> The creation of custom roles and the setup of user-role relationships are not part of the password changer implementation itself. These steps are a prerequisite that you must perform in order to use the password changer securely and correctly.

Role Usage Scenarios

- The user can define a custom role for managing multiple users and their passwords. Essentially, this role would function like a group while still being a role.

  Example: A user can create a user-defined role named `Custom_Role`. `User1, User2, User3, User4`, and `User5` are users, owned by `Custom_Role`. `User1` has been assigned to `Custom_Role`, allowing this user to manage the passwords of the other users who also belong to `Custom_Role` as well.
- Two roles can be created, each managing their own set of users.

  Example: Two roles are created: `AccountAdmin` and `Limited_User_Admin`, each have multiple separate user accounts assigned to them. One of these accounts is `AccountUser1`, which has both roles assigned to it. This allows `AccountUser1` to rotate the passwords of users belonging to both roles.

  `AccountUser1` needs to use the following commands:

  - `USE ROLE AccountAdmin` before doing password rotation for any of the users assigned to that role.
  - `USE ROLE Limited_User_Admin` before doing password rotation for users assigned to this second role, respectively.

Configuration

1. Log into Secret Server.
2. Navigate to **All Secrets** and click the **Create secret** button, the **Create new secret** popup appears.
3. Search for the **Snowflake account** template and select it. The popup refreshes automatically to reflect the fields you must fill in.
4. Complete the following fields:
   a. **Secret name**: give the secret an appropriate name.
   b. **AccountId**: you will find this as a part of your Snowflake URL (starts with lsb followed by several numbers).
   c. **Username**: the username used to sign into the Snowflake account.
   d. **Password**: the password used to sign into the Snowflake account.
   e. **Site**: set a site with a distributed engine that can access Snowflake services.

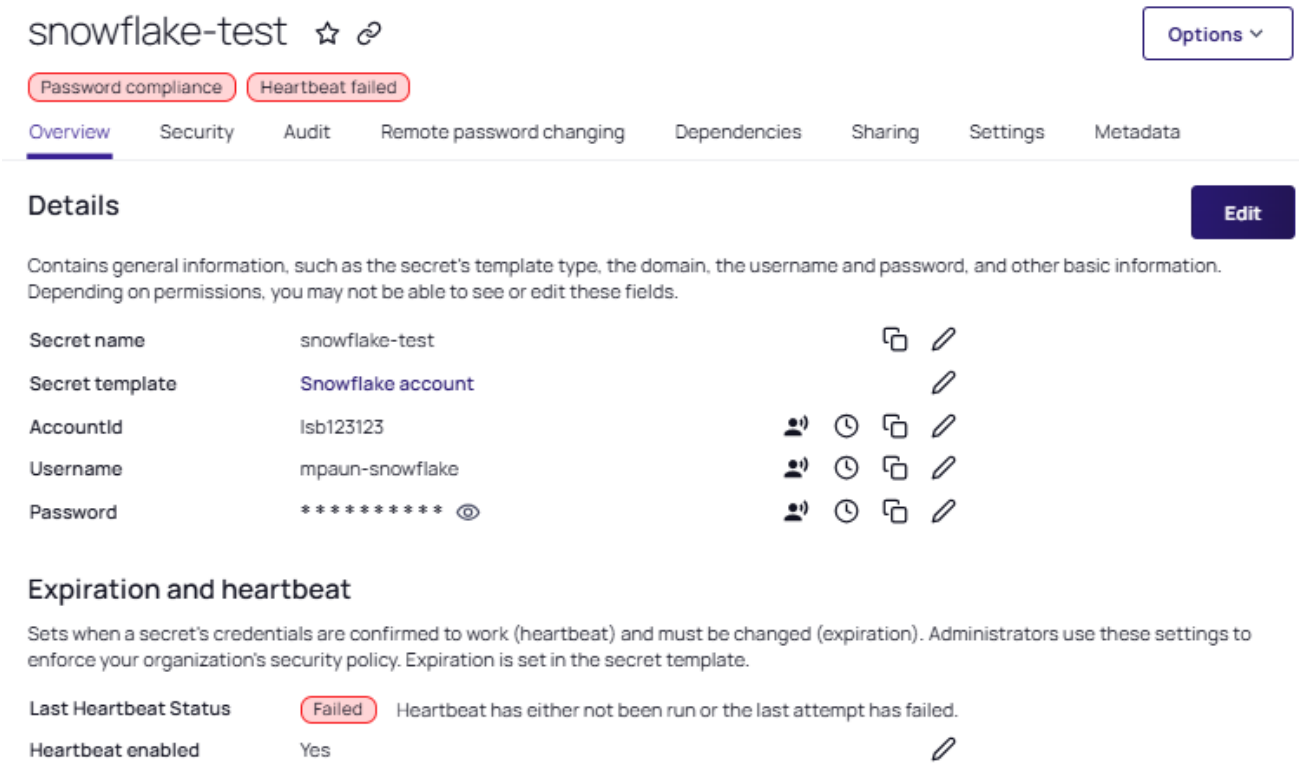
f. Leave **Auto Change Enabled** unchecked and click **Create secret**. The newly created secret loads automatically for viewing.

5. The **Heartbeat** operation runs automatically to check if the entered credentials are valid. If the credentials are valid the status will change from **Pending** to **Success**.

   If the credentials are not valid the status will change from **Pending** to **Failed**.

> The distributed engine checks for RPC every 300 seconds. If the heartbeat state remains in **Pending** for longer than 300 seconds, confirm that the site has an operational distributed engine by accessing **Settings > Sites and engines**.

> To verify the status of the heartbeat processes, Search for **Heartbeat Log**.

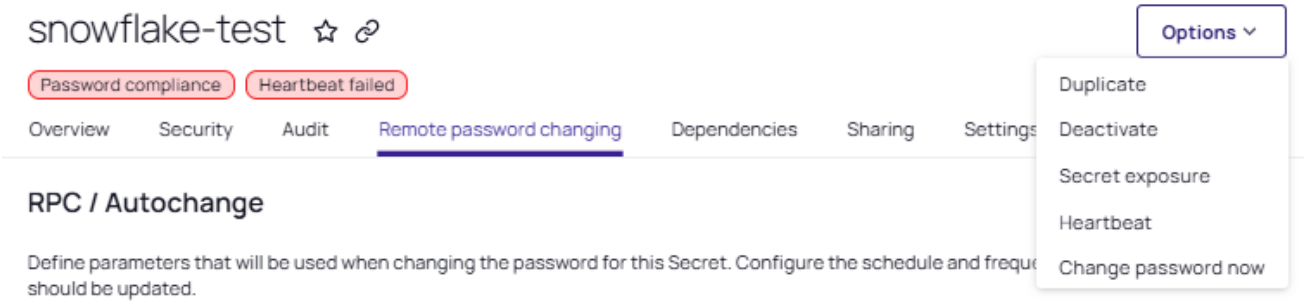


6. Navigate to the **Remote password changing** tab and select **Edit** for the **RPC/Autochange** section.
7. For **Change password using**, select the **Privileged account credentials** option.
   a. If you chose the option above, the **Change password using** option appears, and you must select a secret by clicking on the **No secret selected** link.
   b. A popup will appear where you can search for the secret you want to associate.

c. Select a Snowflake user with the **Limited_User_Admin** role used to process the password change.

d. Click **Save**.

8. (Optional) Access the **Change password now** option button from the top right corner if you want to change the secret password. Alternatively, it can be found under the **Options** dropdown list:



Heartbeat Overview

Heartbeat, which can be integrated with RPC, allows Secret Server to verify if the credentials stored in a secret can successfully authenticate with the target system. This ensures that the credentials are still valid and have not been changed outside of Secret Server.

You can configure "Event Pipelines" on page 295 to track whether an RPC has failed. Heartbeats allow you to check whether a password is incorrect and if the machine is online.

If a guest account exists on the domain, the heartbeat of an Active Directory secret will mistakenly report success. Microsoft disables the guest account by default for security reasons.

Automatic Credential Testing

Heartbeats allow secrets to have their credentials tested automatically to ensure they are accurate and up-to-date. This helps in managing secrets and preventing them from being out of sync.

SMB Fallback

To maximize compatibility across different versions of Windows, Secret Server can make a second attempt to use the secret via SMB if the initial heartbeat fails.

This fallback can be enabled or disabled based on the requirement.

Secret Server makes a second attempt to use the Secret via SMB when the **Use SMB heartbeat fallback** checkbox is selected. When this option is not selected, the second attempt will not be performed.

Heartbeat Flexibility and Usability

- By default, heartbeat is turned off in Secret Server.
- Administrators can enable heartbeat for specific secrets and run it manually if needed.
- The status of the last heartbeat run is displayed in the secret's **Overview** page, under the **Expiration and heartbeat** section.
- Administrators can manually trigger a heartbeat check by accessing a secret and selecting the **Heartbeat** button from the top right of the page.

Heartbeat Status Codes

See "Heartbeat Status Codes" on page 1061 for details.

- **Success**: Successful authentication.
- **Failed**: Unsuccessful authentication.
- **Unable to Connect**: Unsuccessful connection with target machine.
- **Unknown Error**: Unknown error–see the heartbeat log.

Failure Response

- If a heartbeat fails, the secret is flagged as **heartbeat failed** and will not be checked again until the secret items are edited by a user.
- If the target machine is unavailable, the secret is flagged as **heartbeat unable to connect** and will continue to be checked at the next interval.

Configuring Heartbeat

Heartbeat is configured from the secret template designer. The heartbeat interval determines how often the secret credentials are tested.

Enabling Heartbeat in RPC

To enable heartbeat, ensure it is enabled on the **Remote Password Changing Configuration** page:

1. Search for **Remote Password Changing**.
2. Click the **Edit** button.
3. Click to select the **Enable Heartbeat** check box.
4. Click the **Save** button.

Heartbeat must also be enabled on the secret template by setting the **Enable Remote Password Changing Heartbeat** setting.

Heartbeat Failure Alert Notification

Secret Server provides a feature to alert users when a heartbeat check fails for any secret. This ensures that administrators and users are promptly informed about potential issues with credential accuracy or connectivity. Here are the key aspects of configuring and receiving heartbeat failure alerts:

Enabling Email Alerts for Heartbeat Failures

- On the Preferences page, you can enable the setting "Send Email Alerts when Heartbeat Fails for Secrets" to receive email notifications whenever a heartbeat fails for any secret that the user has view access to.
- This setting ensures that users are immediately informed about any issues with the credentials stored in Secret Server.

Personalize Settings

In the Secret Settings tab, users can configure specific email notification settings:

- Send Email When Heartbeat Fails: This option sends an email to the user when a heartbeat function fails for the secret. The email contains the secret name, error code, and details about the failure.
- These settings are user-specific and do not apply to other users who have view, edit, or owner permissions for the secret.

Event Subscriptions

- Secret Server's Event Subscriptions feature allows administrators to set up customizable alerts that send email notifications when specified actions are performed or events occur, such as a heartbeat failure.
- This feature can be configured to alert users or administrators about heartbeat failures, ensuring timely awareness and response to credential issues.

Heartbeat Log

The Heartbeat Log provides a detailed record of all heartbeat activities within Secret Server. Administrators can review this log to monitor the health and accessibility of secrets, ensuring that credentials are valid and services are operational.

Heartbeat Logs

The heartbeat logs for a specific secret can be seen by:

1. Accessing a secret.
2. Selecting the **Audit** tab. Here you can also choose to display certain actions, and whether or not to include password change log audits, from their respective dropdown lists.

The heartbeat logs for all secrets can be accessed by searching for **Heartbeat Log**.

Heartbeat Status Codes

- **AccessDenied**: Account does not have the rights to log into the resource. Example: Remote login is not enabled for a Windows local account.
- **AccountLockedOut**: Account is locked out in the domain or on the workstation for Windows local accounts or Linux accounts.
- **ArgumentError**: Incorrect arguments have been provided to complete the Heartbeat. Example: Trying to use the new Entra ID secret template without a privileged secret mapped.
- **Disabled**: Heartbeat is disabled because the secret used QuantumLock, does not exist, is disabled, or does not have the correct license level activated.
- **DnsMismatch**: secret-server connected to an unexpected host when trying to complete a heartbeat, likely a DNS or network problem.
- **Failed**: The credentials are either incorrect or the account does not have permission to log in.
- **Failed Unknown**: Catch-all for any responses we don't recognize.
- **IncompatibleHost**: An incompatible function was applied to the device or source. Example: Trying to use a Linux password changer for a Windows account.
- **NeedsImmediateRetry**: The heartbeat feature uses PowerShell, and the MaxShellsPerUser amount was exceeded and will be tried again.
- **Pending**: The secret is set to be processed during the next batch of processing.
- **PrivilegedAccountRequired**: Secrets that require a pprivileged account to run a heartbeat, but the account was not linked or was missing when the heartbeat was queued.
- **Processing**: The heartbeat was sent to the engine for processing and secret-server is awaiting a response.
- **Success**: Successful credential validation.
- **UnableToConnect**: Secret Server was unable to contact the target system. Ensure that the domain, IP address, or hostname is correct and resolvable from the server that Secret Server is installed on.
- **UnableToValidateServerPublicKey**: The Linux key-based credentials are incorrect.
- **UnknownError**: Check the heartbeat log on the **Remote Password Changing** page for details, and contact Support for assistance. This error typically refers to other cases where we could not determine the reason for the failure but reached a resource such as Active Directory. Example: "User Name could not be found."

Please keep in mind the pipeline appears to log a heartbeat failure if it receives any status other than: "Success", "Pending", "Disabled", or "Unable to Connect". This means that "Processing" will also be treated as a failure.

Enabling the built-in guest user in Active Directory can cause confusion because heartbeat returns a "success" status for non-existent accounts. To avoid this, disable the guest user when setting up AD.

Remote Accounts Supported

For the most up-to-date list of account types supported by RPC, see "Password Changer List" on page 904.

Running Heartbeat for a Secret

Heartbeat runs in a background thread to check each secret where it is enabled. If the credential test fails, the secret is flagged as heartbeat failed and out of sync. To avoid locking out the account, heartbeat no longer run on that secret until the secret items are edited by the user. If the machine is determined to be unavailable, the secret is flagged as heartbeat unable to connect and the secret continues to be checked on the heartbeat interval.

To manually use heartbeat to check the credentials, the **Secret View** page has a **Heartbeat Now** button. The button marks the password as heartbeat pending. The background thread processes the secret in the next 10 seconds, and when the page is refreshed the heartbeat status is updated.

> Heartbeat does not work on Windows accounts on the server that is running Secret Server. These accounts are flagged with an "Incompatible Host" status.

To run heartbeat for a secret:

1. From **Dashboard**, click the secret you would like to test.
2. Click the **View** button. The **Last Heartbeat** field of the secret shows the last date and time that Heartbeat ran for this secret.
3. To run Heartbeat once more, click **Run Heartbeat** at the bottom of the Secret.
4. Monitor the **Last Heartbeat** field to see the updated status. This may take a few seconds to complete.

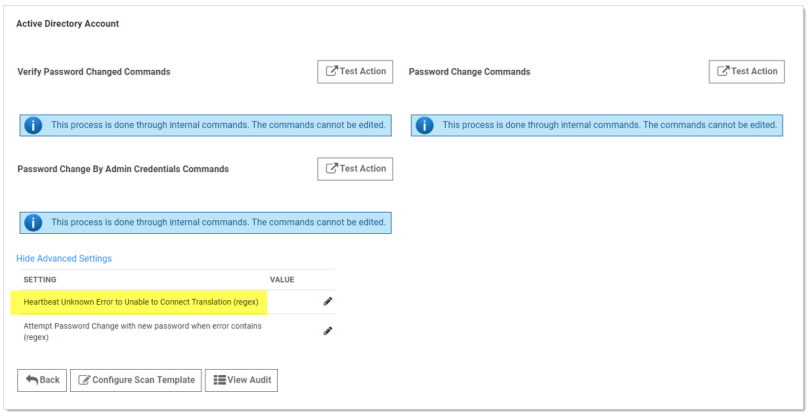
If you receive any Heartbeat status code aside from Success, you can check the Heartbeat log for details. To view the entry, Search for **Remote Password Changing** and then search for the secret name in the **Search** field of the **Heartbeat Log**.

Treating Heartbeat "Unknown Errors" as Connection Failures

> This setting was previously called "Password Change Error Code Translation (regex)."

The Secret Server "Heartbeat Unknown Error to Unable to Connect Translation (regex)" setting can translate UnknownError heartbeat errors into connection errors based on text, such as the error code, in the error message. Using a regular expression, which you define, Secret Server scans heartbeat UnknownError messages for specific text strings. When there is a match, Secret Server changes the UnknownError to an "Unable to Connect" heartbeat error. This setting is useful if a custom command error is interpreted as UnknownError but the message indicates it actually was unable to connect. The translated connection error will cause Secret Server to attempt another heartbeat.

Figure: Heartbeat Unknown Error to Unable to Connect Translation (regex) Setting



> The UnknownError error is very common when running scripts and commands, making the regex discrimination desirable.

Logic:

(RPC UnknownError) AND (Regex match in error message) => RPC status changed to "Unable to Connect"

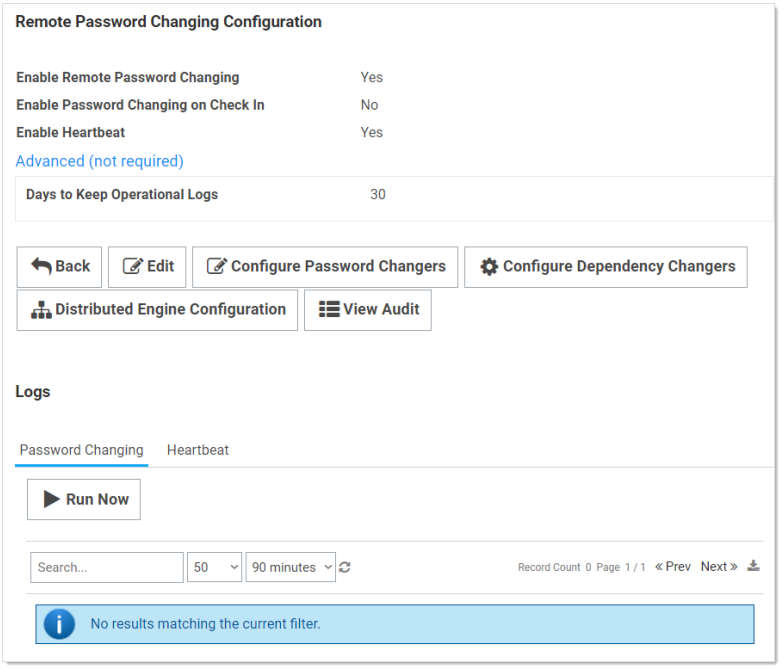
Example:

`.*error code is 10060.*` (any error with the code 10060 changes the RPC status to "Unable to Connect")

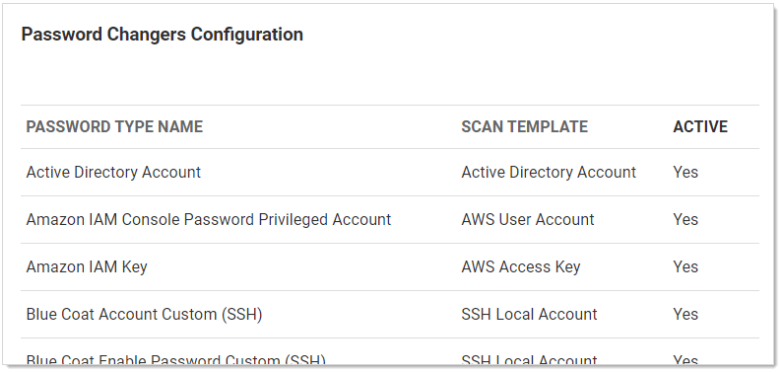
Procedure

To configure the unknown errors to trigger connection failures:

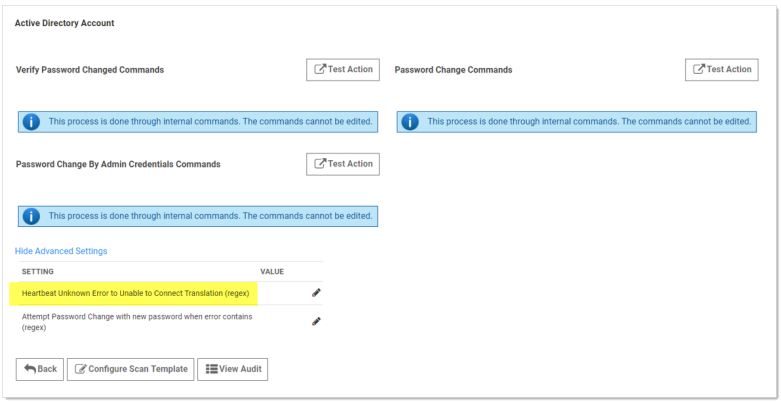
1. Search for **Remote Password Changing**. The Remote Password Changing Configuration page appears:



2. Click the **Configure Password Changers** button. The Password Changers Configuration page appears:



3. Click the link for the desired password type. Its Account page appears:



4. If necessary, click the **Advanced Settings** link.
5. Click the pencil icon next to **Heartbeat Unknown Error to Unable to Connect Translation (regex)**. The Value text box appears.
6. Determine the desired text string to search for.
7. Type the desired regex in the **Value** text box.
8. Click the **Save** icon next to the text box

SSH Key Rotation

SSH Key Rotation allows you to manage your Unix account private keys and passphrases, as well as the passwords for the associated accounts. With key rotation, whenever the password is changed on the secret (manually, during a scheduled auto-change, or when checking in a secret that changes the password on check-in), the public/private key pair will be regenerated and the private key encrypted using a new passphrase. The public key will then be updated on the Unix machine referenced in the secret.

There are two topics addressed here:

- "Basic SSH Key Rotation" below: A step-by-step tutorial on quickly getting started with the default SSH key rotation secret types and password changers.
- "Custom SSH Key Rotation" on page 1069: Provides additional information for users who need to customize the default commands for their environment.

Basic SSH Key Rotation

This topic is a tutorial on how to quickly get started using SSH key rotation to change a Unix account's public and private key and automatically update a remote machine using Remote Password Changing (RPC).

Introduction

SSH key rotation allows you to manage your Unix account private keys and passphrases as well as their passwords. With key rotation, whenever the password is changed on the secret (manually, during a scheduled auto-change, or when checking in a secret that changes the password on check-in), the public/private key pair is regenerated and the private key encrypted using a new passphrase. The public key is then updated on the Unix machine referenced on the secret.

This document is a tutorial showing you how to quickly get started using SSH key rotation using our default key rotation password changers. For an in-depth description of SSH key rotation including modifying the command sets for your environment, see our "Custom SSH Key Rotation" on page 1069 topic.

Requirements

To use our default SSH key rotation commands, the following minimum requirements must be met on the machine being managed:

- SSH key logins should be enabled on the target using keys in OpenSSH format. While a secret can initially be created with keys in PuTTY format, these keys will be converted to OpenSSH format during rotation. Despite this conversion, the PuTTY launcher will continue to function properly, ensuring compatibility and uninterrupted access.
- Public keys should be stored in `[~userhome]/.ssh/authorized_keys` (not `authorized_keys2`).
- Grep and Sed should be installed on the target.
- If doing a privileged SSH key rotation, where a privileged user sets the key for another user, the privileged user must have sudo permissions that do not prompt for a password and the permissions to edit the user's `authorized_keys` file with sudo.

If a system does not meet these requirements it may still be possible to do key rotation by modifying the key rotation command sets. Our "Custom SSH Key Rotation" on page 1069 topic describes how to do this.

Configuring a Secret for SSH Key Rotation

Secret Server comes with two secret templates for SSH key rotation: **Unix Account (SSH key rotation)** and **Unix Account (Privileged Account SSH Key Rotation)**.

Use **Unix Account (SSH Key Rotation)** if:

- The account is able to change its own password and modify its own `authorized_keys` file.
- The account password and key should only be changed by Secret Server (Secret Server will always have the current password and keys).

Use **Unix Account (Privileged Account SSH Key Rotation)** if:

- The account is not able to change its own password or modify its own `authorized_keys` file.
- The account password and key may be changed outside of Secret Server, and Secret Server may not have the current account credentials. A privileged account that is able to change the password and `authorized_keys` files of other users will still be able to change the account credentials.

SSH Key Rotation Using the Secret's Credentials

Creating the Secret

1. Create a new secret in Secret Server using the **Unix Account (SSH Key Rotation)** template.
2. Enter the account user name and password.
3. Upload the private key file.

4. If the private key is encrypted using a passphrase, enter the passphrase.
5. Uploading a public key is optional but recommended. If a public key is not provided, Secret Server will regenerate it from the private key during key rotation, but if the key in `authorized_keys` is not in the same format as the generated key or does not match exactly (including comments), the rotation will fail because it could not find the public key that needs to be removed.
6. After the secret is created you should see a successful heartbeat status. If heartbeat isn't running, make sure heartbeat and RPC are enabled under **Admin > Remote Password Changing**.

Rotating the Key

1. Go to the **Remote Password Changing** tab and click **Change Password Remotely**.
2. Enter the new password or click **Generate** next to the **Next Password** field to generate a random password.
3. Click to select **Generate New SSH Key** to create a new, random SSH key. If you want to supply your own private key, uncheck this option and paste the key into the **Next Private Key** text box that appears.
4. If you have unchecked **Generate New SSH Key** you must enter the passphrase that was used to encrypt the private key at the time it was created. Leave this field blank if the private key was not encrypted with a passphrase. If you have checked **Generate New SSH Key** you have the option to enter your own passphrase, leave it blank (for an unencrypted private key), or click the **Generate** button next to the field to create a new, random passphrase. If you want to change the key without changing the passphrase, you must put the current passphrase in the **Next Private Key Passphrase** text box.
5. Click **Change** to start the key rotation and a password change. After you start the change, you can check the status either in **Admin > Remote Password Changing** or on the **Remote Password Changing** tab of the secret.
6. Once the password change / key rotation is complete the heartbeat status should be successful. You can check the audit log to see notes that the key was rotated and start a session using the key with the PuTTY Launcher.

SSH Key Rotation Using a Privileged Account

To use **Unix Account (Privileged Account SSH Key Rotation)**, you must have a secret that is able to use the sudo command to access other accounts' `authorized_keys` files and change their passwords. This can be any type of Unix secret and can use a password and/or private key to authenticate. If you have a secret that meets these requirements, you can set up SSH key rotation using a privileged account as follows.

Creating the Secret

1. Create a new secret in Secret Server using the **Unix Account (Privileged Account SSH key rotation)** template.
2. Enter the account user name and password.
3. Upload the private key file.
4. If the private key is encrypted using a passphrase, enter the passphrase.
5. Uploading a public key is optional, but recommended. If it is not provided, Secret Server will regenerate it from the private key during key rotation, but if the key in `authorized_keys` is not in the same format as the generated key or does not match exactly (including comments), the rotation will fail because it could not find the public key that needs to be removed.

6. After the Secret is created you should see a successful heartbeat status. If heartbeat is not running, make sure that heartbeat and RPC are enabled under **Admin > Remote Password Changing**.
7. Next go to the **Remote Password Changing** tab and choose the privileged secret that can authenticate to the machine and modify the user's `authorized_keys` file.
8. Click the **Back** button after adding the associated secret.

Rotating the Key

1. Go to the **Remote Password Changing** tab and click **Change Password Remotely**.
2. Enter the new password or click **Generate** next to the **Next Password** field to generate a random password.
3. Click to select **Generate New SSH Key** to create a new, random SSH key. If you want to supply your own private key, uncheck this option and paste the key into the **Next Private Key** text box that appears.
4. If you have unchecked **Generate New SSH Key** you must enter the passphrase that was used to encrypt the private key at the time it was created. Leave this text box blank if the private key was not encrypted with a passphrase. If you have checked **Generate New SSH Key** you have the option to enter your own passphrase, leave it blank (for an unencrypted private key), or click the **Generate** button next to the field to create a new, random passphrase. If you want to change the key without changing the passphrase, you must put the current passphrase in the **Next Private Key Passphrase** text box.
5. Click **Change** to start the key rotation and a password change. After you start the change, you can check the status either in **Admin > Remote Password Changing** or on the **Remote Password Changing** tab of the secret.
6. Once the password change / key rotation is complete the heartbeat status should be successful. You can check the audit log to see notes that the key was rotated and start a session using the key with the PuTTY Launcher.

Troubleshooting

- The SSH Password Changers are targeted to OpenSSH. If using a different SSH library or if the user keys are not in the user's `/.ssh/authorized_keys` file you can check the commands used and modify them as appropriate under **Admin > Remote Password Changing** and clicking **Configure Password Changers**. The password changers used are **SSH Key Rotation** and **SSH Key Rotation Privileged Account**.
- Errors are logged to **Admin > Remote Password Changing**. Additional logs can be found in the Secret Server directory in the log subfolder. That is: `C:\inetpub\wwwroot\secretserver\log`.
- A change was made to how SSH script variables are named to differentiate them from tokens when testing command sets on the Configure Password Changers page. Non-token script variables should begin with an underscore. Anything in the script beginning with a dollar sign not followed by an underscore will be treated as a token and displayed as a field in the test dialog. For example:
  - `$USERNAME`References the username from the secret.
  - `$[1]$USERNAME` References the username from the first linked secret.
  - `$_USERNAME` References a bash variable defined in the script.
- The default command set for the SSH key rotation privileged account password changer assumes that the sudo command will not prompt for a password. If your environment prompts for a password when using sudo the command sets will need to be modified to supply the password. If your environment caches the sudo credentials, the easiest way to handle this is to add the following two lines at the top of each command set on

the SSH key rotation privileged account password changer:

```
sudo -i echo
$[1]$PASSWORD
```

This caches the credentials for the rest of the script.

Custom SSH Key Rotation

This topic discusses how to change public keys for Unix accounts using Remote Password Changing (RPC) in Secret Server. For a step-by-step tutorial on quickly getting started with the default SSH key rotation secret types and password changers, see our "Basic SSH Key Rotation" on page 1065. The current topic provides additional information for users who need to customize the default commands for their environment.

Introduction

SSH key rotation allows you to manage your Unix account private keys and passphrases as well as their passwords. With key rotation, whenever the password is changed on the secret (manually, during a scheduled auto-change, or when checking in a secret that changes the password on check-in), the public/private key pair is regenerated and the private key encrypted using a new passphrase. The public key will then be updated on the Unix machine referenced on the secret.

Secret Server provides secret templates and password changers for SSH key rotation.

Requirements

To use our default SSH key rotation commands, the following minimum requirements must be met on the machine being managed:

- SSH key logins should be enabled on the target using keys in OpenSSH format. A secret can be created with keys in PuTTY format but they will be converted to OpenSSH when the key is rotated.
- Public keys should be stored in `[~userhome]/.ssh/authorized_keys` (not `authorized_keys2`).
- Grep and Sed should be installed on the target.
- If doing a privileged SSH key rotation, where a privileged user sets the key for another user, the privileged user must have sudo permissions that do not prompt for a password and the permissions to edit the user's `authorized_keys` file with sudo.

The default command sets have been tested in the following Linux environments:

- CentOS Linux release 7.0.1406
- FreeBSD bsdRadiusServer 9.3-RELEASE-p5 i386
- Linux Ubuntu 3.13.0-32-generic

If a system does not meet these requirements or has a different configuration than the tested Linux environments, it may still be possible to do key rotation by modifying the key rotation command sets. The command sets that may need to be edited and the process for doing so are described later in this topic.

Secret Templates

Secret Server includes two secret templates for SSH key rotation: **Unix Account (SSH Key Rotation)** and **Unix Account (Privileged Account SSH Key Rotation)**. The first template changes the password and key on the account using the account's credentials. Use this template if both of the following conditions apply:

- The account is able to change its own password and modify its own `authorized_keys` file.
- The account password and key should only be changed by Secret Server, which will always have the current password and keys.

Unix Account (Privileged Account SSH Key Rotation) uses an additional secret to provide the credentials for the connection that performs the password change and key rotation commands. You should use this template if either of the following conditions apply:

- The account is not able to change its own password or modify its own `authorized_keys` file.
- The account password and key may be changed outside of Secret Server, and Secret Server may not have the current account credentials. A privileged account that is able to change the password and `authorized_keys` files of other users will still be able to change the account credentials.

Creating a New SSH Key Rotation Secret

When creating a new secret based on either of these templates you will see the following form:

1. Type the secret name in the **Secret Name** text box.
2. Type the machine in the **Machine** text box.
3. Type the username in the **Username** text box.
4. Click the **Generate** button to create a user password.
5. Click **Private Key** link to upload a file containing the private key.
6. If you are creating a new secret and want to generate a new, random private key, click to select the **Generate New SSH Key** check box. This disables the "Change" links for both the private and public keys.
7. If your uploaded private key was encrypted with a passphrase or you are generating a new key and wish to encrypt it with a passphrase, type that passphrase in the **Private Key Passphrase** text box. Otherwise, leave it empty.
8. If you are creating a new key and want to create a random passphrase for it, click this **Generate** button.
9. If you are uploading a private key, click the **Public Key Change** link to upload the corresponding public key. Uploading a public key is optional, but recommended. If not provided, Secret Server regenerates it from the private key during key rotation, but if the key in the `authorized_keys` file is not in the same format as the generated key, the old key will not be removed when the new key is added.

If neither private key nor public key is attached to the secret, a key rotation creates a new key pair, attaches them to the secret, and adds the new public key to `authorized_keys`.

After the secret is created, you should see a successful heartbeat status. If heartbeat is not running, make sure that heartbeat and RPC are enabled under **Admin > Remote Password Changing**.

> Heartbeat status when either the private key/passphrase or password are incorrect is indeterminate and based on the host configuration. If the system allows log on as long as one of the two is correct, it will return a successful heartbeat when the password is wrong but the key is valid and vice-versa.

If you are adding a secret using the **Unix Account (Privileged Account SSH Key Rotation)** you will also need to specify which privileged account to use during key rotation. To do this:

1. Switch to the **Remote Password Changing** tab.
2. Click the **Edit** button.
3. Click the **No selected secret** link.
4. Choose a privileged Secret that can authenticate to the machine and use the sudo command to access other accounts' authorized_keys files and change their passwords. This can be any type of Unix secret and can use a password and/or private key to authenticate.
5. Click the **Back** button to exit edit mode.

Editing the SSH Key Rotation Templates

To edit a template, Search for **Secret Templates**, choose the template you want to edit in the dropdown list of templates, then click **Edit**.

You can add, remove, or edit any fields you like, but if you change or replace any of the following fields you will need to update the password changer mapping for the template:

- Machine
- Username
- Password
- Private Key
- Private Key Passphrase
- Public Key

> Private key and public key must remain field type "File".

If you change any of the fields listed above, click the **Configure Password Changing** button to map the fields to the password changer. Click the **Edit** button and assign all the password changer fields to the corresponding fields on the secret template.

Password Changers

Secret Server includes two password changers for SSH key rotation: **SSH Key Rotation** and **SSH Key Rotation Privileged Account**. The **Unix Account (SSH Key Rotation)** secret template uses the **SSH Key Rotation** password changer and the **Unix Account (Privileged Account SSH Key Rotation)** secret template uses the **SSH Key Rotation Privileged Account** password changer. Each of these password changers includes a set of command sets designed to change the password and public key on an account using the secret's credentials and using sudo with a privileged account, respectively.

Although you can edit these password changers through **Admin > Remote Password Changing > Configure Password Changers**, clicking on the password changer and then **Edit** and **Edit Commands**, the recommended practice is to copy the existing password changers and then modify the copies. To do this:

1. Search for **Remote Password Changing**.
2. Click the **Configure Password Changers** button.
3. Scroll down to the bottom of the page and click the **New** button.
4. Select the password changer you want to copy in the **Base Password Changer** list and give the new password changer a name.
5. Click **Save**. This creates a new password changer and copies the command sets from the original password changer.
6. Enter the authentication information (see below for more information), clicking the **Save** button in each authentication field set.
7. Make the required changes to the command sets for your environment by editing existing lines, deleting lines, adding new lines, and rearranging lines.

Authentication

The authentication section defines the credentials that will be used to connect to the machine and run the command set. These can be either the credentials of the secret or credentials from an associated secret. The command sets on the **SSH Key Rotation** password changer are designed to be run with the secret's credentials. Any customized password changer based on this password changer should use the secret's credentials in the authentication section.

For more information about tokens beginning with a dollar sign used in the above screenshot, see the "Dependency Token List" on page 1512.

The command sets on the **SSH Key Rotation Privileged Account** password changer are designed to be run with the credentials of an account that can change the password and public key on behalf of other users. Any customized password changer based on **SSH Key Rotation Privileged Account** should use the credentials off one of the secret's associated secrets. This is typically the first associated secret but can be any associated secret if your password changer requires more than one associated secret. The exception to this is validation which does not run a command set by default and uses the secret's credentials. If you modify validation to use a command set you will need to change the default authentication for validation if the command set uses sudo.

Here is a typical authentication for **SSH Key Rotation Privileged Account** (except validation, which is identical to the authentication block used by **SSH Key Rotation**):

Username: `$[1]$USERNAME`

Password: `$[1]$PASSWORD`

Key: `$[1]$PRIVATE KEY`

Passphrase: `$[1]$PRIVATE KEY PASSPHRASE`

Command Sets

Overview

To handle cleanup and error-handling for key rotation two command set types were added: **Post Successful Change** and **Post Fail Change**. A password change using one of the two new password types will execute as follows:

1. Connect to the box using the specified credentials (secret credentials or an alternate secret's credentials).
2. Run the Password Change command set. This will add the new public key to the authorized_keys file. It does not change the password yet nor does it remove the old public key.
3. Verify using the new public key and old password. This verifies that the new key was added correctly.
4. If the verify check is successful, run the Post Success Change command set. This changes the password and, if successful, removes the old public key from authorized_keys if present.
5. If the verify check is unsuccessful, run the Post Failure Change command set. This removes the new public key from authorized_keys and does not change the password.
6. Return the success or failure of the overall process.

Post Successful Change and **Post Failure Change** are advanced command sets that are hidden by default. To see them, scroll to the bottom of the page and click the **Advanced Post Change Commands** link.

Password Change Command Set

In other password types the Password Change command set is only responsible for changing the password. For the two key rotation password changers, the default Password Change command set checks for the existing public key on the secret, and if found, will append a new public key to authorized_keys (the old key is then removed in the Post-Reset Command Set). The password change is done in the Post Successful Change command set only after the key change has been validated.

Verify Password Changed (Heartbeat) Command Set

Following this Reset Command Set, a Verify Password Changed is performed by attempting to connect to the host using the credentials on a secret to validate the new public key that was added to authorized_keys. If a command set is present, those commands are then run after connecting and the validation is a success only if both the connection and the command set are successful. (The command set is normally used when a secret uses alternate secrets as credentials in which case the alternate credentials are specified for authentication and command set does the actual validation of the secret.)

In the case of SSH key rotation, this validation heartbeat is run immediately after the reset command set using the current username, current password, new private key and new passphrase to connect for validation. If connection is successful, the validation is considered successful and Post Successful Change command set is run next to remove the old public key (if current private/public keys exist on the secret) from authorized_keys). If validation is not successful, the Post Fail Change command set is run to remove the new public key added during the reset.

Post Successful Change Command Set

If the Password Change command set and Verify Password Changed are both successful, the Post Successful Change command set is run. This command set finalizes the key rotation by changing the password on the account

and removing the old public key from authorized_keys.

Post Fail Change Command Set

If the Password Change command set is successful but the Verify Password Changed fails, the Post Fail Change command set is run. This command set rolls back the changes made in the Password Change command set by removing the new public key from authorized_keys.

For more information about customizing SSH command sets, see "Creating a Custom SSH Password Changer" on page 1045.

Notes

SSH Key Rotation scripts will typically be more complex than password change command sets that do not do key rotation. These scripts will often include tokens representing values from the secret and associated secrets as well as commands to verify success or failure of previous commands using `$$CHECKFOR` and `$$CHECKCONTAINS`. For more information about these features see the **Editing a Custom Command** topic.

The default command sets for **SSH Key Rotation Privileged Account** use sudo to execute several commands. These command sets assume that the sudo command will not prompt for a password. If your environment prompts for a password when using sudo the command sets will need to be modified to supply the password. If your environment caches the sudo credentials, the easiest way to handle this is to add the following two lines at the top of each command set on the SSH key rotation Privileged Account password changer:

```
sudo -i echo
$[1]$PASSWORD
```

This will pass the credentials from the first associated secret when prompted by sudo and cache the credentials for the rest of the script.

Troubleshooting

- The SSH Password Changers are targeted to OpenSSH. If using a different SSH library or if the user keys are not in the users `/.ssh/authorized_keys` file you can check the commands used and modify them as appropriate under **Admin > Remote Password Changing** and clicking **Configure Password Changers**. The password changers used are **SSH Key Rotation** and **SSH Key Rotation Privileged Account**.
- Errors are logged to **Admin > Remote Password Changing**. Additional logs can be found in the Secret Server directory in the log subfolder. For example: `C:\inetpub\wwwroot\secretserver\log`.
- A change was made to how SSH script variables are named in order to differentiate them from tokens when testing command sets on the Configure Password Changers page. Non-token script variables should begin with an underscore. Anything in the script beginning with a dollar sign not followed by an underscore will be treated as a token and displayed as a field in the test dialog. For example:
  - `$USERNAME` – References the username from the Secret.
  - `$[1]$USERNAME` – References the username from the first linked Secret.
  - `$_USERNAME` – References a bash variable defined in the script.

Secrets

Secrets in Secret Server are individually named sets of sensitive information, such as passwords, API keys, SSH keys, and other authentication credentials. These secrets are created using secret templates, which define the fields, launchers, and remote password changers for different types of secrets. Secret Server ensures that all secret data is securely encrypted before being stored in the database, and it maintains a detailed audit trail for access and history. Secrets can be centrally managed through sharing settings and folder structures, allowing for inheritance of Delinea permissions from parent folders. This robust management system helps organizations securely store, manage, and control access to privileged credentials, reducing the risk of data breaches and ensuring compliance with security policies.

Folders

Folders in Secret Server allow you to organize your secrets into logical groups and control access through permissions assigned to the folders. Secret folders allow you to create containers of secrets based on your needs. They help organize your customers, computers, regions, and branch offices, to name a few. Folders can be nested within other folders to create sub-categories for each set of classifications.

You can assign secrets to these folders and sub-folders. Folders allow you to customize permissions at the folder level, and all secrets within can inherit the folder's permissions. Setting permissions at the folder level ensures future secrets placed in that folder have the same permissions, simplifying management across users and groups.Thoughtfully organizing your secrets into folders and setting granular permissions helps ensure the right people have access to the credentials they need while maintaining security.

You can "favorite" a folder in the main menu by selecting it in the list and right clicking it.

Folder Permissions

If a new folder is a subfolder, it can use the sharing settings of its parent folder if you enable the **inherit permissions from parent** setting for the folder.

Folders can apply one of the following Delinea folder permissions to users or groups in the folder's **Permissions** table:

You can access a folder's permissions table by accessing the folder, clicking on the three horizontal dots by its name and selecting **View Folder** from the dropdown options, and then selecting the **Permissions** tab.

- **View**: Allows the user to see the folder and the secrets in that folder which inherit its permissions. Users need to have this permission for the parent folder to be able to see any subfolders available. Permissions granted to the root/parent folder will be inherited by subfolders.
- **Edit**: Allows the user to create new folders in the root/parent folder, which forces the **Inherit Permissions from Parent** setting on the new folder. This permission also allows for creating new and moving secrets into that folder, as well as renaming the folder.

- **Add Secret**: Allows the user to add a secret into a folder, but does **NOT** grant access to the added secret.
- **Owner**: Allows the user to create new folders in the root folder without forcing inheritance. It also allows the user to move, delete, or rename the folder, as well as change the permissions and inheritance settings on the folder.

Depending on your configuration, these settings could affect the permissions of subfolders and secrets contained in the root folder. Folders are not visible to users that do not have at least the **View** permission. This allows users to create and manage their own folders without making them visible to all users. Some folder permissions include other Delinea permissions.

Table: Included Folder Permissions (Ordered from lowest to highest permissions required)

Permission	Description	Included Permissions
Add Secret	Allows adding new secrets	View
List (Secret)	Allows viewing secret names	None
View	Allows viewing the folder	None
View (Secret)	Allows access to secret contents	List
Edit	Allows for editing secrets, creating and/or renaming subfolders	Add Secret, View
Edit (Secret)	Allows editing of a secret	List, View
Owner	Allows full control over the folder	Add Secret, Edit, View
Owner (Secret)	Allows full control over the secret	Edit, List, View

Personal Folders

In Secret Server, a *personal folder* is a folder that one (and only one) individual has owner access to. No other user can modify sharing permissions on these folders. Users can add subfolders to their personal folder. The purpose of this folder is to allow a user to securely store work-related secrets that other users do not require access to.

If in *break-the-glass* mode, an Unlimited Vault Access can access a user's personal folder in order to recover secrets if needed.

Required Role Permissions for Managing Folders

Folder management is subject to these role permissions:

- The **Administer Folders** role permission allows a user to create new folders and manage folders but specific folder permissions still apply.
- Any user with the Administer Folders role permission can create new folders, but to create folders at the root level, the user also needs the **Create Root Folders** permission.

- Any user who has the **Create Root Folders** permission can add new folders to any folders where they have **Edit** or **Owner** permissions.
- Users must have the **Owner** permission to delete a folder.
- Users can also move folders if they have the **Owner** permission on the source folder and the **Edit** or **Owner** permission on the target folder (where they are moving it). The folder automatically inherits permissions from its parent when it is moved, which is the same as when secrets are moved.

Managing Folders

Managing folders in Secret Server allows you to organize secrets into logical groups and control access through permissions assigned at the folder level. Folders can be nested to create sub-categories, helping to structure secrets based on various criteria such as departments, projects, or regions. Permissions can be set to allow users to view, edit, add secrets, or have full ownership of the folder, ensuring that only authorized personnel have access to sensitive information. Additionally, folders can inherit permissions from their parent folders, simplifying the management of access controls. This hierarchical organization and permission structure help maintain security and streamline the management of secrets across the organization.

Assigning Secret Policies to the Secrets in the Folders

1. Select the folder containing the secrets you would like to assign a policy to.
2. Click on the ellipsis button next to the folder name and select Edit Folder. The Folder Details page appears.
3. Click the **Edit** link next to **Secret Policy**. The Edit Folder popup appears.
4. Click to select the desired policy in the **Secret Policy** dropdown list.
5. Click **Save**.

Creating Folders

To create folders, you must have a role with the "administer folder" permission. You also must have edit or owner permission for the parent folder.

Creating a New Folder

To create a folder:

1. Select **Secrets** from the main menu, and click **>>** to view the Secret Folder-Tree Panel.
2. Click **+** next to **Folders**. The Create New Folder popup appears.
3. Type the new folder's name in the **New Folder Name** text box.
4. Optionally select the Parent folder by clicking **Root folder** link.
5. When done, click **Create new folder**.

Creating a Subfolder

1. Select **Secrets** from the main menu, and click **>>** to view the Secret Folder-Tree Panel. Drill down and click the folder you wish to add a subfolder to.
2. Right click the folder and select **Add Subfolder**. Alternatively click on the ellipsis button next to the folder name and select **Add Subfolder**. The Create New Folder popup appears.
3. Type the new folder's name in the **New Folder Name** text box.
4. If desired, click to toggle the **Inherit Parent Permissions** check box.
5. Proceed to "Editing Folder Permissions" on the next page to customize permissions for the new folder.

Editing Folders

To edit a folder:

1. Select **Secrets** from the main menu, and click **>>** to view the Secret Folder-Tree Panel.
2. Click on the ellipsis button next to the folder name and select **Edit Folder**. The **Overview** tab page appears.

   In the Folder details section you can set basic folder information including the name, folder path, secret type (template), and policies for secrets in the folder. These settings may prevent adding some secrets to the folder.

   - **Folder Name** - click the **Change** link to change the folder name.
   - **Secret policy** - this policy will be applied to all new Secrets which are added to this folder and any existing Secrets that inherit the Policy. Click **Edit**, select the related Secret policy from the dropdown, and click **Save**.
   - **Allowable templates** - click **Edit** and select the related templates from the list or All templates to make those secret templates allowable for this folder. When done, click **Save**.
3. Under the **Permissions** tab you can edit the folder permissions - see Editing Folder Permissions fro details.
4. Under the **Metadata** tab, you can add the related metadata to define attributes or characteristics of the item.
   - Metadata sections can group like data together.
   - Value can store strings, numbers, booleans, dates, and users.
   - The values can be defined by users who have view or edit access to the item as defined by section. For example, only editors can edit certain sections and one specific section can be edited by anyone that can view the item.

   Click **Add metadata**, select the related **Section name**, then select the related **Metadata field** and enter its **Value**. Check to select **May contain personal identifiable information?**. When done click **Save**.

Deleting Folders

> To delete folders, you must have a role with the "administer folder" permission and owner permissions on the folder(s). You also must have edit or owner permission for the parent folder.

To delete a folder:

1. Navigate to the folder in the folder tree on the main menu.
2. Right click the folder and select **Delete Folder**. The Delete Folder pop-up page appears.
3. Click **Delete Folder**.

Editing Folder Permissions

> To edit folder permissions, you must have a role that has the **Administer Folder** permission, and the **Owner** permission for the folder. If **Inherit Permissions from Parent Folder** is disabled, you must also have the Owner permission for the parent folder.

To edit folder permissions:

1. Navigate to the folder you wish to edit: **Secrets > Folders > [Your Folder]**.
2. Click on the ellipsis button next to the folder name and select **Edit Folder**. The Overview tab page appears.
3. Select the **Permissions** tab, and click **Edit**. The Folder Permissions section becomes editable.

   > The **Inherit Permissions** checkbox indicates if the permissions are applied from the parent folder. When inheriting permissions from a parent folder, the permissions cannot be updated here but only in the parent/root folder.

   > Root folders cannot inherit folder permissions.

4. If necessary, click to deselect the **Inherit Permissions** checkbox. The permissions section becomes editable.

   > The Inherit Permissions box needs to be deselected to view Allowable Templates.

5. Change the **Scope** to **All**, to see all available users and groups.
   a. To remove a user, deselect the checkbox next to that user.
   b. To add a user or group, select the checkbox next to each user/group and choose from the Folder and Secret permissions dropdown lists that appear.

      > Applying different filters, such as searching for a user, will not remove any pending changes.

6. Select the permissions for each desired user/group:
   a. From the **Folder Permissions** dropdown list select one of the following:
      - **View** (folder)
      - **Add Secret** (to folder)
      - **Edit** (folder)

- **Owner** (of the folder).

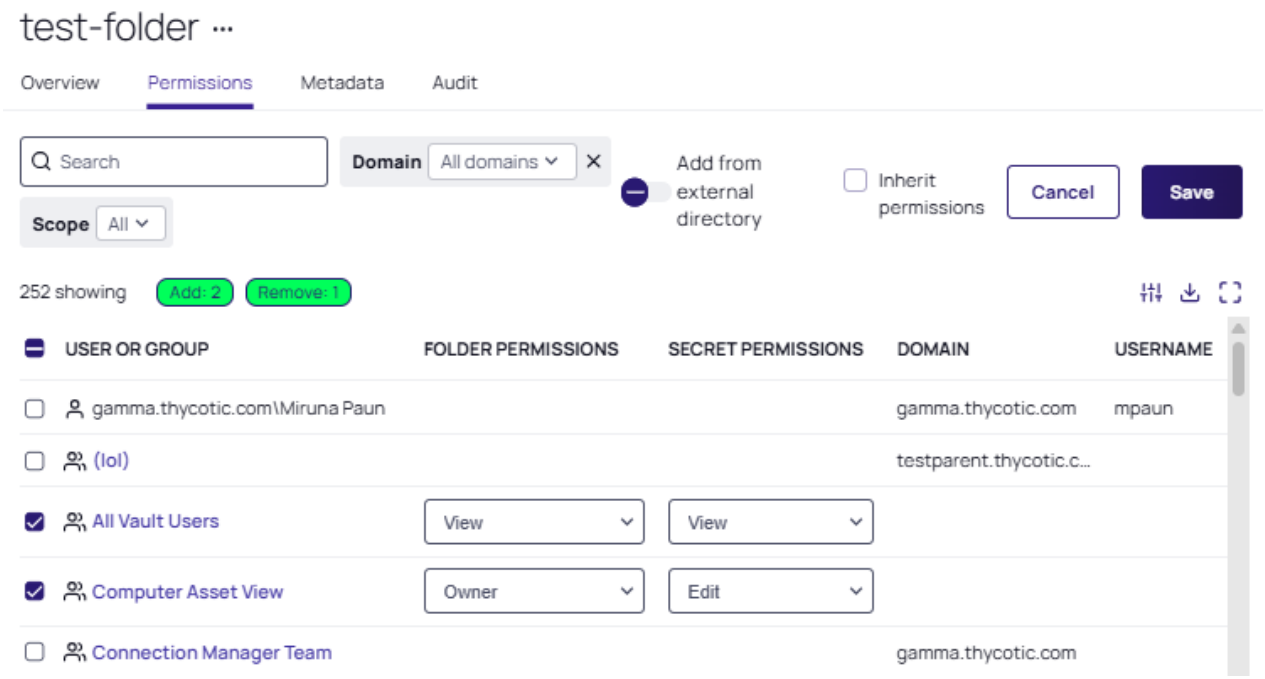
  These options are listed in order of increasing permissions.

b. From the **Secret Permissions** dropdown list select one of the following:

- **None**
- **List** (secrets in folder)
- **View** (secrets in folder)
- **Edit** (secrets in folder)
- **Owner** (of secrets in folder).

  These options are listed in order of increasing permissions.

For example:



The two rounded green rectangles shown in the image above, indicate the current uncommitted changes. Each user or group can have explicit folder and secret permissions. The secret permissions are applied to any secret within this folder that inherits permissions.

7. Click **Save** to commit your changes or the **Cancel** button to remove all pending changes.

Enabling Personal Folders

> The following cannot be edited on personal folders:
>
> - Secret policy assignment
> - Secret template restrictions
> - Folder permissions
>
> You can, however, edit some of them in the secrets themselves or on subfolders.

To use personal folders, you must first enable them:

1. Search for **Folder Settings**.
2. Click the **Edit** button in the **Folders Configuration** section. The entire section becomes editable.
3. Click to select the **Enable Personal Folders** check box.
4. (Optional) Type a new folder name in the **Personal Folder name** text box to customize the root-level folder that contains all personal folders.
5. (Optional) If you want to display a warning message to users when placing secrets in their personal folders:
   a. Click to select the **Show user warning message** check box.
   b. (Optional) Edit the **Warning message text** box.
6. (Optional) Click the **Personal Folder Display Name** dropdown list to choose whether to display the personal folder display name or the username and domain.
7. Click the **Save** button. A personal folder for each user is now created in a root-level folder with the personal folder name specified.

> When personal folders are enabled, a user requires the Personal Folders role permission in their role to be able to view and use their own personal folder.

Modifying Folders with Secret Policies

You can configure secret policies to apply RPC and security settings to an entire folder of secrets.

To create a new secret policy:

1. Search for **Secret Policy**. A Secret Policy page appears.
2. Click **Create secret policy**. The (new) Secret Policy page appears.
3. Type a name for the new secret policy in the **Name** text box.
4. (Optional) Type a description in the **Description** text box.
5. Ensure the **State** check box is set to **Enabled**.
6. When done, click **Save**.

To deactivate a policy that you no longer want, edit the policy and deselect the **Enabled** check box. For information about applying a secret policy to a folder, see "Editing Folder Permissions" on page 1079.

Moving Folders

To move a folder ensure that you have the Owner permission for both the source and destination folders.

1. Expand the folder tree to make both the source and destination folders visible.
2. Drag the source folder and drop it onto the destination folder. The **Move Folder** page appears.
3. Click the **Inherit Policy** dropdown list to select how you want policy inheritance to work for the folder in the new location.
4. Click the **Inherit Permissions** dropdown list to select how you want permission inheritance to work for the folder in the new location.
5. Click **Confirm Move Folder**.

You can also right-click the source folder and select **Move** to see an alternative method of moving folders where you are prompted to select the destination folder.

Moving Secrets Between Folders

Consider the following before moving a secret between folders:

- To add or move a secret to a folder, you must have edit permission on that folder (either direct or through inheritance).
- To move a secret from a folder, you must have edit permission on that secret. If the secret has the "Inherit Permissions from folder" setting enabled, then you must have owner permission to move that secret to a new folder.
- When a secret is moved to a folder, it automatically gets the "Inherit Permissions from folder" setting even if it had specific permissions before the move.

1. Navigate to the folder containing the secret or secrets you would like to move.
2. Click to select the check box on the left for all the secret you want to move. The Bulk Actions button appears at the bottom of the page.
3. Click the **Bulk Actions** button. A popup appears.
4. Click the **Move to Folder** link. The Move Secrets pop-up page appears.
5. Select the target folder for the secret or secrets.
6. Click the **Move Secrets** button. The Bulk Progress popup appears.
7. The secret moves to the selected folder.

Pinning Folders

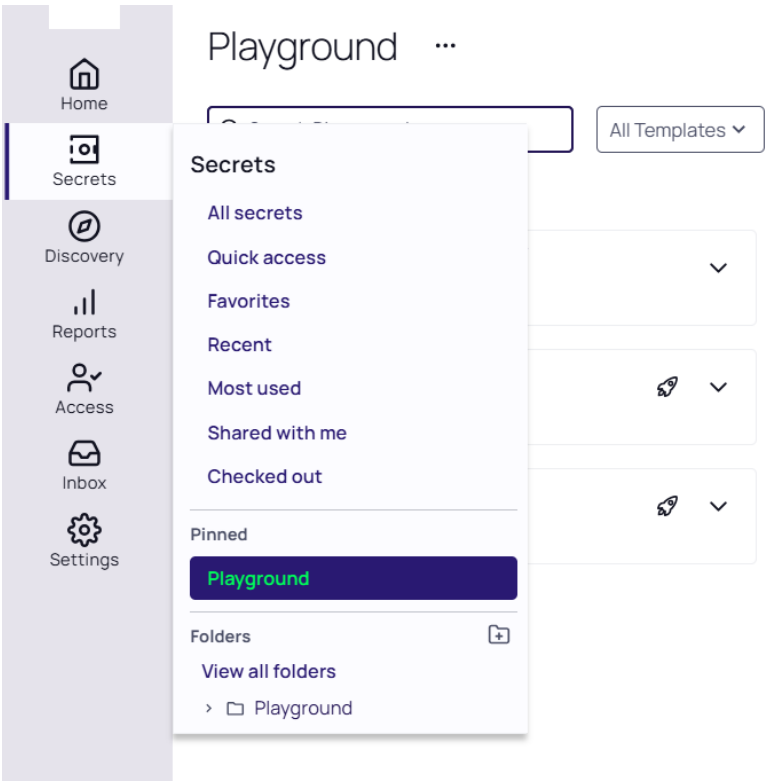
You can pin a folder, limiting the folder tree to show only the contents of that pinned folder. Applying filters to the table in one pinned folder will not affect others, and your settings are remembered when you return to the pinned folder.

Pinning Folders

To pin a folder:

1. Select **Secrets** from the main menu, and click **>>** to view the Secret Folder-Tree Panel.
2. Drill down and click the folder you wish to pin.
3. Right click the folder and select **Pin folder**. The chosen folder will open.

   Now, when you hover over the **Secrets** menu item you can see that the selected **Playground** folder is in the **Pinned** section.



Unpinning Folders

To unpin a folder:

1. Select **Secrets** from the main menu, and click **>>** to view the Secret Folder-Tree Panel.
2. Select the pinned folder in the folders dropdown list, right click on it and select **Unpin folder** from the dropdown.

Alternatively, you can open the pinned folder, click the three dots next to the folder's name on the folder page, and select Unpin folder in the Rename Pin popup.

Custom Naming Pinned Folders

You do not have to use the default name of the top folder as the pin's name. To rename a pinned folder:

1. Select **Secrets** from the main menu, and click **>>** to view the Secret Folder-Tree Panel.
2. Select the pinned folder in the folders dropdown list. On the folder page, click on three dots next to the folder's name. The Rename Pin pop up will open.
3. Type the new name in the **Pin Name** text box.
4. Click **Save**.

The folder dropdown list will now display the new name instead of the default top folder name for the pin.

Secret Folder-Tree Panel

The secrets menu item in the new UI has a collapsible secret folder-tree panel that occupies the full height of the page. This replaces the legacy folder tree at the bottom of the left navigation bar and delivers a significantly improved folder browsing experience. To view the panel, click the **>** icon on the bottom left of the page.

You can create folders, if you have permission to do so, by clicking the folder button on top of the folder panel.

Quick access provides a convenient view of high use secrets as well as keeping track of secrets that have been opened during the current session. Any pinned folder offers the same quick view but is scoped to the context of that folder. For example, only show me favorite or recent secrets from a single folder and its subfolders.

Direct links are available to common filtered views of secrets that allow for searching and advanced filtering within a specific context.

All folders to which you have access appear in the folder tree. A context menu offers options such as creating subfolders or pinning a specific folder. These options are also available when viewing a folder by clicking on the context menu next to the page title.

Secret Access and Workflow Templates

Introduction

Secret Server offers robust secret access and workflow features to enhance security and streamline the management of sensitive information. Secret Server allows administrators to configure access requests, requiring approval before users can access specific secrets. This can be set up to include multi-level and multi-user approval processes, ensuring that access is granted only after thorough validation.

Additionally, Secret Server supports advanced workflows that can be customized to fit organizational policies, including features like timeouts and branching workflows to prevent bottlenecks. The system also integrates with ticketing systems such as ServiceNow and BMC, ensuring that access requests are tied to valid change or incident numbers. These workflows are fully audited, providing a comprehensive trail of all access requests, approvals, and denials, which is crucial for compliance and security.

Simple Access Requests Versus Workflow Templates

In Secret Server, simple access requests and workflow templates serve different purposes for managing access to secrets:

Simple Access Requests

- Single Approval: Simple access requests involve a straightforward process where a single reviewer can approve or deny the request. Once approved, the user gains access to the secret.
- Flexibility: These requests can be approved after being denied or denied after being approved, allowing for changes in decision.
- Basic Functionality: This is the basic form of access control available in older versions of Secret Server, providing a one-step approval process.

Workflow Templates

- Multi-Level Approval: Workflow templates allow for more complex interactions, requiring multiple levels of approval. You can define up to 15 approval steps, where each step can have different reviewers and a specified number of required approvers.
- Structured Process: Once a workflow access request is approved, denied, or canceled, its status cannot be changed, ensuring a structured and auditable process.
- Advanced Features: Workflows can include features like timeouts, branching workflows, and integration with ticketing systems like ServiceNow or BMC for additional validation and compliance.
- Customization: Administrators can customize workflows to fit organizational policies, enhancing security and streamlining management of sensitive information.

For more information, see the following resources:

- "Workflow Overview" on page 1101
- "Access Request Overview" below

Access Request Overview

The access request feature allows a secret to require approval prior to accessing the secret. Note the following:

- Establishing a workflow model, the user must request access from the approval group or groups.
- An email is sent to everyone in the approval groups, notifying them of the request.
- The request can be approved or denied by any members of the approval groups. Approvals can be set using the setting **Require Approval Type** to control who requires approval.
- Access is granted for a set time period.
- If **Owners and Approvers also Require Approval** is enabled, then even owners or those in an approval group needs to request access.
- Requestors cannot approve their own requests.
- The approval window time starts when you submit the approval request.

Approving Requests

Approving access requests in Secret Server involves a structured workflow to ensure secure and compliant access to sensitive information. To enable access requests, administrators can configure secrets to require approval before they can be accessed. When a user requests access, an email notification is sent to the approvers, who can then approve or deny the request.

The approval process can be customized to include multiple steps and reviewers, ensuring that access is granted only after thorough validation. This workflow enhances security by maintaining an audit trail of all requests, approvals, and denials, and can be integrated with ticketing systems like ServiceNow or BMC for additional validation and compliance.

Duo Push Approvals

Users can now approve secret access requests and workflows using Duo push notifications. The push notification includes information, displayed on the user's screen, that helps the approver make the access decision.

Important Duo Security Certificate Authority Changes

> This temporary section includes important information that may affect your access to Secret Server. Please read it carefully.

Cisco Duo is replacing its root certificate authority (CA) bundle. The impact on you depends on the application type configured in your Duo Admin Panel. Follow the steps below:

Determine your Application Type

In the Duo Admin Panel, go to **Applications > Applications** and check the **Application Type** column.

Application Type	Action
Delinea Secret Server or Thycotic Secret Server	Minimal—Duo granted an automatic extension until March 31, 2026
Auth API, Web SDK, or other custom application	Urgent—authentication failures may begin February 2, 2026

If You Have a Published Secret Server

Secret Server uses Windows certificate validation, not embedded certificate pinning. Secret Server Cloud integrations require no changes. Secret Server On-Premises integrations continue to function as long as the web server receives regular Windows Updates to maintain current root CA certificates.

If You Have a Custom Application

Administrators using custom applications, such as Auth API or Web SDK, must take **one** of the following actions to avoid authentication failures:

- **Either** contact Duo (support@duo.com) to request an extension.
- **Or** switch to the published Delinea Secret Server application in the Duo Admin Panel, and update the credentials in Secret Server at **Admin > Configuration > Login > Duo**.

Key Dates

Date	Event
February 2, 2026	Intermittent authentication failures begin for custom applications
March 31, 2026	Duo rotates CA roots; servers with outdated root certificates fail to connect

For details, see Duo's knowledge base article.

Prerequisites

To use Duo push notifications:

- Duo must set up for Secret Server. See "Duo Security Authentication" on page 446.
- Duo user must be set up for Duo two-factor authentication. See "Duo Security Authentication" on page 446.
- The permission "Approve via DUO" must be granted to a role that is assigned to a group that includes all who will be approving requests via Duo. This allows enough flexibility so that those not wanting Duo push approvals can be configured to not receive them.

Assigning the Duo Approval Permission

To associate the permission with users:

1. Search for **Roles**.
2. Click the **Create Role** button to create a new role. Name it "Duo Push Approver" or another name of your choosing.
3. Assign the **Approve Via DUO Push** permission to the new role.
4. Click the **Save** button.
5. If you choose to create a separate group for approvers, do this by navigating to **Access > Groups**.
6. Click the **Create Group** button to create a new group.
7. Add the desired users (chosen approvers) to that group.

You can also assign users to the group later. This method is a shortcut when creating a group.

8. Click the **Save** button.
9. Go to the page for the newly created group.
10. Click the **Roles** tab.
11. Click the **Edit Roles** button.

12. click the **Scope** dropdown list to select **Unassigned**.
13. Click to select the **DUO Push Approver** role.
14. Click the **Save** button. Setup is now complete.

> In addition to having the role you created, the user must be properly set up to receive Duo push notifications. See "Duo Security Authentication" on page 446.

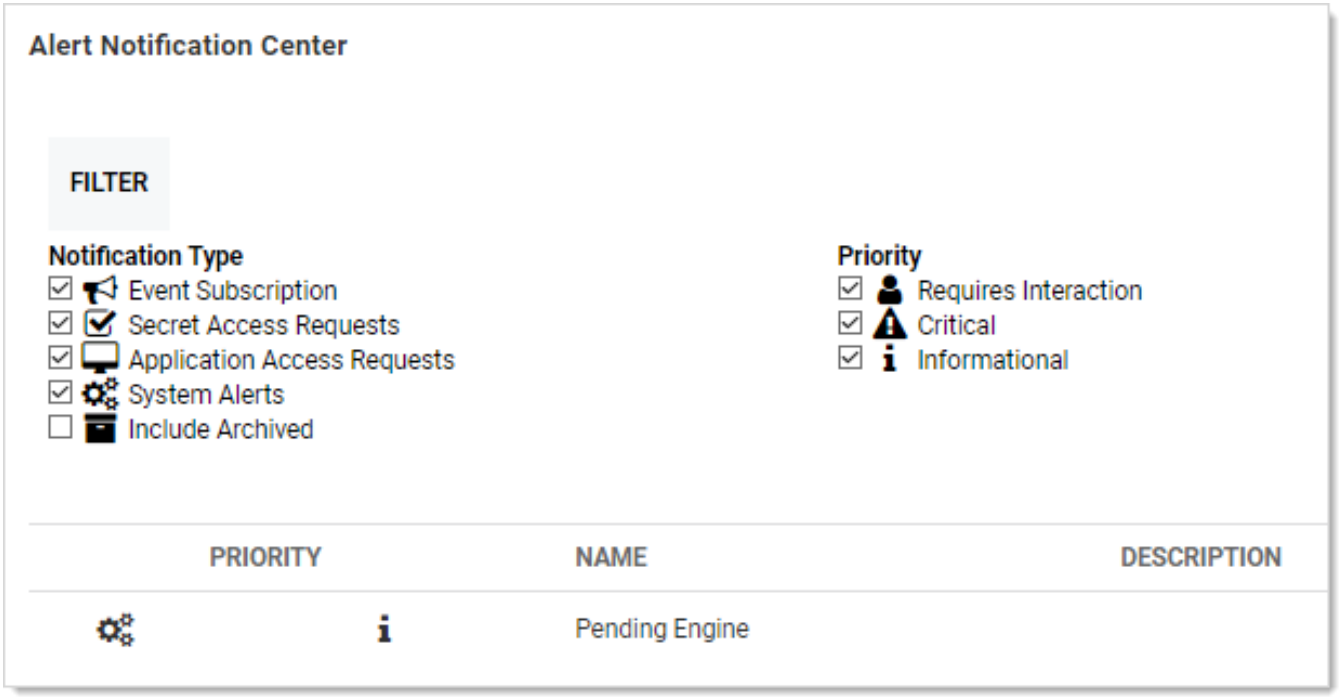
> Any notifications will all be sent out at the same time, and the first response (approve or deny) will be the determinant response. A non-response will not result in either an approve or deny response.

Email Access-Request Approvals

Once a request for access to a secret has been made, approvers receive an email.

The email contains one link to the secret **Access Request Approval** page for that request in Secret Server, and five additional links to approve or deny the request if the **Allow Approval for Access from Email** configuration setting is enabled.

The approver can either click one of the links contained in the email or navigate to the **Notification Center** in the user menu within Secret Server.



If choosing the latter, in the displayed grid click the access request name. This takes you to the secret's Access Request Approval page.

From here, you can accept or deny the request as well as set an expiration date.

The requestor has access to the secret until the specified date.

Selecting the current date is the smallest window of time allowed and grants access to the end of the day.

With **Allow Approval for Access from Email** enabled, clicking one of the five additional links in the email allows access for 1, 2, 4, or 8 hours or deny the request, per the link description in the email.

> The expiration date referred to in approval requests is **not** the same as secret expiration.

Configuring Access Requests

To enable Access Request for a secret, navigate to the **Admin>Secret Policy** and select the related policy from the list.

1. Select the **Security** tab and click the **Edit** button.
2. In the **Require Approval for Access**dropdown select the related option:
   - Approval not required - no approval is required from any roles.
   - Standard exceptions - owners, editors and approvers do not need approval.
   - Owners and Approvers - owners and approvers do not need approval.
   - Owners only - owners do not need approval.
   - Approval always required - always require approval from all roles.

> Users need at least view access to the secret to be able to access the secret even with **Access Request** enabled. If the users do not have view permission they are unable to find the secret with search or browse.

> The email configuration settings need setting up, including valid email addresses, for the users in the approval group for emailing to work.

Requesting Access

To start the request process for access to a secret, the user must simply attempt to view the secret. The user is then sent to the Request page. In there, the user can explain the reason for the request and then click **Request Access** to submit the request.

If a member of the Approval Group either approves or denies the request (see below for details), the requestor is sent an email with the details. If approved, the requestor can access the secret via the link contained in the email.

Checkout Overview

Introduction

The Secret Server*checkout* feature forces accountability on secrets by granting exclusive access to a single user. If a secret is configured for check out, a user can then access it. If **Change Password on Check In** is turned on, after check in, Secret Server automatically forces a password change on the remote machine. No other user can access a secret while it is checked out, except Unlimited Vault Accesss. This guarantees that if the remote machine is accessed using the secret, the user who had it checked out was the only one with proper credentials at that time.

> The exception to the exclusive access rule is Unlimited Vault Accesss. If Unlimited Administration is enabled, users with Unlimited Vault Access role permission can access checked out secrets.

> Secrets with a QuantumLock cannot be configured for check out.

Exclusive Access

Any user attempting to view a checked-out secret is directed to a notification dialog informing them when the secret is available. Secret Server automatically checks in secrets after either 30 minutes or the interval specified on the secret. Users can check in the secret earlier from the secret's page.

Checkout Expiration

Checkout expiration notifies users with a checked-out secret via their Secret Server inbox and inbox rules when a defined checkout period percentage has elapsed. For example, setting checkout expiration to 80% notifies users when 20% of the checkout interval remains.

This setting is available under "user experience" in the configuration page. To set checkout expiration:

1. Go to the **Admin** menu item and click **>>**. The Admin slideout appears.
2. Type `configuration` in the search text box and click the link when it appears below. The Configuration page appears.
3. Click the User Experience link at the bottom of the page. The User Experience page appears:
4. Click the **Edit** button.
5. Click the **Checkout Notification Threshold** spinner to select or enter a notification threshold percentage between 0 and 99. This sets what percentage of the checkout period elapses before an expiration notification occurs. That is, if set to 70, a notification is sent when 30% of the checkout period is left.
6. Click to select the **Enable Secret Check Out Extension** check box. The Max Check Out Extension Time setting appears. This sets the maximum time a secret check out can be extended in minutes. This does not include initial check out time, only the amount of time the check out is extended.
7. Click the dropdowns to set the day, hours, or minutes.
8. Click the **Save** button. The setting now appears on the read-only page.

Checking Out Secrets

Secrets with Change Password on Checkin configured now have the "Change Password Now" functionality available. This will enable the standard functionality of a password change, and the secret will also complete the automatic password change on checking in. This is to allow maintenance and testing of secrets protected in this manner, and a pending password change must be completed before the check-in process is allowed to begin in order to maintain a secure order of operations.

Each secret must be individually set to require check out:

1. From the **Secret View** page, click the **Security** tab to modify a secret's **Check Out** setting.
2. You must configure RPC before **Change Password on Check in** can be set.

3. Enable **Require Check Out** to force users to check out the secret before gaining access.
4. Enable **Change Password on Check In** to have the password change after the secret is checked in.

Checkout Hooks

Overview

In addition to changing the password on check in, secret owners can also specify administrator-created PowerShell scripts, called *hooks*, to run before or after checkout and check in. These are accessed from the **Hooks** tab of the secret, which only shows if checkout is enabled and PowerShell scripts have been created by an admin.

To specify a before- or after-checkout hook, click **Create New Hook** and specify the following settings:

- **Before/After:** Whether the PowerShell script should run before or after the event action.
- **Event Action:** The hook runs at either check in or checkout.
- **Name:** A descriptive name for the hook.
- **Description:** An extended description for the purpose of the hook.
- **PowerShell Script:** Administrator-created PowerShell script to run.
- **Arguments:** Any command line arguments to pass to the PowerShell script.
- **Stop on Failure:** If enabled, Secret Server prevents the event action if the script returns an error. For example, if "Stop on Failure" is selected for a checkout action, then Secret Server prevents the user from checking out the secret if the script fails.
- **Privileged Account:** If needed, the script can run as another secret's identity.

Checkout User Variables for Scripts

Checkout user variables for scripts are special code variables that return information about the user or automated task making the checkout request, rather than system or secret information. For example, the `$USERNAME` variable returns one or more user IDs related to a specific secret, whereas the `$SECRETSERVERUSERID` checkout user variable returns the user ID of the logged-on user or automated task.

These variables may also be useful for Active-Directory-related scripts.

The variables are:

Table: Checkout User Variables for Scripts:

Variable	User Action Returns	Automated Task Returns
`$SECRETSERVERUSERID`	Logged-on user's ID	-1
`$SECRETSERVERUSERNAME`	Logged-on user's name	"System"
`$SECRETSERVERDISPLAYNAME`	Logged-on user's display name	"System"
`$SECRETSERVEREMAILADDRESS`	Logged-on user's email address	Empty string

> You can find the regular "system" variables in the"Editing Custom Commands" on page 1045 subsection of the Custom Password Changers section.

Configuring RPC on Check-in

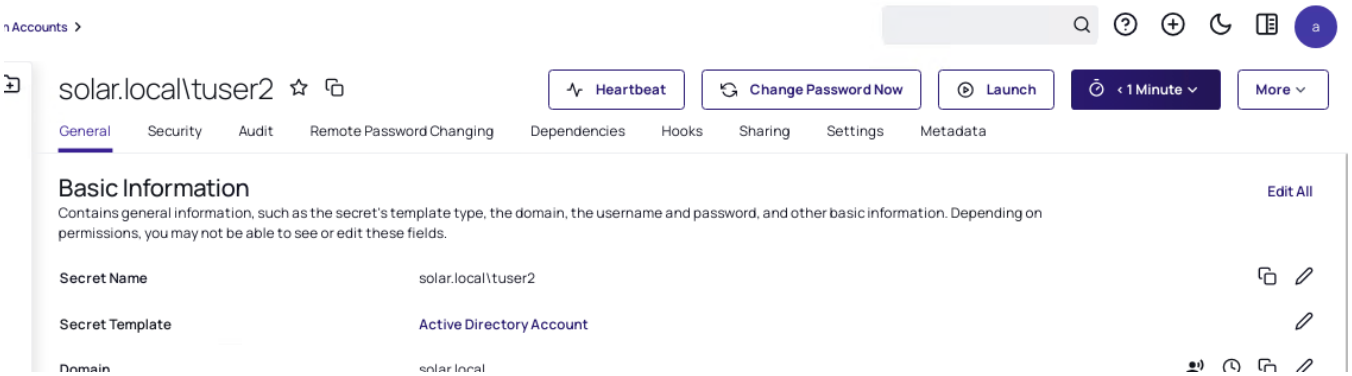
Procedure

To configure password checking on check in, navigate to the **Remote Password Changing Administration** page and set **Enable Password Changing on Check In**. If RPC is turned off, enable it before configuring checkout. Once RPC and checkout are enabled, secrets can be configured for interval that specifies how long a user has exclusive secret access. The configuration of the secret is not impacted by the global level. If the secret did not have any Check-out / Check-in setup, nothing will change if you allow password change in RPC on check-in.

Manual Password Change for Checked Out Secrets

Secrets with "Change Password on Check-in" enabled have "Change Password Now" functionality. This enables the standard password-change, and the secret also completes the automatic password change on checking in. This allows for maintenance and testing of secrets protected in this manner, and a pending password change must be completed before check-in is allowed to maintain a secure order of operations.

The functionality appears as a **Change Password Now** button on the secret:



Forced Check-in

The Forced Check-in allows users with the related role permissions to forcibly check in a secret that is currently checked out by another user. This is particularly useful in scenarios where a secret is checked out and there is an urgent need for another user to access it, such as when the current user is unable to check it in.

When a user with the Force Check In role permission attempts to access it, they will see an option to force the check-in. This action automatically checks the secret out to the user (via the Force Checkin role permission), allowing them to resolve any issues and perform a standard check-in.

To force check-in a user, checkout from the related secret - see Checking Out Secrets for details.

After that, a user should attempt to check out the same secret being logged in under their credentials. On this step, a user will see the Forced Check-in screen and will be able to check in the secret.

QuantumLock Overview

QuantumLock was previously called DoubleLock.

Introduction

Secret Server's *QuantumLock* is a feature that provides an additional security layer by protecting secret data using asymmetric encryption (a public/private key pair) where the private key is a human-generated password. This feature is independent of regular Delinea permissions, Secret Server login access, or physical access to the machine running Secret Server.

A shortcut way of thinking about QuantumLocks is as an extra password for secrets that is held by a set group of users. In addition, both the password and the group of users are reusable for other secrets. In addition, QuatumLocks future-proof our digital security infrastructure against the advancing capabilities of quantum computing.

QuantumLock is an upgrade of the earlier DoubleLock feature. Besides the name change, the difference is QuantumLock offers the option to use a quantum-safe algorithm for encapsulation to protect the private key, specifically CRYSTALS Kyber-1024, which is designed to counter the potential threat from quantum computers to current encryption methods. That threat is closer than you might think—"harvest now, decrypt later" attacks steal encrypted data now for later decryption by quantum computers.

The private key being protected by Kyber-1024 is a human-generated user password. Once encapsulated (encrypted) that password is called a *ciphertext*. Once that private key is decapsulated (decrypted), it is used by a symmetric algorithm, such as AES-256, to decrypt the protected data. This two-step process (key encapsulation followed by symmetric encryption) applies the strengths of both asymmetric (for secure, fast key exchange) and symmetric cryptography (for efficient message encryption), providing a robust, efficient method for secure communication.

Today's asymmetric-key encapsulation methods, such as RSA (Rivest-Shamir-Adleman) and ECC (Elliptic Curve Cryptography), rely on the difficulty of solving mathematical problems, such as factoring large numbers or solving discrete logarithms, with classical computers. However, quantum computers, which operate on principles of quantum mechanics, could solve these problems much faster, rendering these encapsulation methods vulnerable.

Quantum-safe or post-quantum (PQ) algorithms are cryptographic methods that are believed to be secure against quantum computer attacks. They are based on mathematical problems that are considered difficult for both classical and quantum computers to solve, ensuring the security of encapsulated keys, even in the era of quantum computing. PQ algorithm types include lattice-based cryptography, hash-based cryptography, code-based cryptography, and multivariate polynomial cryptography, among others.

Kyber-1024's resistance to quantum attacks is, by design, approximately the same as AES-256's resistance to conventional computer attacks.

The PQ cryptographic algorithm Kyber-1024 is specifically designed for key-encapsulation mechanisms (KEM), a process where a key is encapsulated (encrypted) with a public key, sent over an insecure channel, and then decrypted with a private key. Typically a symmetric key algorithm, such as AES-256 (Advanced Encryption Standard) , is used for encrypting the message content itself because symmetric-key algorithms are faster and

more efficient for large amounts of data than asymmetric-key algorithms. Algorithms like AES are examples of symmetric cryptography.

> You might wonder how well protected the encrypted data at rest is to quantum-computer attacks. Symmetric algorithms, such as AES, are PQ if their keys are sufficiently long, which is not an issue with their typical use cases.

> The Kyber algorithm comes in different security levels, and Kyber-1024 specifically aims at security roughly equivalent to AES-256, with a private key size of 3168, a public key size of 1568, and a ciphertext size of 1568. It is part of Cryptographic Suite for Algebraic Lattices (CRYSTALS), which is a package submitted to the NIST post-quantum standardization effort.

Comparing RSA-2048 to Kyber-1024

QuantumLock without the QuantumLock feature enabled is essentially the same as its predecessor, DoubleLock, and relies on RSA-2048 for key encapsulation.

Comparing the encryption, decryption, and key-generation speeds of RSA-2048 and Kyber-1024 involves understanding the efficiency of these algorithms under practical implementations. The specific speeds can vary based on the software and hardware used for the implementation, but here is a general overview based on their cryptographic principles and typical use cases.

RSA-2048

- Key Generation: RSA-2048 key generation is relatively slow because it involves finding two large prime numbers and calculating their product along with other related mathematical operations. This process is computationally intensive.
- Encapsulation: RSA-2048 encryption is faster than its key generation. However, compared to Kyber-1024, RSA-2048 encryption is usually slower because it involves modular exponentiation, which is a heavy operation especially for large key sizes like 2048 bits.
- Decapsulation: RSA-2048 decryption is also computationally intensive, similar to encryption, because it requires modular exponentiation. RSA decryption is generally slower than encryption due to the nature of the private key operations.

Kyber-1024

- Key Generation: Kyber-1024 generally has faster key generation than RSA-2048. This efficiency comes from its use of lattice-based cryptography, which involves operations on vectors and matrices that are more efficient than the prime number operations in RSA.
- Encapsulation: Kyber-1024 is designed for fast encryption operations. It uses simple arithmetic operations on small integers, making it very efficient and faster than RSA-2048 encryption.
- Decapsulation: Like its encryption, Kyber-1024 decryption is also fast and efficient. The algorithm benefits from the same lattice-based operations, optimized for quick decryption times.

Summary

- RSA-2048 is generally slower across all three operations compared to Kyber-1024. The difference in speed is primarily due to RSA's reliance on large prime numbers and modular arithmetic, which are computationally heavier, especially as key sizes increase to improve security.
- Kyber-1024, being a post-quantum algorithm designed with efficiency in mind, uses lattice-based cryptography that allows for quicker key generation, encryption, and decryption operations. This makes it particularly suitable for environments where speed and efficiency are critical.

> While Kyber-1024 offers advantages in speed and quantum resistance, the choice between RSA-2048 and Kyber-1024 (or any cryptographic algorithm) depends on the specific security requirements, computational resources, and threat models relevant to the application in question.

When to Use QuantumLock

Both Kyber-1024 and RSA-2048 QuantumLocks

Enabling QuantumLock (or the earlier doublelock) on any secret only grants users access if they have access to the QuantumLock and enter their QuantumLock password. Enabling QuantumLock disables the RPC features for the secret. It also prevents heartbeat. Thus, **QuantumLock should not be used for secrets that require a password rotation or heartbeat check**.

QuantumLock use cases include:

- Global admin passwords
- Root account passwords
- Bank account passwords
- PINs, Social Security numbers, or other personal information.

When users protect secrets with QuantumLock, only that user has access to the secret. If multiple users are in a group, members have access to the secret, but each will have their own unique QuantumLock.

> Even an administrator or a user with Unlimited Vault Access privileges cannot recover a QuantumLocked secret if the user forgets his or her password. If there is a single user in a QuantumLock group and that user account is deleted, those secrets will not be accessible by anyone! Thus, we recommend adding at least two users to the group to be safe.

Kyber-1024 QuantumLocks

Enabling the PQ feature of QuantumLock depends on your circumstances. NIST believes quantum computers could break current public key encryption as early as 2025 or as late as 2030. It might be wise to apply it sooner rather than later for long-term data and devices. However, Kyber-1024 is not yet an industry standard, and RSA-2048 is currently uncrackable.

Note that users cannot remove their own QuantumLocks. When attempting to remove their QuantumLocks, users are presented with a 500 error, which means that this is not a supported operation.

QuantumLock Objects and Relationships

QuantumLock was previously called doublelock.

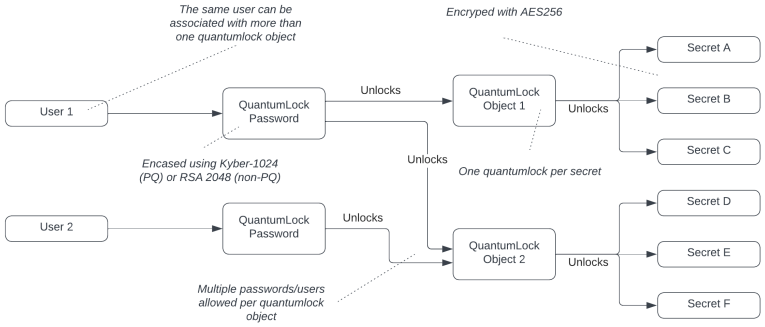
The QuantumLock system is a group of interrelated objects (see the following diagram):

- **QuantumLock user group:** A set of Secret Server users that have access to a single QuantumLock. This is not an object per se—it is the set of users assigned to a QuantumLock object. Each user has a separate password via the QuantumLock password object.
- **QuantumLock object:** A named object that is associated with one or more secrets and one or more users. QuantumLock objects, or simply *QuantumLocks*, secure one or more secrets, and one or more QuantumLock password objects provide access to it. The secrets themselves are encrypted with AES256, and are unlocked using the symmetric key provided by the QuantumLock object.
- **QuantumLock password object:** An encrypted asymmetric password that is associated with one user. The same QuantumLock password object, or simply *QuantumLock password*, is used for all QuantumLocks to which a user has access. Other users associated with the same QuantumLock have their own QuantumLock passwords. Once a user is assigned to a QuantumLock, that user has access to any secret using that QuantumLock, using the user's single QuantumLock password.

  A QuantumLock password has nothing to do with the user's Secret Server access password.

- **Secret:** A secret that has a single QuantumLock assigned to it. Multiple secrets can have the same one assigned to them. The secret is encrypted with AES256, with its symmetric key provided by the QuantumLock object, which is itself secured by one or more QuantumLock passwords, which are encased by Kyber-1024 or RSA-2048.
- **User:** A Secret Server user, which can have a single QuantumLock password assigned to it. Users are assigned to QuantumLock objects.

Figure: QuantumLock Object Relationships



Administering QuantumLocks

Administering QuantumLocks in Secret Server involves managing an advanced security feature designed to protect secret data using asymmetric encryption, where the private key is a human-generated password. QuantumLocks, previously known as DoubleLocks, provide an additional layer of security independent of regular Delinea permissions and Secret Server login access. This feature is particularly useful for securing highly sensitive data against the potential future threats posed by quantum computing. QuantumLocks utilize a quantum-safe algorithm, such as CRYSTALS Kyber-1024, to encapsulate the private key, ensuring robust protection against "harvest now, decrypt later" attacks. Administrators must carefully manage QuantumLock user groups, ensuring that multiple users are assigned to prevent data loss if a single user forgets their password or is deleted. This feature is best suited for protecting global admin passwords, root account passwords, and other critical information that does not require frequent password rotation or heartbeat checks.

Assigning Users to QuantumLocks (Administrators)

> Ensure you have the Administer DoubleLock Keys permission prior to performing this procedure. DoubleLock was the earlier name for QuantumLock.

1. Click **Administration** in the main menu. The Administration page appears.
2. Click the **QuantumLock** link in the **Diagnostics, Logs, Security** section. The QuantumLock Management page appears.
3. Click the desired QuantumLock. Its page appears.
4. Click the **Add or Remove** link in the **Assign Users** section. A table of users with a QuantumLock password appears.
5. If you do not immediately see the desired user, type the user's name in the search text box. The matching users appear below the search text box.
6. Click to select the dropdown list to the right of the search box to limit the search to assigned or unassigned users. These are the users that are already assigned or not to the QuantumLock object (user group).
7. Click to select the check box next to the desired users.
8. Click the **Save** button.

Configuring QuantumLocks (Administrators)

> Ensure you have the Administer DoubleLock Keys permission prior to performing this procedure.

As an admin, to use QuantumLocks on a secret, you must first create complete these steps for a new QuantumLock:

1. One time: Enable the "quantum safe encryption" feature of QuantumLock. See "Enabling Quantum Safe Encryption(Administrators)" on page 1099.
2. One time: Create a QuantumLock password (one time per user). This is automatically required of you when you create a QuantumLock or access a secret with an existing one (that somebody else assigned to you). You can also create one manually ahead of time. See "Creating QuantumLocks (Administrators)" on the next page.

3. One time: Create a QuantumLock, which can be used on multiple secrets by multiple users. See "Creating QuantumLocks (Administrators)" below.
4. One or more times: Assign the QuantumLock to a secret or secret template. See "Enabling QuantumLocks on Secrets" on page 1100
5. One time per user: Assign the user to that QuantumLock. Users without an existing QuantumLock password are required to create one. See "Creating a QuantumLock Password" on page 1100 or "Assigning Users to QuantumLocks (Administrators)" on the previous page
6. Unlimited times: A user unlocks the QuantumLock with his or her QuantumLock password, which in turn gives the user access to the secret associated with the QuantumLock.

> When a user initially unlocks the QuantumLock, they are not required to reenter their password for one hour after they initially unlocked it. After an hour, the QuantumLock returns to requiring the password. The next time they unlock it, the one-hour "waiver window" starts anew.

Creating QuantumLocks (Administrators)

> Ensure you have the Administer DoubleLock Keys permission prior to performing this procedure.

> We recommend reading "QuantumLock Overview" on page 1093 and "QuantumLock Objects and Relationships" on page 1096 before proceeding.

1. Click **Administration** in the main menu. The Administration page appears.
2. Click the **QuantumLock** link in the **Diagnostics, Logs, Security** section. The QuantumLock Management page appears.
3. Click the **Create New QuantumLock** button. If you have never created a QuantumLock before, the Create QuantumLock Password popup appears, and you have to create a QuantumLock password first. Otherwise, you go directly to the Create New QuantumLock page because you already have a QuantumLock password in the system.
4. Type your QuantumLock password in the **Password** and **Confirm** text boxes.

> It is critical that you remember or securely store this password. It cannot be recovered.

> Because it is a secondary password, your QuantumLock password does not have to (but can) meet the same strong requirements as regular Secret Server passwords (as defined by your admin). The only requirement is it must be between 8 and 500 characters long, inclusive.

> A new QuantumLock and QuantumLock password are created together. In fact, it is impossible to create a QuantumLock password without immediately assigning it to a QuantumLock or vice versa. For an existing QuantumLock, you are assigned access to it by its creator. Upon first accessing it, you must create *your* QuantumLock password for it. At least one other user will already have created their password for the same QuantumLock—the creator plus anybody else they granted access to.

5. Click to select the desired key encapsulation algorithm. See "QuantumLock Overview" on page 1093 for details.
6. Click the **Create** button. The Create New QuantumLock popup appears.
7. Type the new QuantumLock's name in the **Name** text box.
8. Click the **Create New QuantumLock** button. The new QuantumLock's page appears. See the following for more information:
   - "Assigning Users to QuantumLocks (Administrators)" on page 1097
   - "Configuring QuantumLocks (Administrators)" on page 1097

Enabling Quantum Safe Encryption(Administrators)

By default, the Quantum Safe Encryption feature of QuantumLock is disabled. That is RSA-2048 and not Kyber-1024 is used by default. To enable the feature:

> Ensure you have the Administer DoubleLock Keys permission prior to performing this procedure.

> We recommend reading "QuantumLock Overview" on page 1093 and "QuantumLock Objects and Relationships" on page 1096 before proceeding.

> These instructions are only applicable if the Quantum Safe Encryption was not previously enabled.

1. Search for Quantum Safe Encryption in the Configuration search.
2. Check the **Enable Quantum Safe** box.
3. Go to **Quantum Lock Management**.
4. Update your password to use Kyber.

Using QuantumLocks

Using QuantumLocks in Secret Server involves leveraging an additional security layer to protect secret data through asymmetric encryption, where the private key is a human-generated password. This feature, previously known as DoubleLock, is independent of regular Delinea permissions and Secret Server login access. QuantumLocks are particularly useful for securing highly sensitive data against future quantum computing threats. When a secret is protected with a QuantumLock, only users with access to the QuantumLock and the corresponding password can decrypt the secret. This ensures that even if Secret Server is compromised, the secrets remain secure. QuantumLocks can be applied to various types of sensitive information, such as global admin passwords, root account passwords, and personal information. However, it is important to note that enabling

QuantumLock disables certain features like Remote Password Changing (RPC) and heartbeat, making it unsuitable for secrets requiring frequent password rotations.

Creating a QuantumLock Password

1. Click the user icon at the top right of Secret Server and select **User Preferences**. Your User Preferences page appears.
2. Click the **Change QuantumLock Password** link. The Enter QuantumLock Password popup appears.

   You cannot create a QuantumLock password until you are associated with a QuantumLock. When you access your first QuantumLock, you are prompted to create a password.

3. Type your desired doublelock password in the **Password** and **Confirm Password** text boxes.

   It is critical that you remember or securely store this password. It cannot be recovered.

4. Click the **Change Password** button. The password is created.

Enabling QuantumLocks on Secrets

1. Navigate to the secret you wish to QuantumLock by clicking **Secrets** on the main menu.
2. Either drill down to the desired secret in the folders on the main menu, or click the secret in the **All Secrets** table to arrive at the secret's page:
3. Click the **Security** tab.
4. Click the pencil icon to the right of **Enable QuantumLock** in the **Other Security** section. The Create QuantumLock Password popup appears.
5. Click to select the **Enable QuantumLock** check box. The QuantumLock dropdown list appears.
6. Click to select the QuantumLock you created earlier.

   Enabling QuantumLock on this secret only grants users access if they have access to the QuantumLock and enter their QuantumLock password. Enabling QuantumLock disables the RPC features for the secret.

7. Click the **Save** button. The QuantumLock is now enforced for the secret.

Recovering QuantumLock Passwords

Introduction

Because users with access to a given QuantumLock each have their own separate password. If you forget your QuantumLock password, you cannot simply ask another person using that QuantumLock for the password. Instead, one of the other users must reassign you to the QuantumLock, and you must create a new password. Because your QuantumLock password is the same for all your QuantumLocks, you must repeat the process for all those QuantumLocks. If no other QuantumLock users are available to assign you to the QuantumLock (there only one

associated QuantumLock password–the one you cannot remember), you are out of luck, and the secret will be destroyed when you receive a new QuantumLock password.

> Because of this, we strongly recommend always having more than one user per QuantumLock if at all possible.

Recovery Procedure

When you forget your QuantumLock passwords, there are multiple steps and considerations, and loss may or may not result:

1. When you forget your QuantumLock password, you typically come to that realization when attempting to access a secret protected by that QuantumLock.
2. Click the **Forgot QuantumLock Password?** link. The Reset QuantumLock Password page appears.
3. At this stage, there are two possibilities:
   - You are the only one with access to the QuantumLocked secret: When you reset the QuantumLock password, the secret and its data is deleted. **This is permanent**.
   - Others have access to the secret via that QuantumLock: You can reset the QuantumLock, and you lose access to the secret, but it is not deleted. You must ask one of those other users to re-assign you to the QuantumLock after you reset it.
4. Type your main Secret Server password in the **Login Password** text box.
5. Click the **Reset QuantumLock Password** button. The password is reset, and if you are the only one with access to the QuantumLock, the secret is deleted.
6. (Optional) Ask one of the others with the QuantumLock password to re-assign you to the QuantumLock.

Setting up QuantumLocks (for users)

To use QuantumLocks, you must:

- Set up a QuantumLock password. See "Creating a QuantumLock Password" on the previous page.
- Have an admin:
  - Create a QuantumLock object.
  - Assign you to that QuantumLock's user group.
  - If you are the only person who should have access to the user group, remove themselves from the group.
  - Tell you the name of the user group (the QuantumLock object name).
- Enable QuantumLock on one or more secrets, assigning a QuantumLock object (group name) to each. See "Enabling QuantumLocks on Secrets" on the previous page.

Workflow Overview

Secret Server introduced *access-request workflows*. These allow users to build more complex interactions based on events within Secret Server than currently possible. The first release of workflows offers access requests.

Workflow templates define the series of steps and reviewers required for an access request. You can assign workflows to secrets or secret policies.

With Access-Request Workflow Templates, you can:

- Require that multiple people approve a request before access is granted
- Require multiple workflow steps, each with different reviewers and number of required approvers, if desired.
- Select "Owners" as a review group

> Access Requests already existed in Secret Server, but with 10.6 they become much more powerful. Previously, if access requests enabled on a secret, requests were granted after a single reviewer approved the request. Now, approval workflows can require multiple approvers, and multiple approval levels.

> Note that the Approval Workflow is available only for Professional (with Licensing Add-On) and Platinum Secret Server users. See the Secret Server Feature Chart for more details.

Multi-Level Workflow

The original access requests are one level or step—anyone approving approves the request—no other input is required. Workflows allow up to 15 approval steps where approval by reviews in step 1 moves the request to step 2, approval at step 2 moves it to step 3 and so forth. Denial at any step denies the request.

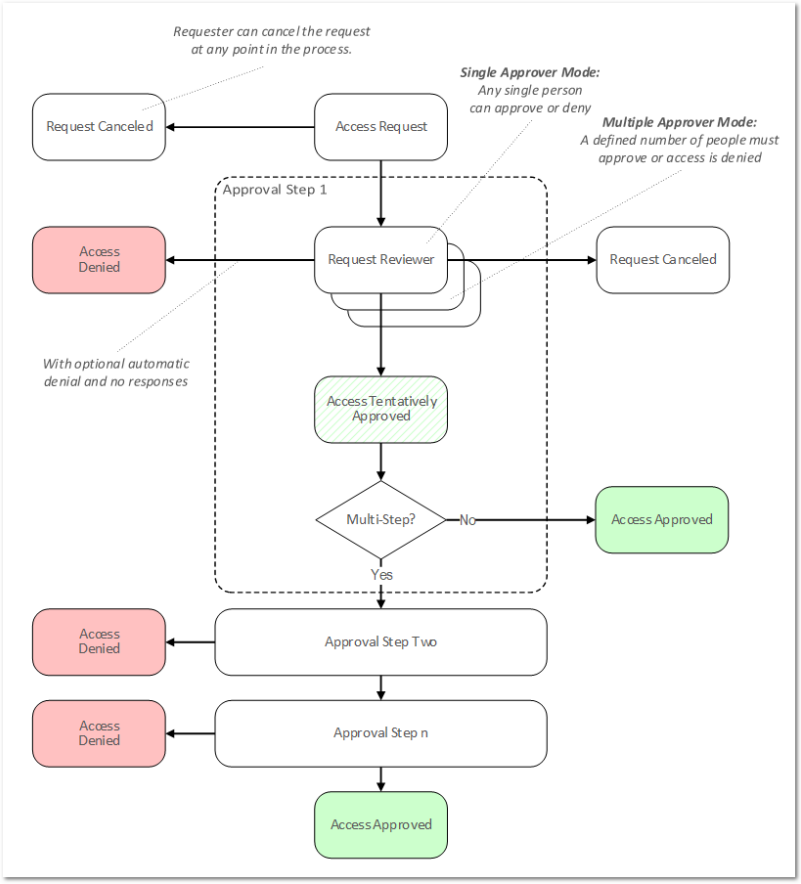
Multiple Approvers to Advance

The new workflow feature can be configured where one approver at a given step is not enough. In effect, approvers in each step can "vote" for approval—you stipulate how many approvers at a step must approve for the approval to move on to the next step.

Approval Process Workflow

The following diagram is the entire process summarized:

Figure: The Approval Process Workflow



Workflow Versus Basic Access Requests

In general, "simple access requests," the only type available to older versions of Secret Server, are the same as a one-step stepped approval. The major exception is that with stepped requests, once a workflow access request has been approved, denied, or canceled, its status cannot be changed. In contrast, simple, non-workflow, access requests retain the original behavior of allowing a request to be approved after it has been denied or denied after it has been approved.

Workflow Step Timeout

Release notes

You can configure workflow steps to time out after a specified number of minutes. Workflow administrators can define approval workflows that notify a different set of users if a step in the workflow is not responded to within a specified time period.

Applications include:

- Improving responsiveness to access requests on time-sensitive secrets by moving the request to another step if not responded to quickly.
- Overflowing to a different region so a secret can be accessed by users in different time zones with different sets of support personnel responding.

Timed out access requests automatically advance to the next step in the workflow. The last step of the workflow cannot time out and must be approved to access the secret.

You can apply multiple timeouts to create workflows that can cascade through multiple steps if the previous steps do not receive the required approvals.

Denying or canceling a request in any step stops the workflow and stops any time out to the next step.

Important: Once a workflow step times out, only the reviewers in the next step can approve the request. If you want reviewers from the initial step to respond after the initial request has timed out, add them to the reviewers of the next step.

Accessing the Workflow Designer

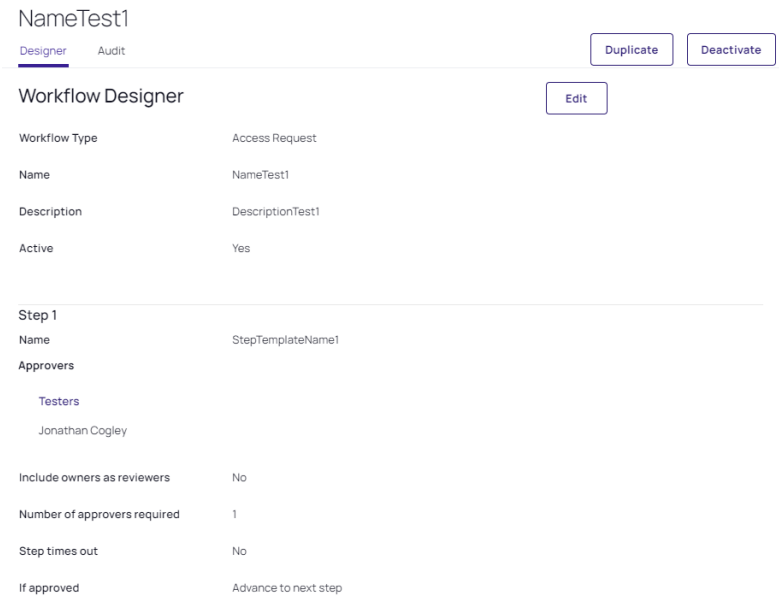
To access workflows:

1. Search for **Workflows**. The Workflows page appears:

   The page lists all active workflows.

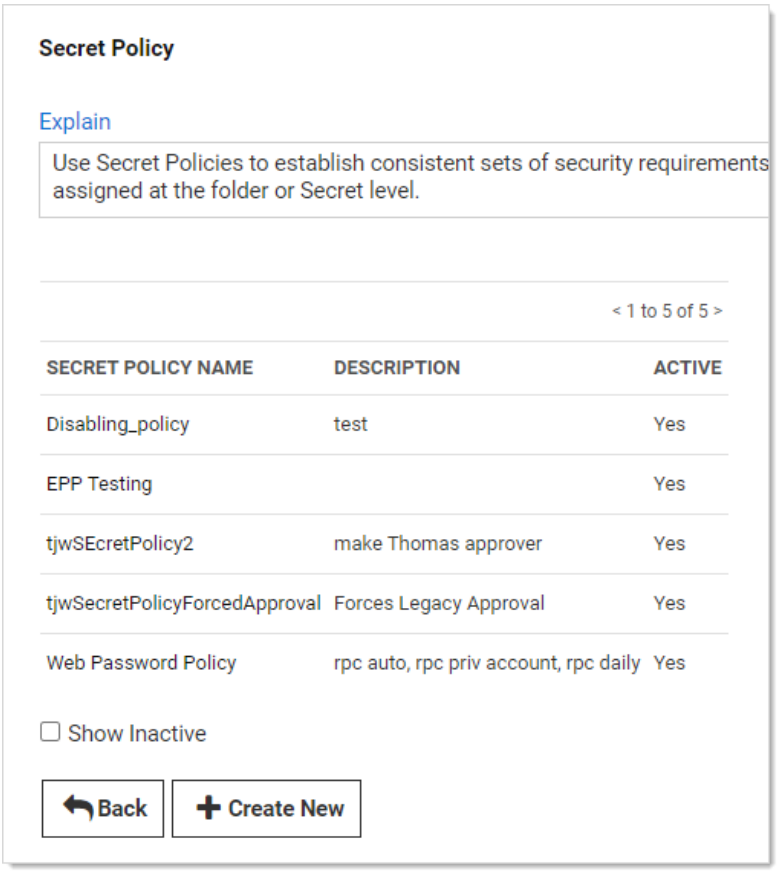
2. (Optional) Click to enable the **Show Inactive** toggle button, under the **Create Workflow** button, to show both active and inactive templates. When the toggle button is disabled, it only shows active workflows.

3. Click any workflow in the list to go to the designer page for that workflow:

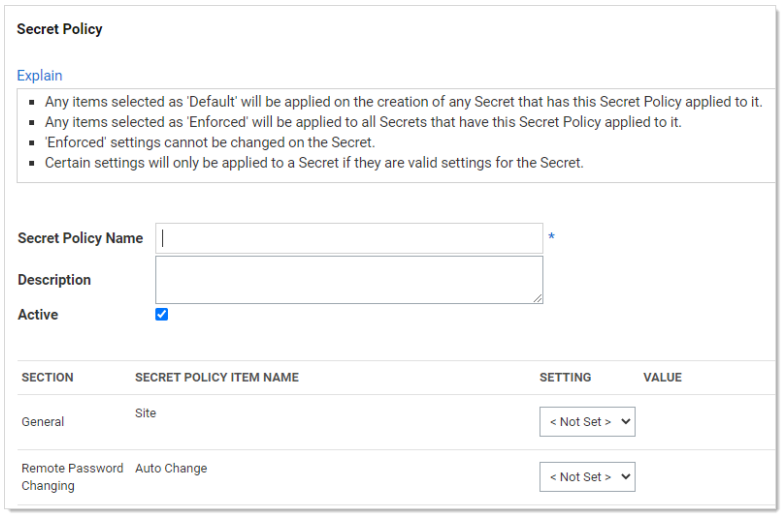


Assigning Workflows to Secret Policies

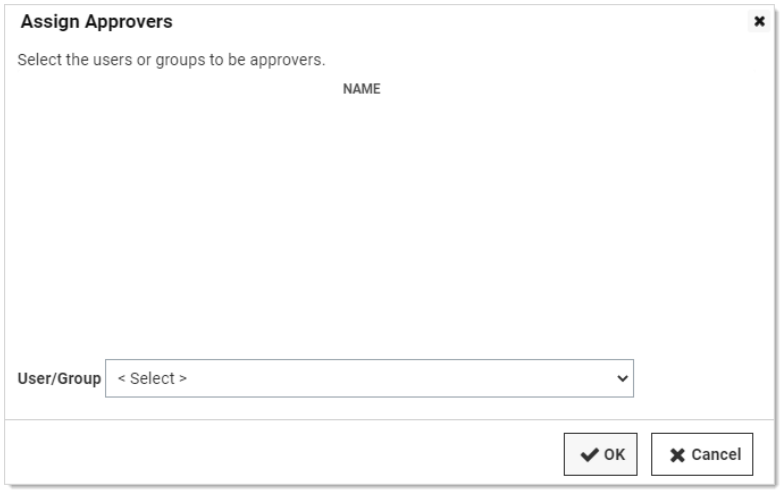
1. Click **Admin > Secret Policy**. The Secret Policy page appears:



2. For this instruction, we are going to create a new policy.
3. Click the **+ Create New** button. Another Secret Policy page appears:

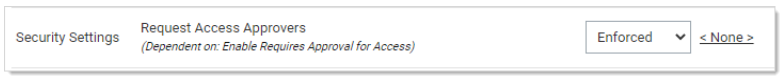


4. Type the new policy name in the **Secret Policy Name** text box.
5. Scroll down the page to the **Security Settings** section of the unlabeled table.
6. Click the **Enable Requires Approval for Access** list and select **Enforced**.
7. Click to select the check box next to the list. The Assign Approvers popup page appears:



8. Click the **Cancel** button. The Request Access Approvers setting become enabled:

> You cannot set approvers and use a workflow at the same time. The intent of the next few instructions is avoid attempting to do so, which causes an error.



9. Click the **Request Access Approvers** list and select **Not Set**.

10. Click the **Request Access Workflow** list and select **Enforced**. A new list appears alongside:

11. Click the new unlabeled list and select the access template workflow to associate with the policy.
12. Click the **Save** button at the bottom of the page. The policy is now available for assignment to secrets and folders, just like any other policy.

Creating New Workflows

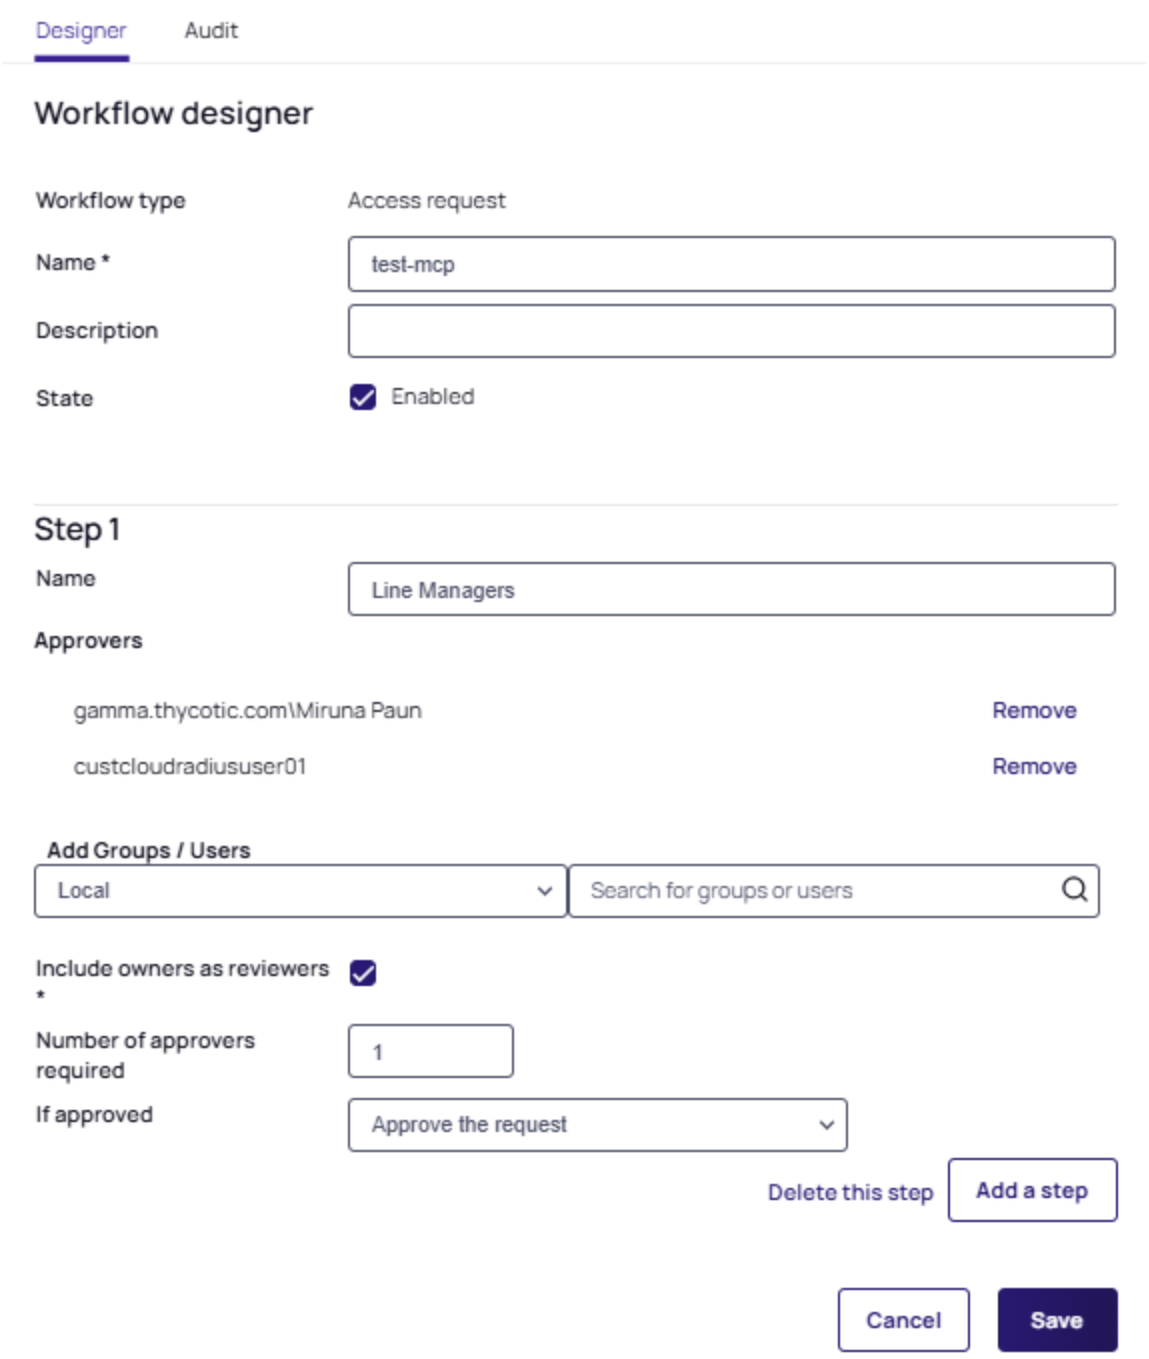
Task 1: Access the Workflow Designer

1. Search for **Workflow**. The Workflows page appears.
2. Select the **Create Workflow** button. The Create Workflow popup appears.
3. Type in the **Workflow name** and **Description** (optional) text boxes, then choose a **Workflow type**.
4. Click the **Create Workflow** button. The Workflow Designer tab loads with the warning that the workflow needs to be activated (enabled) for it to work.

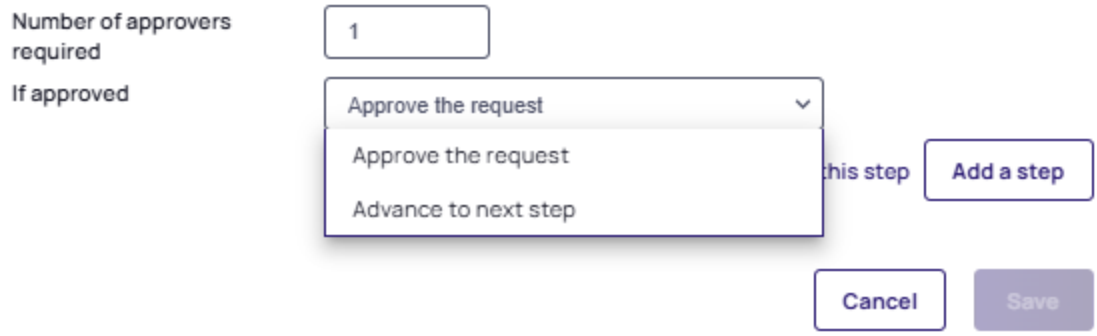
> A new workflow has only one empty step by default.

Task 2: Set up the First Step

1. On the workflow **Designer** tab, click to select the **State** checkbox as **Enabled**.
2. (Optional) Change the default text for Step 1 in the **Name** text box, for example "Line Managers".
3. In the **Add Groups / Users** dropdown list, select the domain where you want to get your approvers from.
4. Type the name of the user or group you desire as an approver in the unlabeled search box to the right. Options appear in the dropdown.
5. Click the desired user or group. The user is added to the **Approvers** section automatically, under the Step 1 name field.
6. Repeat as desired.
7. (Optional) To automatically include the owner of the secret the template is assigned to, select the **Include owners as reviewers** checkbox:



8. If you wish to have multiple approvers required on the step, edit the **Number of approvers required** text box. Otherwise, leave it set to the default 1.
9. Click the **If approved** dropdown list to select what to do next:



10. Once selected, click **Save**.

Task 3: (Optional) Add More Steps

> There are situations where you might want to have only one workflow step. Most Workflows, however, provide options to require multiple approvers or have owners as approvers, which are not available for simple access requests.

1. Select the **Add a Step** button. A new step appears.
2. Repeat the process mentioned in Task 2, keep adding steps as needed.
3. Click the **Save** button to create or save the workflow. The template exits editable mode.

Disabling Workflows

To disable a workflow:

1. Search for **Workflows**. The Workflows page appears:

   The page lists all active workflows.
2. (Optional) Click to enable the **Show Inactive** toggle button, under the **Create Workflow** button, to show both active and inactive templates. When the toggle button is disabled, it only shows active workflows.
3. Click the workflow to delete in the list to go to the designer page for that workflow (not shown).

4. Click the **Disable** button. A confirmation popup page appears.
5. Click the **Yes, Disable** button.

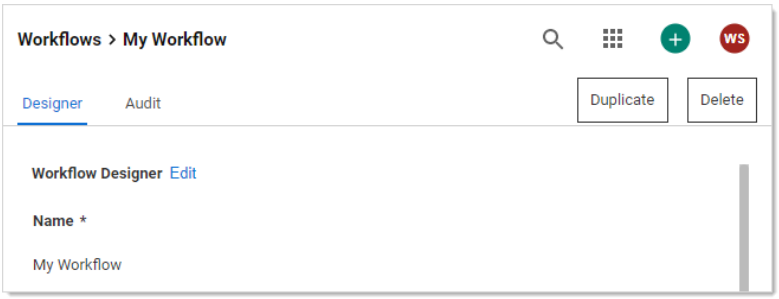
> Because workflows based on the template may still be in play, the template is not completely deleted. Instead, it is disabled. You can reactivate the template later.

Duplicating Workflows

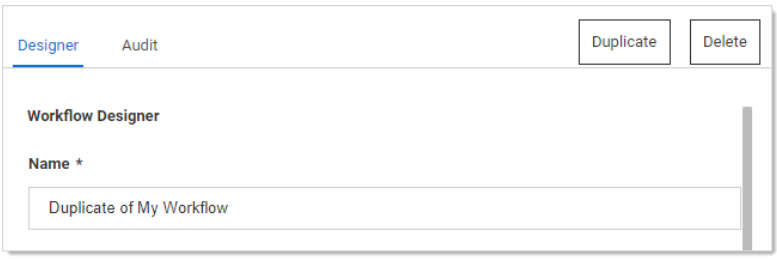
If you need to create a new workflow that is like one your already have, you can save time by copying the similar template and then making the any changes:

1. Search for **Workflows**. The Workflows page appears:

   The page lists all active workflows.
2. (Optional) Click to enable the **Show Inactive** toggle button, under the **Create Workflow** button, to show both active and inactive templates. When the toggle button is disabled, it only shows active workflows.
3. Click the workflow you want to copy in the **Workflow Templates** table. That template appears:



4. Click the **Duplicate** button. The new template appears, filled in the same as the original but with a "Duplicate of" name:



5. Change the name and edit as desired.
6. Click the **Save** button when finished.

Editing Workflows

To edit the template:

1. Search for **Workflows**. The Workflows page appears:

   The page lists all active workflows.
2. (Optional) Click to enable the **Show Inactive** toggle button, under the **Create Workflow** button, to show both active and inactive templates. When the toggle button is disabled, it only shows active workflows.
3. Click the workflow to edit in the list to go to the designer page for that workflow (not shown).
4. At this stage the process is nearly identical to creating a new workflow. The only difference is many of the parameters and additional steps are already completed. Change them as desired. If you want to eliminate an entire step, click the **Delete This Step** link for that step.

> You cannot make any changes to the behavior of a workflow if there are active requests using that template without canceling those requests. An active request is any unexpired request that has not been approved, denied, or canceled by the user. If you do make an alteration, any requests are canceled and those affected are notified by email so they can resubmit their requests. Any user editing the template is notified when he or she tries to save changes on the canceled request.

Workflow Design Best Practices

Consider the following when setting up an access-request workflow:

- Use multiple-step approval workflows when you need to have different people (such as different departments) sign off on an approval request.
- We do not recommend assigning equally important approvers or groups to multiple steps. Having a single step with multiple approvers works better. Remember, steps are best used for hierarchical approval--an approval chain.
- A reviewer can only respond to a request once. If you have the same user as a reviewer in multiple steps, that approver cannot respond if he or she already responded on an earlier step. In addition, the reviewer's earlier approval does **not** count towards the number of approvals required in later steps. Thus, if you want to assign the same user as a reviewer in multiple steps, make sure that you have enough reviewers in each step to approve without that user.
- A well-crafted workflow design ensures there are enough approvers in a group to satisfy the multiple approver (x of n reviewers must approve) requirement, but group membership can change after the workflow is created. Thus, if you remove members from groups used by workflows, ensure there are still enough members in those groups to approve requests.
- Once a workflow step times out, only the reviewers in the next step can approve the request. If you want reviewers from the initial step to respond after the initial request has timed out, add them to the reviewers of the next step.

Secret Import and Export Overview

Secrets are imported or exported as a comma-separated-value (CSV) file or as an XML file:

- The CSV file is easily read and edited in Excel or other spreadsheet applications. The file is grouped by secret template and each cluster of secrets has a header row that contains the template text-entry field names followed by all exported secrets based on that template.
- The XML file is useful for migrating data from one Secret Server installation to another or even from a third-party application to Secret Server.

Secrets are exported in the exact same structure as a secret Import.

This topic has three subtopics:

- "Exporting Secrets" on page 1122
- "Importing Secrets" on page 1124
- "Secret Server Migration Tool" on page 1130

What Gets Imported or Exported

Import or export each include:

- Folders (and their permissions)
- Secret templates
- Secrets (and their permissions)

Import or export each do **not** include users, groups, launchers, configuration, or other related information.

Folders and secret templates are only exportable from Secret Server 10.0 and later.

Before importing, to ensure Delinea permissions are applied correctly, you must recreate your users and groups on the target Secret Server.

The following secret template settings **are** transferred with an export or import operation:

- Edit requires
- Field slug names
- Hide on view
- Is required?
- Keep secret name history
- One-time password settings
- Secret template icons
- Type descriptions
- Validate password requirements on create or edit

The following secret template settings are **not** transferred with an export or import operation:

- Associated secrets
- Launcher settings
- Password changing settings
- Session recording enabled

Migrating to and from Secret Server Cloud

If you use XML import and export to migrate from Secret Server On-Premises to cloud, the major release version (x.x) must be the same. Otherwise, you need to upgrade before you can migrate. Additionally, in Secret Server Cloud before importing, access **Settings > Configuration Search > General > Permission Options**, and make sure the **Allow Duplicate Secret Names** option is set to **Prevent Duplicates Globally**.

It is **not** recommended to use XML import and export to transfer between on-premises and cloud editions. Instead, you should use professional services, or leverage the API instead.

Automatic Secret Export

This feature allows you to automatically export secrets on a schedule to an external location in an encrypted, password-protected archive.

The secret export settings and XML export format matches the existing Export/Import tool (search for **Export / Import**). This feature lets you automate that export process.

To access this feature, your user must have at least one automatic export permission where you can then find it by searching **Automatic Export**.

The export runs under the Delinea permissions of the user who last configured the automatic export, and only secrets that this user is authorized to access are included in the export.

All actions, successful or not, related to this feature are audited and logged.

Export Process

> The actual export of secrets to XML is exactly the same as the standard Export / Import tool—only the triggering differs.

The automatic export follows this process in order:

1. Either a user clicks the Run Export button on the Automatic Export tab or the configured frequency days have passed. Automatic exports are evaluated once per day at 07:00 UTC, and the export runs when the frequency condition is met at that time.

   > Users can manually run the automatic export to determine if the export performs as desired.

2. Secret Server determines if the user who set up the automatic export has either the Run Automatic Export or Administer Run Automatic permission.
3. Secret Server exports secrets to XML, subject to your export settings.
4. Secret Server compresses the XML export into an encrypted, password-protected ZIP archive. The filename for both the XML file and the zipped XML file includes the export date and time—both are named the same, except the file extension. The encryption is 256-bit AES, and the password comes from the Export Password configuration setting.
5. Secret Server saves the archive to the export path (on-premises customers) or to cloud storage (cloud customers).
6. Secret Server logs the results, successful or not, noting any errors. You can view the logs on the Automatic Export Log tab.

Considerations and Settings

Configurations and Returned Data

The Automatic Export page shows the following information and configurations:

Those unique to automatic exports:

- **Enabled**: Whether the feature is enabled.
- **Last Exported:** The last time an automatic export successfully ran.
- **Export Path:** The path the export archives are saved to.

  > On-premises Secret Server customers must have Write to the directory Delinea permissions.

- **Export User:** The user the secret export runs as. Thus, only secrets this user has access to can be exported. This setting is updated automatically to the last user who saved automatic export configuration changes.
- **Frequency (Days):** Number of days between automatic exports. Automatic exports are evaluated once per day at 07:00 UTC.

Those in common with the secret export tool:

- **Export Child Folders:** Whether the export should include child folders, performing a recursive export.
- **Export Folder Paths:** Whether the export should include folder paths.
- **Export Password:** The secret whose password value will be used to password-protect the export archive.
- **Export TOTP Settings:** Whether the export should include Time-based One-Time Password (TOTP) settings.
- **Folder:** The folder the exported secrets are in. If no folder is selected, all secrets are exported. If Export Child Folders is enabled, the folder's subfolder's secrets are included.

Export Storage

Once the XML export is encrypted and archived in a ZIP file, the file is stored at an external location, which differs for on-premises customers and cloud customers. For cloud, only the 10 most recent exports are retained, and older export archives are purged as new exports are stored. This doesn't apply to on-premises customers as their local storage is used.

On-Premises storage export archives are saved in the directory in the Export Path configuration. Secret Server must have write permissions to this folder.

Cloud export archives are listed for viewing and downloading on the Automatic Export Storage tab. You can automate downloading these export archives using the REST API Automatic Export. See the "REST API Reference Download" on page 1522.

Security

Because this feature moves sensitive data outside of Secret Server, it is very important to understand that **anyone with access to the export archive*and*the export password has access to all exported secrets**. This bypasses Secret Server security features and may result in a user having access to secrets they would not have access to in Secret Server.

The export archive is a password protected, 256-bit AES-encrypted zip file. Thus, the only thing preventing a possible breach is the password, so it is important you use a cryptographically strong password to foil brute force attacks.

Automatic Secret Export Permissions

The following permissions relate to automatic secret export:

- **Administer Automatic Export**: The user can do everything the other permissions allow *and* edit the automatic export configuration.
- **Download Automatic Export**: The user can view all of the automatic export tabs *and* download exports from cloud storage (cloud customers only).

- **Run Automatic Export:** The user can view all of the automatic export tabs *and* run the export manually by clicking the Run Export button.
- **View Automatic Export:** The user can view all of the automatic export tabs.

Event Subscriptions

The following automatic export events are available for event subscriptions:

- **Download:** When an export archive is downloaded (cloud customers only).
- **Edit:** When changes are made to the automatic export configuration settings.
- **Export:** When an automatic export executes, automatically or manually.

  This event also triggers when a fatal error occurs during the export causing the export to fail. Non-fatal errors do not trigger this event, but they are logged on the Automatic Export Log tab.

- **Run Export:** When an automatic export is executed manually by a user clicking the Run Export button.

  If you subscribe to both this event and the Export event, both events trigger at once.

Setting up Automatic Exports

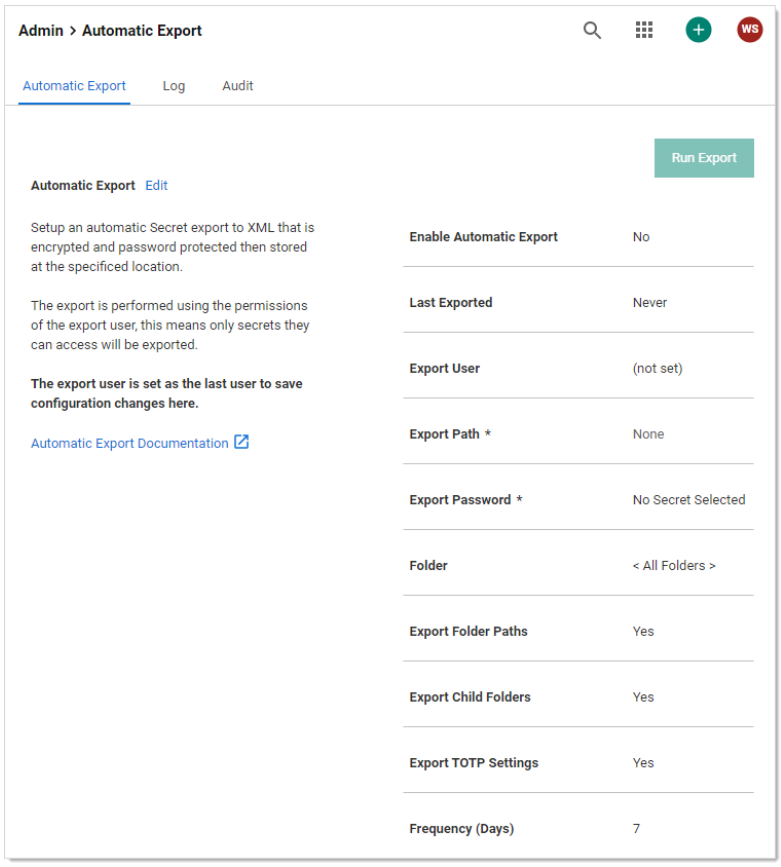
To set up an automatic export:

Only the secrets the user has view access to are exported.

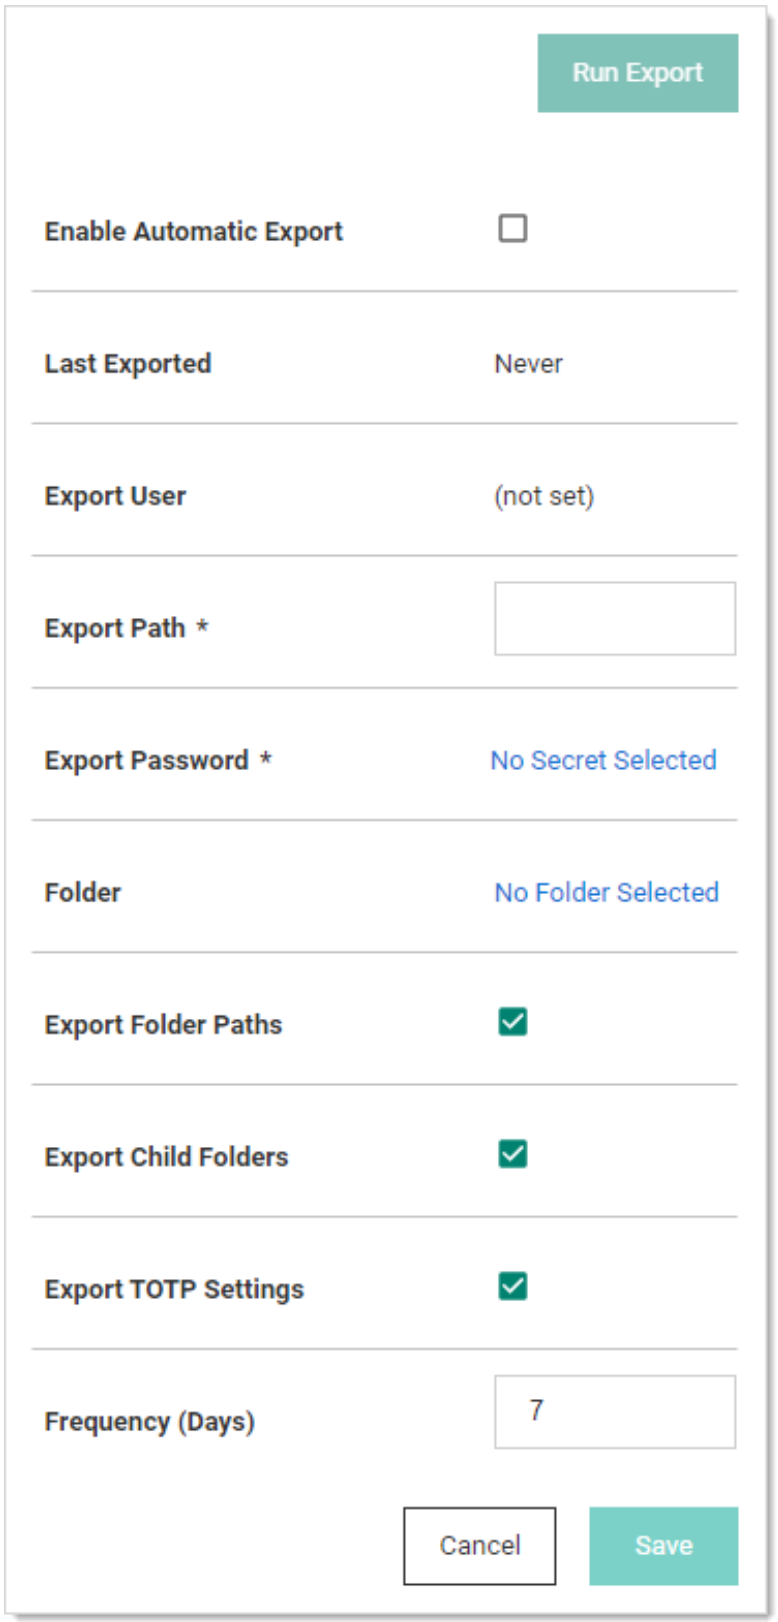
File attachments on the original secret are not exported into the XML file and require using the API to migrate. Secret audits and history are not preserved during the migration.

If you later use the export to import into another Secret Server instance, be sure to first create the AD groups and users using the permissions on the secrets in the original Secret Server instance. Otherwise, they will not be created when the secrets are imported into the new instance.

1. Create a new secret to store the export password in.
2. Search for **See All**. A popup menu appears.
3. Click the **Automatic Export** link. The Automatic Export (configuration) tab appears:



4. Click the **Edit** link next to **Automatic Export**. The page becomes editable:

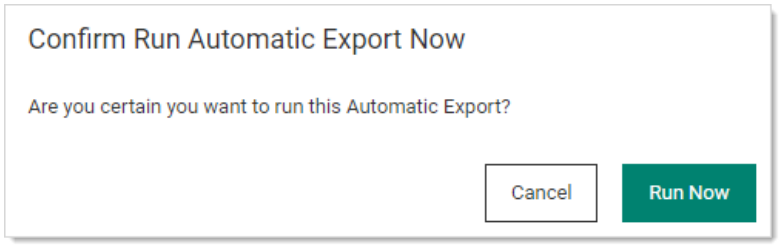


Run Export
Enable Automatic Export
Last Exported
Never
Export User
(not set)
Export Path *
Export Password *
No Secret Selected
Folder
No Folder Selected
Export Folder Paths
Export Child Folders
Export TOTP Settings
Frequency (Days)
7
Cancel
Save

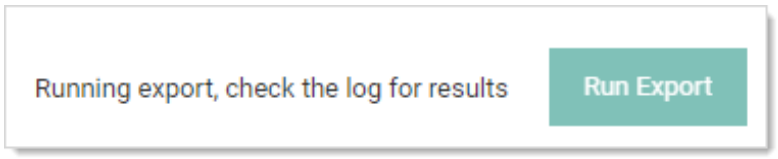
5. Click to select the **Enable Automatic Export** check box.
6. There is no need to set the export user—Secret Server automatically notes who is logged on when you save the export.
7. Type the path to export the secret to in the **Export Path** text box (on-premises users only). On-premises Secret Server customers must have write permissions to the directory.
8. Click the **No Secret Selected** link. The Select Secret popup appears.
9. Click the secret you want to store the password in. Your choice appears as a link next to Export Password:

10. Click the **No Folder Selected** link to choose a folder to export. By default, all secrets are exported if a folder is not selected. The Select Folder popup appears. Click on the desired folder. You chosen folder appears as a link:

11. (Optional) Click to select the **Export Folder Paths** check box. This adds the full folder path to the export. Folder paths in the export file provide organizational structure if secrets need to be imported later.
12. (Optional) Click to select the **Export Child Folders** check box. This option includes any subfolders of the one you chose earlier.
13. (Optional) Click to select the **Export TOTP Settings** check box if you want to include time-based one-time password settings in the export.
14. Type the number of days between automatic exports in the **Frequency (Days)** text box.
15. Click the **Save** button. Any error messages, such as secrets with doublelocks, appear. The page leaves edit mode, and the Run Export button appears.
16. Click the **Run Export** button to text the export. A confirmation popup appears:

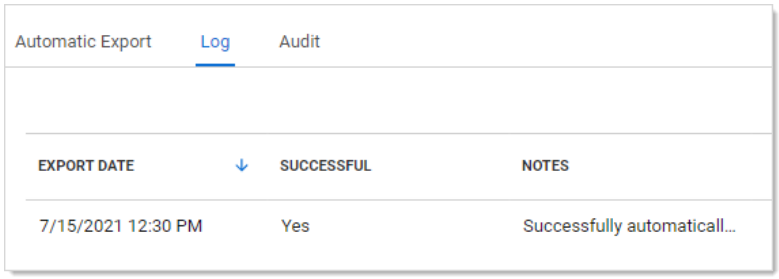


17. Click the **Run Now** button. A notification appears:



And then disappears.

18. Click the **Log** tab to confirm the export worked:



19. Using the stored password, open the zip file to confirm its contents.

Automatic Secret Export REST API

Overview

If you use Secret Server Cloud, you can use a REST API to download exports and view your export storage list.

The automatic export feature has the following endpoints available for cloud customers only. API usage is fully audited.

A typical use of these API endpoints is to automate downloading exports to your backup solution outside of Secret Server (for redundancy).

> Any permission errors when using the API will return a 403 forbidden status code and an API_AccessDenied error message.

Viewing the Storage List

Get a list of the exports currently in storage. Your session must be authenticated, and the authenticated user must have Automatic Export view secret permissions.

Sample Request

```
GET: http://sample.secretservercloud.com/api/v1/configuration/auto-export-storage
```

Sample Response

```
{
    "records": [
        {
            "id": 123,
            "autoExportConfigurationId": 1,
            "storageDate": "2021-07-01T07:00:02.27",
            "filename": "secret-server-export-20210707070002",
            "canDownload": true
        },
        ...
     ],
     ...
}
```

The response is a JSON object with a records property whose value is the list of all the exports in storage. Each list entry has the following properties:

- **id:** The ID for this export in storage, which is used with the Download Export endpoint to download the export.
- **autoExportConfigurationId:** The ID for the automatic export configuration this export belongs to. This may be useful in the future if we support multiple export configurations, but for now it is only used internally.
- **storageDate**: The date and time the export was stored.
- **filename:** The filename for the export archive and the export XML file inside it.
- **canDownload:** Whether the user can download this export archive.

Downloading Secret Exports

Download an export in storage by its ID. Your session must be authenticated and the authenticated user must have Automatic Export Download permissions.

Sample Request

```
GET: http://sample.secretservercloud.com/api/v1/configuration/auto-export-storage/item/
{id}
```

Where **{id}** is the ID of the export you want to download. This value is obtained from the **Storage List** endpoint.

Sample Response

A stream of bytes representing the export archive.

Exporting Secrets

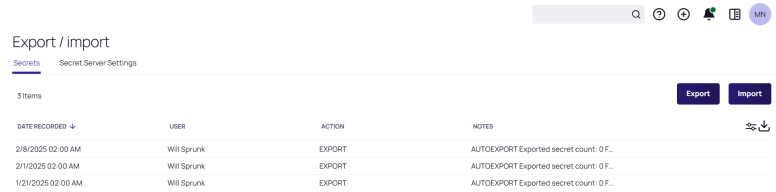
To export a secret, either CSV or XML:

Only the secrets the user has view access to are exported.

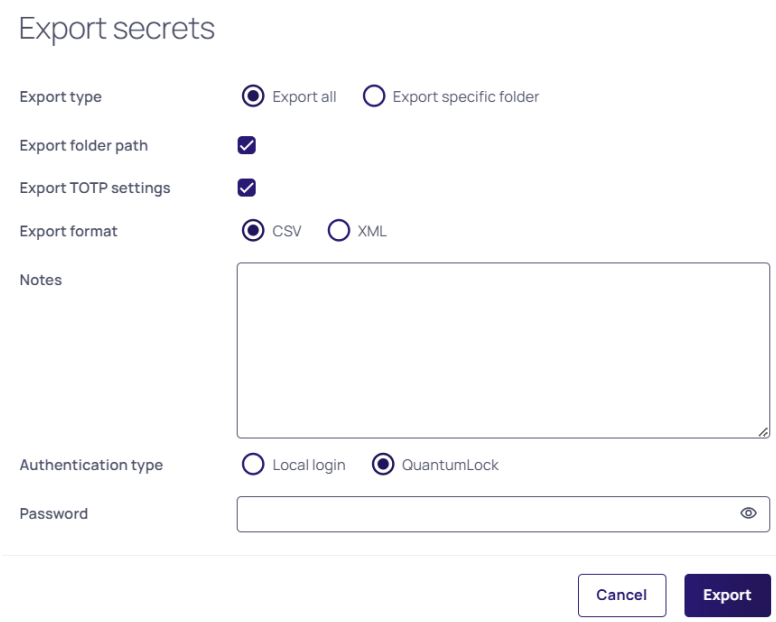
We do not support the import or export of file attachments–the API is required for that.

File attachments on the original secret are not exported into the XML or CSV file and require using the API to migrate. Secret audits and history are not preserved during the migration. Be sure to first create the AD groups and users using the permissions on the secrets in the original Secret Server instance. Otherwise, they will not be created when the secrets are imported into the new instance.

1. Search for **Export/Import** and click **Export** at the top right.



2. The Export page appears:



3. At the top, you have the option to Export All secrets or export the specific folder, all secrets are exported if a folder is not selected.
4. Select the **Authentication Type**. By default, the authentication type will be QuantumLock. The QuantumLock authentication type is required for export if you have authenticated with an external authentication service using SAML, OIDC etc.

5. Type your password in the **Password** text box. The administrative password must be entered, as it is a security measure to verify the permission of the user performing the export.
6. (Optional) Click to select the **Export with Folder Path** check box. This adds the full folder path to the export. Folder paths in the export file provide organizational structure if secrets need to be imported later.
7. (Optional) Click to select the **Export Child Folders** check box. This option includes any subfolders of the one you chose earlier.
8. (Optional) Click to select the **Import with TOTP Settings** check box if you want to include time-based one-time password settings in the export.
9. Click the **Export Format** selection button to choose the type of export. CSV is for Excel and the like, and XML is for migrating to other Secret Server instances.
10. Click the **Export** button. The Export Secrets popup appears. Any error messages, such as secrets with doublelocks, appear.
11. Click the Close button. When the exportation is finished, an `export.csv` file appears in your browser's queue:

Take care with the file—it contains unencrypted passwords.

Importing Secrets

Secret Server's importation feature simplifies integration with legacy systems and allows users to easily add large numbers of secrets from an Excel or comma-separated values (CSV) file. Secrets are batch imported by template, so multiple types of input data need to be imported in several batches. The "Secret Server Migration Tool" on page 1130 topic discusses the addition of existing passwords from other third-party password-storing applications.

We do not support the import or export of file attachments—the API is required for that.

Importing CSV Data

1. Search for **Export / Import**. The Export / Import page appears on the Secrets tab.
2. Click the **Import** button. The Import secrets page appears.
3. Select **CSV** as Import type.
4. Select the related **Secret template** from the drop down list.
5. Check to **Allow duplicate secrets** if you wish to import a secret with the same name as an existing one.
6. Check **Import with Folder** if you included an additional field in the importation text with a fully qualified folder name for the secret to be created in.
7. Check **Change remote passwords** if you wish to execute a password change for each secret on import. This enables the standard functionality of a password change, and the secret also completes the automatic

password change on checking in. This is to allow maintenance and testing of secrets protected in this manner, and a pending password change must be completed before the check-in process is allowed to begin in order to maintain a secure order of operations.

8. Check to enable **Import With TOTP Settings** if needed. If this secret has TOTP settings they will be imported, otherwise ignored.
9. Paste the secrets for importation from MS Excel or a CSV file directly into the **CSV text** text box . The order of the imported fields is based on the template selected. Consider the following:
   - Do not include a header line. The field names are determined by the order, not a header line.
   - The fields **must** be in this order: `Secret Name`, `AccessKey`, `SecretKey`, `Username`, `SecretId`, and `Trigger`.
   - Secret names must be included, but other text-entry fields can be blank unless the secret template indicates that the text-entry field is required.
   - Fields containing commas or tabs must be surrounded with double quotation marks.
   - To include a comma, tab, or newline in a field: Enclose the field in double quotes ("...").
   - To include a double quote character in a field use two double quotes - "" - inside the quoted field:
     - Example input: "pa"",word"
     - Parsed as: pa",word
   - Do not use backslash (\) to escape quotes or commas. Backslash-escaping is not supported.

     Example Table | Desired Value | CSV Field Value | | Hello, world | "Hello, world" | | Hello "world" | "Hello ""world""" | | Hello, "world" | "Hello, ""world""" |
   - Values for File fields may be omitted as they are ignored by the import process.
10. Click **Preview CSV Import** - the CSVimport preview will appear below.
11. If you are happy with what you see, click **Process CSV Import**.

Importing Secrets with XML

Advanced XML importation adds folders, secret templates, and secrets based on an XML file. Delinea permissions can be specified on the folders and secrets or the default is to inherit permissions. This import can only be done by administrators with proper role permissions.

> Migration is **not** supported by Delinea Technical Support.

Procedure

1. Ensure your XML is formatted correctly. If coming from a Secret Server export, you should be good to go. See Example XML File.

   > Do not edit the XML file with Windows Notepad. Instead, use Notepad++, Visual Studio Code, or Atom to make your edits. Windows Notepad can add invisible characters that can prevent importation.

2. Search for **Export / Import**.
3. Click the **Import** button. The Import secrets page appears.
4. Select **XML** as Import type.
5. Check **Inherit folder permissions** to import a secret with the same folder permissions.
6. Check **Change remote passwords** if needed. The passwords on the remote device will be queued for the immediate change after import.
7. Click the **XML file** link and select the related XML file on your device to upload.
8. Click **Upload XML file**.

Example XML File

The XML file should look like the example below, the comments are for explanation only and may be removed before importing, if desired.

> Migration is **not** supported by Delinea Technical Support.

Notes

- Leaving the `<Permissions>` tag empty for a folder will cause that folder to inherit permissions from its parent folder.
- Leaving the `<Permissions>` tag empty for a secret will cause it to inherit permissions from its folder.
- To add a line-break within a Notes field use `##BR##`.

> Please do **not** edit the XML file with Windows Notepad. Use Notepad++, Visual Studio Code, or Atom to make your edits. Using Notepad increases you chances of importation failure.

Sample XML

```
<?xml version="1.0" encoding="utf-16"?>
<ImportFile xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">

Secret Server Migration Tool

Secret Server offers a migration utility for importing secrets from other applications. Currently, the migration tool supports to following applications:

- KeePass (version 1 and 2)
- Password Corral
- Password Safe
- Passwords MAX

Note: This is done with another exportation tool that creates a single XML file. Please contact Delinea Support for details.

Download the Tool

Migrating From KeePass to Secret Server

To migrate from KeePass to Secret Server via the migration tool, follow the steps below:

1. Download the Migration Tool:
   The Secret Server Migration Tool supports importing secrets from KeePass (version 1 and 2). You will need to download this tool.
2. Export Secrets from KeePass:
   Use KeePass to export your secrets into a single XML file. This file will be used for the import process into Secret Server.
3. Prepare for Import:
   Ensure your XML file is correctly formatted. If you are exporting from KeePass, the format should be compatible with Secret Server's import requirements.
4. Import Secrets into Secret Server:
   a. Navigate to Admin > Export / Import in Secret Server.
   b. Click the Import button to access the import page.
   c. Select XML as the import type.
   d. Upload the XML file you exported from KeePass.
   e. You can choose to inherit folder permissions and change remote passwords if needed.
5. Verify Import:

After importing, verify that the secrets have been correctly imported into Secret Server.

Secret Management Overview

Secrets are individually named sets of sensitive information. Secrets address a broad spectrum of secure data, each type represented and created by a *secret template*. You can centrally manage secret security through sharing settings for each secret. Additionally, using folder structure, you can allow one or more secrets to inherit permissions from their parent folder. All secret text-entry field information is securely encrypted before being stored in the database, including a detailed audit trail for access and history.

All Secrets Page

All Secrets is a master table of the secrets stored on Secret Server. It is a one-stop, searchable location for examining the status and properties of secrets. It is a supplement to, not a replacement for, the "Folders" on page 1075. It lists and you can sort by secret template, heartbeat status, sync status, machine, access date, username, and much more.

Click the **Secrets** menu item in the left menu to see the All Secrets Page.

Secret Columns

You can customize which columns are displayed by clicking the on the right side of the title bar. The sortable columns available are (the ones displayed by default are bolded):

- Active
- Auto Change Enabled
- Checked Out
- Checkout Enabled
- Checked Out User ID
- Checked Out User
- Created
- Days until Expiration
- QuantumLock Enabled
- **Favourite**
- **Folder**
- Folder Path
- Heartbeat
- Hide Password
- Inherits Permissions

- Last Accessed (When the logged in user last accessed a secret, not the last time a secret was accessed by anyone)
- Machine
- **Name**
- Notes
- Out of Sync
- Requires Approval
- Requires Comment
- **Secret Template**
- Username

Quick Launch and Actions

You can quickly access several secret actions from the All Secrets table by hovering the mouse pointer over the secret's row:

- Quick Launch: Secrets that display a rocket icon have secret launchers associated with them. Click the icon and a Select Launcher page appears. Click on the desired launcher from the list.
- More Actions: Click the **...** icon to
  - Audit: Brings you to the Audit tab of the secret's page.
  - Details: Brings you to the General tab of the secret's page.
  - Share: Brings you to the Sharing tab of the secret's page.

Other Features

The All Secrets page also allows you to:

- Select multiple secrets for "Bulk Operations" on page 195 by clicking the secret's check box. You can also download multiple secrets in a CSV file by clicking the download icon at the top of the table.
- Select the secret as a favorite by clicking the star icon.
- View supplemental information about the secret by clicking any blank area on the secret's row.
- Click the secret's name to go to that secret's page.
- Filter the secrets shown in the table by template, search text, or activity status.
- Click the "Secret Navigation Slideout" on page 1172.

External Secrets

The external secrets feature, a type of distributed vaulting, integrates Secret Server with external secret management systems, such as "Azure Key Vault Integration" on page 1136 or "AWS Secrets Manager Integration" on page 1143.

Do not confuse Secret Server external secrets with Kubernetes External Secrets Operator.

What Is Distributed Vaulting?

Distributed vaulting is a security approach that stores and manages sensitive data, such as encryption keys, secrets, and certificates, across multiple locations, systems, or environments. This decentralized architecture provides several benefits:

- Centralized Secret Control: Store, manage, and rotate secrets from a single interface. Enforce consistent access policies and Delinea permissions across all secrets. Unified view of all secrets with a single source of truth.
- Competitive Advantage: By implementing distributed vaulting, organizations can gain a competitive advantage by enhancing security, agility, compliance, and customer trust while reducing costs and improving business continuity.
- Enhanced Availability: Data is available even if one location or system is compromised or experiences downtime.
- Improved Development Environment: Securely manage all cloud secrets without impacting developer velocity or CI/CD pipelines. CI/CD (Continuous Integration or Continuous Deployment) pipelines are automated workflows that streamline the software development process. They integrate, test, build, and deploy code changes, ensuring faster, more reliable, and higher-quality software releases.
- Improved Security: By spreading sensitive data across multiple locations, you reduce the attack surface and make it more difficult for unauthorized access.
- Increased Scalability: Distributed vaulting allows for easier expansion and adaptation to growing security needs.
- Connecting with Your Legacy Delinea Vault: Integrating Secret Server On-Premises with Delinea Platform.
- Reduced Single Point of Failure: No single location or system holds all sensitive data, minimizing the risk of catastrophic data loss.

Terminology and Concepts

External vault integration uses several new terms and concepts. Some of the term definitions are slightly different than common usage.

Auditing

All changes to linked secrets are audited and the audit grid indicates how many items we changed. Expanding the panel by clicking on the row shows the changeset that includes the changes for each update. Delinea permission updates include what permissions were assigned or removed from which user.

Creating a Vault

"Creating a vault" links an existing external vault to Secret Server. You are *not* creating the actual external vault. That is, you are creating its internal representation within Secret Server with the external vault. The name must exactly match the name of an already existing external vault. For AKV, the credential secret should have Get, List, and Set Azure Key Vault permissions within Azure under Secret Management Operations.

New Vault Initial State

After successfully validating the connection to the external vault you are prompted to pull in the matching information from the vault. This process only pulls in links to the existing external secrets inside Secret Server. At this point, no data is updated in the external vault.

Secrets first appear as disabled. A disabled secret means Secret Server will not push or pull any data to or from the external vault for that secret.

External Secret

An *external secret* is a secret inside Secret Server that is linked with a secret in an external vault. It is called an *external* secret because it *represents* a linked secret in the other vault.

In short, an external secret is mostly just a metadata mapping to a secret in the external vault.

External Secret Fields

An external secret contains the following fields, which are available on the External Secret page:

- External Vault: The vault on the external machine that contains its matching secret.
- Name: The name of the secret, which cannot be changed.
- Last Push: Indicates the last time a change was pushed to the linked secret on the external vault.
- Linked Secret: A secret in Secret Server that is connected to the external secret and thus to a secret in the external vault. Any changes to it are pushed to the external secret.
- Transform: The formula used to push changes to the linked secret on the external server. For example: `Machine: $secret.field.machine; Password $secret.field.password` would push the value of the machine and password fields into the the linked secret in the external vault. There is a formula editor that shows available fields once a secret is selected.

An external secret can have one of the following states:

- Enabled: Indicates the secret is live and any changes to it triggers an update to the external vault.
- Disabled: Indicates the secret cannot receive any changes. That is, no changes can be pushed to this secret from the external vault.

External Secret Actions

There are several actions that can be taken with an external secret:

- Set External Value: This function accepts any text and assigns it to a secret in the external vault. This function does not require a linked secret or transform and will ignore any of those and just assign the value that is entered.
- View External Value: View the current value for a secret in the external vault, not necessarily a linked secret.
- Push: Merge the transform data from the linked secret and update the value in the external vault. New versions of the external secret will only be added if it has changed values.
- Edit: Edit the secret's metadata.

External Secret Grid

The external secret grid provide a central location in Secret Server to manage external secrets. When selecting external secrets in the grid, you can select to push or edit these items. Bulk edits allow you to update and link multiple external secrets at once.

External Vault

External vault is a vault that is outside of Secret Server—one AKV or AWSSM is hosting. That external vault is where default permissions are assigned via the connector, and you can perform a couple of actions on that vault:

- Push: Update any active secrets in the external vault that are linked with a transform to Secret Server.
- Pull: Retrieve all the secret names in the external vault and create a pointer record.
- Synchronize: Performs a pull (from the external vault) and then a push (to the external vault). Once completed both Secret Server and the external value are updated with the other's changes.

Permissions

Delinea permissions are assigned to the external vault and any secret within the vault uses those permissions by default. On each secret, you can override the vault permissions and assign completely different Delinea permissions.

Role Permissions

Search for **Permissions tab** to set these permissions.

Role permissions:

- Create External Vault Links: Can setup a connection to an existing external vault. Can then assign permissions to other users.
- View External Vaults: Can access the external vault feature but cannot manipulate external vaults.

External Vault Permissions

Vault permissions govern what a Secret Server user can do with the external vault. For example, in AKV:

- Edit Vault: Can change the settings for the vault.
- Edit Vault Permissions: Can assign any Vault permission to any user on the vault.
- Pull: Can execute a pull on the vault.
- View External Values: Can view or set a remote value on any secret within the vault. The user also needs "View Remote Value" or "Set Remote Value" on the secret.
- View Vault: Can view the vault and all information, including Vault permissions.

Vault Secret Permissions

These permissions can be defined on the external vault as well as each secret. The values assigned on the vault are the default permissions used by any secret that inherits permissions from the vault.

> Note: When viewing a Delinea Secret, an “External secrets” tab appears that lists all of the external secrets linked to the secret.

External vault secret permissions:

- Edit External Secret: Able to change any of the fields on the secret including status, linked secret, and transform.
- Edit External Secret Permissions: Can assign any permission to the secret.
- Push: Can run the push action which will apply the linked secret to the transform and then push or update that value in the external vault.
- Set External Secret Remote Value: Can assign a free-form value directly to the external secret. Requires ‘View external values’ on the parent vault.
- View External Secret: Can view the secret and any of the associated information such as permissions and auditing.
- View External Secret Remote Value: Can retrieve and view the actual value for the secret in the external vault. Requires "View External Values" on the parent vault.

Azure Key Vault Integration

In this topic:

- "Introduction" below
- "Connecting with AKV—The App Registration Process" on the next page
- "Creating an External Vault Link" on page 1139
- "Managing External Secrets" on page 1141
- "Bulk Operations with the External Secret Grid" on page 1142
- "Simultaneously Creating Master and External Secrets in AKV" on page 1142

> See "External Secrets" on page 1132 for more on the general topic of Secret Server and external vaults.

Introduction

The Azure Key Vault (AKV) Integration simplifies management and governance of NHI's and secrets from the CSP's native vaults. With AKV you can centrally manage and update secrets to one or more Azure Key Vaults, and rotate passwords or values more frequently. With fine grained roles and permissions, audit and logging, the AKV integration provides increased governance, visibility, and awareness of secrets managed in Azure Key Vault without affecting development velocity or processes. The AKV integration is available on Secret Server Cloud, the Delinea Platform, and Secret Server On-Premises.

With Azure Key Vault Connector, you can:

- Link external vaults to Secret Server.
- Identify and categorize non-human identities into folders.

- Manage and sync secrets from external vaults to a central Delinea vault.
- Control access by applying fine-grained permissions.
- Regularly rotate secrets to maintain a strong security posture.
- Use Secret Server to keep external vaults in sync.

What is Azure Key Vault?

Azure Key Vault (AKV) is a secure cloud service provided by Microsoft Azure for storing and managing sensitive information such as secrets, encryption keys, and certificates. It offers two service tiers: Standard, which uses software encryption, and Premium, which includes Hardware Security Module (HSM) protection. The Delinea AKV connector is a connection to AKV with GUI elements on the Secret Server side.

> Note that Azure Key Vault firewall rules must allow connections from the Secret Server External Secrets service, which uses Azure internal endpoints – Delinea does not publish static outbound IPs for this traffic.

Key features of AKV include:

- **Access Control**: Uses Azure role-based access control (RBAC) for the management plane and either RBAC or key vault access policies for the data plane.
- **Auditing and Monitoring**: Provides logging capabilities for all key vault operations.
- **Certificate Management**: Enables easy provisioning, management, and deployment of TLS/SSL certificates.
- **Encryption**: All secrets are encrypted at rest using a hierarchy of encryption keys protected by FIPS 140-2 compliant modules.
- **Key Management**: Facilitates the creation and control of encryption keys used to protect data.
- **Secrets Management**: Securely stores and controls access to tokens, passwords, API keys, and other sensitive data.

AKV helps solve various security challenges in cloud environments, supporting the "use least privilege access" principle of the zero trust security strategy. It centralizes the storage of application secrets, reducing the chances of accidental leaks.

To use AKV, it must be associated with a resource group within the same application/environment combination. Access to AKV is controlled through two interfaces: the management plane for managing the vault itself, and the data plane for working with the stored data. To learn more access About Azure Key Vault.

Connecting with AKV–The App Registration Process

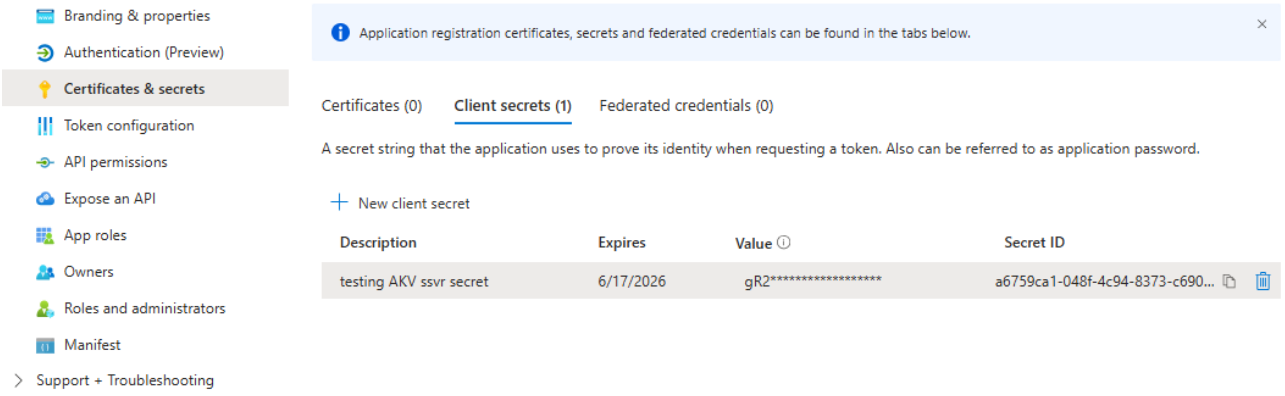
The following two-part procedure makes AKVs available in Secret Server.

Creating a Secret in the Azure Portal

1. Go to your Azure portal.
2. From the **Azure services** section, select **App Registrations**. The aforementioned page loads.
3. Click on the app you want to use from the list.

4. Within the Azure Portal, access **Manage > Certificates and Secrets**.
5. Create a new client secret.

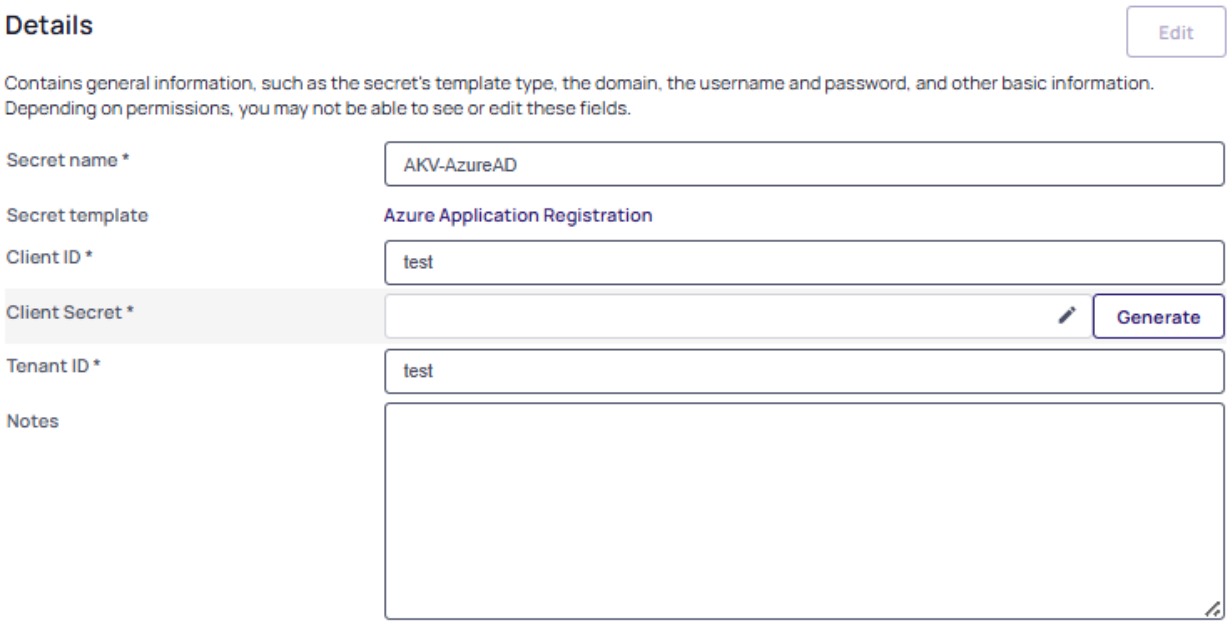
> You must copy the **Value** at the time of client secret creation as Azure will not allow you to go back and copy the value later. If you do not copy the value at this time, you have to create a new client secret.



Creating the Azure App Secret in Secret Server

1. Access Secret Server.
2. Create a new secret using the **Azure Application Registration** template.
3. Fill in the following fields:
   - **Secret name**: give the secret an appropriate name.
   - **Client ID**: Type in the Client ID of the Azure AD Application.
   - **Client Secret**: Type in the Client Secret (Value) for the Azure AD Application.

     Paste the value you copied from the Azure Portal into the **Client Secret** field of the secret in Secret Server:



- **Tenant ID**: Type in the Tenant ID of the Azure AD Application.
- Optionally, fill in the **Notes** field.
- Optionally, change the **Site** field to one you need, otherwise leave as **Default**.

4. Select **Create Secret** to save your changes.

Firewall and Network Requirements

Secret Server External Secrets integration with Azure Key Vault does **not** originate from the Distributed Engine.

Requests to Key Vault are initiated from the Delinea cloud service and are routed using Azure's internal networking.

Because of this:

- Delinea cannot provide a list of specific public IP addresses to allow-list in an Azure Key Vault firewall.
- The integration does not traverse the public internet using a fixed Delinea egress IP.
- If your Azure Key Vault firewall is enabled, you must work with Azure support to allow internal Azure traffic or determine the internal IP ranges and/or Web Application Firewall (WAF) IPs needed for connectivity.

Creating an External Vault Link

> If you intend to use the automatic list feature to select the external vault for the connection, you must have the Key Vault Administrator role inherited in Azure.

1. Access Secret Server.
2. From the left navigation panel, select **Secrets > External Secrets**. The External Secrets page appears.

3. Click the **Create** dropdown button and select **Create External Vault Link**. The Create External Vault Link page appears.
4. For **Type**, select **Azure Key Vault**.
5. For **Credential secret**, select the **No secret selected** link and choose the secret you just created previously in Secret Server during the app registration process. This is the secret that has proper access to query and write to AKV and will be used for all connections.

   The minimum Azure Key Vault data plane permissions required for this secret in Azure under secret management operations are:

   - Get
   - List
   - Set
6. How to grant these permissions in the Azure Portal:
   a. Go to https://portal.azure.com
   b. Navigate to the Key Vault you want Secret Server to manage.
   c. In the **Key Vault** menu on the left, click **Access policies**.
   d. Select **+ Add Access Policy**, to add a new access policy.
   e. In the permissions list, under **Secret permissions**, select the checkboxes for:
      i. Get
      ii. List
      iii. Set

      You can skip other permissions unless you need them.
   f. Click **Select principal**, then search for your App Registration / Service Principal that Secret Server will use.
   g. Select it and click **Select**.
   h. Click **Add**, then **Save** on the main Access policies page.

   That updates the Key Vault's access policy so the Secret Server credential secret has the necessary Get/List/Set rights to the vault.
7. For **Input type**:
   a. If you choose **Automatic List**:
      i. You are automatically presented all available vaults for your Azure subscriptions. Once the Azure key vault account connects, a green **Connected** indicator appears at the top of the page.
      ii. Click to select the checkboxes for the desired vaults.
   b. If you choose **Manual Entry**:
      i. Type the name of the Azure key vault you want to connect to, in the **External Name** text box. This name MUST exactly match the vault name in the external system to correctly link them.

ii. The **Display name** will automatically match the External Name of the vault, unless you manually change it.

8. Select **Save**.
9. You are prompted to synchronize the external vault. This step performs a pull on the vault and then a push on each active and linked external secret. This pulls all the secrets from the linked AKV into the Secret Server UI.
10. Synchronize the vault. The external vault summary page will show these results:
    - Name of the vault.
    - State: enabled or disabled.
    - Last pull status.
    - Number of external secrets
    - Credential secret used
11. Select the **External Secrets** tab to view the list of external secrets.
12. Change the **Status** to **All states** to view the list of external secrets. All external secrets are initially disabled. This means no secrets are synchronized from Secret Server to the AKVs.

> Secret Server's Azure Key Vault External Secrets integration does not use the Distributed Engine or a fixed public egress IP from Delinea that you can allow-list in the Key Vault firewall. Azure routes this traffic internally within its service fabric, and Delinea does not provide a list of static outbound IP addresses for Azure Key Vault calls. If you require Key Vault firewall allow-listing, you must coordinate with Microsoft Azure support for the internal IP ranges or WAF endpoints that would permit access from the Secret Server External Secrets service.

Managing External Secrets

1. Log into Secret Server.
2. Navigate to **Secrets > External Secrets**. The External Secret grid appears.

   After you have linked at least one external vault, you will see a list of external secrets here.
3. In the grid you can:
    - Search for a specific secret.
    - View all secrets, enabled or disabled.
    - View only "enabled" or "disabled" secrets.
    - View or manage permissions.
    - View audit events.
    - View the log.
4. Select a secret in the grid. Now, you can perform a few more actions:
    - **Set remote value**: Sets a new value on the external secret in AKV.
    - **View remote value**: View the current value on the external secret in AKV.

- **Push**: To propagate the changes made through edits to the secret(s).
- **Edit**: Modify the secret and set properties.
- **Enable** or **disable** synchronization for the secret.
- **Select a secret to link to**. That secret serves as the master secret in Secret Server.

  > You can link one or more external secrets to a single master secret. You can sync the same secret/vault from a single master secret to secrets in multiple key vaults.

- Perform Remote Password Changing (RPC) on the master, which propagates to all the enabled linked external secrets.
- **Transform**, which allows you to select the fields you want updated on the external secret(s).

  Transforms are defined in the secret template for the master secret. For example, `Password (password)` links the password field from the master secret and updates all linked enabled external secrets with the value of password field.

  You can also define a string format and insert field values from the linked secret using `$secret.slug.notation`. For example, `Password: $secret.slug.password` sets the external secret value as `password 1234pass`, where `1234pass` is the actual password from the master secret. Transform allows you to copy and paste the slug name or simply click on the + sign to add it in the box below.

Bulk Operations with the External Secret Grid

The external secret grid provides a central location in Secret Server to manage external secrets. When selecting external secrets in the grid, you can select to push or edit these items all at once, which is a bulk operation. This is useful for linking multiple external secrets from one or more vaults to a single master secret.

Performing a bulk operation on multiple external secrets:

1. Select all or a few secrets from the grid.
2. **Push** and **Edit** are now available actions for these secrets.
   - **Push** allows for changes from the master secret or secrets in Secret Server to affect the linked secrets in AKV.
   - **Edit** allows you to perform additional bulk actions such as:
     - Toggle the Synchronization enabled/disabled state.
     - Select **Apply to all** or **Cancel**.

       > The heading shows the number of secrets that will be affected by this bulk action.

Simultaneously Creating Master and External Secrets in AKV

How to create a new master secret along with an external secret at the same time in AKV:

1. Access Secret Server.
2. Create a secret using any template. For this example, use the Azure AD Account secret template.

3. Fill in the secret name, domain, username and password fields and select **Create Secret**. The secret loads automatically on the screen.
4. Select **External Secrets** from the left-hand menu.
5. Click **Create**, then select **Create external secret** from the drop-down.
6. Type in the name of the **External secret**.
7. Choose the **External vault** where you want to create this secret from the drop-down.
8. Choose whether to enable **Synchronization** or not by selecting the checkbox.
9. For **Linked Secret**, click on **No secret selected** and choose the secret you just created.
10. If you want to sync any fields with the external secret, add those to the **Transform** section.
11. From the **Merge secret field** drop-down choose **Password (password)** to sync passwords from the master secret to the linked secret in AKV.
12. Select **Save** to keep your changes.

AWS Secrets Manager Integration

AWS Secrets Manager is a managed service from Amazon Web Services (AWS) that helps securely store, manage, and retrieve secrets. Secret manager supports remote access to their vaults, which we use for this integration.

See "External Secrets" on page 1132 for more on the general topic of Secret Server and external vaults.

Creating a Credential Secret

Step One: In AWS, Create a User and Access Keys

1. Go To **IAM Dashboard**.
2. Click **Users** in the left menu under **Access management**. The Users page appears.
2. Click the **Create User** button. The Specify User Details page of the Create User wizard appears.
3. Type the user name in the **User Name** text box.
4. Click the **Next** button. The Set Permissions page appears.
5. Next, you create a new group for the user or add the user to an existing one. Click the desired existing group or click the **Create Group** button to create one. To create a new group, see **Creating an AWS Group in IAM Dashboard**.
6. Returning to the Set Permissions page, click to select the check box next to the group you want to add the user to.
7. Click the **Next** button. The Review and Create page appears.
8. Ensure the user details are correct.
9. Click the **Create User** button. The new user appears in the table.

10. Click on the new user name in the table. That user's details page appears.
11. In the **Summary** section, on the right, click the **Create Access Key** link. The Create Access Key page appears.
12. Click to select the **Use Case Third-Party Service** selection button.
13. Click the **Next** button. The Set Description Tag - Optional page appears.
14. Type `Secret Server External Vault Integration` in the **Description Tag Value** text box.
15. Click the **Create Access Key** button. The new key is created, and the Retrieve Access Keys page appears. You will see an access key and secret access key. These, along with the username will be needed in Secret Server. Record the values.

Step Two: In Secret Server, Create a Secret

1. Go to the **All Secrets** page.
2. Click the **Create Secret** button. The Create New Secret page appears.
3. Click the **Choose a Secret Template** list and select **Amazon IAM Key**.
4. Click the **Create Secret** button. The Create New Secrets (details) page appears.
5. Fill in the text boxes with asterisks for the username, access key, and secret access key using the recorded values from the last step.
6. Type any name you wish in the **Secret Name** text box.
7. Once again, click the **Create Secret** button. The new secret appears in the All Secrets list.

Step Three: Create an AWS Secrets Manager Link

1. Return to the secrets menu and click **External Secrets**. A page of the same name appears.
2. Click to select the **Enabled** check box if you want to push changes to the vault. Leave it unchecked if you do not want to push changes to it.
3. Click the **Create** button. The Create External Vault Link page appears.
4. Select **AWS Secret Manager** in the **Type** dropdown list.
5. Click the link for the secret you created.
6. If you are using the automatic list feature for external vaults:
   a. You are automatically presented all available vaults for your AWS subscriptions, and Input type is set to Automatic List. Once the AWS key vault account connects, a green Connected indicator appears at the top of the page.
   b. Click to select the check boxes for the desired vaults.
7. If you are not using the automatic list feature:
   a. Set **Input Type** to **Manual Entry**.
   b. Type the name of the AWS key vault you want to connect with in the **Name** text box. The name must **exactly** match the name of the key vault.

8. Type your name for the external vault in the **Display Name** text box.
9. Once you have the correct region, click the **Save** button.

Creating an AWS Group in IAM Dashboard

1. Return to **IAM Dashboard**.
2. Click **User Groups** in the **Access Management** group in the menu on the left. The User Groups page appears.
3. Click the **Create Group** button. The Name the Group page appears.
4. Type a name in the **User Group Name** text box.
5. Add the credential secret if needed.
6. Add needed permission policies. The included, default SecretsManagerReadWrite policy in the **Attach Permissions Policies** table should suffice. If not, add other policies via the search text box in the same section. See **Creating Custom AWS Policies** for details.
7. Click the **Create User Group Button**.

Creating Custom AWS Policies

1. Go To **IAM Dashboard**.
2. Click **Policies** in the left menu under **Access management**. The Policies page appears.
3. Click **Create Policy**. Specify Permissions appears.
4. Click the **Filter by Type** dropdown list and select **Secrets Manager**. The Secrets Manager section appears.
5. Select **Actions Allowed** to view that section. The Access Levels appear.
6. In the **List** section, click to select the **List Secrets** checkbox.
7. In the **Read** section, click to select:
   - DescribeSecret
   - GetSecretValue
   - ListSecretVersionIds
8. In the **Write** section, click to select:
   - CreateSecret
   - PutSecretValue
   - UpdateSecretVersionStage
9. Click the expand the **Resources** section.
10. Click to select the **All** selection button. This allows you to manage all secrets in AWS. For a smaller subset, select **Specific** and scope it to what secrets you want to access.
11. Click the **Next** button at the bottom. The Review and Create page appears.
12. Complete the remaining policy details.
13. Click the **Create Policy** button.

Secret Management Procedures

Secret management is a critical aspect of cybersecurity, involving the secure handling of digital authentication credentials, such as passwords, API keys, and encryption keys. Effective secret management ensures that sensitive information is stored, accessed, and transmitted securely, preventing unauthorized access and data breaches. Key components include creating secret policies, which are sets of rules applied to multiple secrets to enforce security settings and password requirements, and creating secrets by selecting a template and configuring settings such as automatic password changing. Customizing the All-Secrets page allows for efficient management and viewing of secrets by displaying specific columns and filtering results based on various criteria. Additionally, secrets can be deactivated, reactivated, duplicated, edited, and erased as needed to manage their lifecycle and ensure that only active secrets are in use.

Other important aspects of secret management include overriding the secret template's password requirements for individual secrets, setting up password masking to hide actual password characters, and sharing secrets with specific permissions to facilitate collaboration while maintaining security. Viewing secrets involves accessing stored information through the All-Secrets page or individual secret pages, with Delinea permissions controlling who can view specific secrets. Secret configuration options, such as automatic password changing and expiration policies, help manage the security and lifecycle of secrets. The search functionality allows users to find specific secrets based on various criteria, ensuring accurate and up-to-date search results.

Creating Secret Policies

A secret policy is a set of rules that you can apply all at once to multiple secrets. For example, a secret policy could include rules about remote password changing or security settings, and you could apply all of the rules as a single policy to multiple secrets, whether the secrets reside in the same folder or different folders.

Follow the procedure below to create a secret policy:

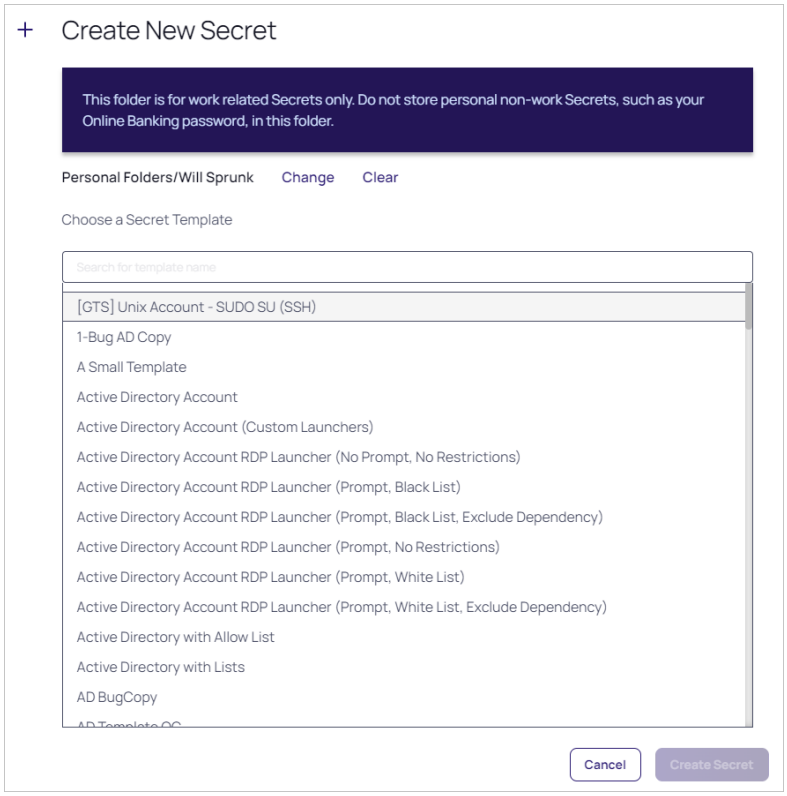
1. Search for **Secret Policies**. The Secret Policy page appears.
2. On the **Secret Policy** page, click **Create secret policy**. A popup appears.
3. In the Secret Policy popup type a **Name** and **Description** for your new security policy.
4. Click to select the **Enabled** check box next to the State field.
5. Click **Save**. The new policy's page appears on the Policy tab and Summary subtab.

   Because you are creating a brand-new secret policy, the value in the setting column for many policy items is *(Not Set)*.
6. Click each subtab in turn and click the **Edit** button to set which parameters are enforced. See the various topics for specifics about each parameter.

Creating Secrets

To create a secret:

1. Click the **+** icon and select **New Secret**. The Create New Secret page appears:

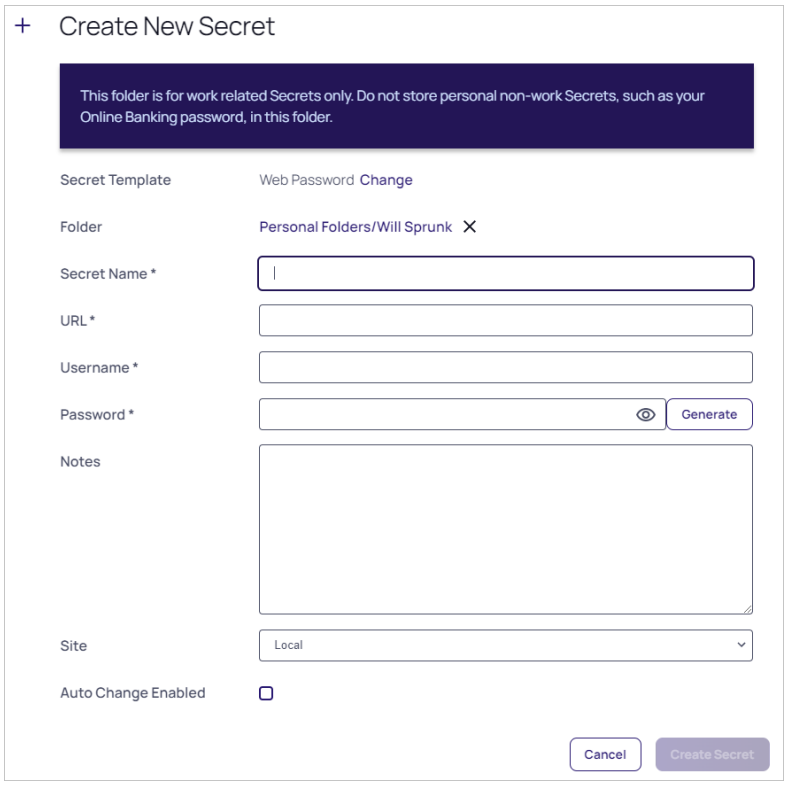


2. Click the **Choose a Secret Template** list or type a template name in the **Search for template name box** to choose a template from which to create the secret .

> If you do not find a suitable template available, you can create a custom template.

3. Click the **Create Secret** button. A Create New Secret page appears.

> These pages differ significantly, based on the secret template you chose. For this instruction, we chose the frequently used Web Password template.



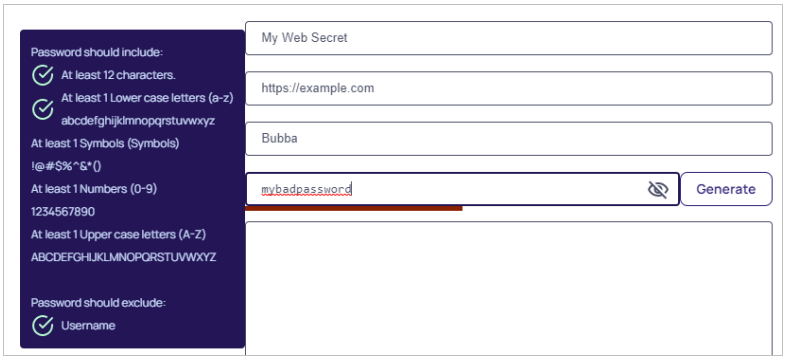
4. Complete the text boxes and selection controls on the page.

> The password generator is governed by a password requirement, which is usually set via the secret template. However, you can override the template for this secret and set the requirement to something different in the Password Requirements section of the Security tab, *after* you create the secret.

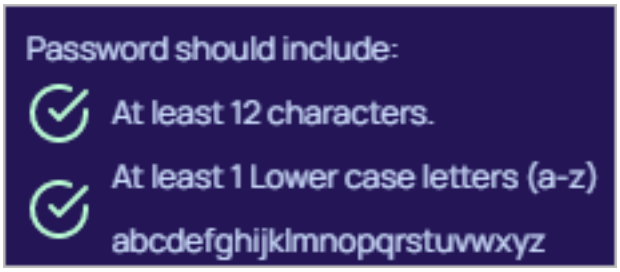
5. Click the **Generate** button to create a strong password that meets the requirements for that type of secret. You can also add your own.

> Click the eyeball icon to see a list of the current requirements and what you have already typed. The maximum password length is 1024.

The bar below the text box indicates the strength of the password you enter–it stays red but gets longer as the password quality improves.



As you meet each requirement, a green checkmark appears next to it.



Once you have met all the requirements, the color bar is full length and green.

6. Click the **Sites** dropdown list to select a site the secret belongs to.
7. (Optional) Click to select the **Auto Change Enabled** check box to enable automatic remote password changing (RPC) for the secret.
8. Click the **Create Secret** button. The new secret's page appears.
9. Click any of the tabs to further configure the secret.

> It is possible to import data as secrets. See "Importing Secrets" on page 1124.

Customizing the All-Secrets Page

On the main menu, there is a **Secrets** folder tree. When you click on the root or any subfolder, you see a list of all the secrets in that folder with multiple columns. You can customize what you see in one of three ways:

Customizing Visible Columns

You can display additional columns on the grid by clicking the icon. This data can be either secret metadata or template text-entry fields that have been set to be available for viewing. To select additional columns to display, click the **Advanced** link and then the **Column Selection** link. You can display the following metadata fields:

- Auto Change Enabled
- Checked out

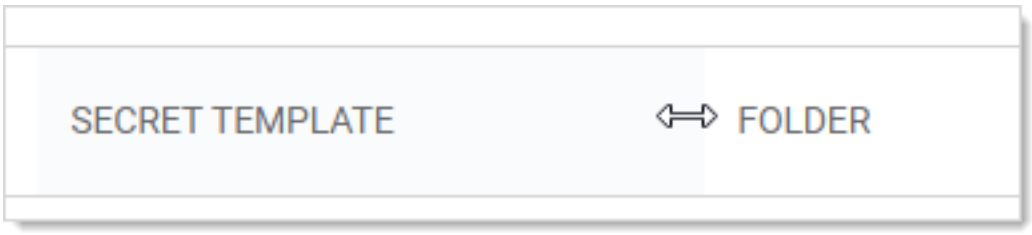
- Checkout Enabled
- Created
- Days until Expiration
- Deleted
- Double Lock Enabled
- Expiration Field Changed
- Folder
- Inherits Permissions
- Heartbeat
- Hide Password
- Last Accessed (When the logged in user last accessed a secret, not the last time a secret was accessed by anyone)
- Machine
- Notes
- Requires Approval
- Requires Comment
- Secret Template
- Username

Filtering Search Results

You can filter secret search results by selecting a folder on the left, either by clicking it or using the search text-entry field above the folder tree. On the right side of the widget, secrets can be filtered further by specifying search criteria in the top text box. The Advanced section allows filtering by secret template and status, as well as the option to include secrets contained in subfolders. Advanced criteria only remain in effect while those options are expanded (visible).

Sizing Columns

You can resize any of the columns by hovering the cursor over the border between them till it turns into a double arrow:



Click and drag to resize the column.

Deactivating and Reactivating Secrets

Secrets are **not** removed forever in Secret Server. Instead, they are *deactivated*. This maintains an audit trail for secrets, even ones that are no longer used. Administrators or users with specific Delinea permissions can view or even reactivate deactivated secrets.

In rare circumstances, such as for regulatory compliance, where deactivation is insufficient, you can instead *erase* secrets. See "Erasing Secrets" on page 1153 for details.

> We strongly recommend against deactivating large numbers of secrets, which negatively affects performance over time. Secret Server is not a transactional system–it is not designed to handle large numbers of deactivations. Deactivated secrets continue to use database table resources forever.

> Users must have ownership and the View Inactive Secrets permission to view inactive secrets. The Deactivate Secret permission is required to deactivate a secret.

To deactivate a secret:

1. Navigate to the secret **View** page by searching or drilling down the folder tree.
2. Click the **Options** dropdown list and select **Deactivate**. A confirmation appears.
3. Click the **Confirm Deactivate** button.
4. The secret is logically deleted and hidden from users who do not have a role containing the View Inactive Secrets permission.

> Secret Server uses deactivations to maintain the audit history for all data. However, deactivated secrets are still accessible by administrators (like a permanent Recycle Bin) to ensure that audit history is maintained and to support recovery. A user must have the View Inactive Secrets permission in addition to Owner permission on a secret to access the secret View page for a deactivated secret. For more information about these permissions, see "Overview of Users, Roles, User Groups, and User Teams" on page 1302 and " Sharing Secrets" on page 1163.

To reactivate a secret:

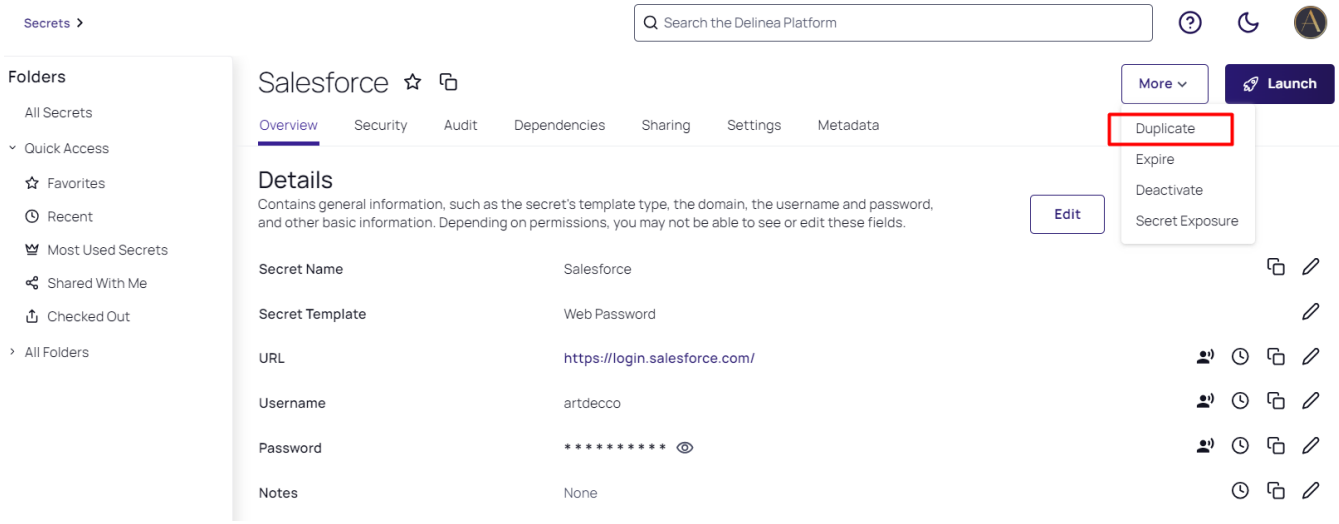
1. Navigate to the secret view page.
2. Click the **Active** menu link and select **Inactive**. The secret list now shows inactive secrets.
3. Click the name link for the desired secret. Its secret page appears.
4. Click the **Options** button and select **Activate**.

> Secrets can also be deactivated and reactivated in bulk. See "Bulk Operations" on page 195.

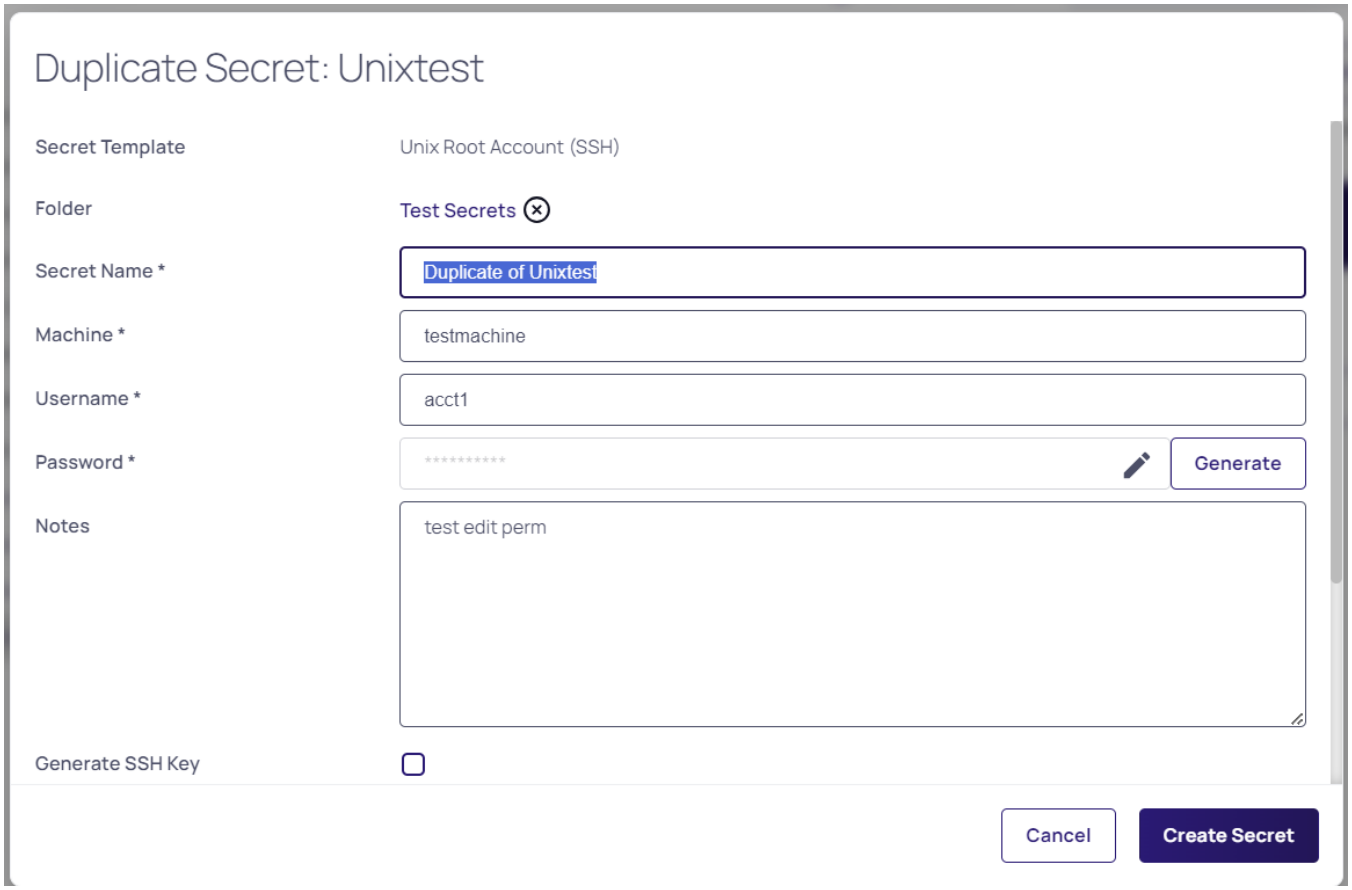
Duplicating Secrets

The secret duplication function allows for easier, automatic secret duplication. Any user with the Owner Secret permission on a secret can create a new secret with information based on the original secret.

1. To duplicate a secret, select the related secret, click **More** at the top right, and select **Duplicate** from the drop-down.



2. Enter the duplicate secret's name, the related machine, user name and password, optionally add a note, and check Generate SSH Key if you would like the SSH key to be generated for the secret. When done, click **Create Secret**.



When duplicating a secret, the following data will be copied over from the source secret to the target:

- Text-entry field information - secret name, machine, username and password.
- Launcher settings - see Secret Launchers and Protocol Settings for details.
- Secret settings - email and expiration settings.
- Double locks - enabled or disabled.
- Permissions - see Secret Permissions for details.
- Audit records - will be written to the source secret and target secret to indicate that a copy operation took place.

> Note that currently the file attachments are not copied.

Editing Secrets

> If using the Dashboard, see "Application Dashboard" on page 182.

To edit a secret:

1. Navigate to the secret's **View** page by searching or drilling down the folder tree.
2. Click the desired tab for the secret configuration.
3. Click the **EditAll Fields** link. All text-entry fields become editable.

> The password generator is governed by a password requirement, which is usually set via the secret template. However, you can override the template for this secret and set the requirement to something different in the Password Requirements section of the Security tab after you create the secret.

4. For passwords, you can create a random password with the **Generate** button (on the General tab). This generates a password according to the rules set at the template level (see secret templates for more information about password requirements).
5. Click the **Save** button.

> For more information, see "Secret Configuration Options" on page 1166.

Erasing Secrets

Erasing a secret permanently destroys (scrambles) the secret's data and makes the secret less visible to both users and admins. For users who have access to inactive secrets, however, the secret is still visible in the folder view for auditors and other secret users to confirm data destruction.

> Erasure is primarily for regulatory compliance. Deactivation is for day-to-day operations.

Erasing and deactivating secrets are not the same thing. When deactivated, secrets are **not** removed forever. This maintains an audit trail for secrets, even ones that are no longer used. Administrators or users with specific Delinea

permissions can view or even reactivate deactivated secrets. See "Deactivating and Reactivating Secrets" on page 1151 for details.

> We strongly recommend against erasing large numbers of secrets, which negatively affects performance over time. Secret Server is not designed to handle large numbers of erasures. Erased secrets continue to use database table resources forever even though their data is destroyed. Erasure is not for cleaning up the secret database.

> Ownership and the **Erase Secret** permission are required to erase a secret. In addition, the erasure must go through an approval process. Users cannot approve their own erasure.

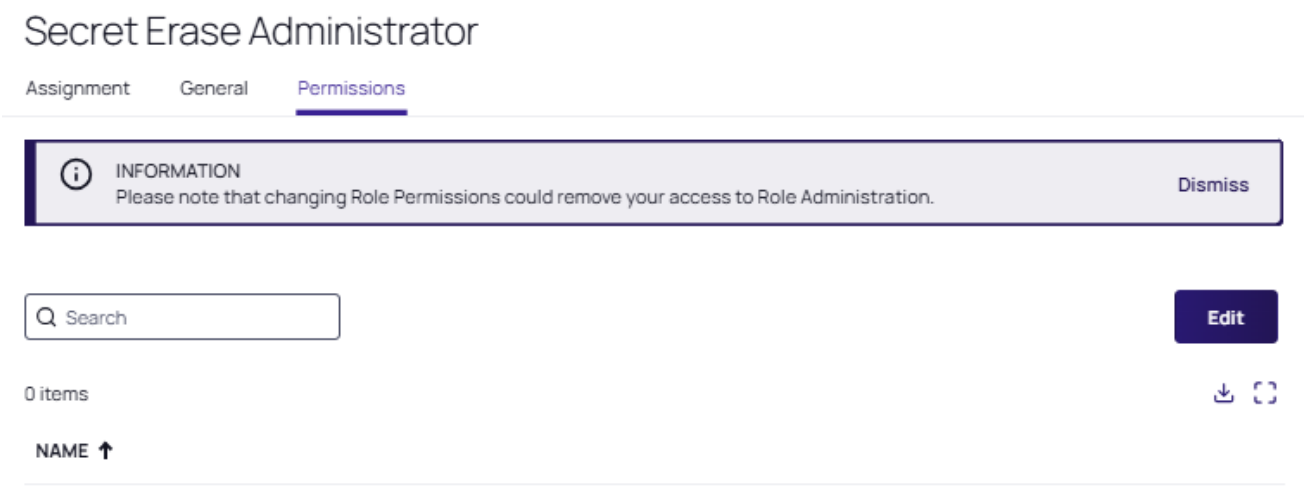
> These instructions assume you know the basics of access requests, groups, roles, and permissions. We also suggest reading the introductory material for "Workflow Overview" on page 1101 if you are not familiar with it.

Task 1: Configuring Secret Erase

> If secret erasure is already configured on this server and you are in the Secret Erasers group, you can skip to Task 2.

> These instructions are applicable for Secret Server and the Delinea Platform ununified mode or Secret Server On-Premises. If you are using Secret Server and the Delinea Platform unified mode, the new role will need to be created in the Delinea Platform

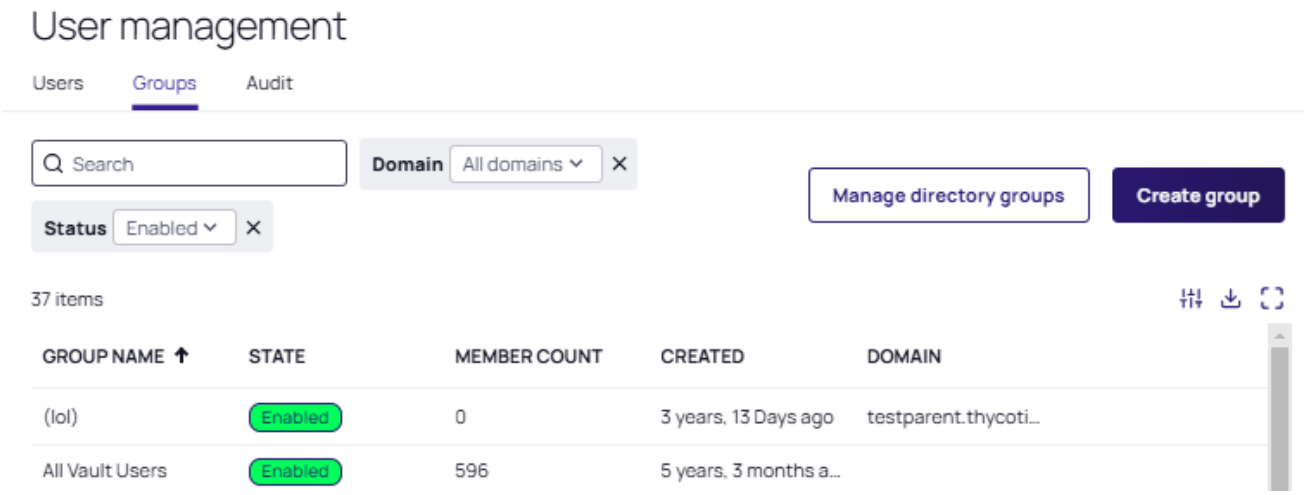
1. Ensure that you have a workflow license for Secret Server.
2. Search for **Roles** in Secret Server.
3. Create a new role named "Secret Erase Requester" or "Secret Erase Administrator" (see "Creating Roles" on page 1287 for details), make sure the **Enabled** checkbox is selected.
4. Assign the **Erase Secret** permission to the secret you just created by accessing the **Permissions** tab for the role and selecting **Edit**:



In the **Scope** drop-down menu select **All**, so that all permissions available are shown, search for **Erase Secret**, select it, and click **Save**.

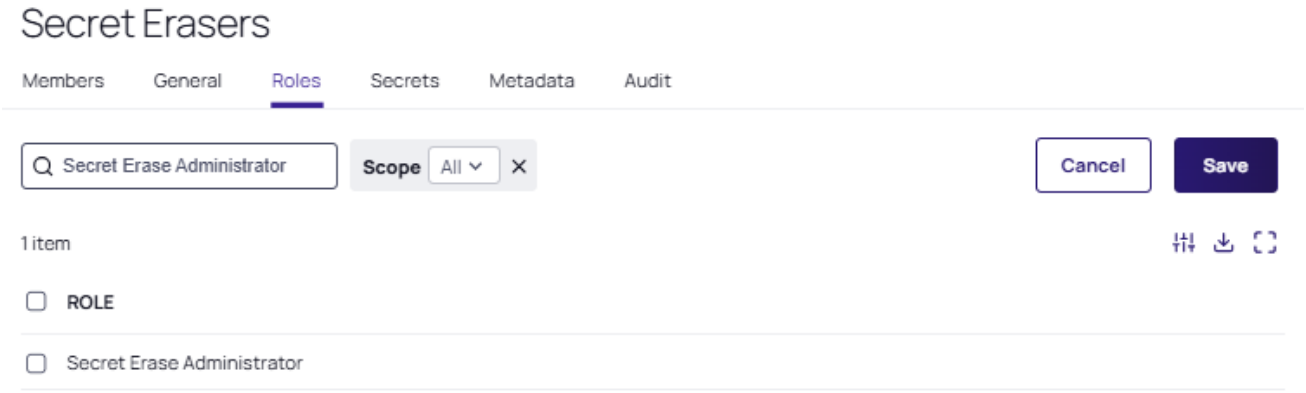
> This role permission allows users with the role to create secret erase requests and view secret erase administration pages.

5. Search for **Groups**. The **Groups** tab of the **User Management** page appears:

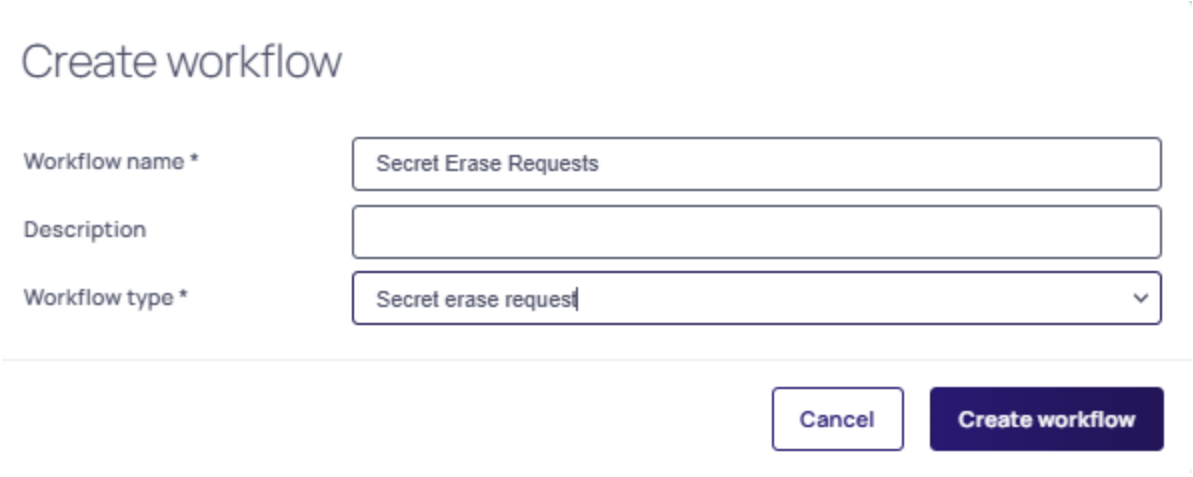


6. Create a group named "Secret Erasers", making sure the **Enabled** checkbox is selected. Once the new group is created its page loads automatically, click the **Roles** tab.

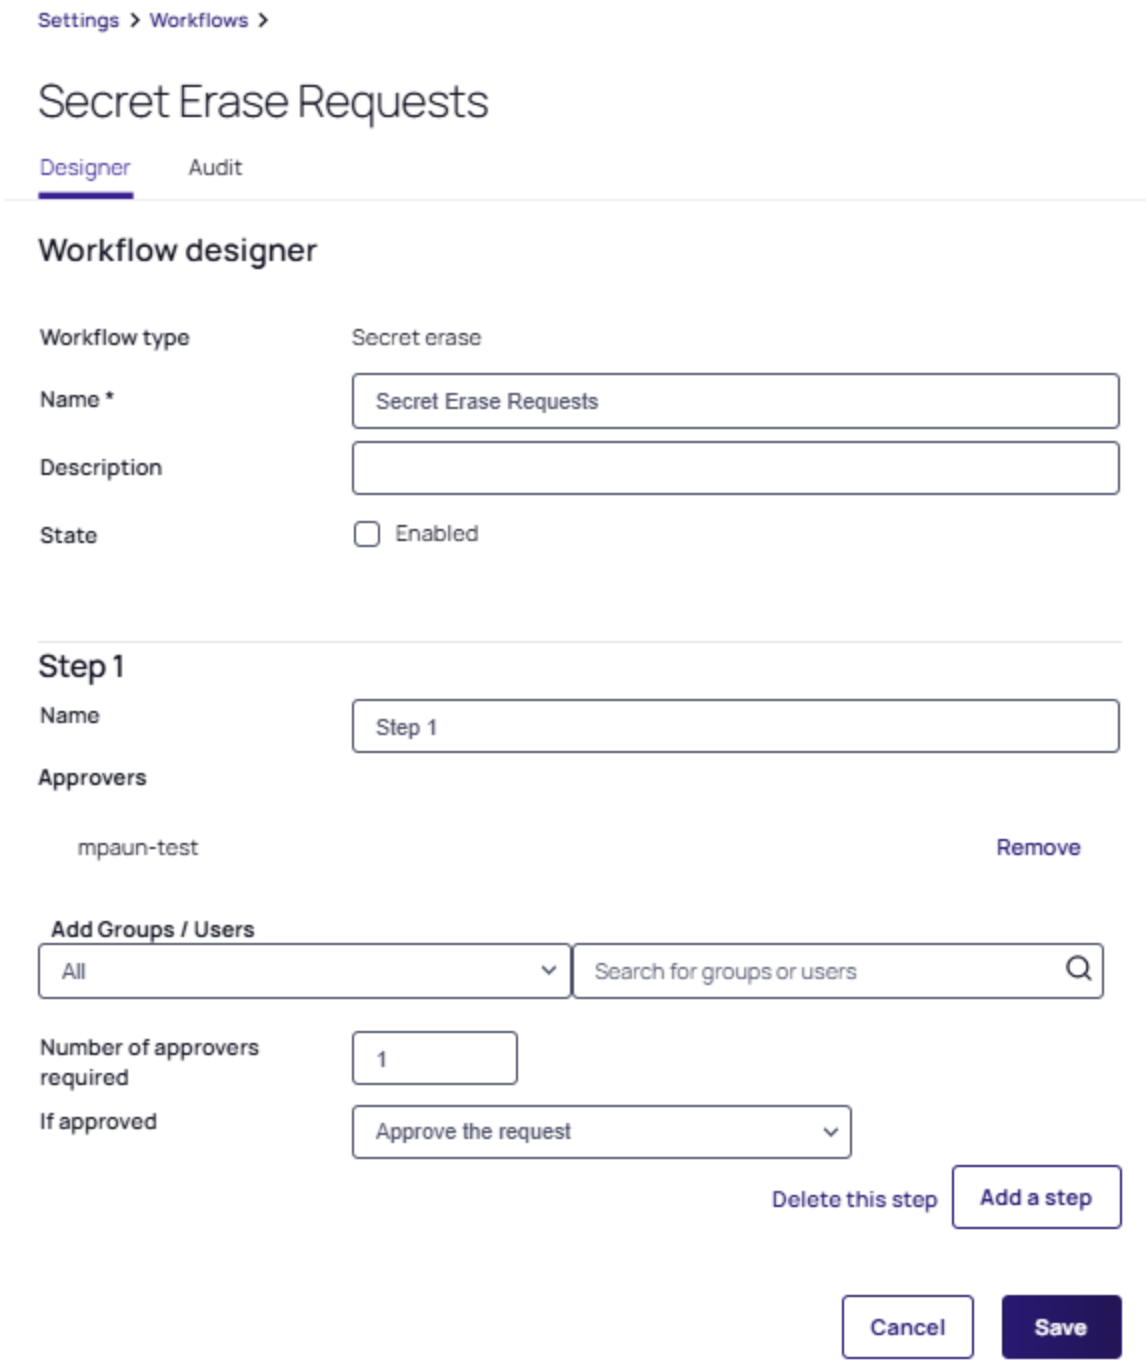
7. Click **Edit**, change the **Scope** to "All", and search for the role you just created, select it and click **Save**:



8. Click the **Members** tab to add yourself to the **Secret Erasers** group.
9. Search for **Workflow**.
10. Create a "Secret Erase Requests" workflow template, assigning it the **Secret Erase Request** type:



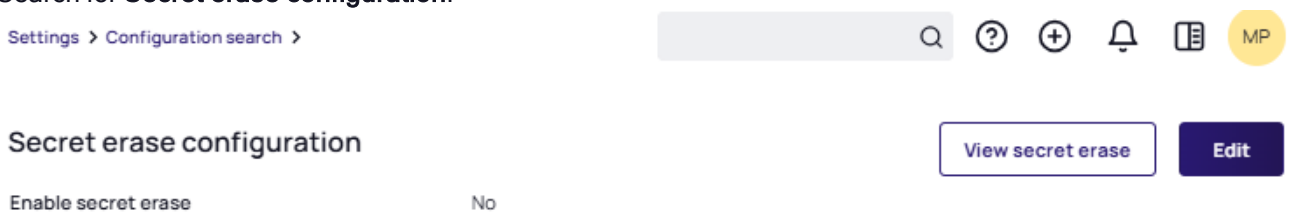
11. The workflow designer (**Designer** tab) loads automatically upon creation. In this tab, assign one or more users or groups as approvers by typing each in the search text box in the **Add Groups / Users** section and then selecting your choice when it appears. This selection then appears in the **Approvers** list box:



When satisfied, make sure the **Enabled** state is checked and click **Save**.

> Typically the approvers you choose should be in the same group as those that can make the requests. You can, however, choose any groups or users you like or make a group just for approvals. It is important to note that the same *user* cannot make both the request and approve it, in order to avoid a single person making an irreversible, potentially very harmful, mistake.

12. Search for **Secret erase configuration**:



13. Click **Edit** and select the **Enable secret erase** checkbox. The **Secret erase workflow** dropdown list appears.
14. Choose from the dropdown list **Secret Erase Request** and click the **Save** button. Secret Erase is now set up.

> If the **< None >** option is the only one available in the dropdown, you will not be able to complete the setup because a valid **Secret Erase Workflow Template** is required to enable **Secret Erase**.

Task 2: Erasing a Secret

1. Ensure the following requirements are met for the secret you intend to erase. Ensure the secret:
   - Is inactive
   - Is owned by you
   - Does not have a pending secret erase request
   - Is not double-locked
   - Is not checked out by another user
   - Is not a discovery secret
   - Is not a domain sync secret
2. For this instruction, create a secret for testing in your personal folder to ensure all the requirements are met.
3. You can erase the secret via a dashboard bulk operation. Erase is accessed by the **Bulk Actions** button, with the **Erase secrets** option nestled under the **Security** section of the Bulk Actions popup. See "Bulk Operations" on page 195 for details.

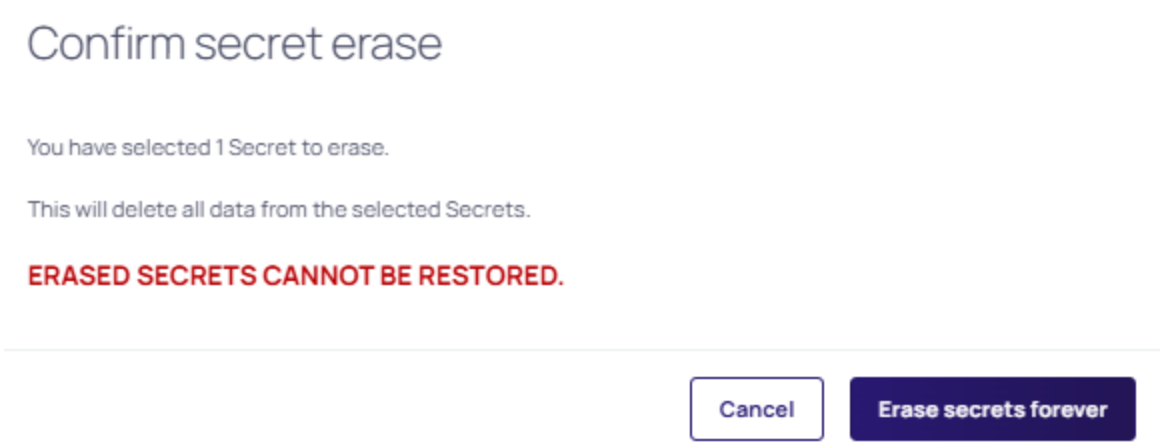
> If the "Erase Secrets" link does not appear in the **Security** section as shown above, you may not have properly configured secret erase (see Task 1), you may have not have enabled the Secret Erase Workflow or the secret might not meet one of the requirements.

4. When you click the **Erase Secrets** link, the Erase Secrets popup appears:

   This is where you set up an erase secrets request. When you complete the process, the access request is sent to the users or user group you designated earlier for approval.

5. Use the calendar and time widgets to set the **Erase After Date**. It must be a minimum of 24 hours away to give the erase secrets request time to process. If you set it to less than that, you cannot continue the process.
6. Type your reason for permanently erasing the secret or secrets in the **Reason** text box. The granter will need this to decide whether to let you take this irreversible, destructive action. Specifically, explain why a deactivation is not sufficient. A reason is mandatory for the request to be processed

7. Click the **Erase** button. A confirmation popup appears:



8. Pause a second, to make sure you are certain.
9. Click the **Erase Secrets Forever** button.

> Errors might occur at this step if the secret is Active at the time of the request and/or if the there is no SecretId.

10. When the erase request is approved, the secret or secrets will be erased by an automated process after the "erase after" date and time arrives.

Overriding the Secret Template's Password Requirements

All secrets inherit a set of password requirements (see "Template Password Requirements" on page 1206) from their parent secret template. After you create a secret, you can choose to use a different password requirement for this one secret, which leaves other secrets based on the template as they were. To choose a different password requirement for the secret:

1. Navigate to the **Secret Details** page by searching or drilling down the folder tree.
2. Click the secret to open the secret's page.
3. Click the **Security** tab.
4. Click the **Edit** Link under **Password Requirements**. The Edit Password popup appears.
5. Click the Password Requirement dropdown list to select the password requirement you desire.
6. Click the **Save** button.

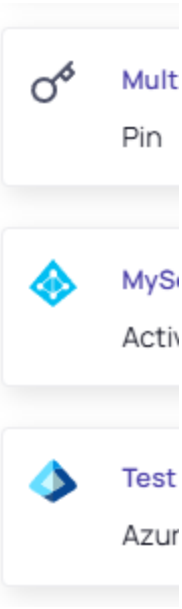
Secret Icons

Secret Icons allows you to display icons for secrets in the secret list, and the secret details page.

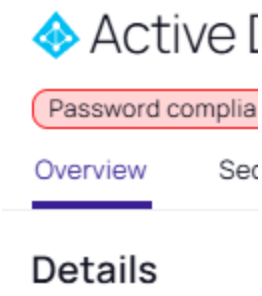
Icon Display in Different Views

Icons display differently depending on the secret view:

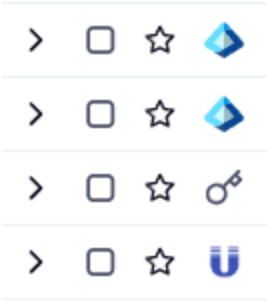
- **Card View**: The icon appears just to the left of the secret title.



- **Detail View**: The icon displays just to the left of the secret name in the title section.



- **Grid View**: The icon has its own "Icon" column, which can be hidden or moved within the column row.



Favicon Gathering

Favicons are icons that are representative of a website. They appear in places such as tabs and bookmarks. Secret Server's favicon is the Delinea D.

By default, Secret Server grabs the favicon from any website that is associated with a secret or secret template, even if secret icons are not enabled. This is for convenience–once you enable secret icons, secrets and secret templates will set their own icon automatically.

You may wish to disable (see the note below) this behavior:

1. Go to **Settings**
2. Search for and select **User Experience**. The User Experience page appears.
3. Click the **Edit** button.
4. Deselect the **Enable icon gathering** checkbox.
5. Click the **Save** button.

> Favicon gathering can cause unexpected traffic to hit the public internet as Secret Server gathers those favicons.

Displaying Icons

Application Level

Before you can use secret icons in any context, you must enable their use in Secret Server:

> Secret icons are disabled by default.

1. Go to **Settings**.
2. Search for and select **User Experience**. The User Experience page appears.
3. Click the **Edit** button.
4. Select the **Show icons for secrets** checkbox.
5. Click the **Save** button.

Template Level

In the general section on any template, there is a **Display Icon** setting that allows users to select a component library icon or clear it to revert to the default skeleton-key icon.

Secret Level

In a secret's **Settings** tab, there is a **Display Icon** setting that allows users to select a component library icon or clear it to use the template setting icon. This supersedes any icon set on its template.

A secret's icon display varies by the presence of a URL field:

- Secrets without a URL field display the icon set on the secret. If no icon is set on the secret, the icon set on the template is used.
- Secrets with a URL field display the icon in the following order:

1. First, the icon set on the secret is used. This is also how the URL's favicon can be overridden.
2. If no icon is set for the secret, Secret Server attempts to fetch the favicon from the URL site. Favicons are icons that are representative of a website. Secret Server's favicon is the Delinea D.
3. If no favicon is available, the icon of the secret's template is used.

Sharing Secrets

This topic applies to **Secret Server On-Premises**, standalone **Secret Server Cloud**, and **Delinea Platform**.

Sharing passwords is crucial for information technology teams. Due to the sensitive nature of sharing secure information, Secret Server ensures shared passwords are tracked and guarded.

Secret Permissions

There are four secret permission levels to choose from when sharing secrets with another user or group:

- **View**: The user may see all secret data, such as username and password, as well as metadata, such as permissions, auditing, history, and security settings.
- **Edit**: Users with Edit permission can modify secret data. They can move secrets to another folder unless the **Inherit Permissions from Folder** setting is enabled, which requires Owner permission to move the secret. The ability to share secrets is now exclusively available to users with Owner permission.
- **List**: The user may see the secret in a list, such as a list returned by running a search, but won't be able to view any other details about the secret nor edit it.
- **Owner**: The user may change all of the secret's metadata.

Password text-entry fields are not visible if a secret has a launcher and the **Hide Launcher Password** setting is on, or if the user does not have the **View Launcher Password** role permission. See the table below for more details.

Secrets can be shared with either groups or individual users. The secret **Sharing** section allows secrets to be configured for access.

Password Visibility

Password visibility in the password text-field depends on secret access permission, role permissions, and secret security policy settings. The following table shows the possible combinations and their password visibility result.

Table: Password Visibility Determinants

Secret Access Permission	View Launcher Password Role Permission	Hide Launcher Password Policy Setting	Password Visible
Owner	No	On	**Yes**

Secret Access Permission	View Launcher Password Role Permission	Hide Launcher Password Policy Setting	Password Visible
Owner	Yes	On	**Yes**
Owner	Yes	Off	**Yes**
Owner	No	Off	**Yes**
Edit	Yes	On	**Yes**
Edit	No	On	**Yes**
Edit	Yes	Off	**Yes**
Edit	No	Off	**Yes**
View	Yes	On	No
View	No	On	No
View	No	Off	No
View	Yes	Off	**Yes**
List	Yes	On	No
List	No	On	No
List	Yes	Off	No
List	No	Off	No

Procedure

To simplify the sharing process, new secrets automatically inherit the settings from the folder they are stored in. That is, the **Inherit Permissions from Folder** checkbox on the **Sharing Edit** page is enabled by default. Given that, secrets inherit all the parent folders' sharing settings, and you cannot set the permissions for the secret. Deselect this option to add or remove users/groups you wish to share the secret with. For more on folder security, see the "Folders" on page 1075 section.

If your configuration is integrated with Delinea Platform and not restricted by teams, as well as having the **Administer Platform Integration** or the **Add from External Directory** permissions, you will see the **Add from External Directory** toggle. Enable that toggle to search directories connected via Delinea Platform and add new users or groups when sharing secret permissions.

To add or remove secret sharing:

1. View the secret you want to share. The secret's page appears on the Overview tab.
2. Click the **Sharing** tab.
3. Click the **Edit** link. The page becomes editable.
4. Ensure the **Inherit permissions** checkbox is deselected so that editing is possible.
5. Enable the **Add from External Directory** toggle. The **Member Type** and **Directory Source** filter dropdowns appear.
6. Change the **Scope** dropdown setting to **All** to view all users and groups, assigned and unassigned alike.
7. Click the **Member Type** dropdown list to limit the scope of your search.
8. Click the **Directory Source** dropdown list to limit the scope of your search.
9. Type into the search text box any user, group name or keyword in their title that whom you want to add to the assigned list or alternatively remove from the assigned list for the secret.
10. When the user or group appears in the dropdown list, select it, grant it one of the four permissions, and **Save**. The user or group appears in the **Shared with** list in the **Sharing** tab automatically.
11. Click **Save** to apply all pending changes, or click **Cancel** to reverse any changes.
12. Repeat the process for additional users or groups.

You can also modify sharing settings for users or groups that already have sharing enabled for the secret. If a user or group is not displayed, they do not have access to the secret.

The **Add from external directory** toggle searches all identity sources configured in Delinea Platform and allows creation of those users and groups in secret-server.

Troubleshooting

When a user cannot see users/groups to share secrets with, despite having been granted all necessary permissions, ensure you haven't customized their permissions outside of the built-in roles. Verify if the user is part of a Secret Server Team, and if so, they need the **Unrestricted By Teams** permission to view users/groups. See User Teams for further details.

Viewing Secrets

To view the information contained in a secret:

1. Locate the desired secret in one of these ways:
   - On the main menu, drill down the folders tree to select the secret.
   - Click the **Secret** menu item on the main menu and find the secret in the **All Secrets** table. You can filter the list or click the magnifying glass icon to search for the secret.
2. Click on the secret's name link. The secret's view page opens to the General tab.
3. Click the desired tab to view specific information. For example, click the General tab and go to the Expiration and Heartbeat section to see if the secret's password has expired and what its expiration interval is. You can

check the history of the secret by clicking the Audit tab.

4. "Editing Secrets" on page 1153 if desired.

Secret Configuration Options

Common Configuration Options

These are the configuration options that are common to every secret:

- **Convert Template:** Change which template is being used to store and display information in this Secret.
- **Copy Secret:** Create a duplicate copy of the secret, which may also be renamed and modified.
- **Delete:** Delete the secret.
- **Edit:** Edit the secret parameters.
- **Favorite:** Click the star from the Dashboard or check this box on the Secret View page to mark the Secret as a favorite. It then displays in the Favorite Secrets widget.
- **Folder:** Folder location of the secret. The secret inherits Delinea permissions of this folder, depending on the Default Secret Permissions setting in the Secret Server Configuration options.
- **Share:** Configure the sharing settings, or permissions, for the secret.
- **View Audit:** View the secret audit log to see which users have accessed the secret and the actions that have been performed.
- **Site:** The site serves as the designated location for storing secrets. Any operations necessitating a Distributed Engine (DE) will utilize the site specified, along with the DEs associated with that site.

Advanced Configuration Options

These are the buttons, fields, and icons that are available for more advanced secrets:

- **Expire Now:** Expire the secret manually.
- **RDP Launcher Icon:** Click to open the Remote Desktop Protocol (RDP) Launcher. See further details in the Launcher section.
- **Run Heartbeat:** Initiate heartbeat, which attempts to verify that the secret credentials can authenticate.
- **Site:** Edit the secret to set the site on the secret. This determines where password changing, heartbeat, and proxied sessions run from.

Searching and Search Indexer

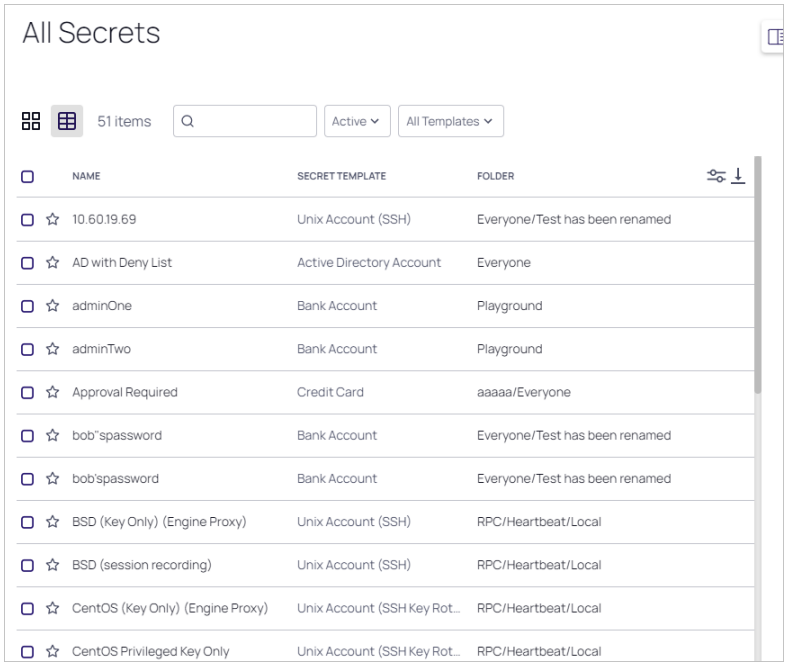
Note: The Search Indexer feature is available only in Secret Server On-Premises deployments. This feature is not available in the Delinea Platform or Secret Server Cloud.

Searching for Secrets

Secret Search can use full text indexes to improve search performance. This is recommended for systems with 10,000 secrets and is important for systems with over 1,000,000 secrets. Full text indexing for secret search is enabled by default in Secret Server Cloud.

To search for secrets:

1. Click the **Secrets** menu item in the main menu. The All Secrets page appears:



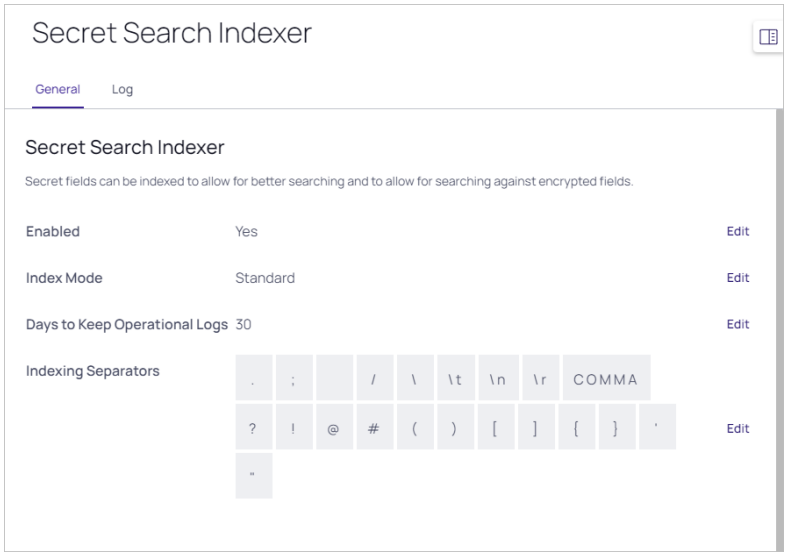
2. Type the secret name or related text in the search box at the top of the page. The All Secrets table now only displays matching secrets. When the extended search indexer is enabled, searches include all text-entry fields that are configured as searchable on the secret's template.

> If the search indexer is not enabled, searches are only performed on the **Secret Name** text field.

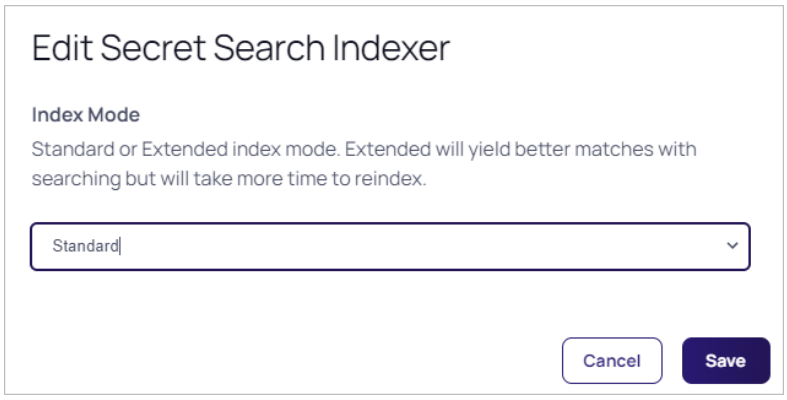
Search Indexer

The *search indexer* allows searching on all text-entry fields set to searchable on the template. To enable and configure the search indexer:

1. Search for **Secret search indexer**. The Indexing Service page appears:



2. Click **Edit** next to the **Enabled** field to ensure the check box is selected. Click **Save** in the popup if you changed anything.
3. Click **Edit** for the Index Mode. A popup appears:



4. Click the dropdown list to select either **Standard** or **Extended**:
   - *Standard search mode* is the default and searches on whole words in a field value. For example, a field value of "My AWS Secret" would match when you search for *My AWS Secret*, *My*, or *Secret*.
   - *Extended search mode* searches for whole words or a partial words by up to twelve characters. For example, a field value of "My AWS Secret" would match when you search for *My AWS Secret*, *My*, *Secret*, *WS*, or *ecret*. This is more useful, but may impact search performance and creates a larger index table.

> Indexing separators are used to split the text text-entry fields into search terms. By default, the separators are semi-colon, space, forward slash, back slash, tab (\t), new-line (\n), return (\r), and comma. Changes to the indexing separators require a full rebuild of the search index.

5. Click the **Save** button.
6. Click **Edit** to change the **Days to Keep Operational Logs** spinner to set the period to keep indexing-related logs that might contain PII. Secret Server automatically deletes logs older than that (in days).
7. Click the **Save** button. The Indexing Service page reappears, and the indexing begins in the background. Depending on the size of the Secret Server installation, it may take awhile. Progress is shown on the Progress bar.
8. If you changed the indexing separators, click the **Rebuild Now** link.

Enabling Full Text Indexing

1. Install Full Text Engine - ensure that the full text engine is installed on your SQL Server.
2. Start MSSQL Filter Daemon Service to support full text indexing.
3. Execute T-SQL Commands:

```
CREATE FULLTEXT CATALOG SsFullTextCatalog AS DEFAULT;
CREATE FULLTEXT INDEX ON tbSecret (
SecretName LANGUAGE 1033,
SecretNameShort LANGUAGE 1033
) KEY INDEX PK_tbSecret ON SsFullTextCatalog WITH CHANGE_TRACKING AUTO;
CREATE FULLTEXT INDEX ON tbSecretItem (
ItemValue LANGUAGE 1033,
ItemValue2 LANGUAGE 1033
) KEY INDEX PK_tbSecretItem ON SsFullTextCatalog WITH CHANGE_TRACKING AUTO;
ALTER FULLTEXT INDEX ON tbSecret START FULL POPULATION;
ALTER FULLTEXT INDEX ON tbSecretItem START FULL POPULATION;
```

The indexing process typically takes about 5 seconds to complete. The changes will take effect within 60 minutes. Alternatively, bouncing the web node will make the changes take effect immediately.

Verification of Full Text Indexing

Utilize extended events or SQL trace via sqlprofiler.exe to monitor the queries.

- If you see *LIKE '%' + @searchTextEscaped + '%'* in the query text, the full text index is not in use.
- If you see *CONTAINS(si.ItemValue, @searchTextFullTextQuoted) OR CONTAINS(si.ItemValue2, @searchTextFullTextQuoted)* in the query text, the full text index is in use.

Secret Expiration Overview

Secret expiration is a core feature of Secret Server that enhances security by ensuring sensitive data is regularly reviewed and updated. Secret expiration allows any template to be set to expire within a fixed time interval. For a secret to expire, a specific field, such as a password, must be selected as the target of the expiration. For example, a secret template for Active Directory accounts might require a password change every 90 days. If the password remains unchanged past the specified time, the secret is considered expired and appears in the Expired Secrets panel on the Dashboard or Home page.

Benefits

- Security: Reminds users to review and update sensitive data regularly.
- Compliance: Helps meet compliance requirements that mandate regular password changes.
- Automation: When combined with RPC, Secret Server can automate the process of changing passwords regularly.

Setting Up Secret Expiration

1. Enable Expiration on the Template:
   - In the Template Designer, enable the `Expiration Enabled?` checkbox.
   - Set the number of days until expiration and select the field to be updated upon expiration.
2. Enable Expiration for Individual Secrets:
   - Once expiration is enabled for a template, it applies to all secrets created using that template.
   - Users with Owner permission can set custom expiration intervals for individual secrets via the Overview tab on the Secret View page.

Managing Expired Secrets

- **Forcing Expiration**: Users can manually force a secret to expire immediately by clicking `Expire Now` on the Secret View page.
- **Resetting an Expired Secret**: Change the field that has expired to reset the expiration interval.
- **AutoChanging an Expired Secret**: Enable AutoChange to allow Secret Server to automatically change the password when it expires. This requires enabling RPC and configuring it on the individual secret.
- **Retry Interval**: Secret Server checks for expired secrets every minute. If a password change attempt fails, it will retry based on the template's retry interval, which defaults to one hour.

Forcing Expirations

To force expiration:

1. Navigate to the **Secret View** page for the desired secret.
2. Click the **Expire Now** button. This forces the secret to expire immediately regardless of the interval setting. The expiration date displays "Expiration Forced."

Setting up Secret Templates for Secret Expiration

To set up expiration on a secret, you must first enable expiration on the template from which the secret is created.

To enable secret expiration for a secret template:

1. Search for **Secret Templates**.
2. On the **Secret Templates** page, click the template name. The page for that template appears.
3. Scroll down to the **Template Expiration** section.

4. Click the **Edit** button.
5. Click the **Expiration Enabled** box.
6. Click to select the check box. Two more fields appear.
7. Type the number of days desired in the **Days until Expiration** text box.
8. Click the Change Required on dropdown list to select which parameter you want updated upon expiration. Your choices are:
   - Computer
   - Domain
   - My Server List
   - Password
   - Server
   - Username
9. Click the **Save** button.

You can override the interval setting for individual secrets.

Enabling expiration for a template enables expiration for all the secrets that were created using that template.

Resetting Expired Secrets

To reset an expired secret, you must change the text field that has expired and is required to change. For example, if the text field set to expire is the password text field and the current password is "asdf," then a change to "jklh" resets the expiration interval and thus removes the expiration text on the Secret View page.

If you do not know which text field is set to expire:

1. Go to the secret template that the secret was created from.
2. Search for **Secret Template**.
3. Select the template.
4. Click the **Edit** button.
5. On the next page, click the **Change** link. In the **Change Required On** text box you can see the text field that is set to expire.

Setting up Secrets

Once you enable expiration for the template, expiration is also enabled for secrets that were created using that template as well as secrets created in the future. The Expiration tab appears on the Secret View page and requires the user to have Owner permission on the secret.

To set a custom expiration at the secret level, you adjust the expiration interval for the secret by clicking the **Expiration** tab in the **Secret View** page. There, you can set the secret to expire using the template settings (default), a custom interval, or a specific date in the future.

Secret Exposure

The Secret Exposure option, available in the **More** menu on a secret page, displays which fields on that secret are configured as Expose for Display in the secret template. Fields set to Expose for Display are not encrypted in the database and can appear as custom columns on the Secret Server dashboard.

To view the exposure status of a secret's fields:

1. Navigate to a secret and open it.
2. Click the **More** button in the secret action bar, and select **Secret exposure** from the drop down.

The Secret Exposure panel lists each field on the secret with the following information:

- **Field Name**: The name of the field as defined in the secret template.
- **Field Type**: The field type (for example, Text, Notes, or URL).
- **Exposed**: Whether Expose for Display is enabled on this field. Exposed fields are not encrypted in the database.

> The Expose for Display setting is configured at the secret template level by an administrator. Only fields where the secret text-entry field data is not considered privileged information should be set to Expose for Display. Password fields cannot be set to Expose for Display. See Secret Template Fields.

Exposed field values may be visible as dashboard columns to any user with access to the Secrets list, even without opening the individual secret.

Secret Navigation Slideout

The Secret Navigation Slideout is a set of useful links to secret. It appears on the top navigation bar.

Click **Open secret panel** next to your user login button at the top right, and the slideout appears.

There are four dropdowns:

Favorites

These are the secrets you set as favorites by clicking the star icon on the secret's row on the All Secrets table.

Dropdown Quick List

When you click the dropdown, you see a list of your favorite secrets:

The initial view shows the folder path to the secret and a "favorite" toggle icon. You may need to hover over the blank space to see an unselected toggle.

> Some changes may require you to refresh the list by clicking the stacked dots icon.

Each list item has its own dropdown. When you click it, a set of information about the secret appears, including a list of users or roles with access to (shared with) the secret.

> You may also have to enter a comment or check out the secret.

Most of the datums can be copied with a single click of the copy icon next to each. You can hover the mouse pointer over the "Shared with" list to see the type of access for that user or role, or you can click "See All" to see the entire list.

Favorites Page

Alternatively, in the slideout, you can click the Favorites title to navigate to the full Favorites page.

Recent

These are the secrets you have opened recently. The dropdown provided for each list item is exactly the same as that provided in "favorites," as is accessing the Recent page via clicking the title.

Most Used Secrets

These are the secrets you have opened the most often. The dropdown provided for each list item is nearly the same as that provided in "favorites," as is accessing the Recent page via clicking the title. The only difference is each list item states the time since last access.

Shared with Me

These are the secrets others have shared with you. No folder path is provided.

The dropdown provided for each list item provides a shortcut to request approval for the secret:

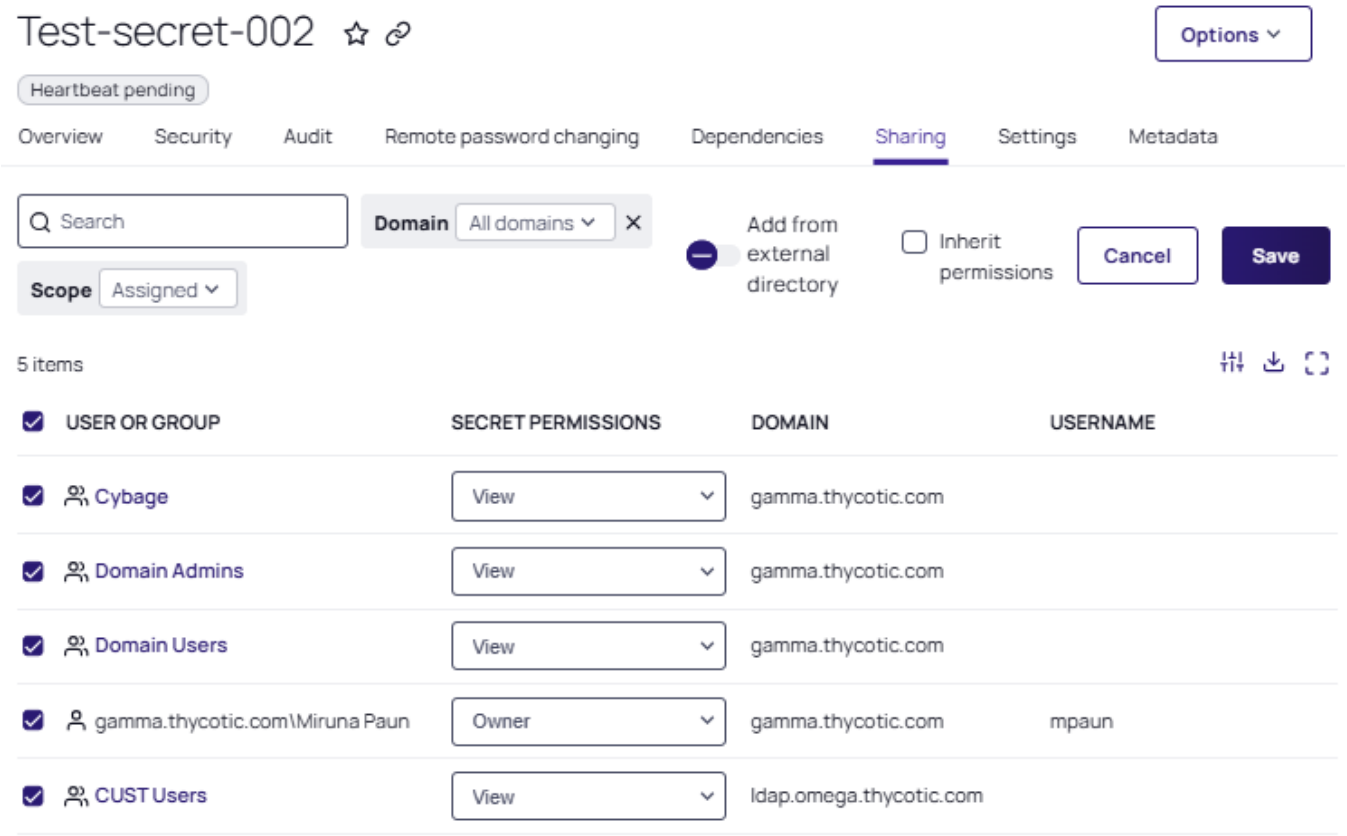
Secret Permissions

For information technology teams, securely sharing passwords is crucial. Due to the sensitive nature of sharing secure information, Secret Server ensures shared passwords are tracked and guarded via Delinea secret permissions.

> Depending on your configuration, folder settings can affect the Delinea permissions of secrets contained in that folder (and its subfolders). Secrets and folders are not visible to users who do not have at least the View Secret (can see details) or the View Lists (can see a list of secrets) permissions. See "Folder Permissions" on page 1075 for more information.

> To simplify sharing, new secrets automatically inherit the settings from the folder they are stored in. The **Inherit Permissions** checkbox (found in the **Sharing** tab of the secret's page) is enabled by default. Secrets inherit all the parent folders' sharing settings. As long as this checkbox is selected, you cannot modify the Delinea permissions for the secret. For more on folder security, see the "Folders" on page 1075 section.

Secrets can be shared with groups or individual users. The **Sharing** tab in a secret's page allows for Delinea secret permissions and access to be configured:



There are four secret permission levels when sharing secrets with another user or group:

- **List**: The user may see a secret in a list, such as a list returned by running a search, but will not be able to view any more details about that secret or edit it.
- **View**: The user can see all data of the secret, such as username, password, metadata, permissions, auditing, history, and security settings.
- **Edit**: Users with Edit permission can modify secret data and deactivate secrets. They can also move secrets to another folder unless the **Inherit Permissions from Folder** setting is enabled. In such cases, Owner permission is required to move the secret. Note that sharing secrets is exclusively available to users with Owner permission.
- **Owner**: The user may change all of the secret's metadata.

> Password text-entry fields are not visible if a secret has a launcher and the **Hide Launcher Password** setting is on or the user does not have the **View Launcher Password** role permission.

> The API calls use Delinea role permissions which are defined in the **tbRolePermission** table. In **tbFolderACL**, roles are not used, and it is less specific about the source, avoiding duplication.

Secret Templates Overview

Secret templates in Secret Server are pre-configured structures that define the fields, launchers, and remote password changers for different types of secrets. These templates simplify the management and automation of secret-related tasks. Here are some key aspects and examples of secret templates:

General Features

- Fields: Secret templates determine the specific fields that will be available for a secret, such as username, password, private key, and more.
- Launchers: Templates can include launchers that facilitate automated login or connection to remote systems.
- Remote Password Changers (RPC): Templates are pre-configured with password changers that can automatically update passwords on remote systems when a secret expires or on a defined schedule.
- Customization: Administrators can view, modify, and manage secret templates through the Secret Server administration panel.

Examples of Secret Templates

Oracle Account Secret Template:

- Purpose: Used for managing Oracle account secrets.
- Features: Includes fields specific to Oracle accounts and is configured with an Oracle-specific password changer.
- Usage: Automatically changes Oracle account passwords when a secret expires.

Windows Account Secret Template:

- Purpose: Used for managing Windows account secrets.
- Features: Includes fields specific to Windows accounts and is configured with a Windows-specific password changer.
- Usage: Automatically changes Windows account passwords when a secret expires.

SAP Account Secret Template:

- Purpose: Used for managing SAP account secrets.
- Features: Includes fields specific to SAP accounts and is configured with an SAP-specific password changer.
- Usage: Automatically changes SAP account passwords when a secret expires.

Azure Active Directory Secret Template:

- Purpose: Used for managing Azure AD account secrets.
- Features: Includes fields specific to Azure AD accounts and is configured with an Azure AD-specific password changer.
- Usage: Automatically changes Azure AD account passwords when a secret expires.

Unix Account (SSH) Secret Template:

- Purpose: Used for managing Unix account secrets with SSH.
- Features: Includes fields for private keys and passphrases, and is configured with a Unix-specific password changer.
- Usage: Automatically changes Unix account passwords and updates public keys when a secret expires.

Managing Secret Templates

- Activation and Deactivation: Secret templates can be activated or deactivated as needed.
- Mapping: Templates can be mapped to specific RPCs to ensure the correct password changer is used.
- Administration: Templates are managed through the Secret Server administration panel, where they can be created, edited, and assigned to secrets.

List of Built-in Secret Server Templates

Secret Server includes many pre-configured secret templates:

Built-in Secret Templates Available Out-of-the-Box

For details about specific RPC secret templates, see "Included RPC Templates" on page 954.

Active Directory Account

Store usernames and passwords for Active Directory authentication, enabling secure access to domain resources and automated account management.

AI Compute Node SSH Key

Manage SSH keys for secure access to AI compute nodes, clusters, or GPU servers, supporting automated provisioning and remote management.

AI Endpoint Certificate

Store certificates and private keys required for mTLS or certificate-based authentication to AI endpoints, ensuring secure and encrypted communications.

AI Model Registry Credentials

Store credentials (usernames, passwords, tokens) for accessing AI model registries or discovery services, enabling automated model deployment and version management.

Amazon IAM Console Password

Store passwords for AWS IAM user accounts to enable secure console access and administrative tasks within the AWS Management Console.

Amazon IAM Key

Store AWS access keys and secret keys for programmatic access to AWS services, supporting automation and API-based operations.

AWS SageMaker Access

Store AWS access and secret keys for connecting to AWS SageMaker, enabling secure automation of model training, deployment, and inference tasks.

Azure AD Account

Store usernames and passwords for Azure Active Directory authentication, enabling secure access to Microsoft cloud services and resources.

Azure AI Compute Credentials

Manage client IDs, secrets, and related information required to access Azure AI compute resources, such as Azure Machine Learning workspaces or inference endpoints.

Azure Application Registration

Stores client ID, client secret, tenant ID, and related fields for Azure application registrations.

Bank Account

Store sensitive banking information such as account numbers, routing numbers, and related credentials for financial system access.

Certificate with Private Key

Stores a certificate together with its private key and metadata such as common name or expiration.

Cisco Account (SSH)

Store usernames and passwords for SSH access to Cisco network devices, enabling secure remote management and configuration.

Cisco Account (Telnet)

Store usernames and passwords for Telnet access to Cisco network devices for remote management and configuration tasks.

Cisco Enable Secret (SSH)

Store privileged enable passwords for Cisco devices accessed via SSH, allowing elevated administrative access for configuration changes.

Cisco Enable Secret (Telnet)

Store privileged enable passwords for Cisco devices accessed via Telnet, allowing elevated administrative access for configuration changes.

Cisco VPN Connection

Store VPN credentials and connection details for Cisco VPN systems, enabling secure remote network access and tunnel establishment.

Combination Lock

Store numeric combinations for physical security locks, safes, or access control systems requiring multi-digit codes.

Contact

Store personal contact information and related sensitive details for individuals or business contacts requiring secure storage.

Credit Card

Store credit card numbers, expiration dates, CVV codes, and related payment information for secure financial transactions.

DevOps Secrets Vault Client Credentials

Store client IDs, secrets, and tokens for accessing DevOps secret management systems, enabling automated credential retrieval in CI/CD pipelines.

Entra ID User Account

Stores username, password, and related properties for user accounts in Microsoft Entra ID.

Generic API Key

Stores API keys or tokens for systems that require key-based authentication.

Generic Discovery Credentials

Store general-purpose usernames and passwords for network discovery tools and services that scan or inventory IT infrastructure.

Google IAM Service Account Key

Store Google Cloud service account keys and credentials for programmatic access to Google Cloud Platform services and resources.

Google Vertex AI Service Account

Securely store Google Cloud service account keys and related details for accessing Google Vertex AI resources, such as training jobs, endpoints, and ML pipelines.

Healthcare

Store sensitive healthcare-related credentials and information, such as medical system access or patient data authentication details.

HP iLO Account (SSH)

Store usernames and passwords for SSH access to HP Integrated Lights-Out (iLO) management interfaces for remote server administration.

Hugging Face API Token

Securely store and manage API keys used to authenticate and connect to Hugging Face services for AI workloads, such as natural language processing, chatbots, or data analysis.

IBM iSeries Mainframe

Store usernames and passwords for accessing IBM iSeries (AS/400) mainframe systems, enabling secure mainframe operations and management.

IBM Watson API Key

Securely store and manage API keys used to authenticate and connect to IBM Watson services for AI workloads, such as natural language processing, chatbots, or data analysis.

MySql Account

Store usernames and passwords for MySQL database connections, enabling secure database access and automated database operations.

Okta Account

Stores username, password, and optional token values for Okta user or service accounts.

OpenAI API Key

Securely store and manage API keys used to authenticate and connect to OpenAI services for AI workloads, such as natural language processing, chatbots, or data analysis.

OpenLDAP Account

Store usernames and passwords for OpenLDAP directory service authentication, enabling secure access to LDAP-based directory resources.

Oracle Account

Store usernames and passwords for Oracle database connections, enabling secure database access and automated database operations.

Oracle Account (TCPS)

Store Oracle database credentials for secure connections using TCP with SSL/TLS encryption, ensuring encrypted database communications.

Oracle Account (Template Ver 2)

Store Oracle database credentials using an updated template format with enhanced security features and connection parameters.

Oracle Account (Walletless)

Store Oracle database credentials for connections that don't require Oracle Wallet, simplifying authentication while maintaining security.

Password

Store general-purpose passwords and related authentication information for various systems and applications requiring secure access.

PIN

Store personal identification numbers and numeric codes for systems requiring PIN-based authentication or access control.

PostgreSQL Account

Stores username, password, and connection details for PostgreSQL database accounts.

Product License Key

Store software license keys, activation codes, and related licensing information for commercial applications and enterprise software.

Salesforce Account

Stores Salesforce login credentials, including username, password, and security token.

SAP Account

Store usernames and passwords for SAP system access, enabling secure authentication to SAP applications and automated business processes.

SAP SNC Account

Store SAP Secure Network Communications (SNC) credentials for encrypted and authenticated connections to SAP systems.

Security Alarm Code

Store numeric codes and access information for security alarm systems, building access controls, and physical security devices.

ServiceNow Account

Stores credentials for ServiceNow user or integration accounts, including username and password.

Snowflake Account

Stores username, password, and optional key or connection fields for Snowflake accounts.

Social Security Number

Store Social Security Numbers and related personal identification information requiring high-security protection and compliance controls.

SonicWall NSA Web Admin Account

Store administrative usernames and passwords for SonicWall NSA firewall web interfaces, enabling secure network security management.

SonicWall NSA Web Local User Account

Store local user credentials for SonicWall NSA firewall systems, enabling secure access to network resources and VPN services.

SQL Server Account

Store usernames and passwords for Microsoft SQL Server database connections, enabling secure database access and automated operations.

SSH Key

Store SSH private keys and related information for secure shell connections, enabling passwordless authentication and automated server access.

Sybase Account

Store usernames and passwords for Sybase database connections, enabling secure database access and automated database management operations.

Teradata SQL

Stores credentials and connection details for Teradata SQL access.

TeradataDB Account

Stores username, password, and related properties for Teradata database accounts.

Unix Account (Privileged Account SSH Key Rotation - No Password)

Manage privileged Unix accounts with automated SSH key rotation capabilities, using passwordless key-based authentication for enhanced security.

Unix Account (Privileged Account SSH Key Rotation)

Manage privileged Unix accounts with automated SSH key rotation and password management for comprehensive security and access control.

Unix Account (SSH Key Rotation - No Password)

Manage Unix user accounts with automated SSH key rotation using passwordless authentication for secure and streamlined access.

Unix Account (SSH Key Rotation)

Manage Unix user accounts with automated SSH key rotation and password management for enhanced security and access control.

Unix Account (SSH)

Store usernames and passwords for Unix/Linux system access via SSH, enabling secure remote administration and automated system management.

Unix Account (Telnet)

Store usernames and passwords for Unix/Linux system access via Telnet for legacy systems requiring this connection method.

Unix Root Account (SSH)

Store root user credentials for Unix/Linux systems accessed via SSH, enabling privileged administrative access and system management.

VMware ESX/ESXi

Store usernames and passwords for VMware ESX/ESXi hypervisor access, enabling secure virtualization infrastructure management and automation.

WatchGuard

Store usernames and passwords for WatchGuard firewall and security appliance access, enabling secure network security management and configuration.

Web Password

Store usernames and passwords for web-based applications and services, enabling secure authentication to online systems and portals.

WebSphere Account

Stores credentials for IBM WebSphere user accounts, including username and password.

WebSphere Privileged Account

Stores privileged IBM WebSphere account credentials with elevated access rights.

Windows Account

Store usernames and passwords for Windows system authentication, enabling secure access to Windows servers and automated system management.

Workday ISU/Implementer Account

Stores credentials for Workday Integration System User or implementer accounts.

Workday Service Account

Stores credentials for Workday service or system accounts used for integrations.

z/OS Mainframe

Store usernames and passwords for IBM z/OS mainframe system access, enabling secure mainframe operations and automated job processing.

Managing Secret Templates

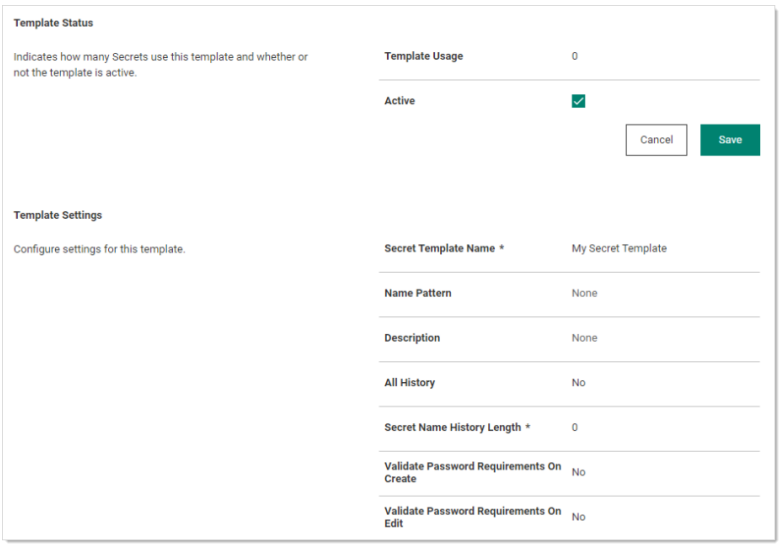
Including these topics:

- Changing a Secret's Template
- Configuring Secret Template Permissions
- Creating and Editing Custom Password-Exclusion ...
- Creating or Editing Secret Templates
- Field Slug Names
- Managing Specific Templates
- Secret Template Fields
- Secret Template List Fields
- Secret Template Settings
- Template Character Sets
- Template Naming Patterns
- Template Password Requirements

Activating and Deactivating Templates

If a template is no longer relevant or outdated, it can be inactivated. This can be done from the specific template's Secret Template Edit page.

1. Search for **Secret Templates**.
2. Click the template name in the **Secret Templates** column. That template's page appears on the General tab.
3. Click **Edit** next to Template Status. The Secret Template Detail Status section enters edit mode:



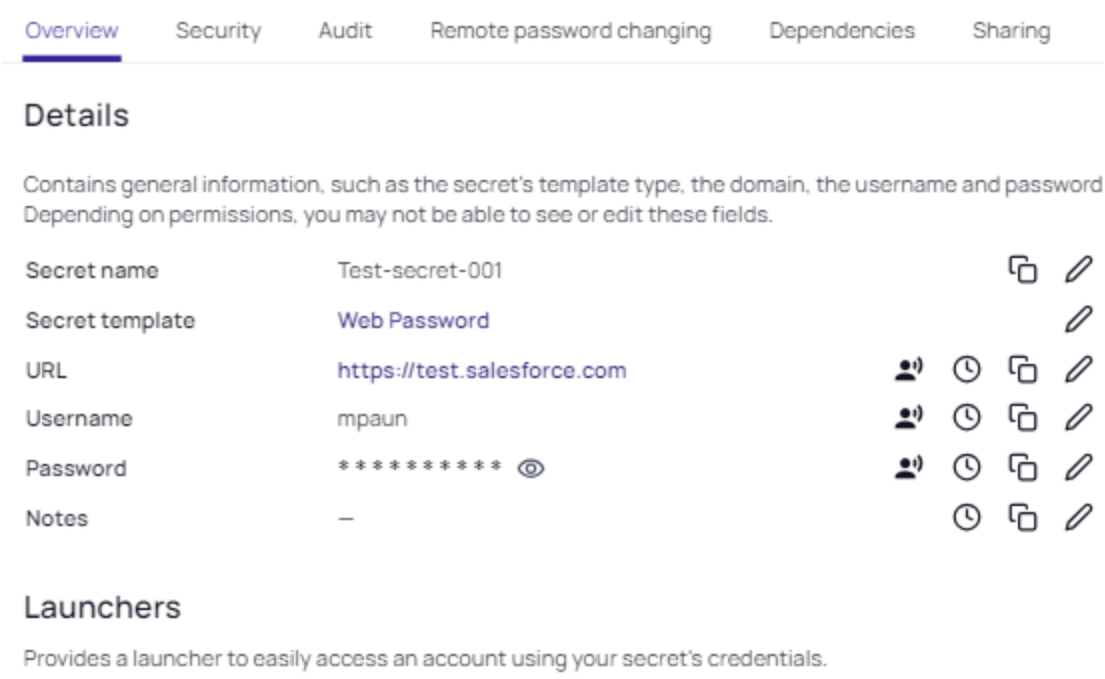
4. To deactivate a template, uncheck the **Active** check box.
5. To activate a template, check the **Active** check box.

Templates can also be inactivated in bulk from the Manage Secret Templates page. Click the **Active Templates** button to navigate to the Set Active Secret Templates page. This screen displays all the secret templates in Secret Server. Each secret template can be set as active or inactive. Once the secret templates are chosen as active or inactive, then saving changes brings the secret templates into effect immediately. Inactivating a secret template does not inactivate any secrets using that secret template–those secrets still exist, but users are not able to create new secrets using an inactivated secret template.

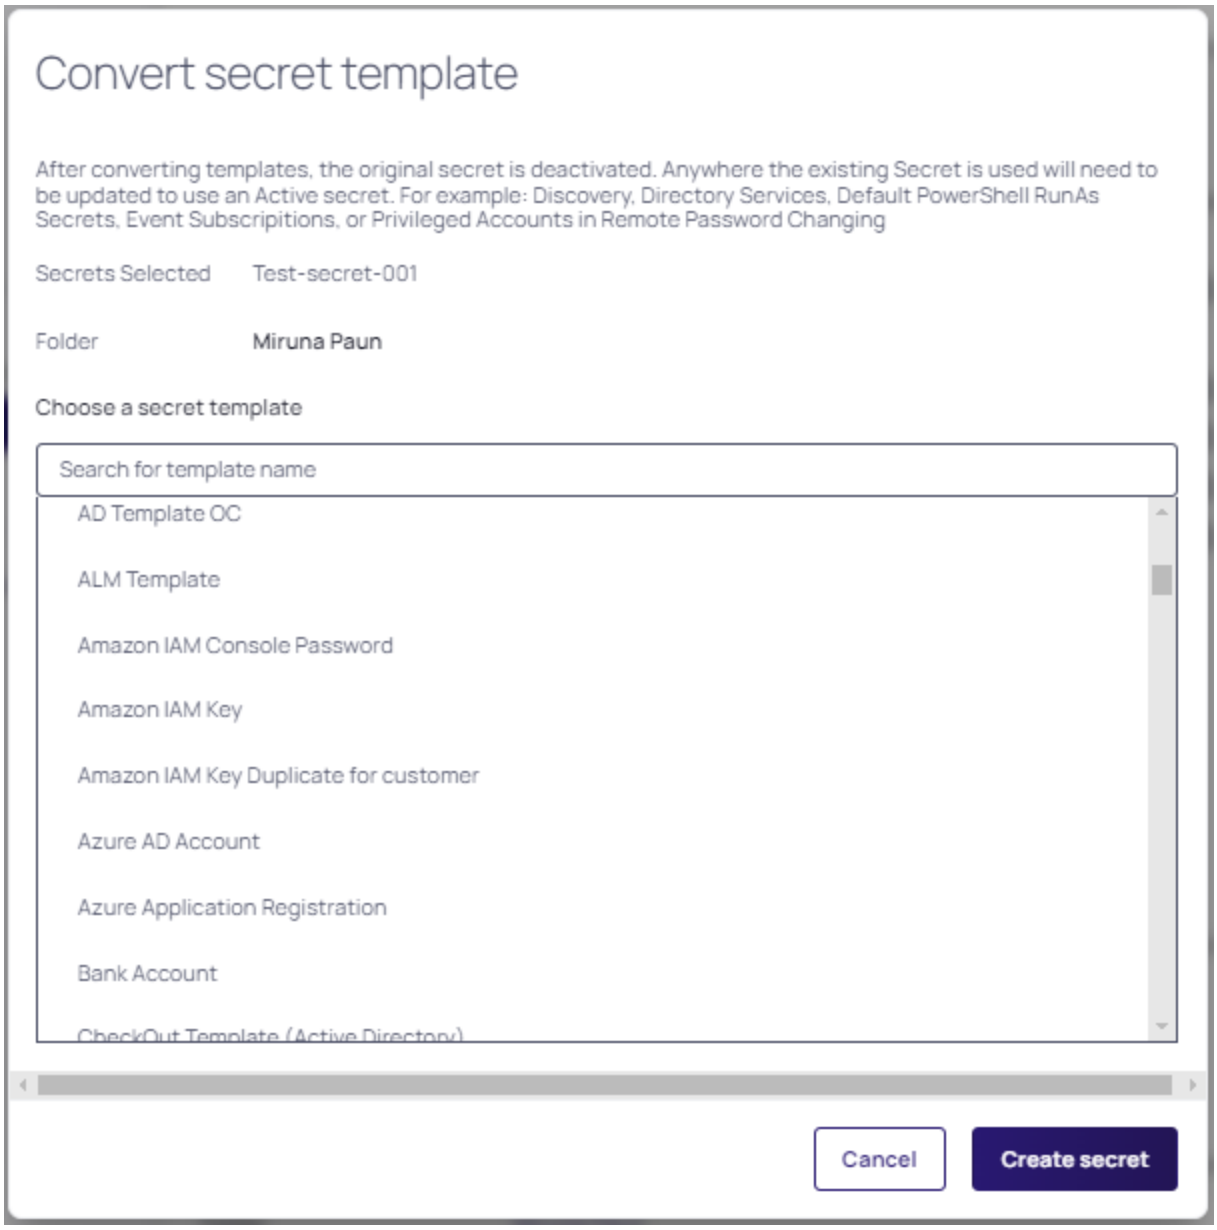
Changing a Secret's Template

To convert secrets from one secret template to another, do the following:

1. Search for and view a secret. Once in the **Overview** page, click on the **Convert Template** button. This button is located under the **Details** section in the form of pencil next to the Secret template field:



2. A pop up for **Convert secret template** appears. Search for the template you want to convert to from the list, and click **Create secret**:



3. The page with all the fields for the new template appears. Map each text-entry field your current template has to a new value. These values are: **New Secret Name**, **URL** (domain), **Username**, **Password**, **Notes**.
   a. If you want to remove the value for a text-entry field instead of converting it, select the `<Remove>` option in the list for that text-entry field.
   b. Click **Create secret**, when done, and then you can choose a new folder to move the secret to.

The Convert Template button is only available to users and groups with the "Owner" permission to the secret you with to convert. You can check what permission the secret has under the **Sharing** tab.

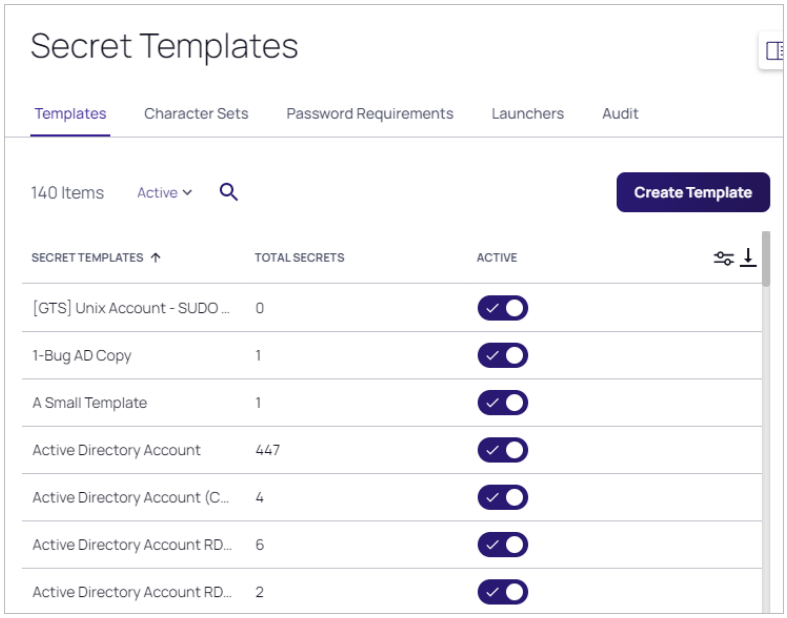
To preserve audit data, when a secret is converted from one type to another, the old secret is deleted, and a new secret is created. An admin can view the old secret by searching for deleted secrets on the dashboard.
A user needs "Add Secret", "Copy Secret", "Deactivate Secret", "Edit Secret", "Own Secret" and "View Secret" role permissions in order to convert a secret to a new template.

Configuring Secret Template Permissions

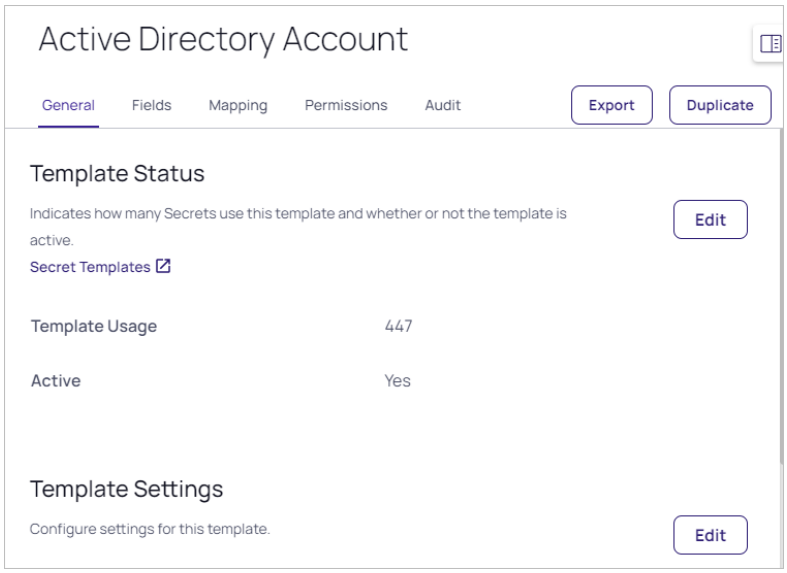
You can assign users and groups to specific secret templates so they can either manage or create secrets based on those templates. This allows you to have more granular control over what secret templates are seen by users and groups when they are managing the templates or creating secrets. To configure Secret Template permissions:

Secret template access is dependent on configuration in **Groups** / **All Vault Users** / **Secrets**. Without modifying this, the group or user assignment on secret templates changes nothing.

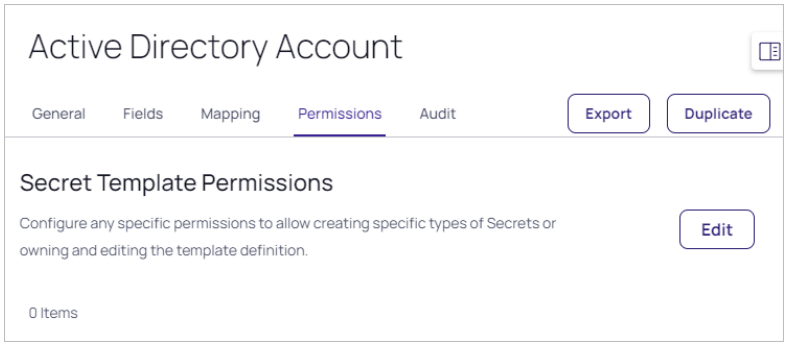
1. Select **Admin > Secret Templates**. The Secret Templates page appears:



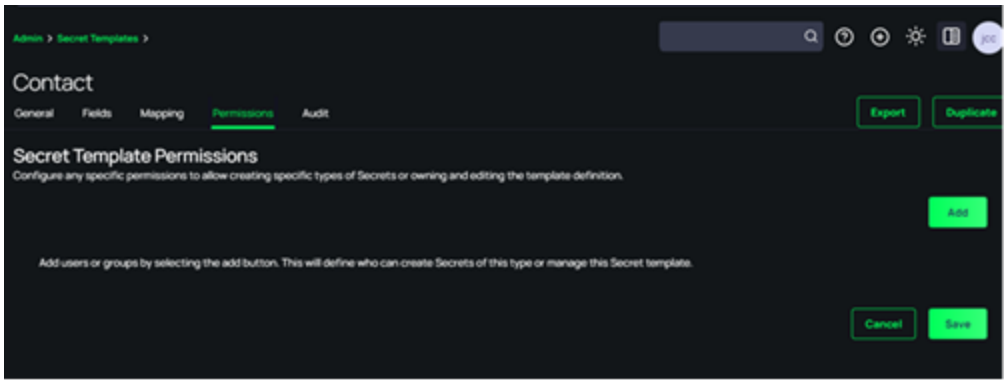
2. Click the name of the template for which you wish to configure Delinea permissions. The Secret Template Detail page appears on the General tab:



3. Click the Permissions tab:



4. Click the **Edit** button in the **Secret Template Permissions** section. The Secret Template Permissions section enters edit mode:

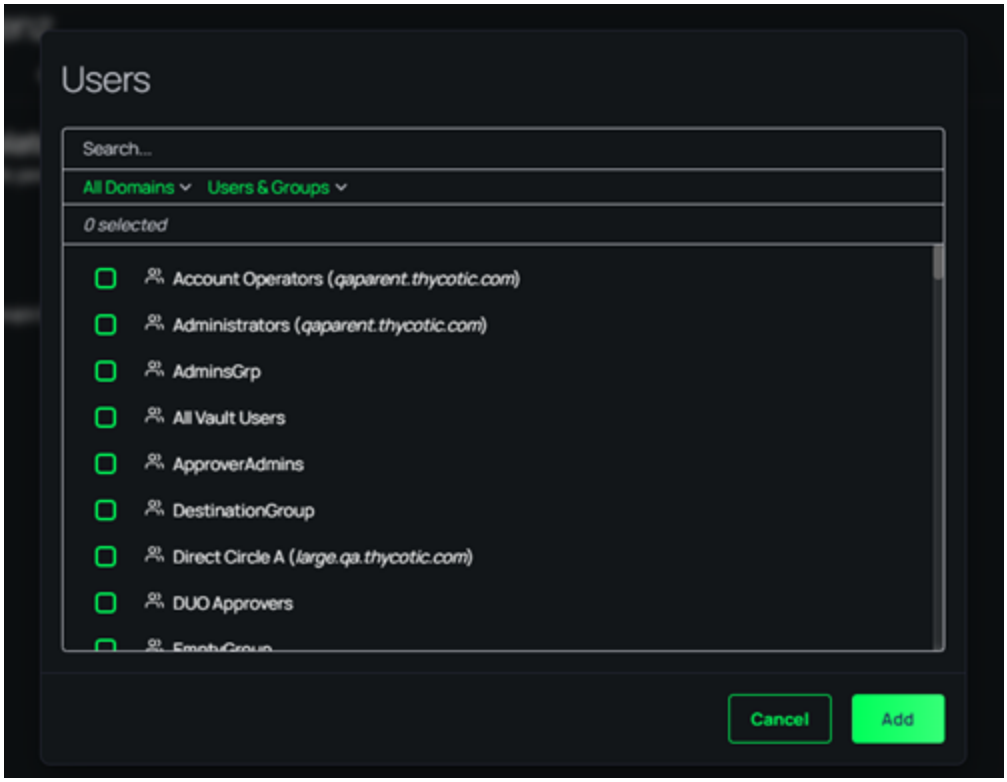


5. To change the Delinea permissions of a user or group that has already been assigned permissions, select a new permission from the **Administrator** drop-down list. Template Create Secret allows a user or group to create

secrets based on the selected secret template. Template Owner allows a user or group to edit a secret template and create secrets based on the selected secret template. By default, the All Vault Users group that targets all users of Secret Server can create secrets based on any secret template.

> User's secret template permissions are based on the permissions directly assigned to them, as well as the permissions assigned to all of the groups the user belongs to. If a user or group does not have Template Create secret or Template Owner permissions, they are unable to create a secret based on that secret template or see that it exists in Secret Server.

6. To add permissions for a new user or group, click the **Add** button. The Users popup appears:



7. Click to select the check box for the user or group.
8. Click the **Add** button.

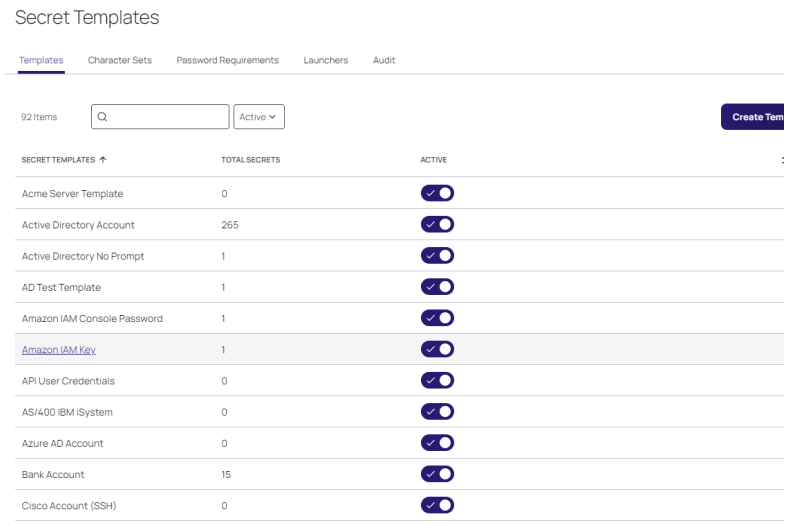
Creating and Editing Custom Password-Exclusion Dictionaries

A custom password-exclusion dictionary is a list of words that you do not want users to choose as part of a password, for example, your company name. The dictionary becomes an option when creating or editing a password requirement object. Those, in turn, appear as options when creating a secret template. Finally, when a secret is created based on that template, the words in the dictionary are not allowed when creating a password (the "weak" warning appears).

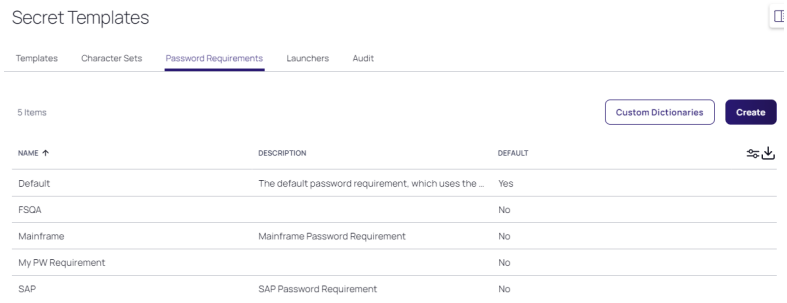
Creating a Custom Dictionary

To create a new custom password-exclusion dictionary for use by secret templates:

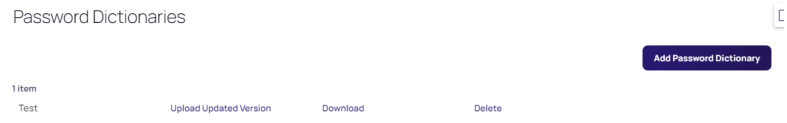
1. Create a text file containing the words you want to exclude, one word per line. These words cannot be used as part of a password on applicable secrets.
2. Search for **Secret Templates**. The Manage Secret Templates page appears:



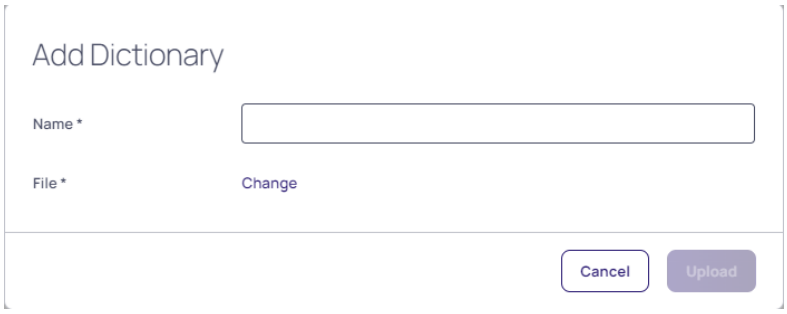
3. Click the **Password Requirements** button. The Password Requirements page appears:



4. Click the **Custom Dictionaries** button. The Password Dictionaries page appears:

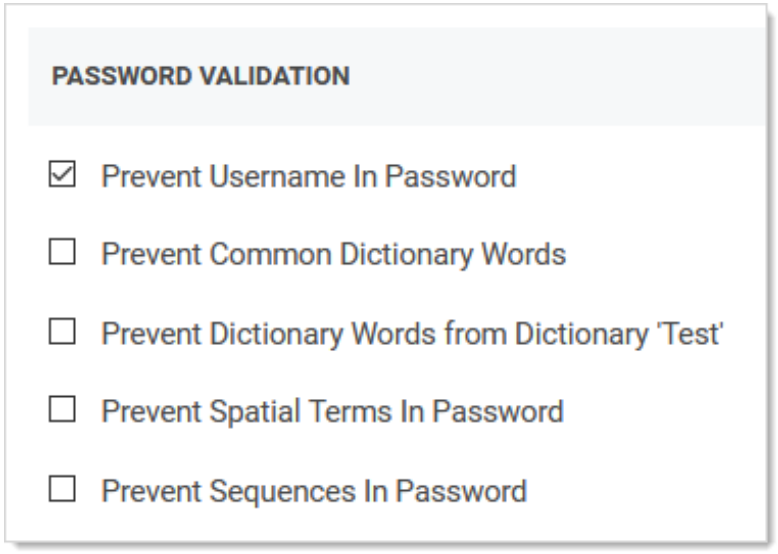


5. Click the **Add Password Dictionary** button. The Add Dictionary popup page appears:



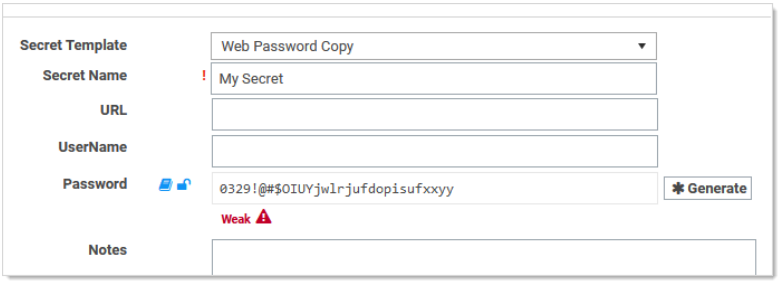
6. Type the name of the dictionary in the **Name** text box.
7. Click the **Change** link to locate your dictionary text file. The name of the file appears on the popup.
8. Click the **Upload** button. The popup disappears, and the file appears on the Password Dictionaries page:

Now, when defining a password requirement, the custom dictionary you created ("test") appears as a prevention option:

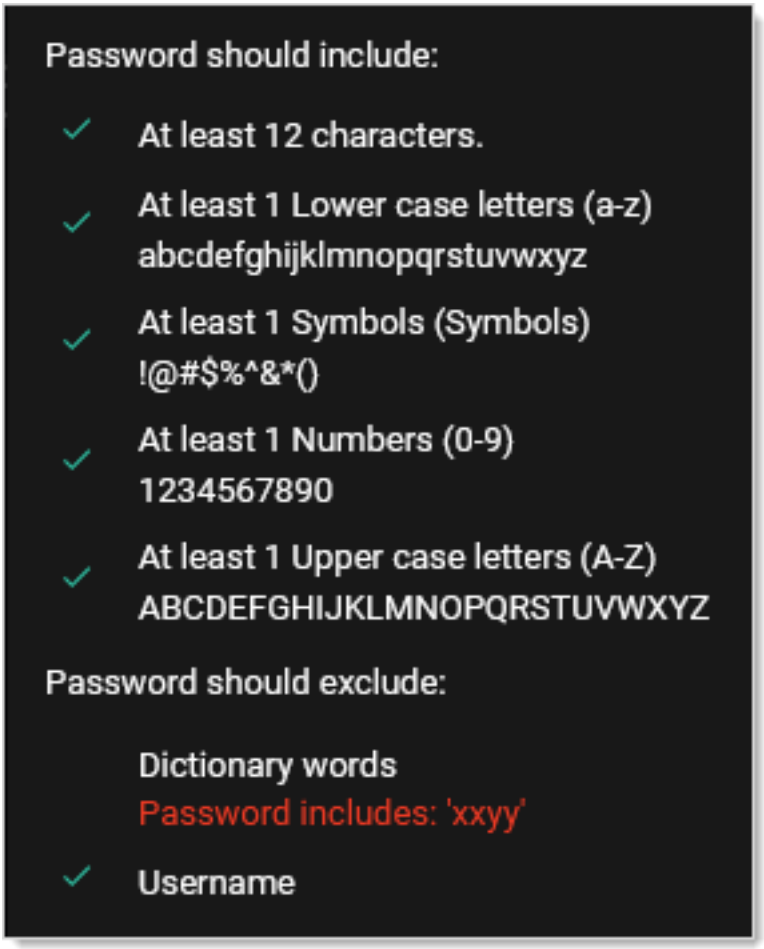


When a user attempts to include one of the excluded words in the dictionary in a secret based on the template using the password requirement, the "weak" warning appears and the user cannot save the password. For example, our dictionary contains the word (string) `xxyy`. The user enters a strong password that contains the string, and Secret Server rejects it anyway:

> The excluded words are not case sensitive. XXyY would have triggered a password rejection too.



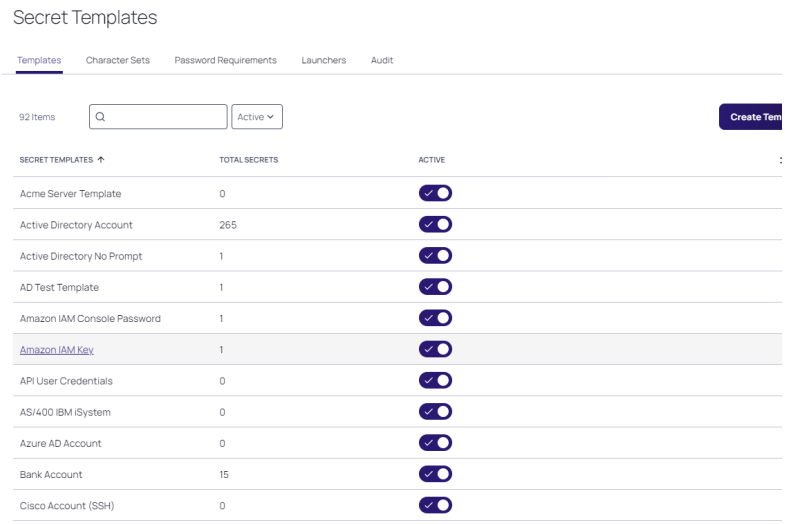
When you hover the mouse pointer over the password strength bar, the disallowed string appears in red:



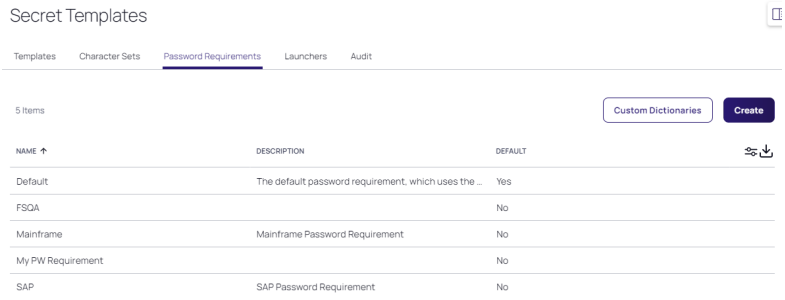
Editing a Custom Password-Exclusion Dictionary

To edit a custom password-exclusion dictionary for use by secret templates:

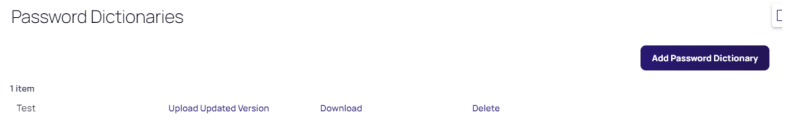
1. Search for **Secret Templates**. The Manage Secret Templates page appears:



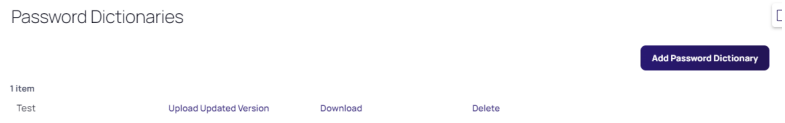
2. Click the **Password Requirements** button. The Password Requirements page appears:



3. Click the **Custom Dictionaries** button. The Password Dictionaries page appears:



4. Click the **Add Password Dictionary** button. The Add Dictionary popup page appears:



5. Click the **Download** link for the desired dictionary.

6. Save the file to your computer.
7. Edit the text file as desired. Do not change the name of the file.
8. Click the **Upload Update Version** link to locate and upload your dictionary text file. The existing dictionary, of the same name, is overwritten.

Creating or Editing Secret Templates

Editing Secret Templates

1. Select **Admin > Secret Templates** in the **Core Actions** section. The Secret Templates page appears.
2. Click the template name in the Secret Templates column. That template's page appears.
3. Click the desired tab for the configuration you want to change. See the Creating or Importing a New Template section for details.

Creating or Importing a New Template

Task 1: Creating the Template

1. Select **Admin > Secret Templates** in the **Core Actions** section. The Secret Templates page appears.
2. Click the **Create / Import Template** button. The Create Template pop-up page appears.
3. If importing the template, click to select the **Import XML** selection button.
4. Type the name of the new template in the **Template Name** text box.
5. Click the **Save** button. The new template's setup page on the General tab appears. The page provides all the options for configuring a secret template, as well as which text-entry fields appear on any secret created from that template.

Task 2: Adding General Settings and Setting an Expiration or One-Time Password

1. On the **General** tab, click the **Edit** link in the **Template Settings** section. The section becomes editable:
2. Edit the settings as desired. They include:
   - **Secret Template Name** text box.
   - **Name Pattern** text box. See "Template Naming Patterns" on page 1206.
   - **Description:** An optional description for the template.
   - **All History** check box: If this check box is enabled, Secret Server keeps all entries for viewing. This feature creates a record of every name used when a new secret is created.
   - **Secret name History Length** text box: If All History is disabled, Secret Server keeps this number of entries for viewing.
   - **Validate Password Requirements on Create?** check box: Ensure requirements are met on secret creation.
   - **Validate Password Requirements on Edit?** check box: Ensure requirements are met when editing secret.

- **Required Permission To Edit Password Change Configuration** dropdown list: Specify which permission is required on the password change configuration on a secret from this template.

3. Click the **Save** button.
4. Click the **Edit** link for the **Template Expiration** section. Secret expiration applies to one field of a secret template (most commonly the password field) and may trigger a password change for that secret if auto-change is enabled for RPC.
5. Click to select the **Expiration Enabled?** check box. Two additional controls appear.
6. Type the days till expiration in the **Days until Expiration** text box.
7. Click the Change Required On dropdown list to select the field to choose the field the expiration is applied to.
8. Click the **Save** button.Secret Server begins providing alerts if the secret text-entry field is not changed within the specified expiration requirements.
9. Click the **Edit** link for the **One Time Password** section if you want the secret to have a one-time password that the user must change.
10. Click to select the **One Time Password Enabled** check box. Additional controls appear:
11. Type or select the options.
12. Click the **Save** button.

Task 3: Defining Fields for the Template

Click the **Fields** tab to add template fields as desired. See "Secret Template Fields" on page 1199.

> To use a custom SSH RPC port, add a field named "Port" to your secret template. Empty port fields are equivalent to the default port, 22.

Task 4: Mapping Launchers and RPC Type

1. Click the **Mapping** tab to configure launchers and RPC.
2. Click the **Edit** button in the **Password Changing** section to enable RPC on secrets based on this template. This enables heartbeat, RPC, and configures the password changer type and fields. For details, see "RPC Overview" on page 900.
3. Click the **Add Mapping** button to add a secret launcher or extended mapping. The Add Mapping popup appears.
4. Click the **Mapping Type** combination list to search for or select a mapping type:

   Launchers:

   - Command Prompt
   - Custom PuTTY Launcher (Port Field on Secret)
   - Custom Launcher with Host Prompt
   - IBM iSeries Launcher
   - Mac Process - Default Client - No Prompt

- PowerShell ISE
- PowerShell Launcher
- PuTTY
- PuTTY With Port Prompt
- Remote Desktop
- SAP Custom Launcher
- SQL Server Launcher
- SQLPlus
- Sybase iSQL Launcher
- TextEdit (OSX)
- Website Login
- Windows Notepad
- z/OS Launcher

Extended Launchers:

Extended Mappings allows you to tie a text-entry field value to a SS defined system type for additional functionality. For example, you may have a generic password secret template that has a username and password text-entry field. For purposes of looking up credentials, such as a ticket system authentication secret, Secret Server needs to know that actual type of the text-entry fields since the text-entry field name can be custom.

- OATH Secret Key: For password changing on the Amazon Root Account using the Web Password Changer. If you enter the OATH secret for two factor, SS generates the one-time password (OTP) automatically for password changing and heartbeat, allowing you to automate that while enforcing two-factor authentication on the AWS root credential.
- Regex List
- Remote Server SSH Key for Validation: Ensures the machine SHA1 digest for validating the machine connected to is correct.
- SSH Private Key: Defines which text-entry fields make up the SSH Key components of Private Key, Private Key Passphrase, and Public Key.
- Username and Password: Defines which text-entry fields contain the username and password.

The popup changes to accommodate your choice.

> A secret launcher launches applications on other machines and automatically logs on using credentials stored in Secret Server. In general, there are three types of launchers: RDP, SSH, and Custom. In addition to user convenience, launchers can circumvent users needing to know their passwords—a user can still gain access to a needed machine but it is not required to view or copy the password out of Secret Server. A Web launcher automatically logs into websites using the client's browser.

5. Click to select or type to search the desired dropdown lists.
6. Click the **Save** button.

Task 5: Adding Secret Template Permissions

1. Click the **Permissions** tab. This defines who can create secrets of this type or manage this secret template.
2. Click the **Edit** button's dropdown and select **Add**. The Users list appears.
3. Type the name of the user or group you want to add in the **Search** text box. Note that the groups are by domain.
4. Click to select the user or group's check box for those you desire.
5. Click the **Add** button. The selected users or groups appear on the Permissions tab.
6. Click the dropdown list next to each to define if the user or group has the Template Create Secret or Template Owner permission. More than one owner is allowed.
7. Click the **Save** button the users or groups now appear in a small table, along with their roles (permissions).
8. To remove a user or group:
   a. Click the **Edit** link for the **Secret Template Permissions** section. The table of users and groups disappears, and the dropdown lists reappear.
   b. Click the dropdown list for the user or group you want to delete and select **<None>**.
   c. Click the **Save** button

Task 6: Viewing the Template's Audit Trail

1. Click the **Audit** tab to view activity on the secret template.

> You cannot drill down on the entries, but you can define what columns to see by clicking the slider icon on the right. You can also click the download icon to download a text file version of the table.

Settings for Specific Template Types

Oracle Account as SYS

Settings for an Oracle Account secret template to work with Oracle connecting as SYS in SysDBA:

- Set **Oracle Account** as the type.
- Set **Oracle Account (AS SYS)** as the password type.
- Create a secret based on the new template to test the template.

SQL Windows Authentication Account Secret Template and Launcher

Settings for an Active Directory template that is specifically for SQL:

> You can copy the existing AD template that you have. However, if you copy an existing template that has launchers attached to it, you may need to delete those launchers on the newly created template.

- Set **Active Directory** as the type.
- If necessary, create a field called **Server**.
- Add the following parameters for Windows settings (see "General Settings" on page 670):
  - Name: SQL Server Launcher - Windows Authentication
  - Active: Yes
  - Process Arguments: -E -S $Server ($Server should match the field name you created or observed earlier)
  - Run Process as Secret Credentials: Yes
  - Load User Profile: Yes
  - Use Operating System Shell: No
  - Use Additional Prompt (in General Settings): No

Secret Template Settings

These include:

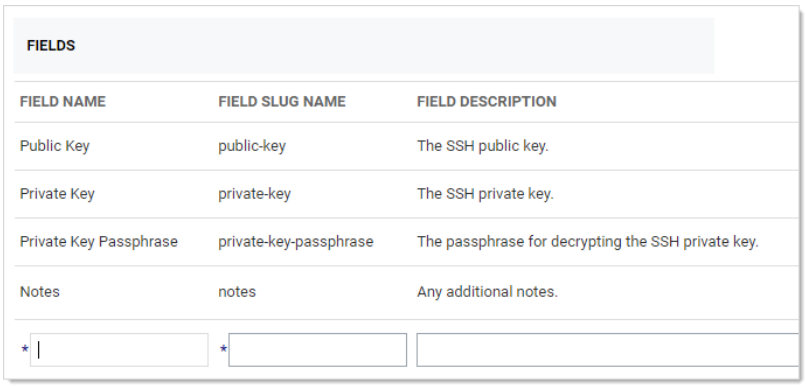
- "Field Slug Names" below
- "Secret Template Fields" on the next page
- "Introduction" on page 1201

Field Slug Names

A *field slug name* in Secret Server is a unique human-readable identifier for a data field in a Secret Server template. The field slug name is available for integrating with third-party applications via API calls. Slug names are programmatically available for API calls but are not visible to template users (secret creators). Instead, they are displayed as references in secret templates.

> If you are not planning to access Secret Server with an API, slug field names are not for you–leave the suggested name as is.

Figure: Field Slug Name in a Secret Template



Field slug names are automatically generated, based on the field name, when the field is created. For example, "User Name" became "user-name." Characters that are potentially problematic for programming, such as spaces, are swapped out. The automatically generated name is unchangeable by human users, unlike the field name. If API calls were based on the field name, human users with access to the template could break those calls, simply by changing the name.

With Secret Server 10.7.X+, The generated field slug names are now user-definable. You can edit the generated names to:

- Conform to a naming convention used in your API calls.
- Maintain the same name for a field across secret templates to simplify coding by developers.

The only requirement is that each slug field name is unique to that template.

If you are wondering how Secret Server internally uniquely identifies fields, there is an internal ID that is not accessible by users or APIs. It is not available read-only (for API use) because we want to futureproof integrations from internal changes to Secret Server.

The user-definable field slug names are also automatically generated when you upgrade from a version of Secret Server that did not have user-defined field slug names. If there are two fields with the same field name, the second (and later) generated field slug name has an incremented number appended to it.

Secret Template Fields

If you want to programmatically manipulate fields, see "Field Slug Names" on the previous page.

To use a custom SSH RPC port, add a field named **Port** to your secret template. Empty port fields are equivalent to the default port: 22.

Field Types

Template fields can be specified as one of several different types to enhance customization:

- **File**: File attachment link. File attachments are stored in the Microsoft SQL Server database.
- **General List**: Preconfigured selectable list for launcher enhancement or general use. See "Introduction" on the next page.
- **Notes**: Multi-line text-entry field.
- **Password**: Password type text-entry field.
- **Text**: Single-line text-entry field.
- **URL**: Clickable hyperlink.
- **URL List**: Preconfigured selectable list for general use. See "Introduction" on the next page.

Editing Fields

The secret template designer provides several settings to customize secret template text-entry fields:

- To add a secret text-entry field, fill out the values and click the **+** button.
- To delete a text-entry field:
  1. Click **Add Field**.
  2. Click on a field name to edit the details of that field.
  3. From the template details you can edit the active status.
  4. Only active fields will appear in the template, so in order to remove a field from showing, flag it as not active.
- To edit a text-entry field, click the icon. Click either the icon to save or the **X** icon to discard the changes.

Text-Entry Field and Control Settings

The settings available for text-entry fields are:

- **Field Name**: The name of the text-entry field. This name is used for the **Create New** dropdown list on either the dashboard's **Create Secret** Widget or Home page.
- **Field Slug Name**: A unique identifier used in API calls and other interactions. The slug allows the display name to change without breaking interfaces linked to fields.
- **Description**: The description of the text-entry field.
- **Type**: The type of the text-entry field. See below for a description of the different text-entry fields.
- **Is Required**: Whether the text-entry field should require a value. These checkboxes are checked for correct content when the user attempts to create this secret. A validation error is displayed if not entered correctly.
- **All history**: Select this checkbox to save all history of this field.
- **Searchable**: Whether the text-entry field should be indexed for searching. By default, passwords are not indexed. File attachments and history cannot be indexed for searching.
- **Edit Requires**: The minimum Delinea permissions on the secret needed in order to edit the value on the secret. The options are Edit, Owner and Not Editable. This enables the secret text-entry field to be locked down at a more granular level than other text-entry fields on the template.

- **Viewing requires edit**: If checked, this text-entry field is not displayed to users when viewing the secret. The text-entry field is only be displayed when the secret is in **Edit** mode.
- **Expose for Display**: If checked, this field can be shown as a Custom Column on the Secret Server Dashboard. See Secret Exposure for more detaild.

> Applies to: Text, Notes, URL, List (auto-checked), and URL List (auto-checked) field types.

> All text-entry fields that are set to **Expose for Display** are **not** encrypted in the database. Only check this value if the secret text-entry field data is not considered privileged information. Sensitive fields (such as Password) are secure by design and cannot be set to **Expose for Display**.

- **Dropdown options**: Add the values that will appear as dropdown options for the text fields.

The order of the text-entry fields in the Template Designer grid is the same as those that appear when the user views or edits a secret created from the template. The order can be modified through the up and down arrows on the grid.

Default values can be specified on each text-entry field by clicking the edit defaults button . These added values appear as a list on any secret created from this template.

Secret Template List Fields

Overview

Introduction

With secret template list fields, administrators can create new lists that can be shared by multiple secrets. Clicking on an existing list goes to the details page for that list where the user can set the list's name, description, and the options available in the list.

You can also group list options by category, which make using very large lists easier. For instance, a list of machines might have the machines categorized by function, such as "Web Server" or "Database Server." You could also use categories for locations, such as "London," "New York," or "Tokyo."

List categories are displayed on the secret and on the launcher dialog, with the options sorted alphabetically within categories. Categories are also sorted alphabetically. Options can be duplicated in multiple categories and will show up in each one. In addition to manually adding categories and options, you can also upload a file containing the list options.

In general, there are two types of list fields:

- **Allow Lists**: These lists display a searchable dropdown of the server names or IPs entered in the list for the user to select from. Only entries from this list are allowed to be used.
- **Deny Lists**: With deny lists, a user can type in any server name or IP address, and Secret Server then compares these entries with a list of blocked entities.

If both types of list are set, the user sees a dropdown of all items in the **Allow list** that are not also in the **Deny list**. This setup is helpful when using the same allow list on multiple secrets, where you do not want some of those servers used with specific secrets. Using both lists, customers do not need to create separate versions of almost identical allow lists and can instead just choose to restrict some options.

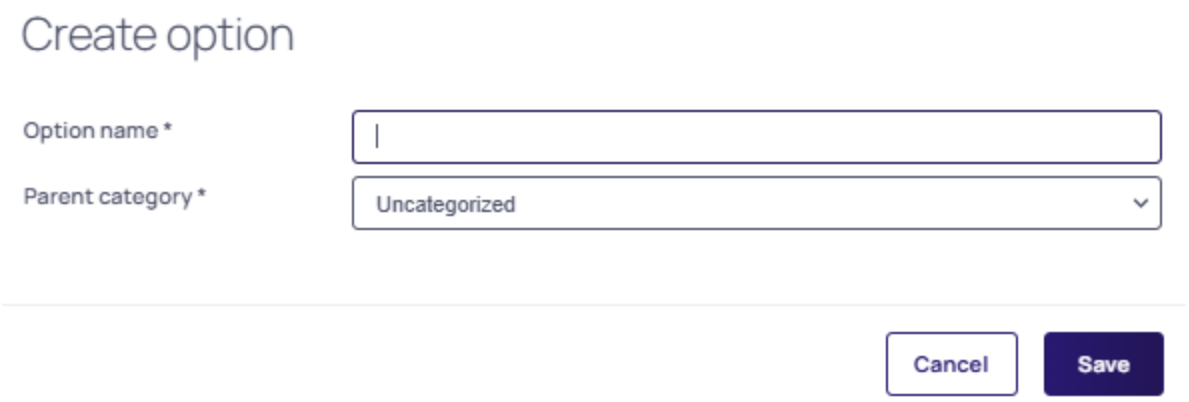
Comma-Delimited Lists

There are two types of list filtering in Secret Server: the above mentioned list filtering, as well as the ability to assign a text or notes field on the secret as a comma-delimited list of server names. The former has the benefit of being shared between secrets, but the latter is useful as a one-off on a single secret. A comma-delimited list can be either an allow or a deny list.

Adding a New List Field

Task 1: Create the List

1. Search for **Categorized Lists**. The Lists page appears.
2. Select the **Create List** button. The Create List popup appears.
3. Type the name in the **Name** text box.
4. (Optional) Type a description in the **Description** text box.
5. Click the **Save** button. The List detail page for the new list appears.
6. Select the **List Options**tab.
7. If you want to create a list with no categories, choose **Create Option** from the dropdown.
8. In the **Parent Category** field choose **Uncategorized** and **Save:**

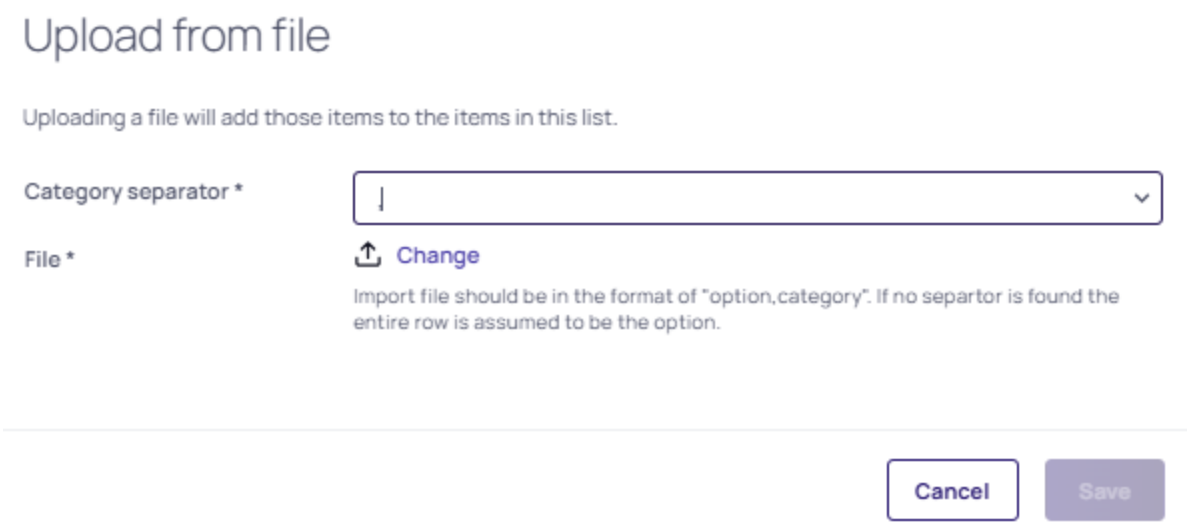


9. If you want to create categories from a comma-delimited list:
   a. Select the expand arrow next to the **Create Option** button.
   b. Choose **Add from File**.

c. Choose a **Category Separator**, either a comma or a semi-colon.

d. Upload a `.csv` file.

The Import file can only be a `.csv` file and should be in the format of "option,category" with one pair per line. If no separator is found the entire row is considered to be the option:

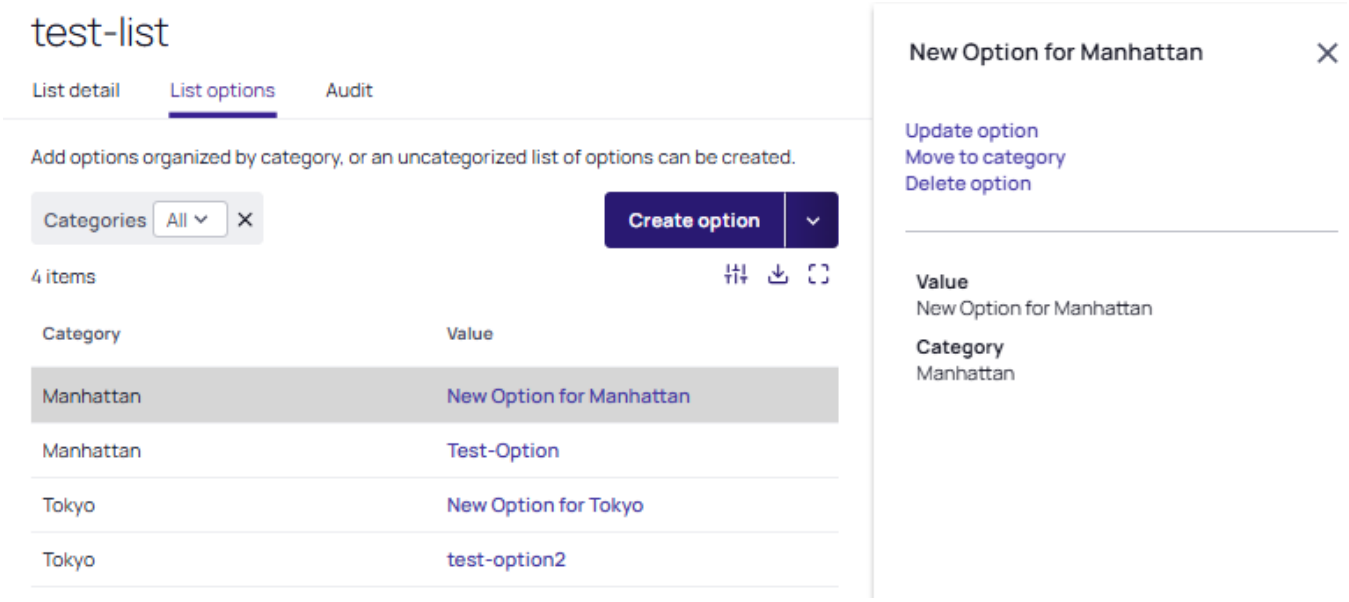


10. To create a category, select **Create Category** from the **Create Option** dropdown. The Create Category popup appears.
11. Type in the **Category** name and click **Save**. The category name now appears in the category dropdown list. For this example, Manhattan was entered.
12. Add another category the same way.
13. Click **Create Option**. The Create Option popup appears.
14. Type the name for the Option in the **Option Name** text box.
15. From the **Parent Category** dropdown, select the category you just created, e.g. Manhattan.
16. Click **Save**. The new option appears in the list with the option name you gave as the Value.
17. Repeat the process for the other category you created. You now have a new categorized list available for secrets (via a secret template with the list).

If you ever want to view past changes to a list or category, click the **Audit** tab for the list.

Editing Using the Side Menu

After creating an option it is possible to edit it in the **List options** tab:

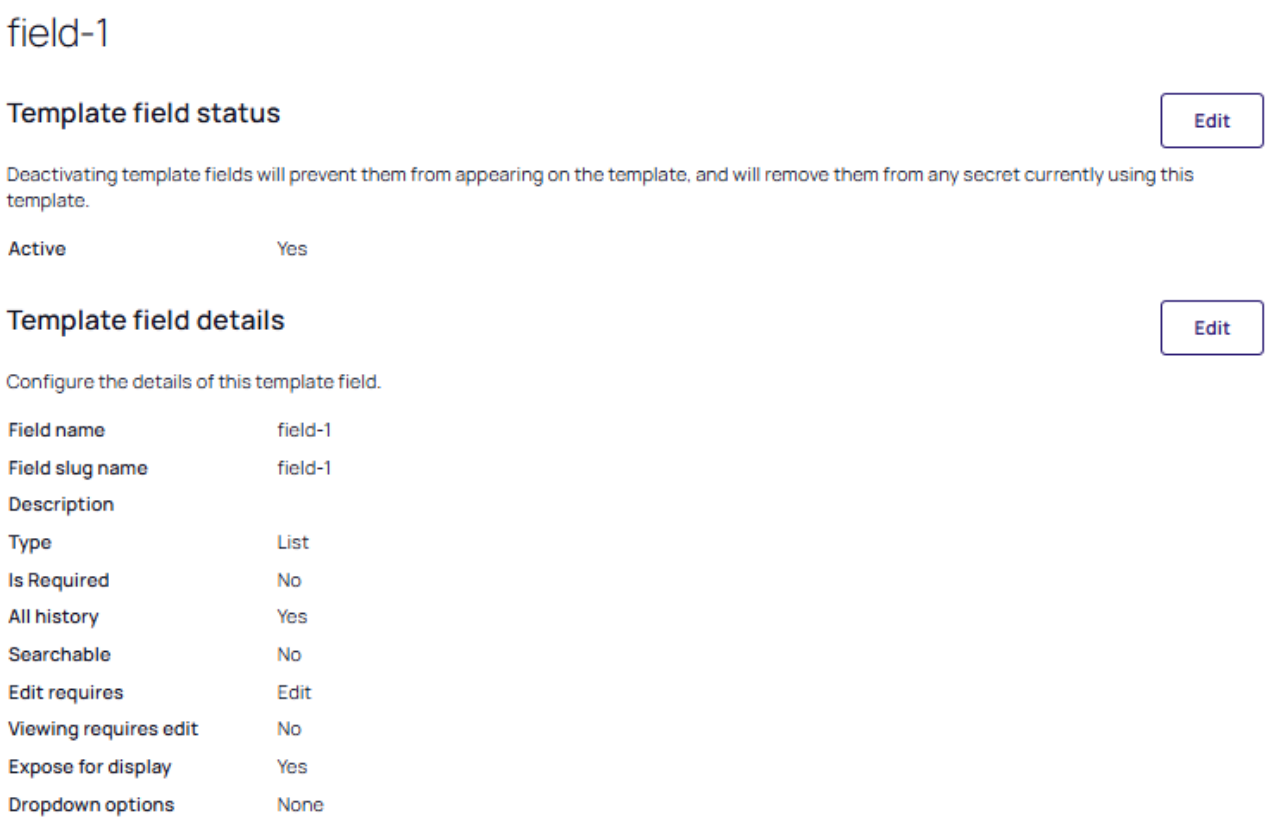


1. Click on one of the options you created.
2. A sidebar appears where you can:
   a. **Update Option**: Rename the option.
   b. **Move to Category**: Move the option to another category in the same list.
   c. **Delete Option**: Remove the option from the category list.

Task 2: Create a Template Using the List

1. Search for **Secret Templates**. The Secret Templates page appears.
2. Select **Create/Import Template**. The Create Template pop up appears.
3. Leave the option button set to **New**.
4. Type in a name in the **Template Name** text box.
5. Click **Save**. The General tab page for that new template appears.
6. Select the **Fields** tab.
7. Click **Add Field**. The Add Field popup appears.
   a. Type a name in the **Name** text box for the first (and currently only) field.
   b. The **Field Slug Name** automatically updates to match the name.
   c. (Optionally) add a description for the field.
   d. In the **Data Type** dropdown list, select **List**.
   e. Select **Save**. The new field appears in the table.
8. Select the field you just created. Its configuration page appears.

9. (Optional) Click the **Edit** button in the **Template Field Details** section to further customize the field:



Task 3: Create a Secret Based on the Template

1. Select **Secrets** from the main menu.
2. Click the **Create secret** button. The Create new secret popup appears.
3. In the **Choose a secret template** list, select the secret template you created in Task 2.
4. The **Create New Secret** popup updates to reflect your chosen template.

> Note that one of the dropdown lists is labeled with the same name as the list field you created earlier.

5. Give the secret a name.
6. For the list field you created, from the dropdown, select the name of the list of categories you created.
7. Leave the **Site** set to **Default**.
8. Select **Save**. The secret Overview tab loads automatically. Note that there is a new tab called **List Fields**.

If you add a List field into any Secret template, when creating a secret based on that template you are prompted to select one Categorized list. When you edit that secret, you'll now find a **List fields** tab on it, from where you'll be able to find every list field from the template, and have the option to add more categorized lists.

Please note that list fields are simply metadata. To use them for restricting targets, edit the secret template by modifying the appropriate launcher mapping so that user input is limited based on your specified list fields. Then, select the list field from the template fields.

Template Character Sets

Character sets are a collection of distinct characters that are used in password requirements and password rules. Custom sets can be created, and both ASCII and Unicode are supported. For more information on setting up compliance checks and password generation standards, see "Template Password Requirements" below. The five standard character sets are:

- Lower Case (a-z)
- Upper Case (A-Z)
- Numeric (0-9)
- Non-Alphanumeric (!@#$%^&*())
- Default – Includes all the above

To manage character sets, click the **Character Sets** button on the **Administration > Secret Templates** page. Only character sets which are not currently used by a password requirement can be deleted.

Template Naming Patterns

Secret Server supports naming patterns for secret templates. Naming patterns are a way for administrators to maintain consistency for secret names and can help ease both browsing and grouping secrets by name. Patterns are created using regular expressions. Regular expressions are a formal set of symbols commonly used to match text to patterns. For example, the regular expression `^\w+\\\w+$`, allows `NTDOMAIN01\USER3454` but not `USER3454` on `NTDOMAIN01`.

Regular expressions are beyond the scope of this document. They are very powerful and can get quite complex–books have been written on the topic. Microsoft offers a good overview at their Regular Expression Language Quick Reference Web page.

Template Password Requirements

Overview

A password requirement is a stored Secret Server object that defines the requirements on a password text-entry field to validate user-entered passwords or make auto-generated passwords conform to set specifications. You can have multiple password requirements, but only one can be set to the default.

A password requirement is made up of a minimum and maximum length, a set of characters, and optional rules such as "At least three upper-case characters" or "The first character must be lower-case". The default password requirement is 12 characters from the default character set with at least one upper-case, lower-case, numeric, and symbol character.

Creating a Custom Password Requirement

To create a new password requirement:

1. Search for **Secret Templates**, and select the **Password Requirements** tab.
2. Click the **Create** button. A popup appears.
3. Type the name of the new password requirement in the **Name** text box.
4. (Optional) Type a description of the new password requirement in the **Description** text box.
5. Click the **Minimum Password Length** spinner to select or type a minimum allowed password length.
6. Click the Character Set dropdown list to select a character set for the password. The out-of-the-box default is `abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ1234567890!@#$%^&*()`.
7. If you want the password requirement to become the new default, click to select the **Is Default** check box.
8. Click to select the desired password no-no check boxes. The options are:
   - **Prevent Username**: Do not allow the username to be part of the password.
   - **Prevent Spatial Pattern**: Do not allow strings of characters based their order on the keyboard, such as `qwerty` or `asdfg`.
   - **Prevent Sequential Pattern**: Do not allow strings of characters based on their order in the character set, such as `abcd` or `5678`. Note: As character sets are case sensitive, `AbCd` is allowed.
   - **Prevent Dictionary Words**: Do not allow everyday English words in the password.
9. Click the **Save** button. The popup closes and the page for the new requirement appears (containing the choices you just made for the details and generation sections):
10. Scroll down to the **Password Validation** section.
11. Click the **Edit** button. The section expands.
12. Most of the validation rules are ones you have already set with these two exceptions, which you can now set:
    - **Prevent Dictionary Words**: Do not allow everyday English words in the password.
    - **Prevent Words from Dictionary ...**: Do not allow words that appear in the named dictionary. In our example, the dictionary is named "Test."
13. Go to the **Starting and Ending Character Validation** section.
14. Click the **Edit** button.
15. To require specific starting characters, click to select the **Require Specific Starting Characters** check box. Two hidden controls appear. This allows you to make rules such as "password must start with three symbols and end with two lowercase letters."

"Start and end with" rules can decrease the password entropy (resistance to brute force attacks).

16. Type or click the spinner to set the number of required starting characters.
17. Click the **characters from** dropdown list to select the character set to draw the characters from.
18. Repeat the procedure for any desired ending characters.
19. Click the **Save** button. An edit button now appears for the Character Count Validation section.
20. To set character count validation rules:
    a. Click the **Edit** button for the **Character Count Validation** section. The section expands.
    b. Click the **Add Rule** button and select one of the following types:
        - **Minimum Required Characters Rule**: For the first rule type, type the number of characters and select what character set they must come from, for example, "Minimum 5 characters from Upper Case (A-Z)."
        - **Maximum Consecutive Characters Rule**: For the second rule, type the number of characters and select what character set they must come from, for example, "Maximum 5 characters from Lower Case (a-z)."
        - **Repeating Characters Rule**: Sets a limit on how many times any single character can appear in a password. You can set it anywhere between one and the maximum length of the password requirement. For example, the rule "At most 1 of the same character" means that any character can only appear one time in a password: `Bztyopz` is invalid because there are two `z` characters, and `Bztyopx` is valid because no character appears more than once
        - **Repeating Consecutive Characters Rule**: Sets a limit on how many times any single character can appear in a sequence in a password. You can set it anywhere between one and the maximum length of the password requirement. For example, "At most consecutively 2 of the same character" means any character can only appear one time in a password: `Bzty1fxeee` is invalid because there are three `e` characters at the end of the password. `Bzty11fxe` is valid because no character appears more than twice. Finally, `Bzetey1efxe` is valid, even though there are three `e` characters, because they do not appear next to each other.
    c. Once you create more than one rule, the **Minimum Required Character Count Rules** dropdown list appears. This allows you to set whether you want a minimum number of rules enforced from those you created or all of them.
    d. Create as many additional character count validation rules as you desire by clicking the **Add Rule** button and repeating the procedure.
    e. Click the **Save** button.
21. Review the **Password Rule Strength** section to see how strong your choices are and any recommendations for improvement. The two tests are:
    - **Entropy Score**: The difficulty of cracking the password in a brute-force attack.
    - **Total Strength Score**: An overall weighted measure of password strength for passwords generated by the password requirements. Any rule conflicts will appear in the recommendations section.

> The explicit character rules cannot conflict with the implicit ones you created earlier or you will get an error when saving. For that reason, we suggest leaving the password requirements character set to the default. Carefully consider any other conflicts if you get an error.

> To set a custom password requirement for a specific secret, use the "Customize Password Requirement" in the Security tab of a secret.

> You can enable or disable the validation of manually entered passwords at the secret template level via the "Validate Password Requirements on Create" and "Validate Password Requirements on Edit" settings.

> The "What Secrets Do Not Meet Password Requirements" report shows secrets containing a password that does not meet the password requirements set for its secret template.

> Password requirements cannot include rules with overlapping character sets. For example, if an attempt is made to add both a "Minimum of 1 upper-case" rule and a "Minimum of 3 Default" rule to a new password requirement, an error displays.

Assigning Requirements to a Secret Template

To assign requirements to a secret template:

1. Navigate to **Secret Templates.**
2. Select the template you wish to edit.
3. Navigate to the **Fields** tab.
4. Select the **Password** field.
5. Select Edit for the **Template Field Details** section.
6. For **Password Requirement**, select your desired requirement.

Managing Specific Templates

This section addresses specific secret templates, rather than templates in general.

Configuring SAP SNC Account Secret Templates

Introduction

The "SAP SNC Account" secret template is an expansion on the original "SAP Account" secret template. It takes advantage of SAP's Secure Network Communication (SNC), which is a protocol that encrypts communication between Secret Server and an SAP Server. The SAP SNC Account template includes all the original fields from the SAP Account secret, adding a few more as well.

New Template Fields

The following is an introduction to the new template fields (in addition to those also found in the SAP Account secret template):

> Please see the SAP .NET Connector 3.0 Programming Guide for additional information.

- **SNC Partner Name:** Matches the snc/identity/as value set in your SAP Server configuration.
- **SNC My Name:** For most SAP configurations, you can ignore this. See the connector programming guide for cases where it may be required.
- **SNC Quality of Service:** Dropdown list to select the service quality or protection used for SNC communication. Choose one of the following protection options:
  - Authentication Integrity (includes authentication)
  - Authentication Integrity Privacy (includes integrity protection and authentication)
  - Authentication Only
  - Default Protection
  - Maximum Protection
- **SNC Single Sign On:** Dropdown list to set to true if you wish to use single sign on. If you set this to false, you authenticate with your username and password on the secret.
- **X.509 Certificate:** Click the **Change** link to upload an X.509 certificate for authentication.

Server-Side Setup

Prerequisites

SAP Server Setup

Follow the latest SAP documentation for configuring the SAP server and your SAP users to use SNC. For example:

1. SSH into your SAP server.
2. Edit the configuration file: `/sapmnt/<SystemID>//profile/profilename.pfl`
3. Add the SNC settings to the end of this file. For example:

```
snc/enable = 1
snc/gssapi_lib = /usr/sap/NPL/SYS/exe/run/libsapcrypto.so
snc/identity/as = p:CN=vhcalnplci,OU=Test,O=Thycotic,C=US
snc/accept_insecure_cpic = 1
snc/accept_insecure_gui = 1
snc/accept_insecure_r3int_rfc = 1
snc/accept_insecure_rfc = 1
snc/permit_insecure_start = 1
snc/extid_login_diag = 1
```

```
snc/extid_login_rfc = 1
snc/data_protection/min = 1
```

4. Verify that the library file path exists on your server (make sure that `libsapcrypto.so` is actually in that directory).
5. Reboot your server.
6. When the server is finished, reconnect and restart the SAP server with these commands:

```
su npladm
startsap all
```

SAP NCO Files

As with the original SAP Account template, you include the `SAPNCO.dll` and `SAPNCO_UTILS.dll` files in your Secret Server or distributed engine installation. See "SAP Heartbeat and Password Changing" on page 1041 for more information.

SAP Cryptographic Library

In addition to the SAP NCO DLL files, you need to obtain the SAP Cryptographic Library. This should include the library DLL (`sapcrypto.dll`), the license ticket, and the configuration tool (`sapgenpse.exe`). Add the DLL file to your Secret Server or distributed engine installation following the same steps as the SAP NCO files. For more information on this library, see the SAP Identity Management Configuration Guide .

SAP Server Certificate

1. Open SAP Trust Manager (STRUST).
2. Download your SAP's server certificate from the STRUST transaction. Assuming you setup your SAP server correctly, this should be located in the **SNC SAPCryptolib** folder.
3. If nothing exists under SNC SAPCryptolib, right click on the folder and select **Create** to create a new PSE under **SNC SAPCryptolib**.
4. Open the PSE.
5. Enter a password if prompted. (If not, use the **Password** button to set a password).
6. Click the SNC SAPCryptolib folder.
7. Double click the **Subject** under **Own Certificate**.
8. Confirm the certificate details appear in the **Certificate** section.
9. Click the **Export Certificate** icon button at the bottom to open a dialog box, which allows you to download the certificate.

> If the button is not enabled, you may need to click the Display or Edit (pencil and glasses) button and click the Base64 selection button when prompted and then the green checkmark button to complete the download.

Personal Security Environment Setup

As with your SAP server setup, you should consult the latest SAP documentation for more information when setting up your Personal Security Environment (PSE). These instructions are provided to illustrate the options to configure the SAP SNC Account secret template in Secret Server, but SAP's documentation may provide more information about your options pertaining to the creation of a PSE. To set up your PSE:

1. In your client environment (your Secret Server or distributed engine server), create a directory to stage your setup. For example, I used `C:\SAPSNC`.
2. Add the two SAP NCO files (sapnco.dll and sapnco_utils.dll), the SAP Cryptographic library (sapcrypto.dll), your ticket license file, and sapgenpse.exe to this directory.
3. Copy the server certificate you exported from your SAP instance to this directory.
4. Add two system environment variables to your server:
   - SECUDIR should be the directory you just created (for instance `C:\SAPSNC`)
   - SNC_LIB should be the full path of the SAP Encryption library (for instance `C:\SAPSNC\sapcrypto.dll`).
5. Following SAP's instructions, use SAPGENPSE (or other tools that SAP may provide) to generate the PSE, including the cred_v2 file and the X.509 certificate. See Configuring the Use of the SAP Cryptographic Library for SNC. For example, you could run these commands from a command prompt window with Windows Administrator permissions in the `C:\SAPSNC` directory:

   ```
   sapgenpse get_pse -p target.pse -x <PASSWORD> <DISTINGUISHED NAME>
   sapgenpse seclogin -p target.pse -x <PASSWORD> -O <DOMAIN\USER>
   sapgenpse maintain_pk -a <CERT FILE FROM SAP GUI> -p target.pse -x <PASSWORD>
   sapgenpse maintain_pk -v -l -p target.pse -x <PASSWORD>
   sapgenpse export_own_cert -o target.crt -p target.pse -x <PASSWORD>
   ```
6. When you create the server credentials with the sapgenpse "seclogin" command, specify a Windows or Active Directory user for the credentials. You have two options here:
   - Specify the same user who runs your Secret Server or distributed engine as the one who is allowed to use the PSE you just setup. This is the easier option. Secret Server
   - Specify a different Windows or Active Directory user. If you choose this option, you need to also create a secret for that user in Secret Server as either a Windows or Active Directory secret. Add this secret to your SAP SNC secret's associated secrets.

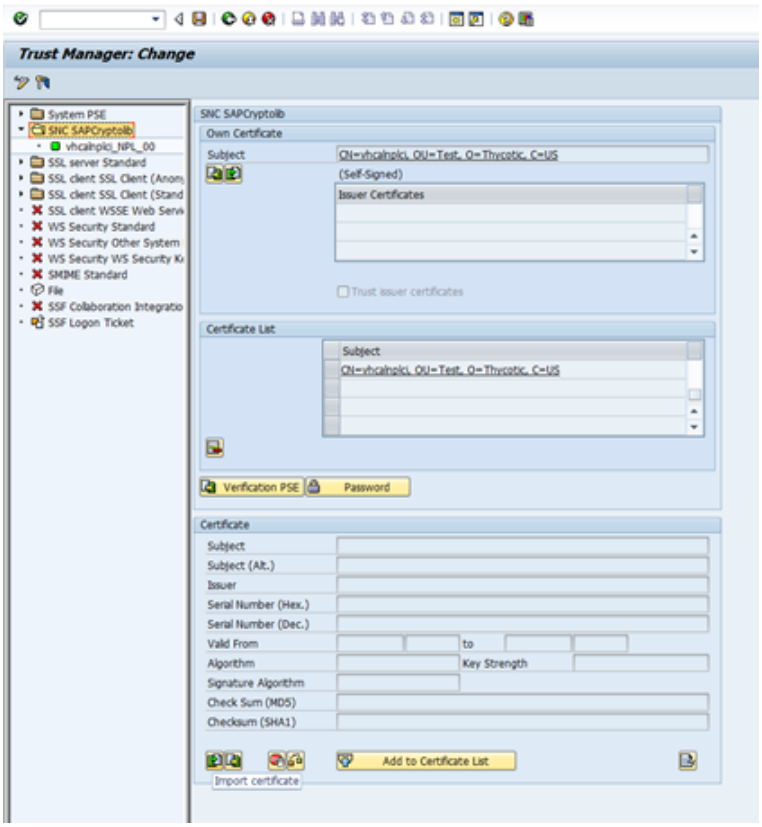
For more information about using the SAPGENPSE tool, see Creating the Server's Credentials Using SAPGENPSE.

Importing PSE information to the SAP GUI

1. As above, refer to SAP's documentation for details on getting your PSE recognized by your SAP server. This is just an example.
2. Import the certificate you created above ('target.crt' in my example) through the STRUST transaction in the SAP GUI:

a. Go to **STRUST \> SNC SAPCryptolib**.

b. Click the entry below the SNC SAP Cryptolib folder. In the example below it is vhcalnplci_NPL_00.



c. If prompted for a password, type it and then click the green checkmark button.

d. Click the Import Certificate icon on the far left on the bottom (hover over). The Import Certificate dialog box appears.

e. Type your certificate's file path.

f. Click the green checkmark button. The dialog disappears.

g. Confirm the certificate details are now in the **Certificate** section.

h. Click **Add to Certificate List**.

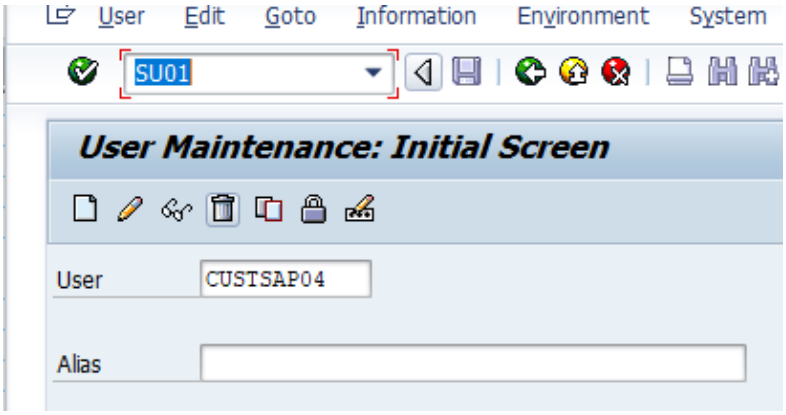
> If the button is not enabled, you may need to click the Display or Edit (pencil and glasses) button.

i. Confirm the certificate now appears in the **Certificate List** section.

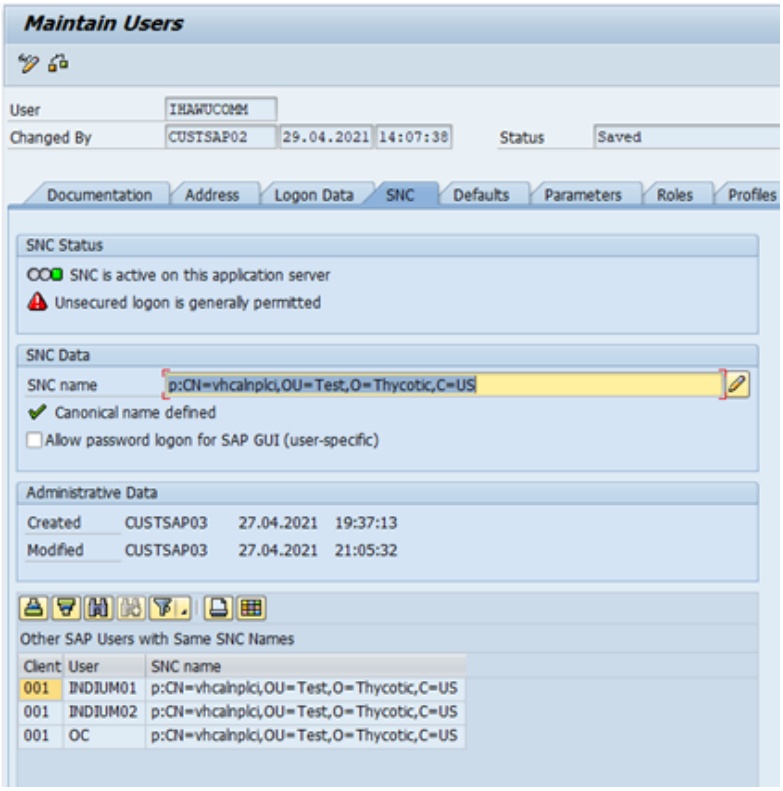
j. Save and exit.

3. Go to the **SU01** function.

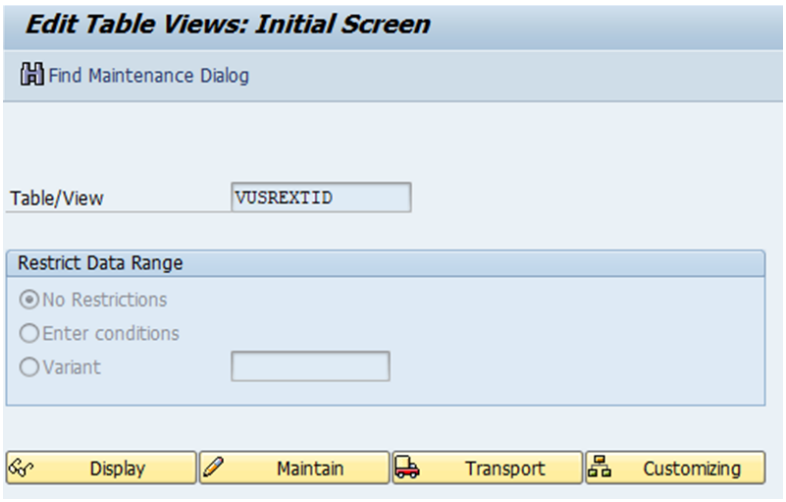
4. Type your SAP user's name in the **User** text box.



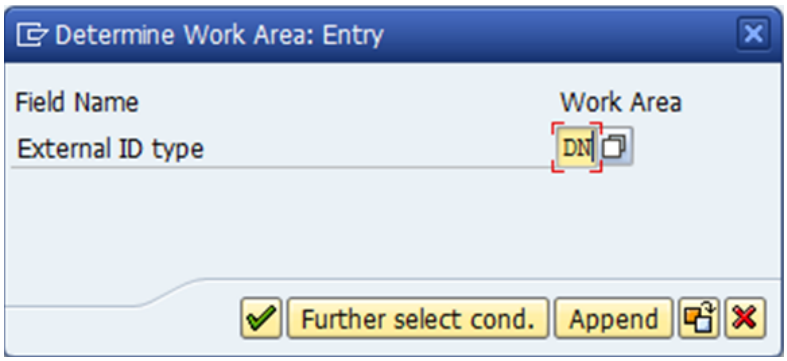
5. Click the pencil icon to edit.
6. In the **SNC** tab, define the SNC name using the syntax: `p:<YOUR USER'S DISTINGUISHED NAME>`.



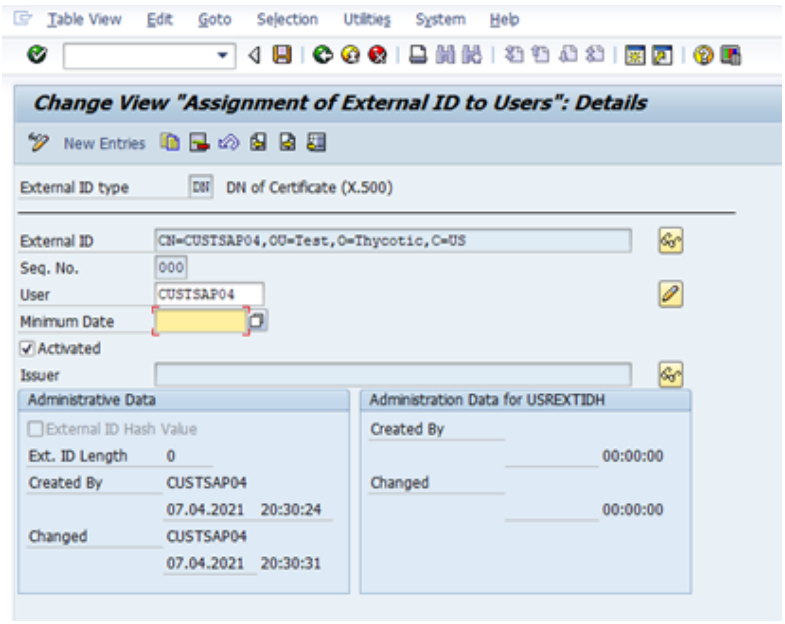
7. Save and exit the **SU01** transaction.
8. Go to the **SM30** transaction.



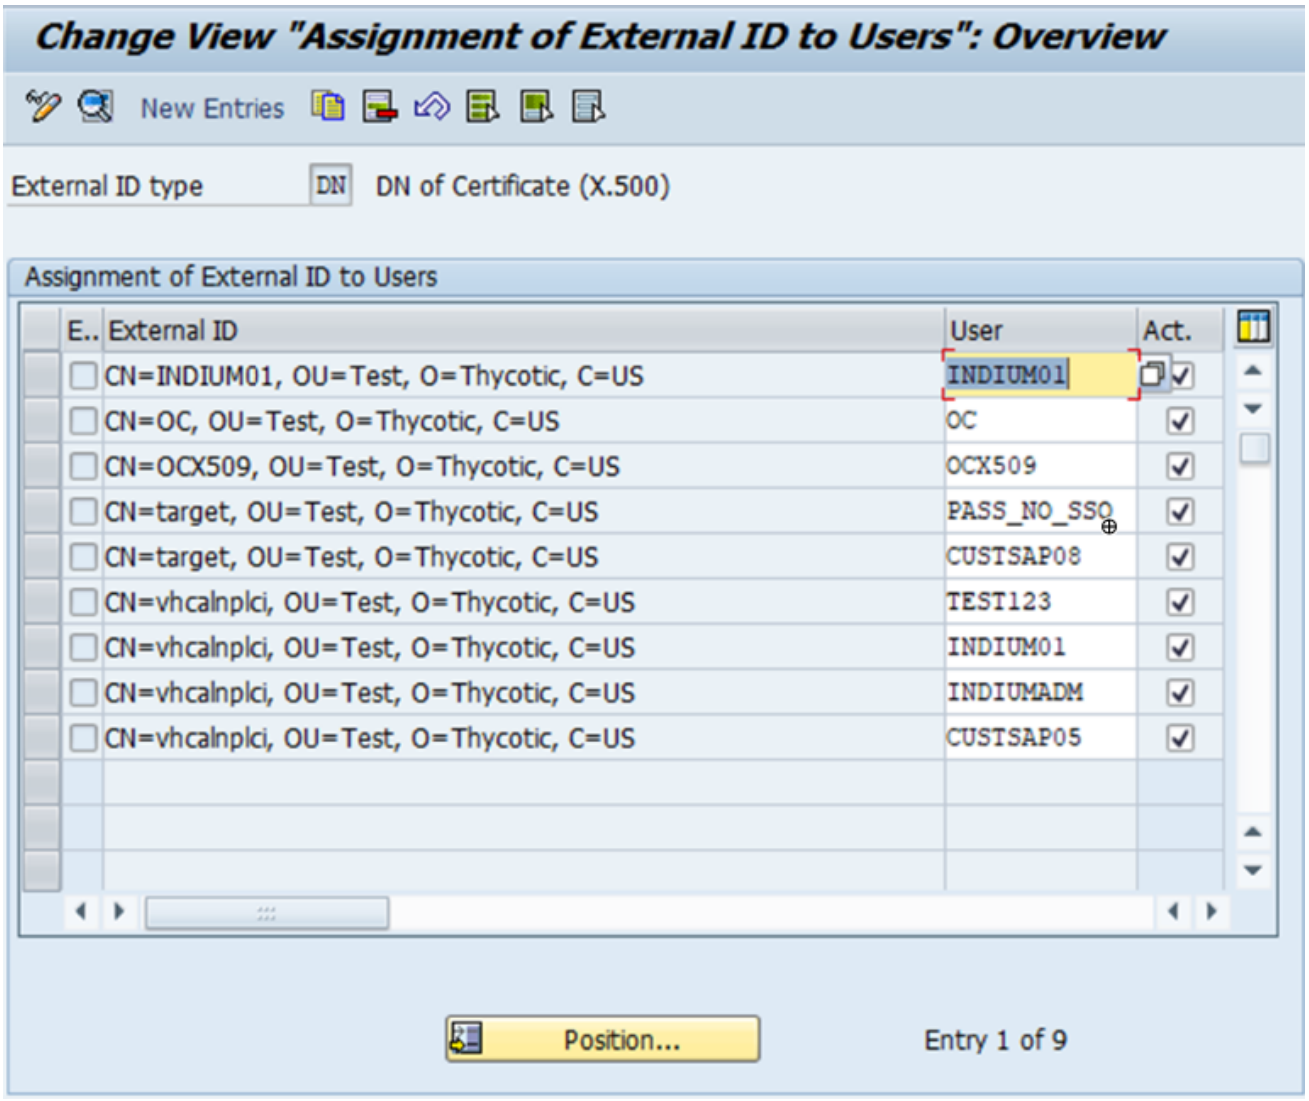
9. Type `VUSREXTID` in the **Table/View** text box.
10. Click the **Maintain** button. A dialog box appears:



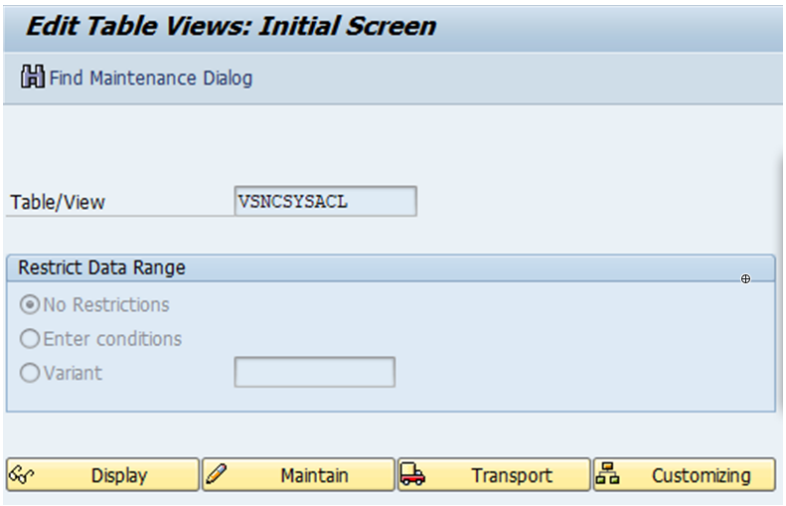
11. Select **DN** as the work area.
12. Click the check mark icon button.



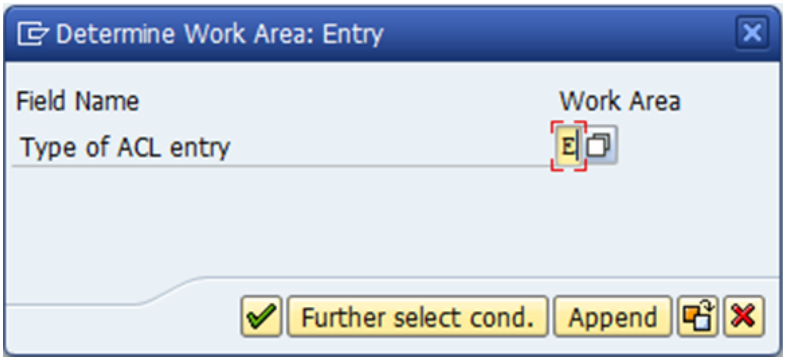
13. Click the **New Entries** button. The Change View "Assignment of External ID to Users" panel appears:



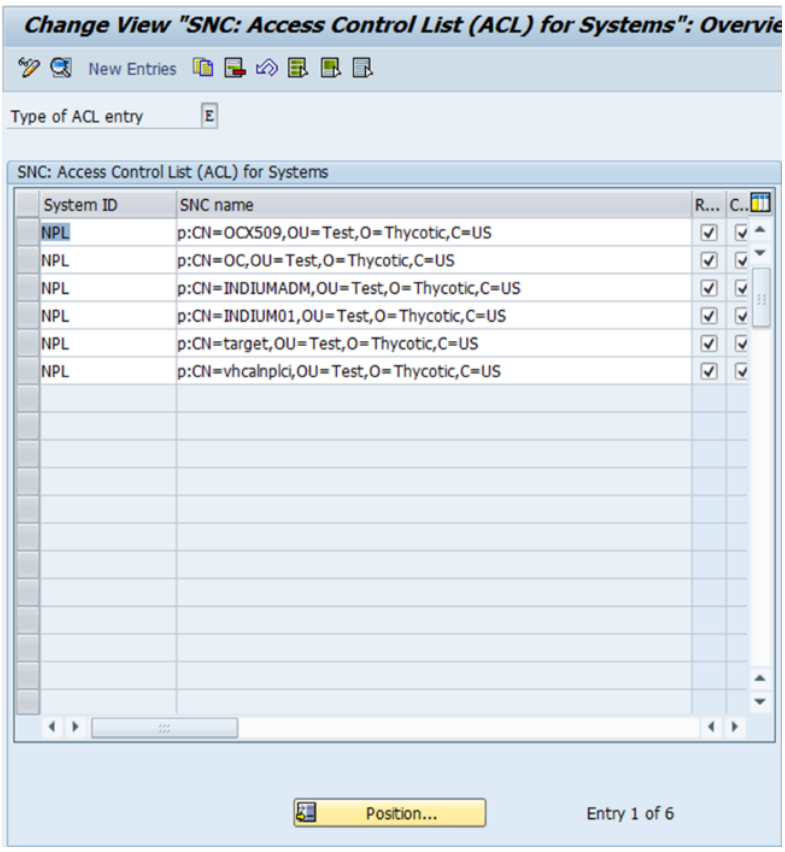
14. Click the Details (magnifying glass) icon. A details panel appears.
15. Fill out the fields as follows:
    a. Replace the **External ID** with your own
    b. Click to select the **Activated** check box.
    c. Type your SAP username in the User text box.
    d. Type a sequence number in the **Seq. No.** (sequence number) text box. For example, 000.
    e. Save and exit.
16. Return to the SM30 function.



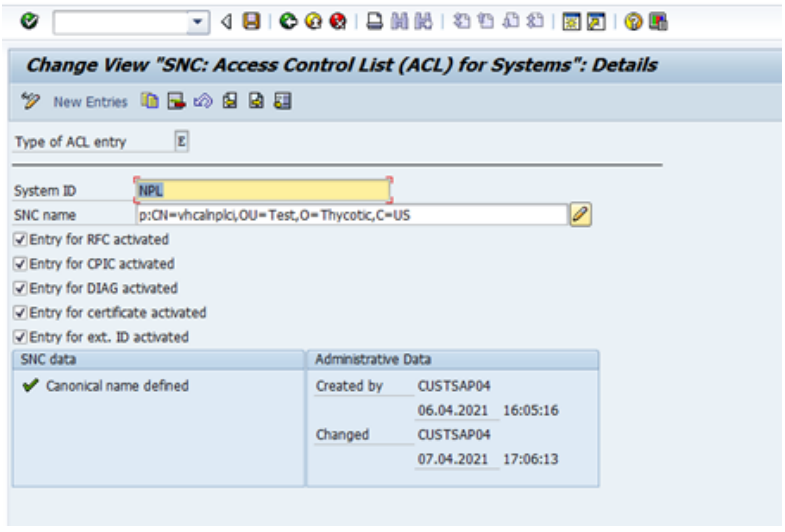
17. Type VSNCSYSACL in the **Table/View** text box.
18. Click the Maintain button. A dialog box appears:



19. Select **E** as the work area.
20. Click the check mark icon button. The dialog box disappears.
21. Click the **New Entries** button. The Change View "SNC: Access Control List (ACL) for Systems" panel appears:



22. Click the Details (magnifying glass) icon. A details panel appears.



23. The **System ID** should match the system ID of your SAP instance. The **SNC name** should be the distinguished name of the server. There should only be one entry in this table for the server.
24. Confirm that a "Canonical name defined" message appears.

25. Save and exit

Creating an SAP SNC Secret in Secret Server

SAP SNC Account secrets are created in the same way as the original SAP Account secrets but have additional fields, as described above. For details that apply to both the SAP Account and SAP SNC Account secrets, see "SAP Heartbeat and Password Changing" on page 1041 for details.

If your PSE was created for a Windows or Active Directory user other than the one who runs Secret Server or distributed engine, you need to add that user to your SAP SNC Account secret's associated users. To do this, add your user as either a Windows Account or an Active Directory secret. Next, open your SAP SNC Account secret and navigate to the Remote Password Changing tab to add that secret as an Associated Secret.

Another alternative way to user/password login, is to login via an X.509 certificate. Leave blank if another authentication is to be used. If used, the certificate should have no line breaks, and should not include Begin Certificate nor End Certificate lines.

If you do not use single sign-on or if you choose to use the username and password without the X.509 certificate for authentication, the X.509 certificate may be omitted.

Troubleshooting

SAP Account Secret Work but SAP SNC Secrets Do Not

SNC uses port 4800 to communicate. If the original SAP Account secrets work but SAP SNC secrets do not, be sure that port 4800 is not blocked by your firewall or VPN.

Client-Side Errors

If you experience client-side errors (such as generating a client certificate), right click on your SAP DLL files (`sapcrypto.dll`, `sapnco.dll`, or `sapnco_utils.dll`), and make sure that they are not blocked by your OS.

Distinguished Name Errors

If you run into an error message a distinguished name (DN) error, such as `Exception: LOCATION CPIC (TCP/IP) with Unicode ERROR GSS-API(maj): No credentials were supplied Unable to establish the security context target="p:CN=vhcalnplci, OU=Test, O=Thycotic`, check your spacing in the distinguished name. SAP can be strict about adding or removing the spaces after commas in the DN.

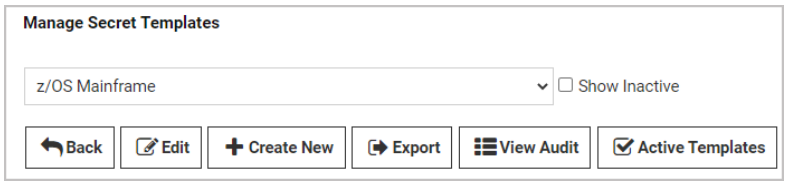
Create and Customize an IBM iSystem (AS/400) Template to use the new IBM iSeries (AS/400) Password Changer

The IBM iSeries (AS/400) Terminal password changer is based on the z/OS Mainframe password changer. It uses the 5250 terminal connection and scripting to perform the password change and heartbeat. You can modify the script for any advanced configuration requirements, and Delinea Professional Services is available to help you.

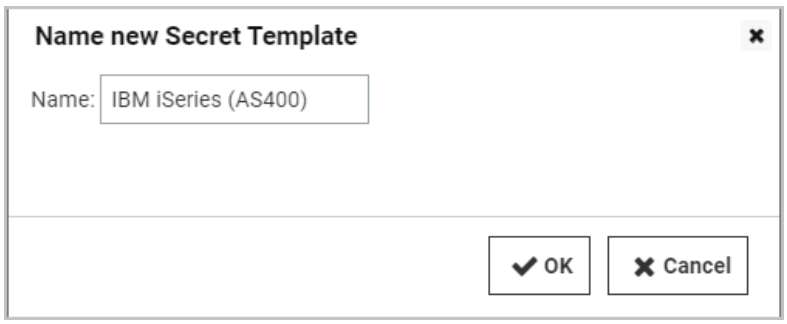
You can also change passwords on the AS/400 using SSH. See "Creating a Custom Password Changer for IBM AS/400" on page 1021.

Create an AS/400 Secret Template

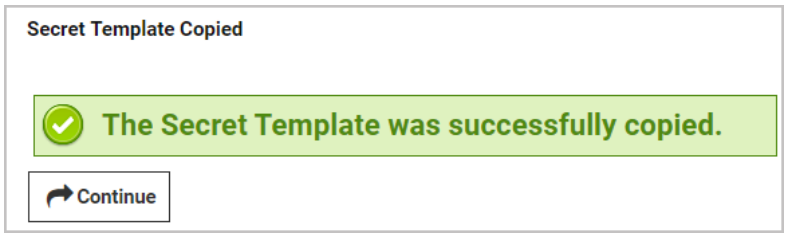
1. Search for **Secret Templates**.
2. On the **Manage Secret Templates** page, select the **z/OS Mainframe** template from the drop-down list.
3. Click the **Edit** button.



4. On the **Secret Template Designer** page, click the **Copy Secret Template** button.
5. On the popup page, type `IBM iSeries (AS400)` in the **Name** text box.



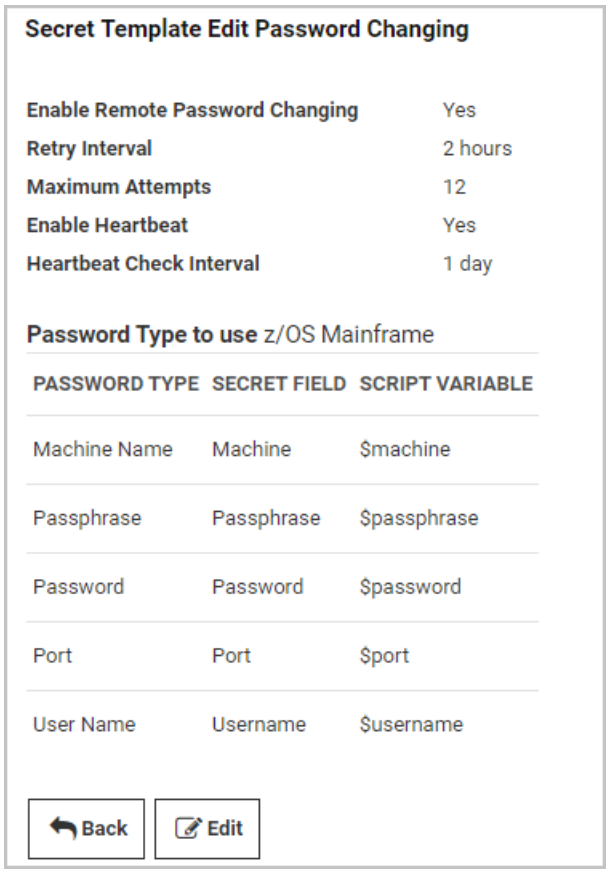
6. Click the **OK** button.
7. On the confirmation page, click the **Continue** button.



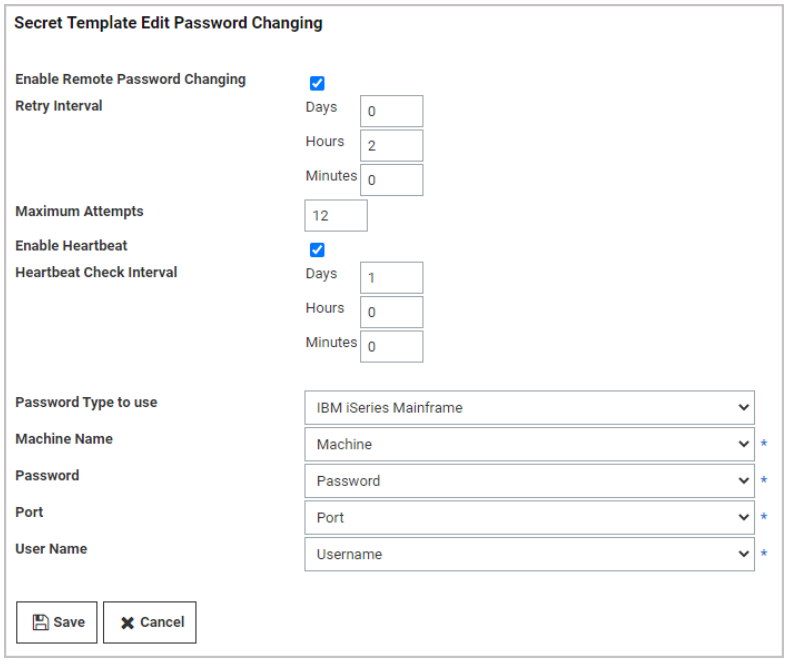
Optional: on the **Secret Template Designer** page, you can deactivate the **Passphrase** field by clicking the deactivate icon to the right of the **Passphrase** row. Unlike the z/OS, the iSeries does not need an additional passphrase and will not have an option for it unless adjusted. Unless your environment specifically requires the passphrase text-entry field, we recommend deactivating it.

Modify Your AS/400 Secret Template to use the AS/400 Password Changer

1. On the **Secret Template Designer** page, click the **Configure Password Changing** button.
2. On the **Secret Template Edit Password Changing** page, click the **Edit** button. The page becomes editable.



3. Next to **Password Type to Use**, click the drop-down list and select **IBM iSeries Mainframe**.

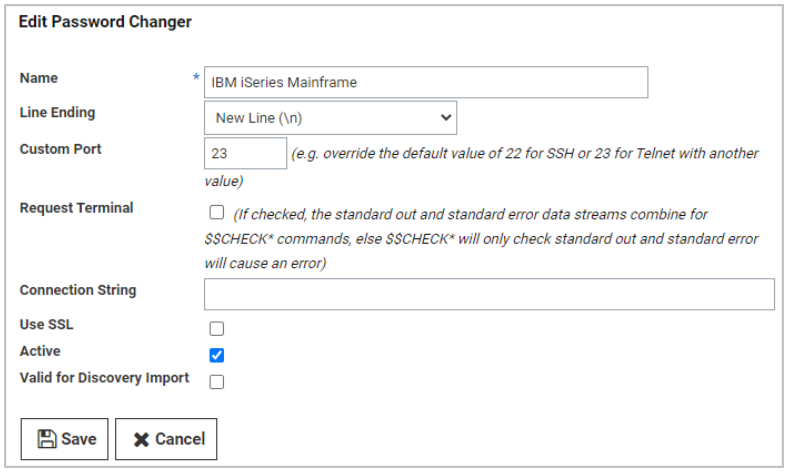


4. Make required changes, if any, to the text boxes and lists.
5. Click the **Save** button. The page is no longer editable.
6. Click the **Back** button.
7. On the **Secret Template Designer** page, create secrets based on the new template as desired.

Customize Your AS/400 Password Changer for Your Environment

For the default IBM iSeries (AS/400) systems, the default password changer configuration requires no adjustment. However, additional parameters and connection string options are available.

1. Search for **Remote Password Changing**.
2. Click the **Configure Password Changers** button.
3. On the **Password Changer Configuration** page, click the **IBM iSeries Mainframe** link.
4. On the **IBM iSeries Mainframe** page, scroll to the bottom and click **Edit**.
5. On the **Edit Password Changer** page, adjust ports and other parameters as desired.



6. Click the **Save** button.

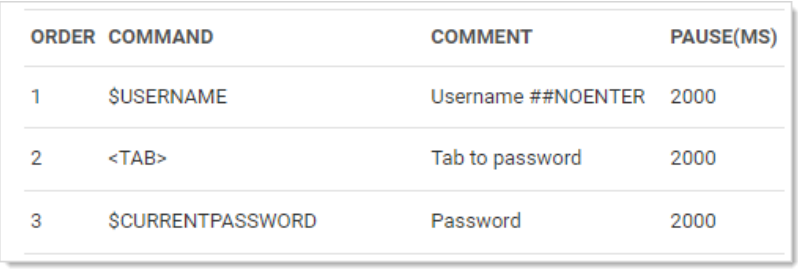
The *trace* function can be a powerful tool for troubleshooting and debugging, especially for complex RPC implementations in unique environments. The trace function logs emulator input, mainframe output, and ASCII screenshots of what is happening on the terminal GUI. To write a trace file to the Secret Server website or engine, just add TRACEto the connection string. If using the model option, this needs to be an integer, for example, model=4.

It is important to delete trace files after debugging—they could contain sensitive data.

Additional Functions, Adjustments, and Parameters

For unique IBM iSeries environments, the IBM iSeries password changer offers extra features, options, adjustments and parameters for customization, including the commands in the table below. To implement these commands successfully, it helps to keep in mind that the password changer is emulating user input. Some of these commands are designed for very fine emulations of unique IBM iSeries environments, and Delinea Professional Services can help you with these. Other commands are implemented and tested on a base environment, so before implementing them in a production environment, you should verify that they are working as expected through testing or by using the trace function.

The commands below are followed by an <ENTER> command by default. To prevent this, you must add ##NOENTER in the *comment* of the previous command. For example:



ORDER	COMMAND	COMMENT	PAUSE(MS)
1	$USERNAME	Username ##NOENTER	2000
2	<TAB>	Tab to password	2000
3	$CURRENTPASSWORD	Password	2000

Table: Secret Template Commands

Command	Action	Description or Example
<Backtab>	Tab to the previous input field.	
<Clear>	Clear the screen.	Mostly used for trace.
<Close>	End the session to the mainframe.	
<Delete>	Delete a character under the cursor; can be used with <MoveCursor(#, #)>	
<DeleteField>	Delete the entire text input or field.	
<DeleteWord>	Delete the current word if available, otherwise delete the previous word.	
<Disconnect>	Disconnect the password changer's connection to the mainframe.	
<Down>	Move cursor down.	
<Enter>	Send the Enter key press command.	

Command	Action	Description or Example
<Erase>	Erase previous character on a selected text input.	<Erase>
<EraseEOF>	Erase end-of-field of current text input.	<EraseEOF>
<Execute( )>	Execute commands in shell.	<Execute(USRMGR)>
<HexString(#)>	Insert a control character in a text field or string.	<HexString(41)>
<Key(#)>	Execute named iSeries keys.	Execute unique keys via hex, character code, or key symbol.
<Left>	Move cursor left.	
<PF(#)>	Execute program function.	Program function keys 1 to 24
<PA(#)>	Execute program attention.	Program attention functions 1 to 3
<MoveCursor(#, #)>	Move the cursor by row and column.	<MoveCursor(10,2)>
<Right>	Move cursor right.	
<Tab>	Tab to the next line.	
<Up>	Move cursor up.	

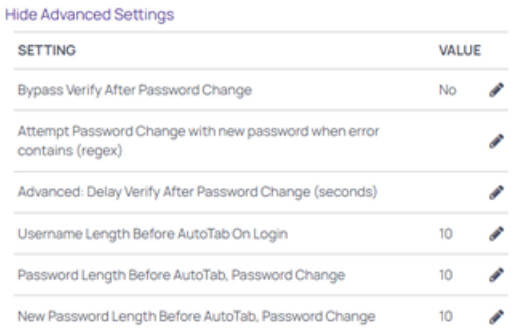
IBM iSeries Mainframe

Usernames and passwords can run into length issues during remote password changing and heartbeat. The issue stems from the behavior in the client; when a user logs in and enters a username of 10 characters, the client will auto-tab to the next field (the password field). The heartbeat and remote password changing process automatically inserts this tab, which can cause improper behavior in the headless client when the username or password is 10 characters.

This can be avoided by setting three properties on the Custom Commands for the IBM iSeries Mainframe password changer:

- Username Length Before AutoTab on Login
- Password Length Before AutoTab, Password Change
- New Password Length Before AutoTab, Password Change

Go to **Remote Password Changing** > **Configure Password Changers** > **IBM iSeries Mainframe**.



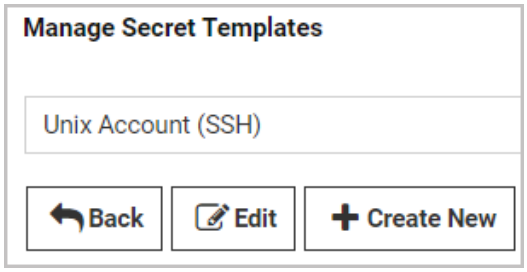
Typically, the console will auto-tab after 10 characters. If your environment behaves differently, note in the console how many characters are entered until auto-tab to the next field occurs, and enter that number into the proper field.

Creating a Unix Account Secret Template that Uses Key Authentication Instead of a Password

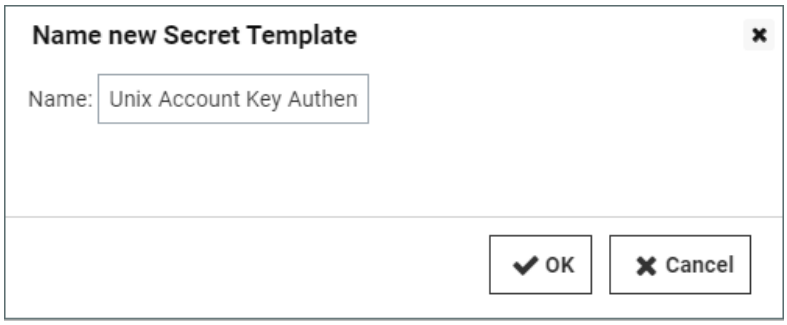
To create a Unix account secret template that uses key authentication only instead of a password, begin by using an existing **Unix Account (SSH)** template as a baseline.

Create the New Template

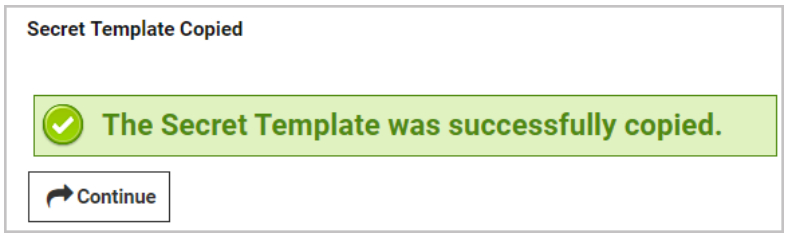
1. Search for **Secret Templates**.
2. Select the built-in **Unix Account (SSH)** template from the drop-down menu and click **Edit**.



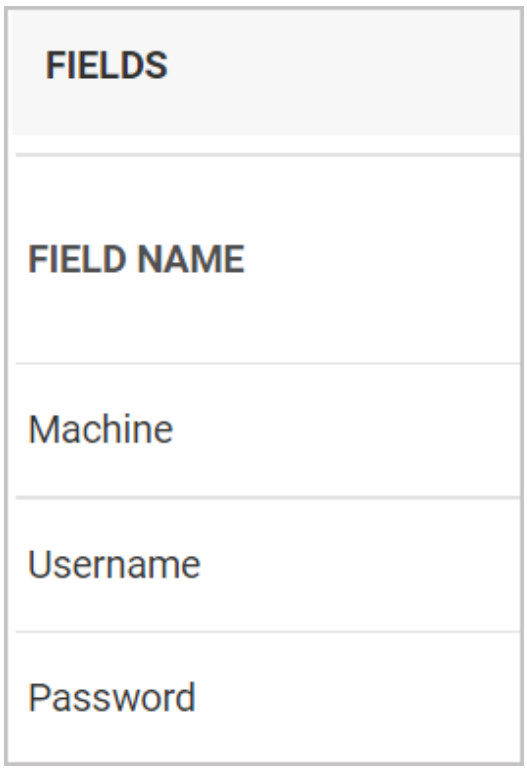
3. On the **Secret Template Designer** page, scroll to the bottom and click **Copy Secret Template**.
4. Give the new template an appropriate name, such as *Unix Account Without Password (SSH)* or *Unix Account Key Authentication Only (SSH)*.



5. Click **OK**.
6. On the **Secret Template Copied** confirmation page, click **Continue**.



7. On the **Secret Template Designer** page, scroll down to the **Fields** section and under **Field Name**, find the **Password** row.



8. At the right end of the **Password** row, click the **Edit this field** icon
9. In the **Password** row under **IS REQUIRED**, uncheck the box. Optionally, you can also select **Not Editable** from the **Edit Requires** drop-down list.

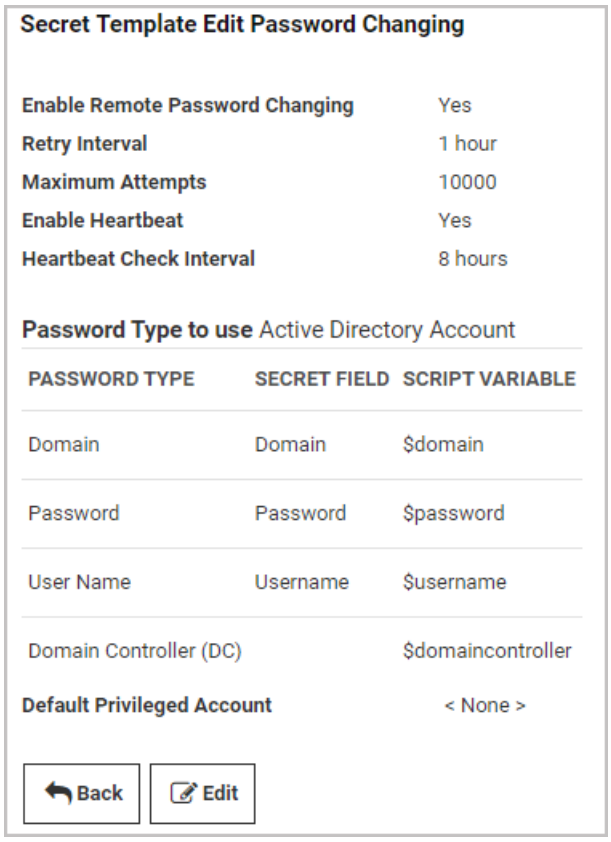
10. At the right end of the **Password** field, click the **Save this field** icon

You now have a Unix account (SSH) Secret template that displays key authentication fields instead of a password field.

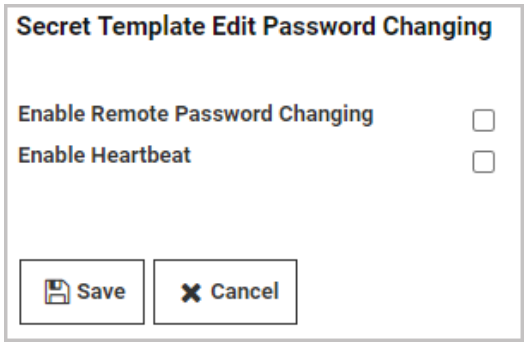
Disable Remote Password Changing and Heartbeat

Your new template has inherited characteristics from the **Unix Account (SSH)** template you based it on, including having **Remote Password Changing** and **Heartbeat** enabled by default. But because your new template has no password, it cannot be remotely changed and heartbeat cannot validate on an empty password. Therefore, you must disable these features by editing your new template using the procedure below:

1. In the **Secret Template Designer** window, scroll to the bottom and click **Configure Password Changing**.
2. In the **Secret Template Edit Password Changing** window, click **Edit**.



3. In the next **Secret Template Edit Password Changing** window:
   a. Uncheck **Enable Remote Password Changing**.
   b. Uncheck **Enable Heartbeat**.



4. Click **Save**.

> Some Secrets based on the **Unix Account (SSH)** might display the **Password** field as well as the **Private Key** and **Private Key Passphrase** (key authentication) fields. If a user signs in using this template with correct credentials in the key authentication fields but a blank or incorrect password in the Password field, the default PuTTY launcher will use key authentication to connect.

Configuring Oracle Secret Templates

Secret Server now has four Oracle templates, three current and one legacy:

- Oracle Account
- Oracle Account (TCPS)
- Oracle Account (Template Ver 2)
- Oracle Account (Walletless)

Introduction

Overview

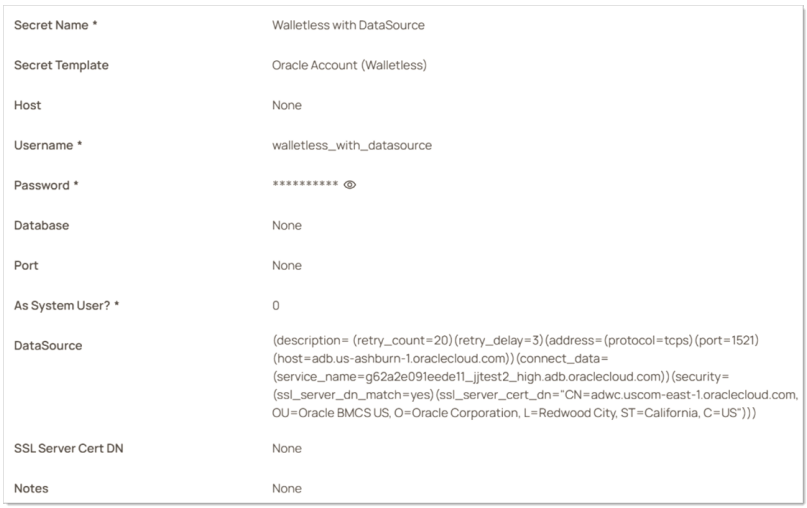
Secret Server now has three secret templates based off the Oracle Managed Data Access NuGet library. Unlike earlier Oracle secret templates, templates, using the NuGet library does not require `Oracle.ManagedDataAccess.dll` to be installed alongside Secret Server or its engines. Additionally, two of these templates support Oracle's TCPS connection protocol. You can run the new templates alongside the earlier Oracle secret templates, but we recommend using the new templates when creating new Oracle secrets.

DataSource Field

All three new templates include an optional DataSource field. The DataSource field acts like a connection string to the Oracle database. When used, it is not necessary to fill out the Host, Database, Port, or SSL Server Cert DN fields. On the secret template's page, "none" appears in each of those fields.

Without DataSource:

With DataSource:



As System User Field

All new templates also have the “As System User” field. It allows connections to the database as the system user. Setting this to “1” allows database connections with the SYSDBA privilege. Setting this to “0” connects with the default role.

Templates

Oracle Account

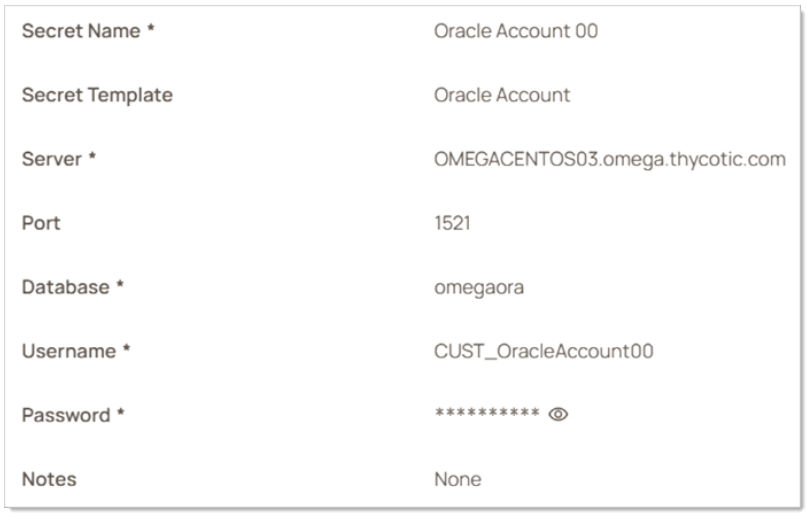
This is the deprecated original template that maintained for legacy implementations. I requires that `Oracle.ManagedDataAccess.dll` is installed alongside Secret Server or its engines.

Oracle Account (Template Ver 2)

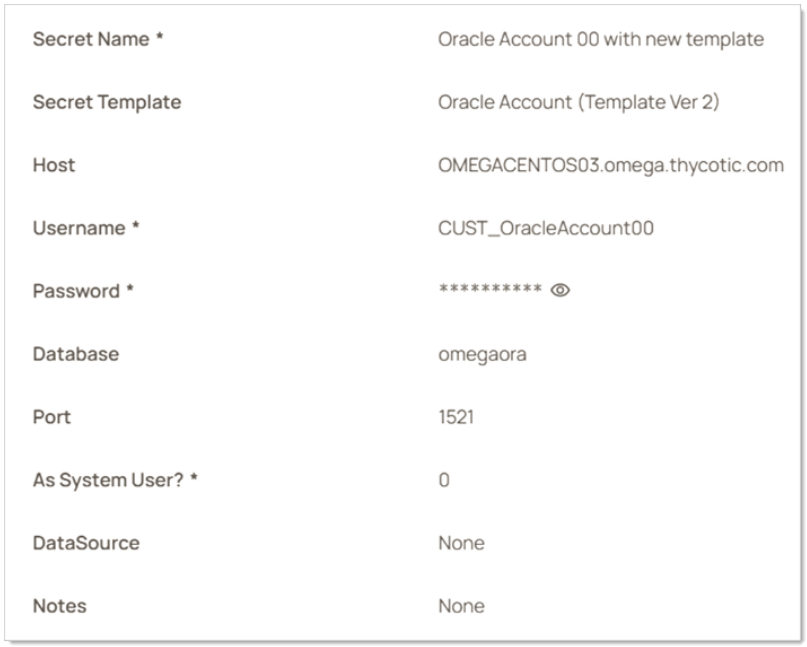
Oracle Account (Template Ver 2) is the closest equivalent to the original Oracle Account template. It does not support Oracle TCPS, but it does use the Oracle Managed Data Access NuGet library. The fields on this secret template are the same as in the original Oracle Account template with a few exceptions. We added two new fields, the DataSource and “As System User” fields described above. Additionally, the “Server” field is called “Host” in the new template to more closely match the terminology in Oracle’s connection string.

Original template:

Secrets



New template:



See "Oracle Account Secret Template for RPC" on page 1034 for more using this template.

Oracle Account (TCPS)

Overview

You can make TCPS connections using the "Oracle Account (TCPS)" secret template and an Oracle Wallet. As described by Oracle, “Oracle Wallet is a container that stores authentication and signing credentials.”

> See Understanding Oracle Wallet for more information, and refer to the documentation on your specific Oracle database for detains on obtaining and using your wallet.

Wallet Location

Prior to setting up Oracle Account (TCPS) secrets, you will need to place copies of your Wallet files on the same server(s) as your Secret Server site(s) where you will have Oracle Account (TCPS) secrets. Afterwards, use the "Wallet Location" field to note the location of your wallet files on your newly created secret. Note that you will need to ensure that the user running Secret Server's app pool (or engine when applicable) is granted Delinea permissions to access the directory where the wallet is located.

TNS Admin

The "TNS Admin" field is optional. If you have a `tnsnames.ora` file, specify its containing directory in this field.

As with wallets, you should consult documentation specific to your Oracle database for information on using `tnsnames.ora`. However, in general, `tnsnames.ora` file is a configuration file containing network service names mapped to connect descriptors (for local naming method) or net service names mapped to listener protocol addresses.

> See Local Naming Parameters in the tnsnames.ora File for more information.

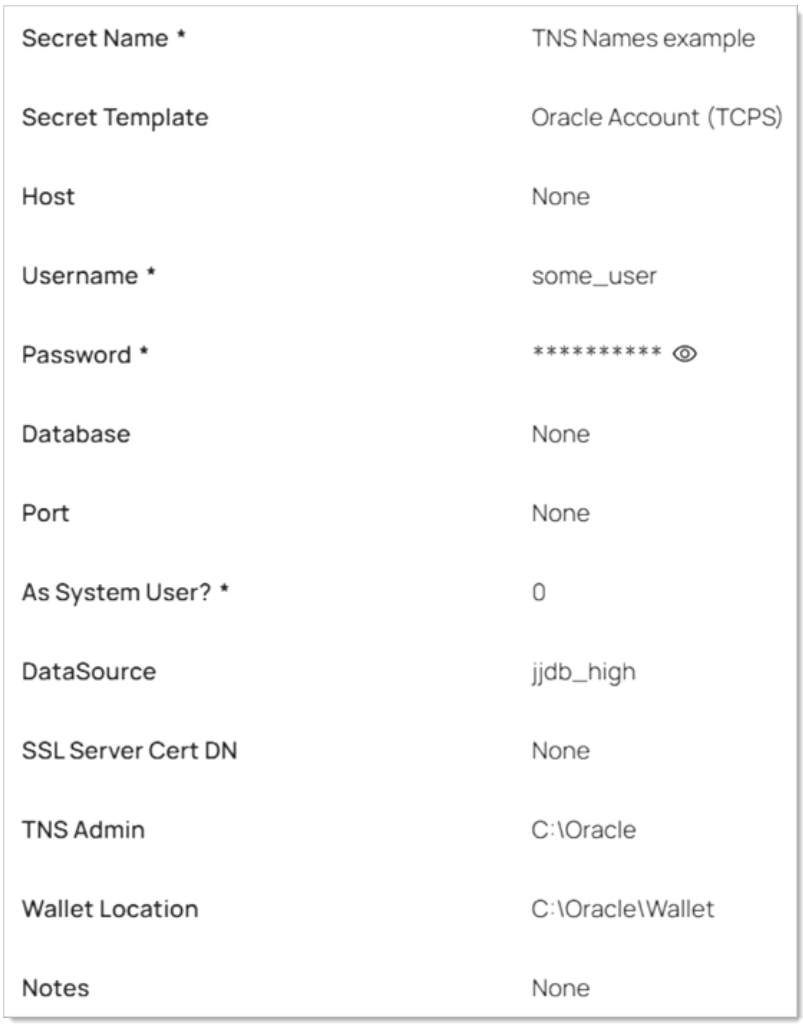
Thus, you can use the `tnsnames.ora` file as an alternative way to specify a connection string. First, put the directory of the `tnsnames.ora` file in the "TNS Admin" field. Second, format the contents of `tnsnames.ora` as `<ALIAS> = <CONNECTION STRING>`. Paste the desired alias from inside the `tnsnames.ora` files in the DataSource field of the secret. For example, if we had a file at `C:\Oracle\tnsnames.ora`, the contents might be as follows:

```
jjdb_high = (description= (retry_count=20)(retry_delay=3)(address=(protocol=tcps)(port=1522)
(host=adb.us-ashburn-1.oraclecloud.com))(connect_data=(service_name=g62a2e091eede11_jjdb_
high.adb.oraclecloud.com))(security=(ssl_server_cert_dn="CN=adwc.uscom-east-
1.oraclecloud.com, OU=Oracle BMCS US, O=Oracle Corporation, L=Redwood City, ST=California,
C=US")))

jjdb_low = (description= (retry_count=20)(retry_delay=3)(address=(protocol=tcps)(port=1522)
(host=adb.us-ashburn-1.oraclecloud.com))(connect_data=(service_name=g62a2e091eede11_jjdb_
low.adb.oraclecloud.com))(security=(ssl_server_cert_dn="CN=adwc.uscom-east-1.oraclecloud.com,
OU=Oracle BMCS US, O=Oracle Corporation, L=Redwood City, ST=California, C=US")))
```

In this example, `jjdb_high` or `jjdb_low` are both aliases. We would choose one, say `jjdb_high`, and paste it into the DataSource field on my secret. I would include `C:\Oracle` in the TNS Admin field. My secret would appear as in the following screenshot:

Secrets



Oracle Account (Walletless)

Oracle has recently announced its support of TCPS without requiring the use of wallets. See Securely Connecting to Autonomous DB Without a Wallet (Using TLS) for details.

Because walletless connections utilize TLS instead of “mutual TLS,” this is potentially less secure than a wallet-based authentication, so you should do your own research before deciding if this is the right approach for you. The advantage of the walletless template is that it allows a secure TCPS connection with the simplicity of the “Oracle Account (Template Ver 2)” template. No wallet files need to be deployed to a server.

The fields on this template are the same as Oracle Account (Template Ver 2) with the addition of the “SSL Server Cert DN” field, which can be found in the TLS connection string. Refer to documentation on your specific Oracle database about how to enable walletless connections, as well as how to obtain the TLS connection string to fill in fields on this secret template.

Privileged Password Security Policy Template

To use the privileged password security policy template, follow the steps below:

1. Download the privileged password security policy template.
2. Open the template as a Microsoft Word document.
3. Remove the "About this Template" and "Customizing the Template" instructions and other author comments.
4. Replace the term "Company X" with the name of your organization.
5. Replace the current logo or add your company logo in the upper left corner.
6. Update all of the company-specific contact information (highlighted yellow).
7. Update the effective date.
8. Revise any policy guidelines to meet your organization's policies.
9. Revise the Violations section to meet your organization's policies.
10. Save your changes.
11. Obtain your management and auditors' approval of the completed policy.
12. Distribute the policy according to your management guidance.

SSH Authentication Templates

Overview

With this Secret Server feature, admins can use private SSH keys for PuTTY launcher sessions as well as for RPC tasks (configurable through password changer settings) and Unix and Linux discovery. Passphrases can additionally be stored, if necessary, to decrypt the private keys for additional security. The Unix Account (SSH) secret template includes text-entry fields for the private key and passphrase by default.

The SSH Key template is included by default and can be used to store SSH keys that can later be selected for use in RPC, discovery or launcher authentication for other secrets:

Secret Server also supports SSH key rotation on secrets.

The **Unix Account (SSH Key Rotation)** and **Unix Privileged Account (SSH Key Rotation)** secret templates use password changers that change the public key in the account's `authorized_keys` file as well as change the password on the account. Secret Server ships with a password changer and custom command sets that allow an account to change its own public key and password, and a password changer and custom command sets that changes a user's public key and password using a privileged account. These scripts can be customized for different Unix environments.

Settings

Typical settings for these templates include:

- **Secret Template Name**
- **Name Pattern:** You can use a naming pattern to enforce a standardized name for this Secret Template. The naming pattern uses regular expressions.
- **Description**

- **All History:** Save all history of secret names using this template.
- **Secret Name History Length:** Number of secret names to keep in history for this template.
- **Validate Password Requirements On Create:** If enabled, password fields must meet the password requirements when a secret is created.
- **Validate Password Requirements On Edit:** If enabled, password fields must meet the password requirements when a secret is edited.
- **SSH Key Format:** PuTTY or OpenSSH. PuTTY's PPK format is proprietary and mainly used within the PuTTY suite, primarily on Windows systems. OpenSSH's key format, being open and standardized, enjoys broader support and compatibility across different platforms and SSH clients.
- **Required Permission To Edit Password Change Configuration:** Specifies which permission is allowed to edit the password change configuration on a secret from this template.
- **SSH Key Algorithm:** ECDSA (strongly recommended) or RSA (for backwards compatibility). See "ECDSA Versus RSA" below for details.
- **SSH Key Bit Size (RSA only):** 1024, 2048, or 4096 bits.

ECDSA Versus RSA

ECDSA (Elliptic Curve Digital Signature Algorithm) and RSA (Rivest-Shamir-Adleman) are both cryptographic algorithms used for securing data, but they operate on different mathematical principles and offer distinct characteristics, especially when employed as SSH key algorithms:

- **Security:** Both RSA and ECDSA provide high levels of security, but they achieve this through different means. RSA's security is based on the factorization problem of large integers, while ECDSA's security relies on the elliptic curve discrete logarithm problem. Generally, ECDSA can achieve comparable security to RSA with a much shorter key length. For instance, a 256-bit ECDSA key is roughly equivalent in security to a 3072-bit RSA key.
- **Performance:** ECDSA keys are typically smaller than RSA keys for a comparable security level, which means they can be faster for generating and verifying signatures due to the reduced computational complexity. This can lead to quicker SSH key exchanges and potentially faster connections, especially important in environments with a high volume of SSH traffic.
- **Compatibility:** RSA is more universally supported across different systems and SSH implementations due to its longer presence in the market. ECDSA support is widespread but slightly less universal, which could affect interoperability in diverse environments.
- **Key Length and Scalability:** RSA keys usually start at 2048 bits for adequate security, with 3072 and 4096 bits being common for increased security. ECDSA keys, due to their efficiency, start at 256 bits (equivalent to P-256 curve), with P-384 and P-521 being options for higher security needs. This makes ECDSA more scalable and efficient as security demands increase.

In summary, ECDSA offers a more efficient and potentially faster alternative to RSA for SSH key algorithms, especially where high security with lower computational overhead is desired. However, RSA's universal compatibility and long-standing reputation may make it a preferable choice in environments prioritizing interoperability and proven security mechanisms.

Secret Server Cloud

Secret Server Cloud is a scalable, multi-tenant cloud platform that offers the same robust features as the on-premise Secret Server Professional edition. Hosted on the Microsoft Azure platform, Secret Server Cloud ensures that all backend services, databases, and redundancy are securely managed by Delinea, eliminating the need for customers to manage these components directly. This cloud-native solution provides enterprise-grade Privileged Access Management (PAM) capabilities, including secure vaulting of privileged credentials, automated password management, and comprehensive auditing and reporting tools. Secret Server Cloud is designed to help organizations quickly secure and manage their privileged accounts, ensuring compliance and reducing the risk of cyber attacks.

Secret Server Cloud Quick Start

Overview

Secret Server is a scalable, multi-tenant cloud platform that provides the same features as the on-premise Secret Server Professional edition. With Secret Server Cloud, all backend services, databases, and redundancy are securely managed by Delinea and hosted on the Microsoft Azure platform. Customers do not have direct access to the databases or application file system.

> End users are also referred to as "business users."

Cloud Versus On-Premise Secret Server

For documentation purposes, Secret Server Cloud is the same as the corresponding on-premise edition. However, there are some feature differences:

- **Site Connectors:** On-premise versions can use multiple site connectors to manage engine connections, such as RabbitMQ or MemoryMQ. The cloud version manages this for you as an Azure service and is not configurable.
- **CRM Integration:** On-premise versions can integrate with CRMs via direct database connections or the ConnectWise API. This is not currently available in Secret Server Cloud.

Getting Started

This section walks you through an initial configuration of your cloud instance. To see additional documentation for Secret Server Cloud features, please refer to the support resources section at the end of this document.

System Requirements

> All cores are physical unless otherwise noted.

A distributed Engine server is required to communicate with Secret Server Cloud. Distributed engine server recommended specifications:

A distributed engine server is required to communicate with SSC. Distributed engine server recommended specifications:

- Windows Server 2016 or Above
- CPU: 4-core 2 GHz (minimum)
- Memory: 4 GB of RAM (minimum)

Engine Connectivity

Secret Server Cloud's Architecture Diagram shows the network topology of your cloud instance. Your on-premises distributed engines do not need any inbound TCP/IP ports open (unless using RADIUS authentication). If you do not have outbound firewall policies in place, no firewall configuration is necessary. If you do, the distributed engines need outbound access to:

- Secret Server Cloud's multi-tenant front-end Web server
- A shared service bus
- A customer-specific service bus
- A Content Delivery Network (CDN)

The protocols and endpoint details are in the architecture diagram mentioned above.

Initial Setup

After you sign up for a trial, you can choose your URL name and provision your instance:

> To see additional documentation for Secret Server Cloud features, please refer to the support resources section at the end of this document.

1. After you sign signed up for a Secret Server Cloud trial, you received an email from Delinea Sales. Click the **Cloud Portal** link in that email to begin your setup. The Setup Page appears in your browser.
2. Choose your location in the **Cloud Environment** dropdown list.
3. Click the **Continue** button. The Delinea One Portal appears.
4. Create the password for your first user account with administrator credentials. This account will be assigned to the email address you entered to request the trial.
5. After confirming the password, click the **Set Password and Login** button. The Delinea log on page appears.

> This is the backup admin account that you may need in a "break the glass" or Unlimited Vault Access situation. Delinea recommends you store the password in a secured physical location such as a safe or locked file cabinet. You can reset the password using an email reset, but **if this password is forgotten or you no longer have access to the email account, Delinea cannot reset this password**.

6. Click the blue button that matches the location you just chose. A setup page appears.
7. Type a name for your subdomain. Do not use special characters or spaces.
8. Read the Business User (End User) License Agreement.
9. Click to select the check box to signify agreement.

10. From the dropdown, select **Yes** or **No** to signify your organization's oversight of EU information.
11. Click the **Accept** button. It may take several minutes for your new Secret Server Cloud to spin up.
12. When initialization is complete, click go to your Secret Server Cloud URL and click the **Login with Delinea One** button. You are automatically redirected to your new Secret Server Cloud dashboard.

> For information on how to install a distributed engine, please refer to "Distributed Engine Installation " on page 761.

Configure Active Directory Integration

Active Directory integration allows users to log in with their domain credentials. Connections to your domain are routed through the distributed engine service running in your network.

1. On the dashboard, create a new Active Directory secret from the create secret widget in the upper right hand corner.

   > The domain account should be able to read users and groups from the domain you want to sync. For detailed information on the rights required, please see the "Active Directory Rights for Synchronization Account" on page 511.

2. Type the domain, username, and password in the **Create Secret** form.
3. Save the secret.
4. Search for **Active Directory**.
5. Click **Edit** and check the boxes for **Enable Active Directory Integration** and **Enable Synchronization of Active Directory**.
6. Click the **Save** button.
7. Click the **Edit Domains** button.
8. Click the **Create New** button.
9. Type your FQDN and a friendly domain name that users will see on the login page.
10. Click **Sync Secret** to select the secret you just created.

    > The domain site is set to default. This means that the Active Directory authentication and synchronization will run through the distributed engine service installed on your network.

    > Do **not** select "Enable Login from AD." If you do, you cannot set the domain groups later in this instruction.

11. Click the **Save and Validate** button.
12. Click the **Back** button.
13. Click the **Edit Synchronization** button. The Synchronization Edit page appears.

14. In the **Available Groups** list, click each domain group that you want to log on in Secret Server Cloud instance and click the **<** button to move the group to the **Synchronized Groups** list.
15. Click the **Save** button.
16. Click the **Synchronize Now** button to start the user and group synchronization immediately. The synchronization process runs automatically, but to get immediate results, you can start it manually.

Test Heartbeat and Remote Password Changing

Heartbeat ensures the secrets you have stored have the correct password, and Remote Password Changing (RPC) changes passwords on demand or a schedule.

1. Search for **Remote Password Changing**.
2. Click the **Edit** button.
3. Click to select the **Enable Remote Password Changing** and **Enable Heartbeat** check boxes.
4. Click the **Save** button.
5. Click the **Run Now** button in the **Remote Password Changing and Heartbeat Log** sections. This runs the heartbeat and RPC processes immediately.
6. Go to the secret you created for domain synchronization in the previous section or create a new test secret to use.
7. A brand new secret's **Last Heartbeat** status should be pending or processing. Once heartbeat completes you should one of these statuses:
   - **Unable to Connect:**Secret Server could not reach the target machine. This could be a firewall issue or the machine name or IP address is wrong.
   - **Failed:**Secret Server could connect but could not authenticate. This likely means the password on the secret is incorrect.
   - **Success:**Secret Server successfully connected with the username and password.
8. You can test password changing by viewing a secret and clicking the **Change Password Remotely** button.

   This will change the password on the target system.
9. You can view the status of password changes and heartbeats in the log at **Admin > Remote Password Changing.**

Next Steps

- Add another user to the Administrator role in Secret Server. This allows you to have another administrator besides the initial user account created. To assign roles, Search for **Roles** and click the **Assign Roles** button.
- Add a folder and share it with the group you synchronized from Active Directory. Create and edit folders from the Folder Tree View on your Dashboard.
- Create a secret in that folder for other users to see. When creating a secret, you can click the **Folder** link to save it to another folder.

- Have other users log on. Any users synchronized to Secret Server through the domain synchronization can log on with their domain credentials.
- Enable Google two-factor authentication by going to **Admin > Users**, editing the specific user, and assigning a two-factor option.

Troubleshooting and Resources

Get Error: "Site (Default) engines are not currently online" When Saving Domain

This can occur when Secret Server was not able to complete a round trip with the installed engine service. This validation may take several minutes for Secret Server to perform after the engine has been approved and assigned to the site. To address the issue:

1. On the server you installed engine on, check the logs in the install directory `C:\Program Files\Thycotic Software Ltd\Distributed Engine\log`.
2. If you see a message for "Could not configure, trying in 30 seconds" or a "Bus Broken Down Error" verify that the engine is approved and assigned to your default site.
3. Go to the site under **Admin > Distributed Engine > Manage Sites**.
4. Click the **Validate Connectivity** button.
5. If a success message appears and the engine status shows as online, try saving the domain again.

Secret Server Character Limits

Secret Server allows the following number of characters for the fields:

- Folder Name: 128. Error Message when exceeded - *The folder name must be 128 characters or less*.
- Group Name: 250. Error Message when exceeded - *Application Error*.
- Role Name: 255. Error message when exceeded - *Please choose a Role name with between 1 and 255 characters*.
- Secret Name: 1,992. Error Message when exceeded - *Invalid Secret Name*.
- Secret Text Fields: 9,999. Error message when exceeded - *Secret item value exceeds max length characters.*
- Secret Note Field: 9,999
- Request field 600 (This is a comment field used when requesting access to a secret). No error message given, it prevents exceeding 600 characters. If you paste in more than that it clips the text and still lets you save.
- Local User Username: 128
- Local User Display Name: 256
- Local User password: 500

Third Party Key Management in Secret Server Cloud

> Managing your own encryption key or using a third-party provider, such as Amazon Web Services Key Management Services (AWS KMS) or Azure Managed HSM, has very serious ramifications if not carefully handled—you can lose access to your Secret Server data. When using a third-party key provider, Secret Server requires access to the third-party key for the website to be accessible and secrets to be available. If the third-party key is deleted, Secret Server becomes permanently unable to decrypt any data—all access to secrets is lost. If the credentials that Secret Server uses to access the third-party key are blocked or disabled, the Secret Server website becomes inaccessible until the prior credentials are restored by the customer.

Introduction

Secret Server protects your secrets using a master encryption key, as well as an additional intermediate encryption key that is unique for each secret. These effectively act as internal passwords that Secret Server itself needs to unlock your data, for example, any time you view or update a secret.

Key Management in Secret Server Cloud (SSC) allows you to add an additional layer of encryption using a third-party provider to protect these encryption keys for added protection and control. To do this, you must first set up your own encryption key with a third party that you fully control, and then provide Secret Server limited access to it. This external encryption key is used to protect the Secret Server encryption keys. You can revoke Secret Server's access at any time if the need arises, rendering secrets unusable.

> Once enabled, if you delete your external third-party encryption key or the credentials you gave Secret Server no longer work, you will not be able to access your existing secrets.

You can change your key management configuration through Secret Server's user interface or by using the REST API. If key management has already been enabled, you can switch to a new configuration or disable key management completely. To make any change, your existing key management configuration must still be valid, so your secrets and the master encryption keys can be converted to the new configuration. Your new settings are validated before they can be saved.

Secret Server Cloud currently supports the AWS Key Management Service and the Azure Managed HSM Service. It does NOT support Azure's Key Vault due to performance limitations of that service.

Azure Managed HSM Service

The Azure Managed HSM Service is a highly available, managed single-tenant cloud service for creating, managing, and using encryption keys, using FIPS 140-3 Level 3 validated HSMs.

> Although Managed HSM is supported and is under the Key Vault branding of Azure, we do not support the non-Managed HSM Key Vault (Standard or Premium) service. Please see What is Azure Key Vault Managed HSM, for more information on security, pricing, SLA, and more.

Azure Managed HSM Guidelines and Best Practices

- The Managed HSM service must be located in the same region as your cloud subscription. Contact Delinea support if you have any questions about what region this is.
- Only an AES 256 symmetric key is supported at this time. No other key will work.
- You will be fully in charge of managing your keys, key availability, security settings, etc. A misconfiguration or Azure outage unrelated to Secret Server can block your access to Secret Server as it no longer can access the underlying encryption key. Read and follow all best practices for soft-delete, purge protection, security domain backup, full backups, and replication.
- Managed HSM offers the ability to configure automatic key rotation through the CLI.

  We do NOT recommend configuring this setting, as it can disable the previous key after expiration.

  To rotate your key, use the UI to create a new version, and switch Secret Server to the new version. Then after a day, ensure the key rotation was successful, that secrets are readable, and then consider setting an expiration date or disabling the previous version.
- You are responsible for ensuring that the configured app registration client secret that Secret Server uses to access the key is not expired, and for updating the client secret before it expires.

Amazon Key Management Service

Key Management Service (KMS) is a managed service provided by AWS that allows you to create, manage and use encryption keys for your applications and services. With KMS, you can create symmetric keys or asymmetric keys to encrypt and decrypt data. These keys can be used to protect sensitive data such as passwords, credit card numbers, or personally identifiable information (PII).

A KMS key is a cryptographic key used to encrypt and decrypt data stored in Amazon Web Services (AWS) such as S3, EBS, or RDS. KMS keys are stored securely in the AWS Cloud, and you can control access to them by using IAM (Identity and Access Management) policies. You can also use KMS to audit key usage and generate key usage reports.

For details on AWS KMS pricing see AWS Key Management Service Pricing. Secret Server Cloud requires one AWS Key ("CMK"), and the number of requests per month will vary depending on how often secrets are accessed.

Configuring Key Management

To enable key management, you will first create an encryption key with your third-party provider, then an API account that Secret Server will use in order to access the key. After the external encryption key is setup, you will update Secret Server with the details.

Changing your key management settings will trigger "maintenance mode" and a secret key rotation that will re-encrypt all your secret keys. No one will be able to access secrets until the rotation finishes, and it must finish successfully before further key management changes can be made.

By navigating to Secret Server's key management page, you can change your key management settings, as well as view the audit history showing all key management updates.

- Details on how to configure AWS Key Management Services.
- Details on how to configure "Azure Managed HSM Services" on page 1250.
- Details on how to configure "Secret Server Key Management via the REST API" on page 1254.

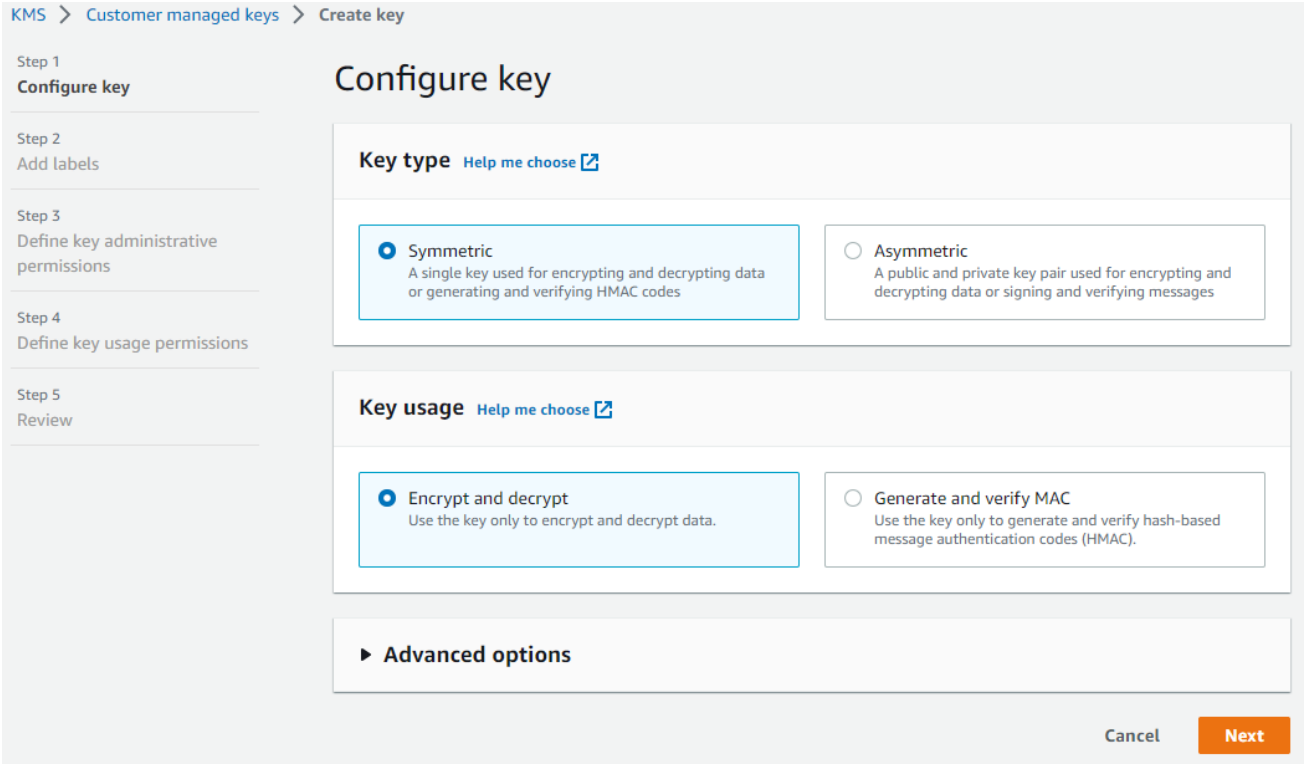
AWS Key Management Services

Task 1: Setting up the Encryption Key and IAM User in AWS

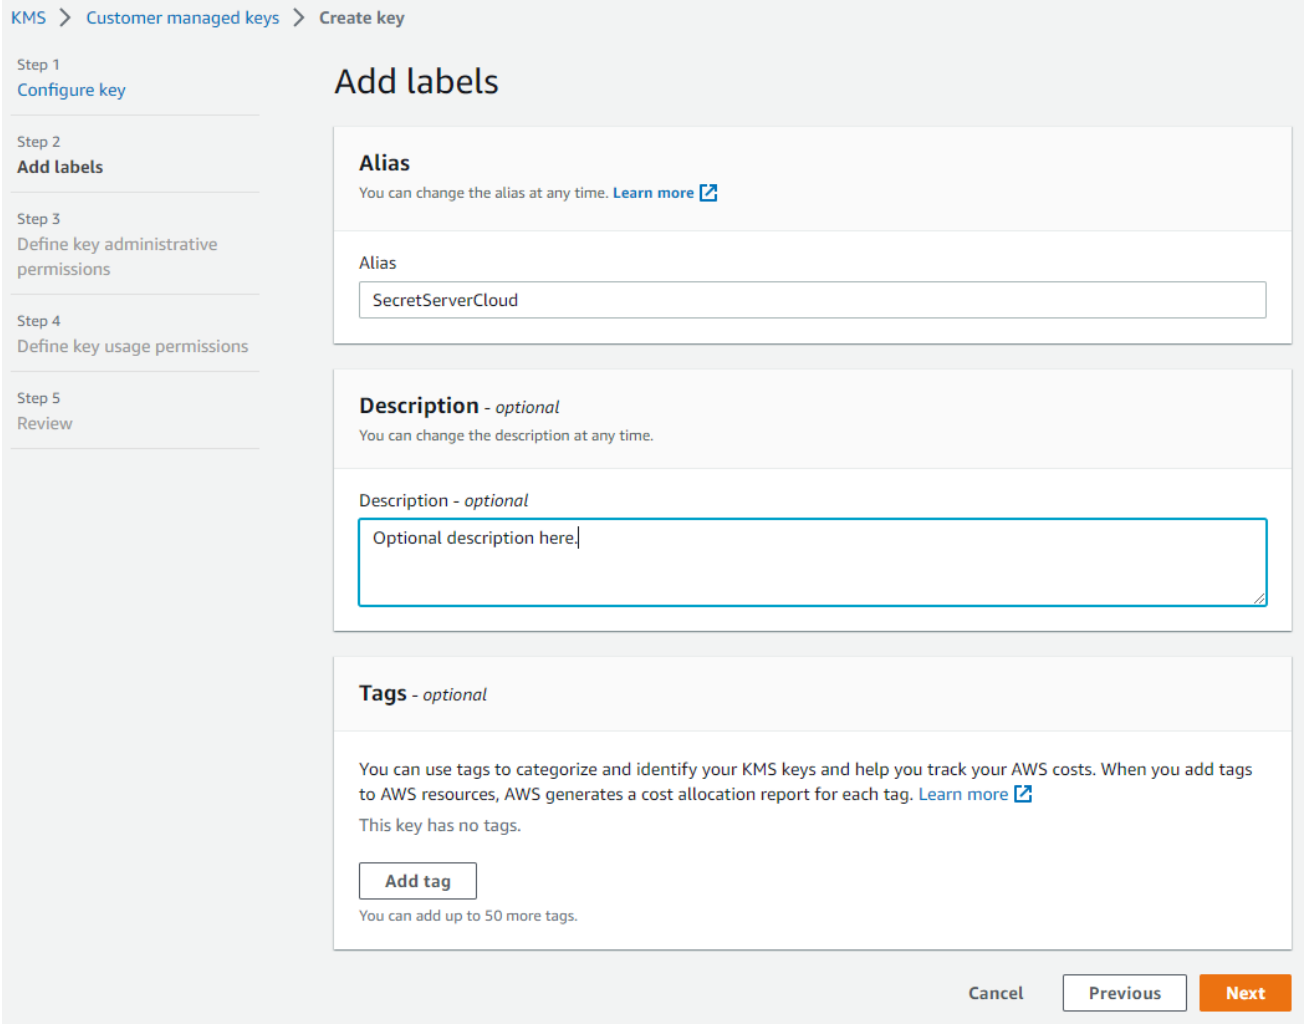
1. Log into the AWS Console website.
2. Under **Services**, search for **IAM** (Identity and Access Management). This is where you will configure both your encryption key and an IAM user that Secret Server uses to access the encryption key.
3. Click the **Users** button on the left menu.
4. Click the **Add User** button.
5. Type a name (such as SecretServerCloud) in the **User Name** text box.
6. Click to select the **Programmatic Access** checkbox in the **Access Type** section.
7. Click the **Next: Permissions** button, the Permissions page appears. On the **Permissions** page, no special permissions are needed.
8. Select the **Next: Tags** button. The Tags page appears.
9. Click the **Next: Review** button, the Review page appears.
10. Select the **Create User** button. A Success page appears confirming the user was created.
11. Both the access key ID and the secret access key appear (click the **Show** link).
12. Click the **Download .csv** button to save the credentials.

> Be sure to **save both the access key ID and the secret access key**! If you lose them, you can never view the secret access key again. Even after you enter them in SSC, you cannot retrieve the secret access key.

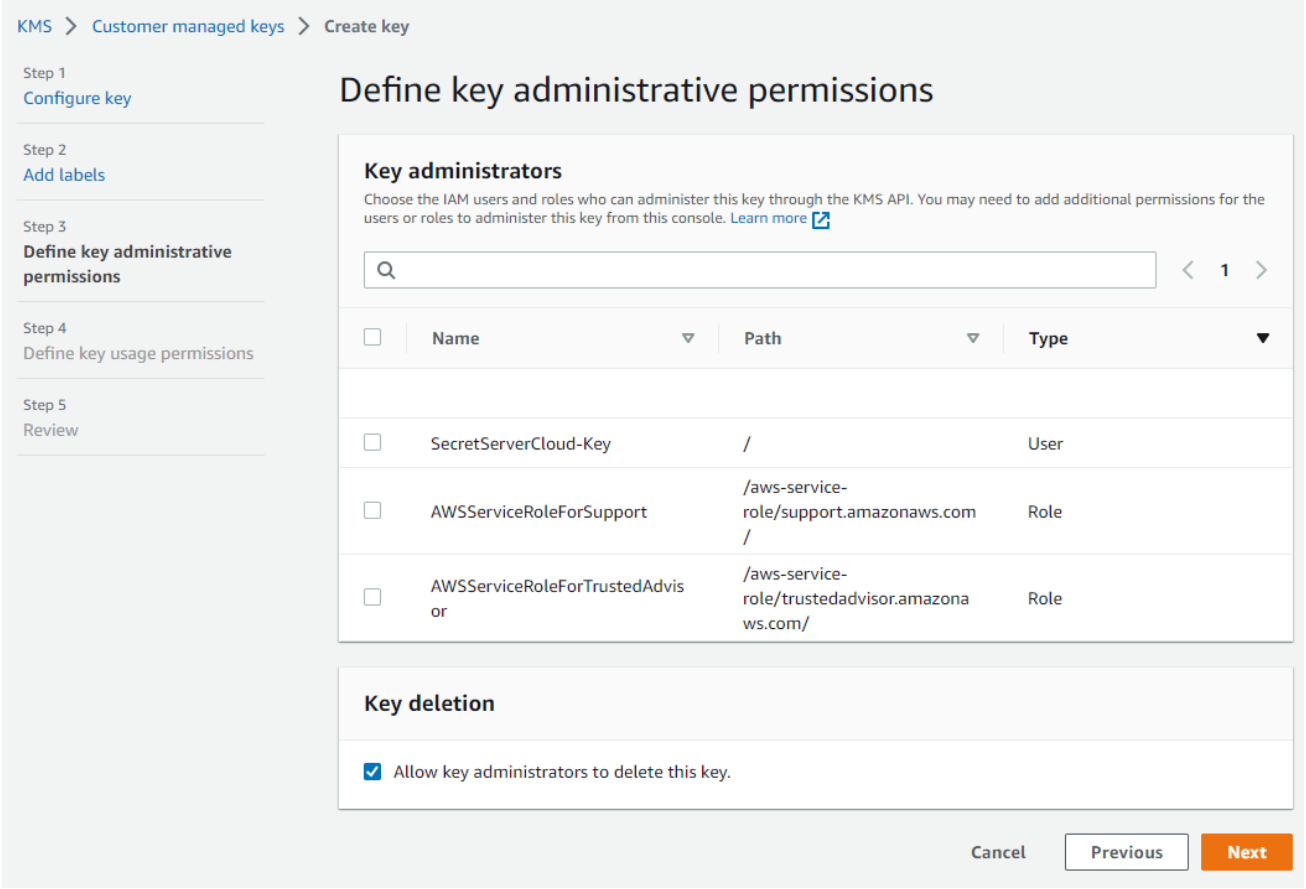
13. Once the download completes, click the **Close** button.
14. Under **Services**, search for **Key Management Service**.
15. Select the **Customer managed keys** link in the left-hand menu.
16. Click the **Create Key** button. The Configure Key page, the first page of the Create Key wizard, appears:



17. Ensure the **Key type** selection button is set to **Symmetric**.
18. Ensure the **Key usage** selection button is set to **Encrypt and decrypt**.
19. Click the **Next** button. The Add Labels page appears:

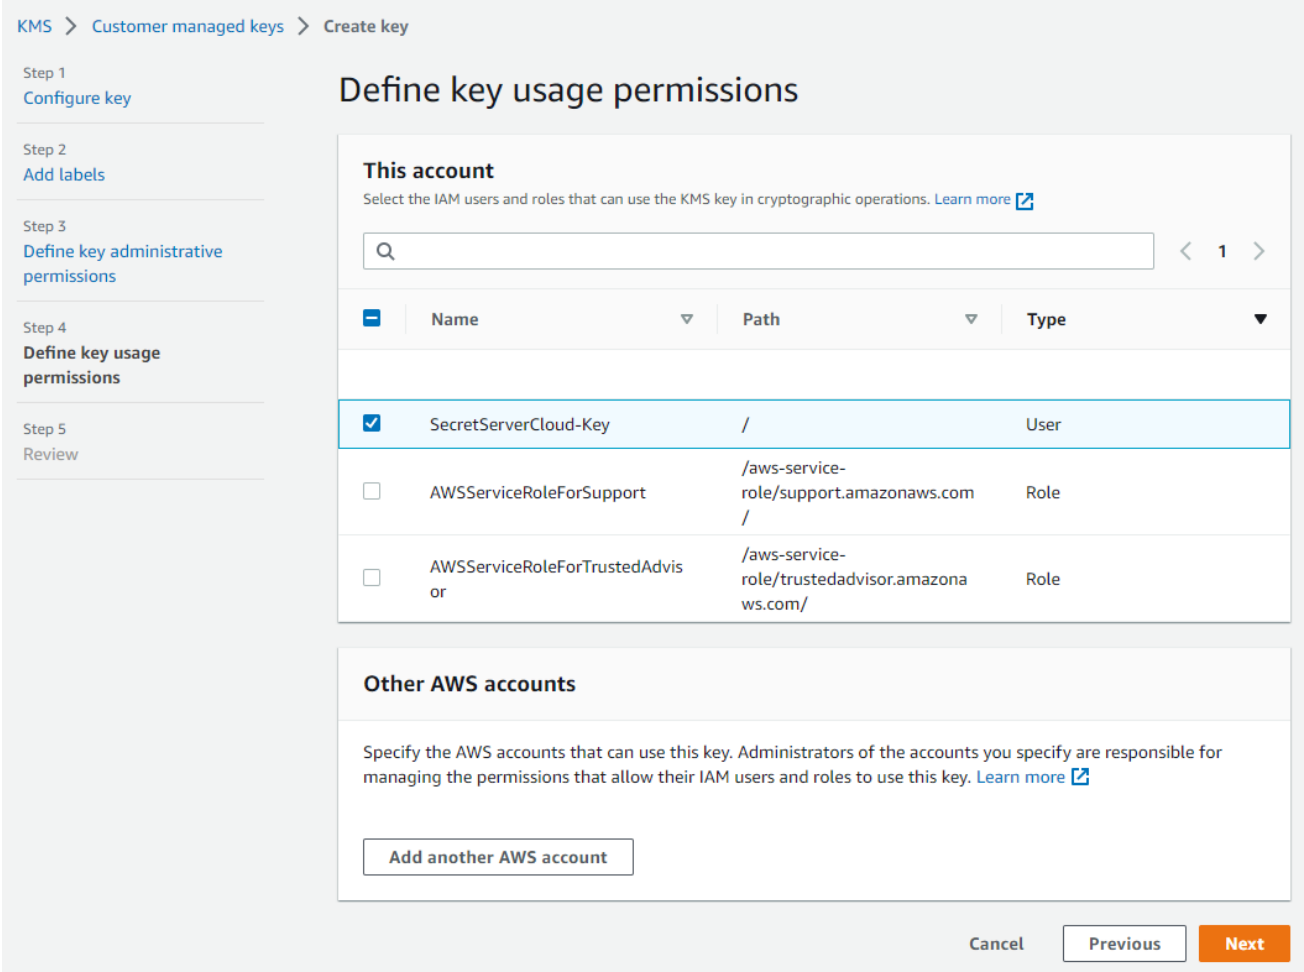


20. Type `SecretServerCloud` in the **Alias** text box.
21. (Optional) Type a description in the **Description** text box.
22. (Optional) Click the **Add tag** button to add KMS tags.
23. (Optional) Click the **Learn More** link for any of the settings to access more information.
24. Select the **Next** button. The Define Key Administrative Permissions page appears:



Leave the page as is.

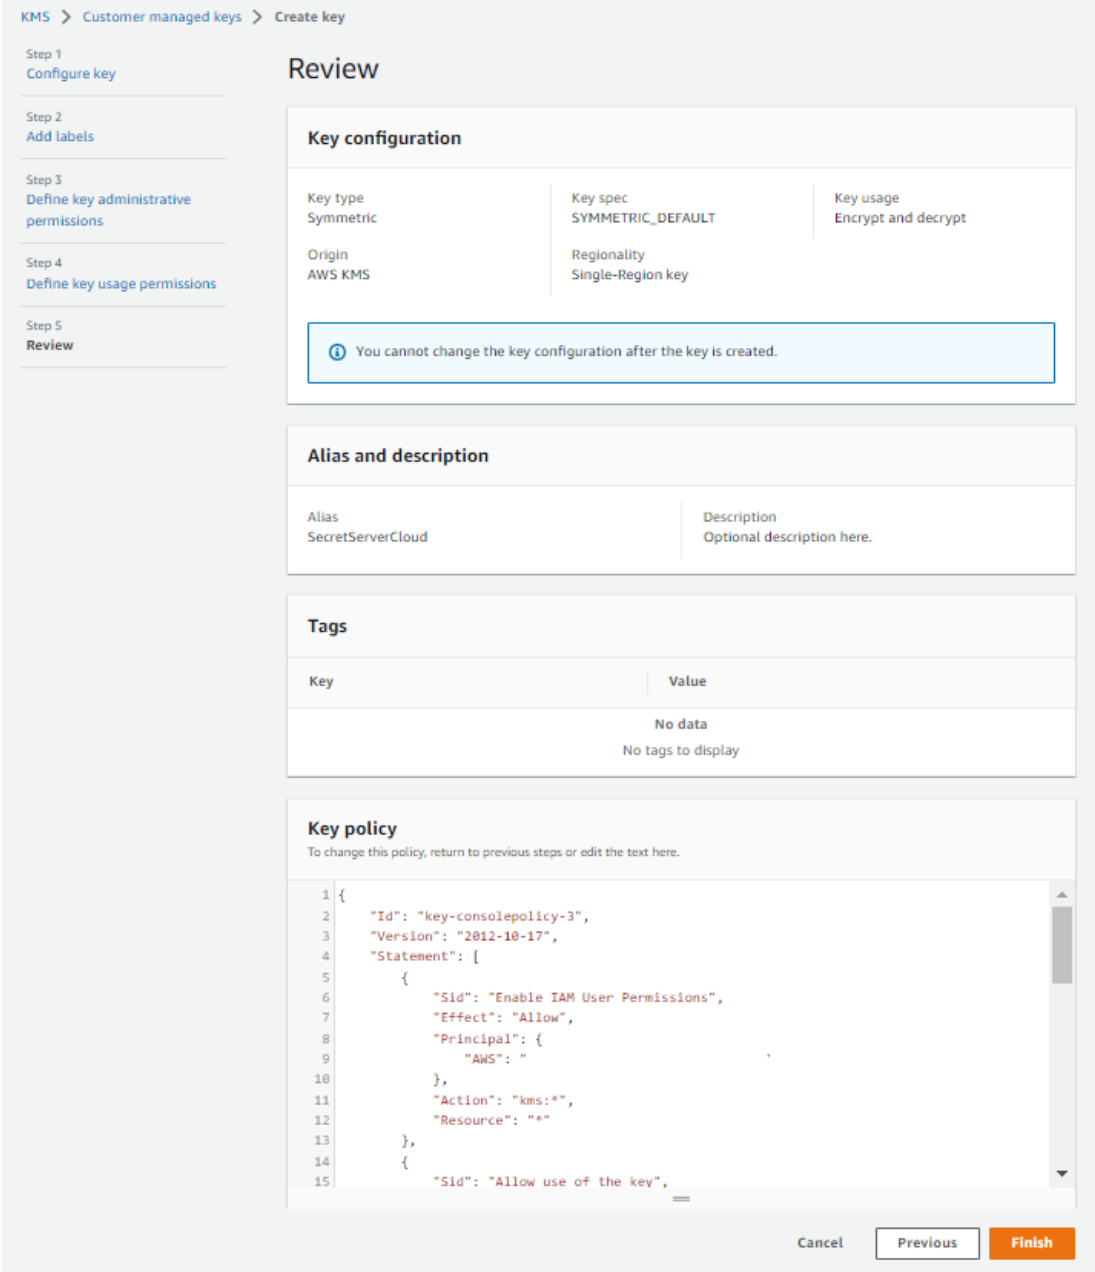
25. Click the **Next** button. The Define Key Usage Permissions page appears:



26. Select the checkbox next to the **SecretServerCloud-Key** name in the table to give that user access to the key.

> Do **not** give access to the user you created earlier for SSC. It is unnecessary for Secret Server to have administrative access to the key.

27. Click the **Next** button. The Review page appears:



28. Ensure the settings are as desired.
29. Click the **Finish** button. The new key appears in your **Encryption Keys** list.
30. Select the new key in the list. The Summary section on the key's page appears.
31. Copy and save the contents of the read-only **ARN** text box. You will need it later.

AWS supports automatically rotating this key every year. You can change that setting on this page in the **Key Rotation** section (select the **Rotate this Key every year** checkbox). Once rotated, the key management settings in Secret Server do not require further changes, and your existing secrets can still be accessed by the old encryption settings.

Only new secrets, however, will be created under the new version of the encryption key, and you must perform a secret key rotation inside SSC if you want to update all secrets to use the new version of the AWS key. Search for **Secret Key Rotation** and click the **Rotate Secret Keys** button to perform the operation.

> As a security best practice, we recommend performing a secret key rotation inside of SSC on a regular basis to refresh the encryption keys on your secrets.

Task 2: Adding Encryption Key and User Details in Secret Server

1. Log into SSC.
2. Search for **Key Management**. The Key Management page appears on the Configuration tab.
3. Click the **Edit** button. The page becomes editable.
4. From the **Key Management Type** dropdown list, select **Amazon KMS**. New fields appear.
5. Type the AWS key details that you saved earlier in the remaining three text boxes.
6. Select the checkbox signaling that Maintenance Mode will be enabled and a Secret Key Rotation will be triggered.
7. Click the **Save** button.

Task 3: Secret Key Rotation

Once you save your changes, your new settings are validated and a secret key rotation is triggered. You can now view the progress of the rotation:

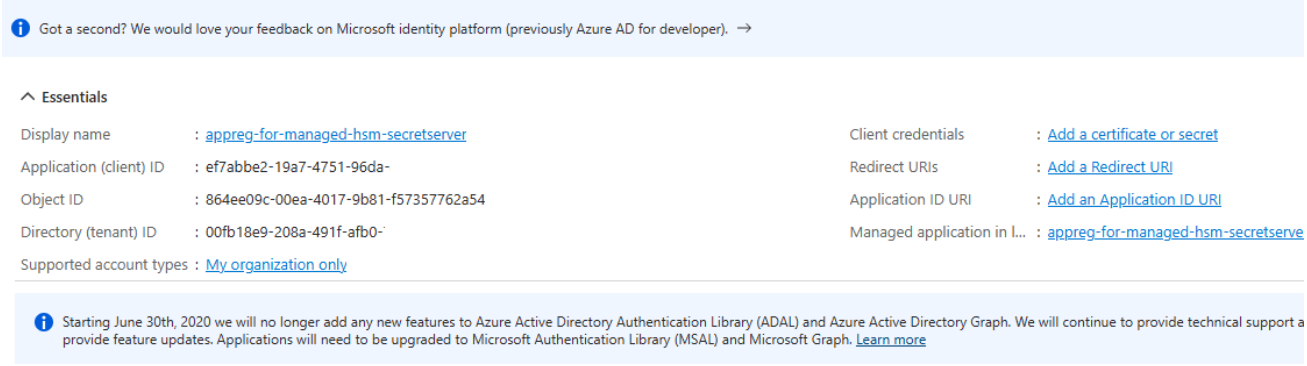
1. Search for **Secret Key Rotation**.
2. Click the **Rotate Secret Keys** button to perform the operation.

> Later, you can repeat the process to change the AWS encryption key or you can select **None** for the **Key Management Type** in task 2 to disable it completely.

Azure Managed HSM Services

Task 1: Setting up the Encryption Key and an Application Registration

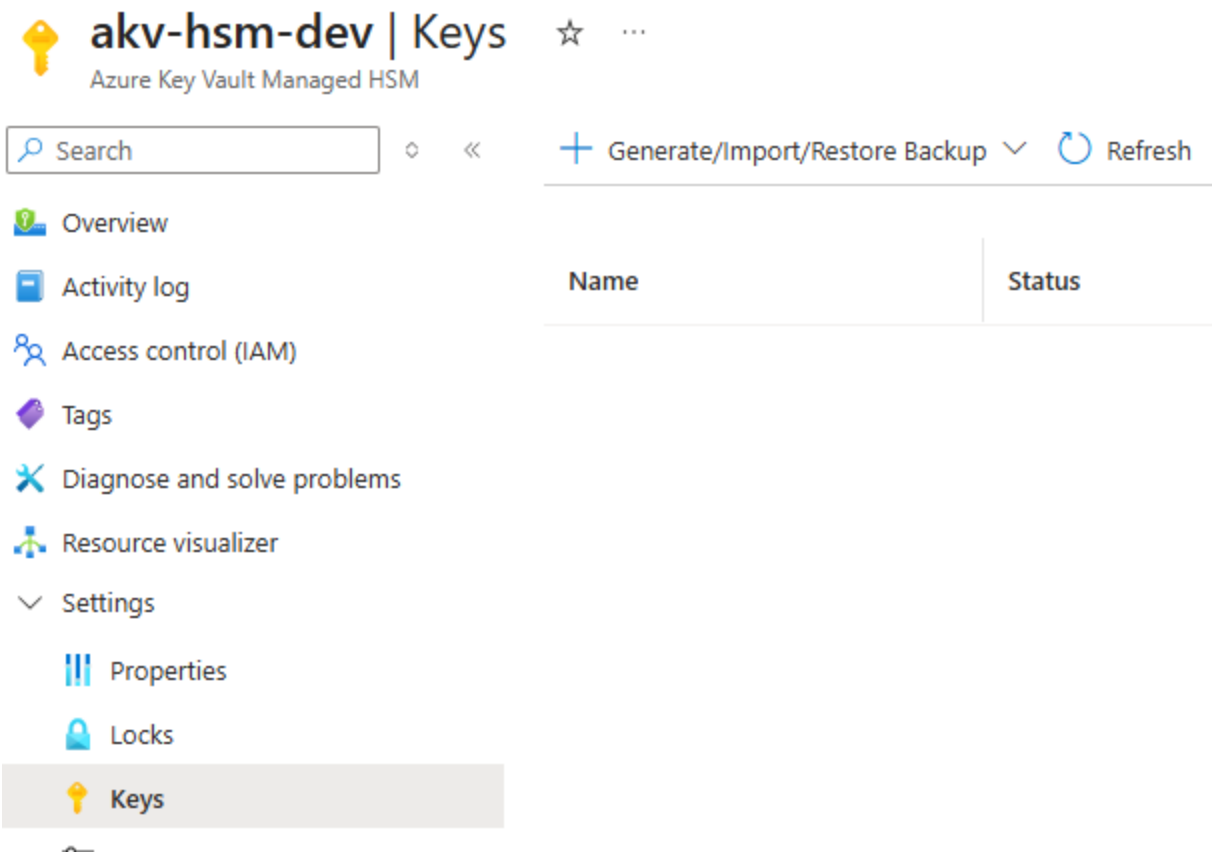
1. Go to Azure, Entra ID.
2. Click **App Registrations** on the left.
3. Select **New registration**.
4. Name the registration and click **Create**:



5. Copy the **Directory (tenant) ID** and the **Application (Client) ID** for later.
6. Click **Add a certificate or secret**, located next to the client credentials.
7. Select **New Client Secret**.
8. Add a description and an expiration.

> It is incredibly important to then set up procedures to ensure that a new client secret will be created and updated in Secret Server later before this expiration period is reached, to prevent loss of access to your Secret Server instance.

9. Select **Add** to save your changes.
10. **Copy the Value. You will not get an opportunity to copy this data again**.
11. Read through and plan via the Azure Managed HSM documentation.
12. Create your **Azure Key Vault Managed HSM** and **Activate** it.
13. Utilizing a user that has Azure permissions (Local RBAC or IAM, depending on your configuration), Search for **Keys**.
14. Click **Generate/Import/Restore Backup**, and then choose **Generate**:



15. Name your key.
16. Choose key type **AES-HSM**, and key size **256**. No other key type or size will work.
17. Ensure the operations include wrap key and unwrap key, and create the key.
18. Copy the key identifier URL field and key name.
19. Under **Settings**, go to **Local RBAC**.

    It is possible to use IAM security. Please read and adjust your Azure permissions as necessary if you use IAM.

20. Click **Add**.
21. For **Role**, use **Managed HSM Crypto User**.
22. For **Scope**, use **single key**.
23. For **key name**, use the key name of the key you created earlier.
24. For **security principle**, select **App Registration and secret**, and select the app registration you created earlier.

    You will not see the new entry directly on the Local RBAC page. It will display when navigating to the key and clicking **Role Assignments**:

Task 2: Adding the Encryption Key and Application Registration Details in Secret Server

1. Log into SSC.
2. Search for **Key Management**. The Key Management page appears.
3. Click the **Edit** button. The page becomes editable.
4. From the **Key Management Type** dropdown list, select **Azure Managed HSM**.
5. Type in your Azure Managed HSM Tenant ID value.
6. Type in your Azure Managed HSM Principal ID (this is the Application/Client ID) value.
7. Type in your Azure Managed HSM Principal Secret (the secret value of the client secret).
8. Type in the Azure Managed HSM Key URL that you saved earlier.
9. Select the checkbox that states Maintenance Mode will be enabled and a Secret Key Rotation will be triggered.
10. Click the **Save** button.

Task 3: Secret Key Rotation

Once you save your changes, your new settings are validated and a secret key rotation is triggered. You can now view the progress of the rotation:

1. Search for **Secret Key Rotation**.
2. Click the **Rotate Secret Keys** button to perform the operation.

> Later, you can repeat the process to change the Managed HSM encryption key or you can select **None** for the **Key Management Type** in task 2 to disable it completely.

Best Practices for Azure Managed HSM Configuration

Azure's Key Vault Managed HSM Service is a highly available, single-tenant cloud service for creating, managing, and using encryption keys with FIPS 140-3 Level 3 validated HSMs. While Managed HSM is supported under Azure Key Vault branding, non-Managed HSM Key Vault tiers (Standard or Premium) are not supported.

For more details on security, pricing, and SLA, see What is Azure Key Vault Managed HSM?.

Guidelines and Best Practices

- **Region Alignment**: The Managed HSM service must be located in the same region as your cloud subscription. Contact Delinea Support if you are unsure which region applies.
- **Key Type**: Only **AES 256 symmetric keys** are supported. No other key types will work.

- **Responsibility for Key Management**: You are fully responsible for managing your keys, availability, and security settings. Misconfiguration or an Azure outage unrelated to Secret Server can block access if the encryption key becomes unavailable.
  - Follow Azure best practices for Soft-delete, purge protection, security domain backup, full backups, and replication.
- **Key Rotation**:
  - Managed HSM supports automatic key rotation via CLI. **We recommend NOT configuring this, as it can disable the previous key after an expiry time**.
  - To rotate keys safely:
    1. Use the UI to create a new key version.
    2. Switch Secret Server to the new version.
    3. Wait at least one day to confirm successful rotation and that secrets are readable.
    4. Then consider setting an expiration date or disabling the previous version.
- **App Registration Secret**: Ensure the client secret used by Secret Server to access the key does not expire. Update it before expiration to avoid service disruption.

Customer-Managed Encryption Keys – Critical Considerations

Managing your own encryption key or using a third-party provider (e.g., AWS KMS or Azure Managed HSM) carries serious risk if not handled correctly:

- Secret Server requires continuous access to the third-party key for the website and secrets to remain accessible.
- If the third-party key is deleted, Secret Server becomes permanently unable to decrypt any data—all access to secrets is lost.
- If credentials used by Secret Server to access the key are blocked or disabled, the website becomes inaccessible until credentials are restored.
- **Important**: If you delete your external encryption key or the credentials become invalid, you will not be able to access existing secrets. **Delinea cannot recover them.**

Secret Server Key Management via the REST API

Secret Server Cloud (SSC) has a REST API for retrieving or updating your key management configuration.

To view the API documentation:

1. Log into your SSC instance.
2. Click the question mark icon in the top right corner close to your profile avatar. A small drop-down menu of documentation options appears.
3. Select the **REST API Guide**.
4. Click on the documentation link that fits your authentication style: Bearer tokens, simple Tokens/Services, or

Windows Integrated Authentication.

5. Search for `KeyManagement` to view that section of our API.

When changed via the API, maintenance mode and a secret key rotation still occur.

Secret Server Cloud Text Field Character Limits

These values are valid for Secret Server Cloud only. Platform groups, roles, and users have different limits.

Character limits as of June 2024:

- Folder Name: 128 characters. Error message: "The folder name must be 128 characters or less."
- Group Name: 250 characters. Error message: "Application Error."
- Local User Display Name: 256 characters.
- Local User password: 500 characters.
- Local User Username: 128 characters.
- Request field: 600 characters. This is a comment field used when requesting access to a secret. No error message is given when surpassed. Instead, it prevents exceeding 600 characters. If you paste in more than that, it clips the text and still lets you save.
- Role Name: 255 characters. Error message: "Please choose a Role name with between 1 and 255 characters."
- Secret Name: 1,992 characters. Error message: "Invalid Secret Name."
- Secret Note Field: 9,999 characters. Error message: "Secret item value exceeds max length characters."
- Secret Text Fields: 9,999 characters. Error message: "Secret item value exceeds max length characters."

Secret Server Cloud Offboarding

This topic only applies to standalone **Secret Server Cloud**.

Privacy Policy

See the Delinea Privacy Policy for details on how your data is safeguarded.

Data Protection

At all times, even after your license expires, Delinea maintains strict security controls of your data. Only a tiny group of operations staff can access it and only with approval from at least one other person. You can get a SOC2 audit report for your instance, which requires an NDA, by emailing the RFP Helpdesk. The NDA is required because proprietary Delinea information is present in the report.

Refer to additional documentation on "Removing Deactivated User PII" on page 1306.

Your Data When Your Subscription Ends

Once your subscription ends:

1. Your instance enters a two-week grace period.
2. After the grace period expires, the instance is scheduled for deletion two weeks in the future. Your instance is inaccessible but all data is retained.
3. Once the deletion date arrives, your instance is eligible for deletion and can be deleted at any time at Delinea's discretion. In most cases, Delinea retains customer data substantially beyond the deletion date.

If desired, you can request that Delinea deletes your instance right away, and we will promptly respond. **Once deleted, your instance is not recoverable and your data is gone.**

Session Recording Overview

Delinea offers basic and advanced recording options to choose from, enabled by different tools and configurations that capture varying levels of content.

Basic session recording supports logging keystroke metadata for RDP and SSH sessions without requiring an agent across both Windows and Mac environments. Users can search for keystrokes, and the session playback interface displays this additional activity information.

Advanced session recording offers more granular capabilities and process metadata.

The following tools record videos:

- Protocol Handler
- Protocol Handler on a session connector server
- Web Password Filler
- ASRA (Advanced Session Recording Agent)
- Privileged Remote Access

The following tools record keystrokes:

- RDP Proxy
- SSH Proxy
- ASRA (Advanced Session Recording Agent)
- Protocol Handler on a session connector server

The following tool can record process metadata:

- ASRA (Advanced Session Recording Agent)

Basic Session Recording

> macOS Catalina requires additional configuration to use basic session recording. See "macOS Catalina Security" on page 1263.

Basic session recording is a licensed feature in Secret Server. It relies on the protocol handler to be configured on client machines through Secret Server's launcher. Using this launcher, Secret Server captures second-by-second screenshots on the client machine during a user's recorded session. The images are compiled into a video that can be downloaded and played back for auditing and security purposes. Activity recorded in the session is based on screen changes only.

> This is valid for Mac Launchers. RDP/SSH launchers upload recorded video segments every second. See Session Recording Example Architectures for more details.

The Secret Server Session Connector uses a modified Protocol Handler that supports keystroke recording. Session monitoring allows administrators with the Session Monitoring permission to view all active launched sessions within Secret Server. If session recording is enabled on a secret, an administrator can watch the user's session in real time.

Admins can review active and ended sessions by searching for **Session Monitoring**. To select what data is searched across sessions, check the options available in the Search across columns search filters.

Some search filters require additional components to be installed or configured, such as:

- **Proxy Session Client Data**: Search within keystroke data of proxied SSH sessions. This requires the SSH proxy to be enabled, and for SSH sessions to use it.
- **RDP Keystroke Data**: Requires an ASRA to be installed on the target or alternatively, for the RDP proxy or session connector components to be available.
- **RDP Application Name**: Requires an additional ASRA be installed on the target.

To view a recording, click the **Play** icon on the session. Hover over the session line to make the Play icon appear. The Watch Session Recording page appears.

If there is logged session activity, such as keystroke or application data, you can search through session activity and jump to points within the video playback. The playback also displays an activity map to show points of high activity, such as screen changes, keystrokes, and processes started and stopped.

Selecting an activity in the grid also shows additional details such as the full folder path where the application started and the user that performed the operation.

> SSH Keystroke data is shown in one-minute segments. In a short session of less than a minute, the "jump to" only goes to the beginning of the video.

For active sessions, there are two actions that can be taken:

- **Watch Live**: When session recording is enabled for a secret, an admin can view and replay the user's activity in real time.
- **Terminate**: Sends a message to the business user or terminates their session.

The business user will see an alert dialog pop up on their machine with the message. Session Recording does not need to be enabled for this to work. When Session Recording is enabled, however, the functionality exists on both the secret itself, and the session in Session Monitoring. For ended sessions, admins can watch the recorded video and view the SSH log if session recording was turned on for the secret.

Limitations

Certain scenarios cannot be properly video recorded on the client machine:

- When using **Show SSH Proxy Credentials** and connecting manually.
- When using tabbed SSH clients.

In these cases, video recording in Protocol Handler only records the first launched session.

SSH Session Replay

SSH Session Replay provides video-like playback capability for recorded proxied SSH sessions, by replaying captured data through a terminal emulator.

Requirements

SSH Session Replay is available when:

- Using Local Proxy
- Using a Distributed Engine version of 8.4.85.0 or later.

Additionally, the following settings must be configured:

- **SSH Record Keystrokes** should be enabled in Proxy Session Recording.
- **Session Recording Enabled** is set to **Yes** on the secret.

Advanced Session Recording

Advanced Session Recording (ASR) is a licensed feature of Secret Server that adds capabilities to those offered by basic session recording. You install the Advanced Session Recording Agent (ASRA), which uses the Remote Desktop Protocol, on any client machine where you want more information from the sessions recorded.

ASR is not available to those using our Mac launcher.

Older ASRAs (earlier than 7.7) require a Distributed Engine configuration with RabbitMQ or MemoryMQ installed.

ASR enhances launcher sessions, which typically only include screenshots, keystrokes, and process activity.

ASR features include:

- **Screen Capture**: The Secret Server launcher records second-by-second screen images compiled into a playback video of the user's session. This is essentially the same as basic session recording.

- **Logged Processes**: The ASRA logs all processes started and stopped during a user's session.
- **Recorded Keystrokes**: The ASRA records all user keystrokes during the session, which can be disabled.

In addition, ASR includes these enhanced video playback features:

- **Searchable Video**: You can search video activity to find locations where specific activities occurred, such as certain keystrokes or processes that ran.
- **Enhanced Playback**: Sessions recorded using ASR display additional data on playback, such as the current active window, the used processes, and the keystrokes in the session.
- **On-demand video processing**
- **Recording all sessions**
- **Inactivity timeout**
- **Maximum session-length protection**

The Windows Protocol Handler encodes your session in WebM format in real-time and sends the recording to Secret Server. There is an **Enable On-Demand Video Processing** option in Secret Server, which leaves the recordings in the WebM format that Chrome and Firefox can playback without any further processing, saving server processing time.

Edge now also supports WebM playback natively, so recordings in WebM format can be played directly without conversion. You also have the option to click the **Request Video Processing** button, and the video will be converted to the H.264/MP4 format.

> The Mac protocol handler does not yet support this feature, so any recordings created with it are converted to the chosen legacy video codec format. We recommend H.264/MP4. You can set the advanced session recording agent to "Record All Sessions." If someone logs into a server directly without launching from Secret Server, or even logs in at the console, the full session is recorded, including metadata.

See "Installing the Advanced Session-Recording Agent" on page 1271 for details on configuring ASRAs. See Session Recording Configurations for more in-depth information specific to recording settings.

Advanced Session Recording Requirements

> This applies to ASRA and Secret Server. See below for additional details.

> Secret Server Cloud customers have the option to add more storage as needed.

> All cores are physical unless otherwise noted.

Table: Advanced Session Recording Requirements

Web Server (Secret Server)	Database Server (SQL Server)	ASRA (Client Machines)
8 CPU Cores	8 CPU Cores	2 CPU Cores
32 GB RAM	32 GB RAM	16 GB RAM (4 GB for the agent itself)
50 GB Disk Space	100+ GB Disk Space	25 GB Disk Space
Windows Server 2019 or newer	Windows Server 2019 or newer	Windows 7 or newer
IIS 7 or newer	SQL Server 2012 or newer	ASRA 7.7
.NET 4.8 or newer	.NET 4.8 or newer	.NET 4.8

Basic Session Recording Requirements

All cores are physical unless otherwise noted.

Table: Basic Session Recording Requirements

Web Server (Secret Server)	Database Server (SQL Server)
8 CPU Cores	8 CPU Cores
16 GB RAM	16 GB RAM
25 GB Disk Space	100+ GB Disk Space
Windows Server 2019 or newer	Windows Server 2019 or newer
IIS 7 or newer	SQL Server 2012 or newer
.NET 4.8 or newer	.NET 4.8 or newer

Windows Server 2022 supports RDS CALs licensing.

Caveats and Recommendations

General

System requirements apply to both physical and virtual machines.

- Delinea does not support these Web servers:
  - Any Client OS
  - Domain Controllers
  - SharePoint Servers
  - Small Business Server (SBS)
  - Windows Server Essentials
- For best performance, we recommend using dedicated (clean) servers for hosting Delinea products.
- If .NET and IIS features are not already installed on the Web server, the Delinea Installer adds and configure them automatically.
- If you are experiencing an issue with Local Site configured for web processing, Delinea recommends moving to DE processing for optimal performance and correct functional problems.

Components Supporting Session Recording

Things that can record video:

- Protocol Handler (PH)
- PH on a session connector server
- Web Password Filler (WPF)
- Advanced Session Recording Agent (ASRA)
- Remote Access Service (RAS)

Things that can record keystrokes:

- Remote Desktop Protocol (RDP) Proxy
- Secure SHell (SSH) Proxy
- ASRA
- PH on a session connector server
- RAS

Things that can record process metadata:

- ASRA

Things that can record nothing:

- Secret Server Session Connector (SSSC)

Database

- Database disk storage depends directly on how many recorded videos are stored to disk. For active users, we recommend you **use a 1 TB shared or local drive for archival or storage space**. For light users, we recommend beginning with 300 GB. Monitor your disk space usage closely, and tailor it for best results.

- **Carefully consider how quickly your allotted storage might be exhausted**. Once again, it is highly variable, but you might expect around 15 hours of recording per GB of storage. Using the example of encoding capacity used in the Session Recording section, if you wanted to record one year of usage by your 60 8-hour users, you would need around 11 TBs of storage (given vacations and holidays). Our recommended 1 TB would last nearly a month in that scenario. A session retention policy using the automatic deletion feature is likely your best option.
- If MS SQL Server is not already installed on your database server, the Delinea Installer can setup SQL Express on the Web server; however, **SQL Express is only for trials and sandbox environments**. Delinea does not support using SQL Express in a production environment due to size and performance limitations.

> Please see Microsoft documentation on SQL Express at: https://docs.microsoft.com/en-us/sql/sql-server/editions-and-components-of-sql-server-2017

Network Bandwidth and Video

- For Secret Server 10.6 ASR requires around 300 Kbps. Older versions of Session Recording require 1-3 Mbps.

> Our Mac launcher uses the older bit rate.

- Session recording bandwidth requirements vary widely based on monitor resolution and image complexity - higher resolutions and more complex images (simpler screen images compress better) use more bandwidth. For example, with a 1024×768 screen resolution, the required network bandwidth is typically between 0.1 Mbps and 1 Mbps.
- If your connection cannot support the needed bandwidth, the session data is still transmitted, but it takes longer to process each session.
- If a user tries to cancel the transmission, this activity appears in the audit record for the Session Recording Secret.
- All sessions are recorded at 1080p.

> Before Secret Server 10.6, session recordings 1080p or higher were not supported due to a limitation in Microsoft IIS. The session video would be recorded but may have been corrupted.

- Sessions are recorded using the H.264 MPEG-4 codec.

Session Recording

- Server hosting session recording requires fixed RAM and disk space. We strongly recommend that you **do not apply dynamic settings**.
- **Do not record more sessions than you can encode**. If more concurrent sessions are recorded than the system can process, the sessions wait in a queue and are processed when enough server resources become available, which could be in a very long time or perhaps never if your storage is overwhelmed.
- The frame rate we can encode varies dramatically based on many factors, so **testing what encoding rate your session recording configuration can sustain is a must**. From there, you can get an idea of what is possible. For example, let us say you found that we can process 20 FPS on average on your Xeon processors. Given that

rate, we could encode around 1 minute of a session recording in 3 seconds, or 1 hour in 3 minutes, or 1 day in 72 minutes--giving you perhaps 480 session hours per day. You could then parse that figure based on your typical usage to arrive at a maximum potential usage, for example, 60 people doing 8-hours of session recording.

- Typically, you can record **up to one hundred sessions at a time per web node**, load balanced, which should handle large use cases.
- CPU usage during video processing varies depending on concurrent users and recording length. We recommend that you **closely monitor CPU percentages on your web server** during video processing, as well on your client machines during recording, to increase CPU count for machines, if needed.
- We recommend that you **set up RabbitMQ as the backbone service bus** in session recording environments. To setup RabbitMQ, see "Installing RabbitMQ" on page 104.

> For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments.

Session Recording Web Node Connectivity Failures

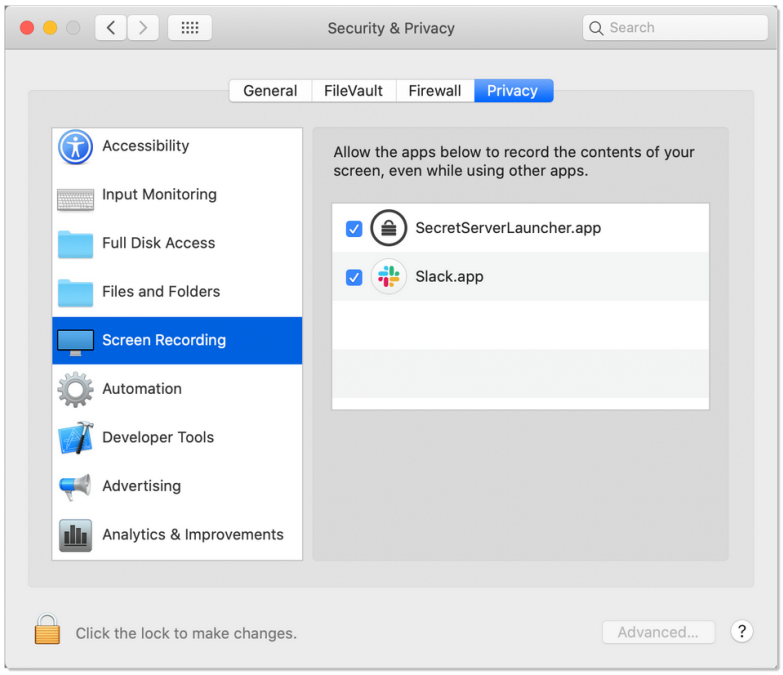
In the event that a session recording web node is disconnected, there is a caching mechanisms:

- Protocol Handler - The information is cached on the machine when just using basic Session Recording.
- Web Password Filler - When recording a browser session if the Web Password Filler loses connectivity to Secret Server's web server over 443, the session is disconnected, and whatever had been recorded up to that point is sent to Secret Server when the connection is restored.
- Advanced Session Recording Agent - If the connection is lost over port 443, the session is unaffected. ASRA will record locally and then when connectivity is restored it will send the data to Secret Server.
- Session Recording with the Proxy - You can block port 443 without any issues when using the proxy but, if you were to block the Proxying port the session would be disconnected.

macOS Catalina Security

macOS Catalina enforces security policy around screen recording. To use the session recording feature of the Delinea launcher on MacOS Catalina, you must first:

1. Go to **System Preferences > Security & Privacy > Screen Recording** on your Mac.
2. Allow recording for the SecretServerLauncher.app:



Configuring the Maximum Concurrent Recording Sessions per Web Node

To set the maximum number of concurrent recording sessions allowed per web node, follow the procedure below on your Secret Server web server node dedicated to session recording:

1. Navigate to the `web-appSettings_config` file (default location `C:\inetpub\wwwroot\SecretServer\web-appSettings.config`).
2. Right-click the file to open it with Notepad.
3. Before the final `appSettings` line, insert the following string:

   ```
   <add key="PrefetchCount.ConvertVideoMessage" value="7"/>
   ```
4. At the end of the string, set the value for the maximum number of concurrent sessions you want for this node. In the example above, the maximum number of sessions is set to `7`.
5. Save the notepad file.
6. Restart IIS on the server.

Configuring Session Recording

Overview

Session recording allows you to record an RDP or PuTTY session, with optional metadata, and play it back in Secret Server.

The Windows protocol handler encodes your session in WebM format in real time and sends the recording to Secret Server. There is an "Enable On-Demand Video Processing" option in Secret Server which leaves the recordings in WebM format, which Chrome and Firefox can playback without any further processing, saving server processing time. If an on-demand recording is viewed with Internet Explorer or Edge (which do not support WebM playback),

you can click the "Request Video Processing" button and the video is converted to H.264/MP4, which they can then play. If "Enable On-Demand Video Processing" is not checked, then all sessions recorded by the Windows protocol handler are automatically converted to H.264/MP4.

> The Mac protocol handler does not yet support this feature, so any recordings created with it are converted to the chosen legacy video codec format. We recommend H.264/MP4.

You can set the advanced session recording agent to "Record All Sessions." If someone logs into a server directly without launching from Secret Server, or even logs in at the console, the full session is recorded, including metadata.

Session Recording General Settings

1. Search for **Session recording general settings**.
2. In the **Session Recording**section, click **Edit**.
3. When **Enable Session Recording** check box is selected, the following Session recording settings appear:

> For testing and proof of concept deployments, Secret Server's "Internal Site Connector" on page 785 is sufficient for session recording. For production deployments we strongly recommend "Installing RabbitMQ" on page 104 for a more-robust message queue.

- **Hide recording indicator**: The user will see no indication that their session is being recorded.
- **Enable on-demand video processing**: Defers processing of video until playback is requested in order to improve performance.
- **Enable inactivity timeout**: Allows inactive recorded sessions to be terminated after a period of inactivity.
- **Inactivity timeout (minutes)**: Inactive recorded sessions will be disconnected after this amount of time, in minutes.
- **Max session length (hours)**: Recorded sessions will be disconnected after this amount of time, in hours.
- **Use hardware acceleration**: Check to allow using hardware for session recording acceleration.
- **Save videos to**: Select the location for saved videos:
  - Database
  - Disk
- **Enable moving to disk**: Enable moving to disk of session recordings to a specified file location after a specified period of time. Sessions moved to disk will be deleted from the database but can be loaded from file.
- **Archive location dependent on site**: Choose whether or not you wish to save your Session Recording Sessions in different locations based on Active Sites.
- **Use temporary archives**: Stores temporary session recording data at the archive path instead of the database in order to improve performance.

> Note that if **Use temporary archives** is enabled, then **Live Session Recording** will not work. Set it to **No** if you need to use Live session recording.

- **Folder path***: Specify the location path.
- **Encrypt archive on disk**: Check to save video on the disk as an encrypted archive.
- **Days until moved to disk**: The number of days before the saved video moved to disk.
- **Legacy video codec**: This setting only applies to sessions recorded with Protocol Handler for OSX. As of 10.6, H264 is always used by new versions of the Protocol Handler for Windows, regardless of this setting. See Using Legacy Video Codecs below.

See "Session Recording Settings" on page 1269 section below for more details.

Using Legacy Video Codecs

You can select a legacy video, but it will only apply to sessions recorded by the Mac protocol handler. Delinea recommends the H.264 codec, because it produces the highest quality videos and requires no additional installation. If you want a different legacy codec, ensure that the codec you select is correctly installed on the same machine as Secret Server. It does not need installation on any client machines, where the session recording is occurring.

Available legacy codecs:

> On Windows Server 2008 and above, you can install Window Media Player by adding "Desktop Experience" from the features of Server Manager.

- Microsoft Video 1 (testing only): Microsoft Video 1 is deprecated in favor of Microsoft Video 9 and should not be used for production. Microsoft Video 1 does not support browser-based playback of sessions.
- Microsoft Video 9: High compression level and quality. Requires Windows Media Player. This option produces comparable video sizes to Xvid for moderate activity in an RDP session.
- VP8: High compression level and quality. VP8 is bundled with Secret Server. This option produces comparable sized video to Xvid for moderate activity in an RDP session.
- Xvid: Provides similar quality and compression to DivX and is freely available. This option produces approximately 20 MBs of video for 1 hour of moderate activity in an RDP session. See https://www.xvid.com/

Enabling Session Recording on Secrets

You must enable session recording on the Security tab for each secret. Once session recording is enabled, Secret Server records that session when the launcher is used. Search for **Secrets**, select the related secret from the list, select the **Security** tab, scroll down to the Other security section, and click Edit next to **Session recording enabled**. In the Edit security popup, check to select **Session recording enabled**, and click **Save**.

To view the recorded session after it is completed, on the related secret page select the **Audit** tab, and in the **Actions** dropdown, select **Session Recording View** and **Session Recording Downloaded**.

You can also search recordings from the Session Monitoring page under **Admin > Session Monitoring**.

The Session Monitoring page lets users search and filter sessions based on session data, secrets, users, groups, launcher type, date, and folders. This page is also where any recordings appear when using the Record All Sessions option (see below), because such recordings are not tied to a specific secret.

> Browser playback is only supported in Secret Server 10.2 and higher. Older versions of Secret Server prompt the user to download the recording.

To view a session, hover over the related row and click the Play icon that appears. This takes you to the Web playback interface. The video playback shows an activity map to quickly skip to sections of higher usage.

As noted above, if using the "On-Demand Video Processing" option, Chrome and Firefox can play the video. If you try to view an on-demand video using Internet Explorer or Edge, a warning message appears.

If you click **Download video**, the recording is downloaded on your local drive.

Extending Session Recording with Custom Launchers

You can configure Secret Server with custom launchers to run arbitrary programs, which can then be recorded by session recording. To do so:

1. Define a custom launcher:
    a. Search for **Launchers**. The Manage Launcher Types page appears.
    b. Click the **Create** button.
    c. Set the **Launcher Type** dropdown list to **Process**.
    d. Type a name for the custom launcher in the **Launcher Name** text box.
    e. Type a process name in the **Process Name** text box.
    f. (optional) Type process arguments in the **Process arguments** text box.
    g. Customize other Options as needed.
    h. Click the **Save** button.
2. Associate the launcher with a secret template:
    a. Search for **Secret Templates**. The Secret Templates page appears.
    b. Select the desired template from the list.
    c. Under the **Mapping** tab, in the **Launchers** section, click the **Add mapping**.
    d. In the **Add mapping** popup, in the **Mapping type** dropdown select your custom launcher.
    e. Customize any other options as needed.

Secret Server 10.8 added two new options to custom launchers:

Record Multiple Windows Option

If this option is not checked, only the main window of the main launcher process will be recorded (this was always the behavior prior to Secret Server 10.8). If it is checked, multiple windows as well as child processes are recorded.

Without this enabled, the main window of the main process sometimes does not show anything useful, depending on the application, resulting in a blank recording. With this enabled, recordings are generally more accurate. This also applies to applications that can open or undock separate windows or those that launch additional processes, such as an application launching PowerShell and then launching other applications from the command prompt.

Record Additional Processes Option

Here you can type an optional comma-separated list of processes to record if found, running under your same user account, that are not started or terminated by the custom launcher. "Track Multiple Windows" must be enabled for this option to be available.

In the example above of launching PowerShell and then opening Notepad, if "Track Multiple Windows" is enabled, both PowerShell and Notepad would be recorded automatically, because the OS can tell that Notepad is a child process of PowerShell. This even works multiple levels deep—for example, launching PowerShell, then the command prompt, and then launching in PowerShell again, finally followed by Notepad.

In some cases, though, you may wish to record an additional process that was already running before the custom launcher was launched or may want to start running one later. To this end, any process names specified in this option are checked for periodically, and recording is attempted on them as well.

Example

If you wanted to run an X11 server such as Xming and then PuTTY with X11 forwarding, you could configure a custom launcher with these values:

Process Name: `C:\Program Files\PuTTY\putty.exe` Process Arguments: `-X -ssh $MACHINE -l $USERNAME -pw $PASSWORD` Record Additional Processes: `Xming.exe`

In this case, Xming should already be running before the launcher was used and would remain running after the session has ended. It would have no parent/child relationship with PuTTY at all. However, while the launcher session was active, any windows it spawns would still be recorded, allowing the X11-forwarded applications to be recorded, not only the PuTTY window.

Advanced Session Recording

Metadata Recording

By default, session recording creates videos of the launched session. Secret Server supports logging additional metadata, such as keystrokes for RDP and SSH sessions. When these options are enabled, users can search for keystrokes or applications across sessions, and the session playback interface shows additional activity information.

Remote Desktop session metadata requires Secret Server and the advanced session recording feature, which in turn requires an installation of an advanced session recording agent (ASRA) on the target servers. See "Installing the Advanced Session-Recording Agent" on page 1271.

SSH keystroke data relies on the Secret Server SSH Proxy. This can be enabled under **Admin >SSH Proxy**. See "SSH Proxy Configuration" on page 833 for more information. Once proxying is enabled recorded SSH sessions will log SSH traffic which can be searched and is displayed in the session playback interface.

RDP Proxy and Advanced Session Recording Agent (ASRA) are able to capture RDP metadata.

Record All Sessions

You can configure the ASRA to record all sessions. This causes it to record video, keystrokes, and process metadata for anyone logging into the server, even when not using Secret Server, including logging into the console. Since these recordings are not tied to any specific secret, you must go to the **Admin>Session Monitoring** page to view them.

Session Recording Settings

Under **Admin >Configuration>Session Recording** there are several settings for configuring how Secret Server handles session recordings:

Hide Recording Indicator

When viewing a secret, the launcher icon normally indicates if the session will be recorded or not via the recording icon. When launched into, a notification window also informs the user that their session is being recorded. If "Hide Recording Indicator" is checked, users cannot tell which secrets have recording enabled based on the icons, and if they launch a recorded session, they will not be warned that their session is being recorded.

Enable On-Demand Video Processing

The Windows protocol handler encodes the recording on the fly in WebM format and streams the video to Secret Server. Once the session has ended, Secret Server reconstructs the video and leaves it in WebM format, which Chrome and Firefox can natively play back.

WebM is an audiovisual media file format that is a royalty-free alternative to HTML5 audio and video.

Internet Explorer and Edge currently have issues playing back WebM videos, so if you are using those browsers and try to view an on-demand recording, you are presented with a "Request Video Processing" button, which converts the video to H.264/MP4, as soon as possible, which IE or Edge can then play back.

If this option is not checked, all sessions recorded by the Windows protocol handler are converted to H.264/MP4 automatically. If you have many IE or Edge users, Delinea recommends leaving this option unchecked, but this will increase the processing time of videos and increase the load on your Secret Server servers that have the Session Recording role enabled.

This setting has no effect on sessions recorded with the Mac protocol handler, which is always encoded using your legacy video codec choice.

Enable Inactivity Timeout (Minutes)

If enabled, if a session appears idle, users are given a five-minute warning that they will be disconnected. A prompt appears that lets them choose to disconnect immediately or to continue the session. If no response is received, the session is disconnected five minutes later.

This feature was added in Secret Server 10.6.26 and is currently only supported in the Windows protocol handler (not Mac).

Max Session Length (Hours)

This sets a hard limit to how long a recorded session may last. This includes both launched from Secret Server, as well as recorded sessions if using ASRA and the "Record All Sessions" option. This option helps prevent accidental recordings over the weekend, or even longer, if someone forgets to disconnect their session.

> This feature was added in Secret Server 10.6.26 and is supported by both the Windows and Mac protocol handlers.

Use Hardware Acceleration

If enabled, when processing H.264/MP4 files, this setting makes Secret Server attempt to use hardware acceleration for video processing if possible (GPU or CPU). Delinea recommends this setting is always enabled because Secret Server will fall back to not using hardware acceleration if necessary.

> This feature was added in Secret Server 10.6.0.

Save Videos to

This configuration includes:

- **Database**: Stores the information from a recorded session as encrypted data to your database.
- **Disk**: Stores the recorded session as a video file directly to the specified folder path.

Archive Location Dependent on Site

If you save recordings to disk, enabling this option lets you pick a separate path for each of your sites. This is useful in large environments that need many recordings spread out across multiple devices and locations.

> See below for a note about using network shares for storage.

Folder Path

If you save recordings to disk, this is where they are saved. If you use the "Archive Location Dependent on Site" option, this is the default storage location for newly added sites, until you customize their folder path to something else.

> See below for a note about using network shares for storage.

Encrypt Archive on Disk

This setting encrypts the session videos when stored on disk. Videos stored on disk are played back through the Secret Server UI but cannot be viewed directly from the file system.

Enable Archiving to Disk

After the specified number of days have passed, all recorded session information in your database is transferred to the specified folder path as video files and cleared from the database.

Session Recording Retention Schedule

Enable Deleting

After the specified number of days have passed, all recorded videos in your database will be cleared and video files in your archive path will be deleted.

Setting Notes

- To use "Save Videos to Disk" or "Archive to Disk," the Application Pool service account must have write permission to the specified file path.
- To delete videos from the archive path, the Application Pool service account must have "modify" Windows NTFS permissions.
- After saving a change to **Configuration>Session Recording**, the configurations for "Save Videos To Disk" and "Enable Deleting" will immediately be applied to all existing session recordings.

Using Network Share Path

In a clustered environment Secret Server needs to use a network path when saving the files to disk. All nodes need access to the path to read the videos back to the user.

To archive or save to a file path that is a network share, instead of a local folder:

- The Secret Server IIS application pool must be running as a service account. See "Running the IIS Application Pool As a Service Account" on page 63 for details.
- You must grant access to the network share (using Windows ACLs) to the account running the Secret Server IIS application pool.
- Ensure your file server is configured with SMB Multichannel enabled, to avoid corrupted session recordings.

Installing the Advanced Session-Recording Agent

Session Recording Metadata Overview

By default, Secret Server session recording creates videos of launched sessions. Secret Server supports logging additional keystroke metadata for RDP and SSH sessions without requiring an agent across both Windows and Mac environments. When these options are enabled, users can search for keystrokes or applications across sessions and the session playback interface displays the additional information.
SSH metadata relies on the Secret Server SSH proxy.

Recording Remote Desktop session metadata requires the installation of an Advanced Session Recording Agent (ASRA) on the target server. In this scenario Secret Server's protocol handler is still used to launch the session and record the session video, and the ASRA records the metadata only.

ASRA can optionally record any session on the target server. If enabled and the session was not launched from Secret Server, ASRA will record video, keystrokes, and process metadata for the session and upload both to Secret Server once the session is disconnected. This works even if someone logs into the console directly or Remote Desktops into the server without using Secret Server at all. Live viewing of this type of session is not supported.

If you are licensed for session recording, you can install unlimited numbers of ASRAs.

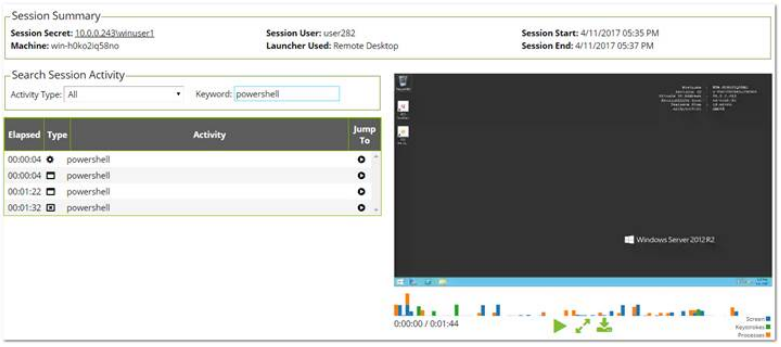
How Advanced Session Recording Agents Work

1. Once the ASRA is installed, it contacts the ASRA callback URL to determine if it should record metadata or video any time someone logs on to the computer.
2. A user logs on.
3. The ASRA sends Secret Server the computer's hostname, the username of the user who logged on, any domain name if available, and a list of the computer's IP addresses.

   > This data is not logged by Secret Server unless you enable DEBUG logging, only for troubleshooting purposes.

4. Secret Server checks for any recently-launched protocol handler sessions with matching details, and tells the ASRA if it should record the session.
   - If there is a match, the ASRA starts recording metadata and sends it back to Secret Server over the chosen response bus for the duration of the session.
   - If there is no match and "Record All Sessions" is enabled for the ASRA, the ASRA records both the video and metadata for the session.
   - If there is no match and "Record All Sessions" is not enabled, the ASRA records no video or metadata and waits for the next person to log in.
5. Once a recording session has been closed:
   - If the session was launched from Secret Server using the protocol handler, the video from the protocol handler is matched up to the metadata provided by the ASRA and combined.
   - If the session was not launched from Secret Server and "Record All Sessions" is enabled, the ASRA uploads both the video recording and the metadata to Secret Server.
6. On the Session Monitoring page, additional icons are presented based on what extra metadata is present for that session, such as keystroke data for both RDP and SSH, and process data for RDP.
7. Once the session recording has been processed, on the Session Playback page the additional metadata is visible:

   And on the Session Monitoring page:



In this example, we searched for activity where the user typed in the word “PowerShell.”

Record All Sessions

Recording video and metadata for all sessions on a server including console access requires Distributed Engine and ASR to be enabled as described above. ASRA must be installed on the target server, and it must be set to "Record All Sessions." If the server is set to “Only Record Secret Sessions,” the ASRA will only provide metadata when people launch into the server from Secret Server. Secret Server When recording all sessions, they appear on the Session Monitoring page. They are not tied to any specific secret because the sessions are not started by Secret Server.

Secret Server Configuration

First, session recording must be enabled (**Admin > Configuration > Session Recording**). As that page warns, Delinea highly recommends using RabbitMQ when using session recording in any production environments. See "Configuring Session Recording" on page 1264 for more information.

> For the highest scalability and reliability, Delinea recommends using RabbitMQ. MemoryMQ is an easier but less capable alternative and can be used for trials and proof of concepts but **should not** be used for production environments. Two exceptions are very small deployments and customers that do not use open-source software for compliance reasons.

SSH Metadata

To record SSH keystroke data, enable the SSH proxy (**Admin > SSH Proxy**). Individual secrets then require configuration of the Enable Proxy setting and the Enable Session Recording setting. Then when the SSH session is launched and recorded, keystroke data is recorded, which can be searched and is displayed in the session playback interface. See "Session Recording Overview" on page 1256 and "SSH Proxy Configuration" on page 833 for more information.

Remote Desktop Metadata

To record RDP session metadata, first distributed engine needs to be enabled (**Admin > Distributed Engine**) with an appropriate response bus site connector, which should be a RabbitMQ site connector in production environments. The ASRAs will communicate with the chosen site connector to return any recorded metadata. Next, the Advanced Session Recording feature must be enabled (**Admin > Advanced Session Recording**), and an ASRA callback URL entered. HTTPS should always be used in production environments. Individual secrets then

just need the Enable Session Recording setting enabled, and the computer you launch into must have the ASRA installed. The secrets do not have to use SSH proxy since the ASRA is what records the metadata. See "Session Recording Overview" on page 1256 for more information.

Session Recording Worker Role

> All cores are physical unless otherwise noted.

There is a dedicated Session Recording Worker role. If you have a clustered Secret Server environment, you can pick which nodes process recordings on the **Admin > Server Nodes** page. In a large environment with many recordings, you can configure nodes to be dedicated just to session recording, letting other nodes run the Background Worker and other roles. Session recording processes multiple videos at once, which can be controlled with the PrefetchCount.ConvertVideoMessage AppSetting (default: 2). We recommend setting this AppSetting to half the number of CPU cores on the server as a starting point. This setting applies only when using a RabbitMQ site connector, which is another reason Delinea highly recommends using Rabbit if you are using session recording.

Advanced Session Recording Agent

First, create one or more collections to group the ASRAs together, for example, for different domains or environments. Each collection has a unique installer that you can download from their page – the installer is customized to know which collection it is associated with. On the collection, you can specify if you want new agents to **Record All Sessions**, or to **Only Record Secret Sessions**. New agents adhere to this setting, and you can toggle it for individual agents, once they have registered.

Agent Manual Installation

The downloaded installer can be manually installed on a computer by running the setup.exe inside the zip file. It can also be deployed using group policy software installation or other MSI management software. The ASRA installs itself in `C:\Program Files\Thycotic Software Ltd\Session Recording Agent` and adds a Windows service, Delinea Session Recording Agent.

> Only 64-bit Windows operating systems are currently supported. .NET Core is also required.

Agent Updates

The ASRA does not automatically update, so new versions must be manually installed or re-deployed using the Group Policy MMC.

Agent Uninstallation

You can deactivate specific ASRAs or an entire collection in Secret Server, and the next time the ASRA reaches out to the ASRA callback URL, it will uninstall itself. Since it only reaches out when someone logs on to the computer, it will remain uninstalled until someone logs on again. The ASRA can also be manually uninstalled directly on the computer like any normal Windows application, but then Secret Server will still show it in the list of active ASRAs under its collection. It should also be deactivated in Secret Server to keep the agent list accurate. If "Record All Sessions" is enabled for this server, you will get a prompt to stop the Delinea Session Recorder application when

you attempt the uninstall because it is running and recording your session, as expected. To avoid these issues, we recommend using the Deactivate feature in Secret Server and then logging into the machine, and it will uninstall itself on its own.

Agent Group Policy Installation

Task 1: Review the Prerequisites

The ASRA requires a 64-bit operating system with .NET Core or greater installed on the client machine. This is the version that ships with Windows 8.1 and Windows 2012 R2.

Task 2: Download the Advanced Session Recording Agent Installer

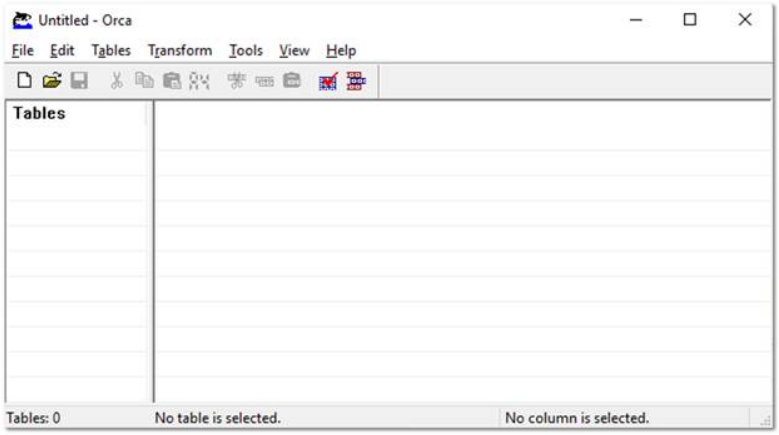
1. Log on to Secret Server.
2. Search for **Advanced Session Recording**.
3. Click on an existing collection, or create a new one, as appropriate.
4. Click the **Download Session Recording Installer(64-bit)** button. The installer is downloaded to your computer.

> The zip file is customized for each collection. Be sure to download the installer from the collection you want your new ASRAs associated with.

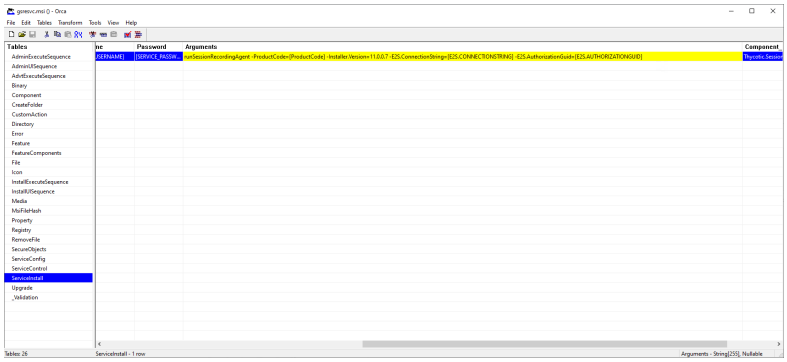
Task 3: Customize the Installer

For a normal manual installation, you extract the zip file, and run setup.exe. There are settings saved in setup.exe.config that customize the installation of the MSI file contained in the zip (gsresvc.msi). When you deploy the ASRA using Group Policy software installation instead of a manual one, the only other files in the zip you need is the MSI, which is deployed from a network share, and an MST (Master Software Tools?) “Transform” file which configures the custom settings.

1. Install Microsoft’s free MSI editing tool, Orca, if you do not already have it installed.
2. Extract the ASRA zip file into its own folder.
3. Right click on the MSI file (gsresvc.msi) in the folder where you extracted the zip and select **Properties** to verify that there is a **Digital Signatures** tab indicating that the MSI was signed by Delinea Software.
4. Launch Orca.



5. Open the extracted MSI file (gsresvc.msi). The Tables list appears.
6. Click the **Transform** menu at the top
7. Select **New Transform**.
8. In the **Tables** list, click **ServiceInstall**. Only one row should be listed on the right.



> This screen shot shows the Arguments column dragged wider to see its contents. When you initially see it, it will be very narrow, barely showing the contents.

9. Scroll to the **Arguments** column and copy and paste its contents into a text editor. It should look like this example. Be sure to select the entire column. You might need to adjust the column width.

> The entire string of text is essentially a CLI command with parameters that begin with a hyphen. For illustration purposes we put each parameter on its own line below.

```
                    runSessionRecordingAgent
-ProductCode=[ProductCode]
-Installer.Version=10.6.000000
-E2S.ConnectionString=[E2S.CONNECTIONSTRING]
-E2S.AuthorizationGuid=[E2S.AUTHORIZATIONGUID]
```

Everything highlighted is what we will customize. The fields in brackets are what setup.exe would normally customize.

10. In your text editor, open the setup.exe.config XML file from the zip. You will get the Globally Unique Identifier (GUID) from it.
11. In your text editor, replace each of these with the correct values as listed below. The GUID will require looking in setup.exe.config in the XML block. The values are as follows:
    - **ProductCode** should always be: "{A7FA0ADA-BEED-4841-9D3E-9D700B36F653}" (not in setup.exe.config).
    - **Installer.Version** should match your Secret Server version (visible in Secret Server in the bottom right corner).
    - **E2S.ConnectionString** is the callback URL for Secret Server Cloud is the Cloud URI.

      > Secret Server Cloud does not list a Callback URL on the Advanced Session Recording page.

    - **E2S.AuthorizationGuid** is a unique GUID specific to the ASRA collection that you downloaded the installer file from. You can find it in the setup.exe.config file (in setup.exe.config). This is unique for each ASRA Collection.
12. Back in Orca, delete everything in the ServiceInstall Arguments column.
13. Copy and paste the customized version you just created from your text editor into the Arguments column.
14. Click the **Transform** menu.
15. Click **Generate Transform**.
16. Save the file as `gsresvc.mst` in the directory you extracted the installer into. This transform file now contains your customizations for the ServiceInstall Arguments.
17. Close Orca.
18. Check the MSI file's digital signature again to ensure that it was not edited: If you right-click the MSI file and select **Properties** again, the Digital Signatures tab should still show that the MSI is signed by Delinea Software. You created your own custom MST transform file, but the MSI itself should be unchanged. Orca can edit the MSI file itself, but that will invalidate Delinea's digital signature and it is unnecessary.

Task 4: Set up a Network Share

1. Place the `gsresvc.msi` and `gsresvc.mst` files on a network share on your domain controller.
2. Give "Authenticated Users" read access to this share.

> Computers in the domain will access this network share to get the installer files before any users log into the machine. It will be the machine account authenticating to the network share, before any users have logged in.

Task 5: Create a Group Policy with Software Installation to install the MSI

1. Open the Group Policy Management Console (**Start\ > Administrative Tools > Group Policy Management**).
2. Expand the **Forest** and **Domain** nodes until you locate the domain on which you are installing the ASRA.
3. Right click on **Group Policy Objects** and click **New**.
4. Enter a descriptive name for your GPO, such as " Delinea Session Recording Agent Installation," and click **OK**.
5. Right click on the newly created **GPO** node and click **Edit**.
6. Select **Computer Configuration > Policies > Software Settings > Software Installation**.
7. Right click on the **Software Installation** node and select **New > Package**.
8. Browse to the MSI on your network share using the share's UNC path, not its folder path. For example: `\\ServerMachineName\Shared and not C:\Shared`.
9. Click **Open**.
10. Click to select the **Advanced** option button.
11. Click **OK**. The name is automatically be set to "Delinea Session Recording Agent", since that is the product name in the MSI file.

    > You can customize the name here, but if you use something else, that is what you will want to check for in the Verify Configuration section, instead of "Delinea Session Recording Agent."

12. On the **Modifications** tab, click **Add** and select your MST transform file. Be sure to again use a UNC path like `\\ServerMachineName\Shared, not C:\Shared`.

    > If you wish to have the ASRA uninstalled when it falls out of management, click on the Deployment tab and click to select the box next to "Uninstall this application when it falls out of the scope of management".

13. Click OK.
14. In the group policy object editor, expand **Computer Configuration > Administrative Templates > System**.
15. Click the **Logon** node.
16. Right-click **Always wait for the network at computer start-up and logon** and select **Properties**.
17. Click **Enabled**.
18. Click **OK**. This helps reduce the number of reboots required for this policy to take effect as noted in the description of this option.

Task 6: Link your Group Policy Object to an OU

1. Open the Group Policy Management Console (**Start > Administrative Tools > Group Policy Management**)
2. Expand the **Forest** and **Domain** nodes until you locate the domain on which you are installing the Secret Server protocol handler.
3. Right-click the Organizational Unit (OU) for which you want Secret Server protocol handler to be installed and select **Link an Existing GPO**.
4. Select the GPO you created earlier.
5. Click **OK**. The GPO is now linked the entire OU.

> To immediately force the group policy change and install the software on a client machine, open a command console on the client machine (start > run > cmd), type `gpupdate /force`, and restart the client machine. You can also wait for the group policy to go into effect, which usually takes one to two hours, but a reboot will still be required due to the mechanics of group policy software installations.

Task 7: Verify Configuration at the Domain Level

1. Go to **Start > Administrative Tools > Active Directory Users and Computers**.
2. Right-click the OU for which Secret Server Protocol Handler is now configured and select **All Tasks > Resultant Set of Policy**.
3. Check to select the box next to **Skip to the final page of this wizard without collecting additional information**.
4. Click **Next** twice.
5. Click **Finish**.
6. In the new **Resultant Set of Policy** window, expand **Software Settings** under **Computer Configuration**.
7. Click to select **Software installation**.
8. **Delinea Session Recording Agent** should be visible in the **Installed Applications** column.

Task 8: Verify the Configuration of a Domain Member

1. From a command prompt, run `gpresult /h report.html` to output a report for just that one computer to the specified HTML file, which you can then view in a browser.
2. The Delinea session recording agent should be visible in the Installed Applications section.
3. Once the computer has rebooted and completed the installation, the software shows up in Apps and Features (Add Remove Programs). As usual, the Delinea Session Recording Agent Windows Service is installed in `C:\Program Files\Thycotic Software Ltd\Session Recording Agent`.

Stability and Compatibility with Older ASRAs

The latest Advanced Session Recording Agents (ASRAs) use more reliable durable message exchanges, which are not compatible with earlier (already deployed) ASRAs. Version 7.7+ of the ASRA only requires HTTP connectivity to Secret Server, the distributed engine response-bus site connector is no longer required.

To prevent this from breaking older Advanced Session Recordings, exchanges remain permanently transient. Newer ASRAs use HTTP uploads, which do not use the message queue. Older versions of ASRAs will continue to function as they have, while newer ASRA versions do not use the message queue and will have "durable" behavior over HTTP. We recommend updating your ASRA to version 7.7 or later as soon as possible.

Enabling Inactivity Timeout

If enabled, if a session appears idle, users are given a five-minute warning that they will be disconnected. A prompt appears that lets them choose to disconnect immediately or to continue the session. If no response is received, the session is disconnected five minutes later.

This feature was added in Secret Server SP2 and is currently only supported in the Windows protocol handler (not Mac).

Enabling On-Demand Video Processing

As described above, this feature was added in Secret Server 10.6.24 to greatly improve session recording performance.

The Windows protocol handler now encodes the recording on the fly in WEBM format and streams the video to Secret Server. Once the session has ended, Secret Server reconstructs the video and leaves it in WEBM format, which Chrome and Firefox can natively play back.

Internet Explorer and Edge currently have issues playing back WEBM videos, so if you are using those browsers and try to view an on-demand recording, you are presented with a "Request Video Processing" button, which converts the video to H.264/MP4, as soon as possible, which IE or Edge can then play back.

If this option is not checked, all sessions recorded by the Windows protocol handler are converted to H.264/MP4 automatically. If you have many IE or Edge users, Delinea recommends leaving this option unchecked, but this will increase the processing time of videos and increase the load on your Secret Server servers that have the Session Recording role enabled.

This setting has no effect on sessions recorded with the Mac protocol handler, which is always encoded using your legacy video codec choice.

Recording Metadata

By default, session recording creates videos of the launched session. Secret Server supports logging additional metadata, such as keystrokes, for RDP and SSH sessions. When these options are enabled, users can search for keystrokes or applications across sessions, and the session playback interface shows additional activity information.

Session metadata requires Secret Server and the advanced session recording feature, which in turn requires an installation of an advanced session recording agent (ASRA) on the target servers. See "Installing the Advanced Session-Recording Agent" on page 1271.

SSH keystroke data relies on the Secret Server SSH Proxy or Session Connector (via the Protocol Handler). This can be enabled under Admin > SSH Proxy. See the "SSH Proxy Configuration" on page 833 for more information. Once proxying is enabled, recorded SSH sessions log SSH traffic, which can be searched and is displayed in the session playback interface.

Recording All Sessions

As of Secret Server SP2, you can configure the ASRA to record all sessions. This causes it to record video and metadata for anyone logging into the server, even when not using Secret Server, including logging into the console. Since these recordings are not tied to any specific secret, you must go to the **Admin > Session Monitoring** page to view them.

System Capacity Specifications

This applies to both ASR and basic session recording. See below for details.

Table: Session Recording Capacities

Web Node	Maximum Concurrent Session Conversions per Node	Maximum Processing Time per Session	Recording Processing Time per Maximum Length Session
Dedicated for session recording	4	2 hours	10 minutes
Shared for front-end processing and session recording	2	2 hours	20 minutes

See "Configuring the Maximum Concurrent Recording Sessions per Web Node" on page 1264

Overview of Users, Roles, User Groups, and User Teams

Users

Users in Secret Server represent individual people, each with a unique username and other attributes. Users are assigned to groups, and roles are assigned to them either directly or via groups. This setup allows for granular control over what each user can access and perform within the system.

Delinea Roles and Role Permissions

Roles

Secret Server uses a role-based access control (RBAC) mechanism to regulate system access. Each user and group must be assigned to a role. Secret Server ships with three default roles: Administrator, User, and Read-Only User. Each role contains various Delinea permissions to match the job function of the user. Roles can be customized by assigning multiple Delinea permissions to a role, which can then be assigned to a user or group.

The Unlimited Vault Access Delinea permission allows the user to have Unlimited Vault Access rights when Unlimited Vault Access is enabled in the configuration. By default, it is disabled.

To see the built-in roles and what Delinea permissions they possess, click the desired role link on the **Admin > Roles page**.

Delinea Role Permissions

Delinea role permissions in Secret Server are granular and can be assigned to roles to control what actions users can perform. Some examples of Delinea role permissions include:

- **View Active Directory**: Allows a user to view, but not edit, Active Directory settings.
- **View Configuration**: Allows a user to view, but not edit, general configuration settings.
- **View Secret**: Allows a user to view which secrets exist in the system.
- **Administer Teams**: Allows a user to create, edit, and view all teams.

For a comprehensive list of Delinea role permissions, visit the "Secret Server Role Permissions List" on page 1288.

User Groups

User groups in Secret Server allow administrators to manage users collectively. Users can belong to different groups and inherit the sharing Delinea permissions and roles attributed to those groups. This simplifies the management of Delinea permissions and roles that can be assigned to a user. Groups can also be synchronized with Active Directory to further streamline management.

For a comparison of user groups and teams, see "User Teams Overview" on page 1317.

User Teams

User teams in Secret Server are special groups created to restrict what users can see. A team bundles users and groups to assign them the same rules regarding visibility of other users and sites. This is particularly useful for managed service providers or large companies that need to isolate users by department or customer.

Team-related Delinea permissions include:

- **Administer Teams**: Users can create, edit, and view all teams.
- **Unrestricted by Teams**: Users can view all users, groups, and sites, regardless of team affiliation.
- **View Teams**: Users can view all teams.

For a more in-depth overview, including a comparison of user groups and teams, see "User Teams Overview" on page 1317.

Overview of Users, Roles, User Groups, and User Teams

Users

Users in Secret Server represent individual people, each with a unique username and other attributes. Users are assigned to groups, and roles are assigned to them either directly or via groups. This setup allows for granular control over what each user can access and perform within the system.

Delinea Roles and Role Permissions

Roles

Secret Server uses a role-based access control (RBAC) mechanism to regulate system access. Each user and group must be assigned to a role. Secret Server ships with three default roles: Administrator, User, and Read-Only User. Each role contains various Delinea permissions to match the job function of the user. Roles can be customized by assigning multiple Delinea permissions to a role, which can then be assigned to a user or group.

The Unlimited Vault Access Delinea permission allows the user to have Unlimited Vault Access rights when Unlimited Vault Access is enabled in the configuration. By default, it is disabled.

To see the built-in roles and what Delinea permissions they possess, click the desired role link on the **Admin > Roles page**.

Delinea Role Permissions

Delinea role permissions in Secret Server are granular and can be assigned to roles to control what actions users can perform. Some examples of Delinea role permissions include:

- **View Active Directory**: Allows a user to view, but not edit, Active Directory settings.
- **View Configuration**: Allows a user to view, but not edit, general configuration settings.
- **View Secret**: Allows a user to view which secrets exist in the system.
- **Administer Teams**: Allows a user to create, edit, and view all teams.

For a comprehensive list of Delinea role permissions, visit the "Secret Server Role Permissions List" on page 1288.

User Groups

User groups in Secret Server allow administrators to manage users collectively. Users can belong to different groups and inherit the sharing Delinea permissions and roles attributed to those groups. This simplifies the management of Delinea permissions and roles that can be assigned to a user. Groups can also be synchronized with Active Directory to further streamline management.

For a comparison of user groups and teams, see "User Teams Overview" on page 1317.

User Teams

User teams in Secret Server are special groups created to restrict what users can see. A team bundles users and groups to assign them the same rules regarding visibility of other users and sites. This is particularly useful for managed service providers or large companies that need to isolate users by department or customer.

Team-related Delinea permissions include:

- **Administer Teams**: Users can create, edit, and view all teams.
- **Unrestricted by Teams**: Users can view all users, groups, and sites, regardless of team affiliation.
- **View Teams**: Users can view all teams.

> For a more in-depth overview, including a comparison of user groups and teams, see "User Teams Overview" on page 1317.

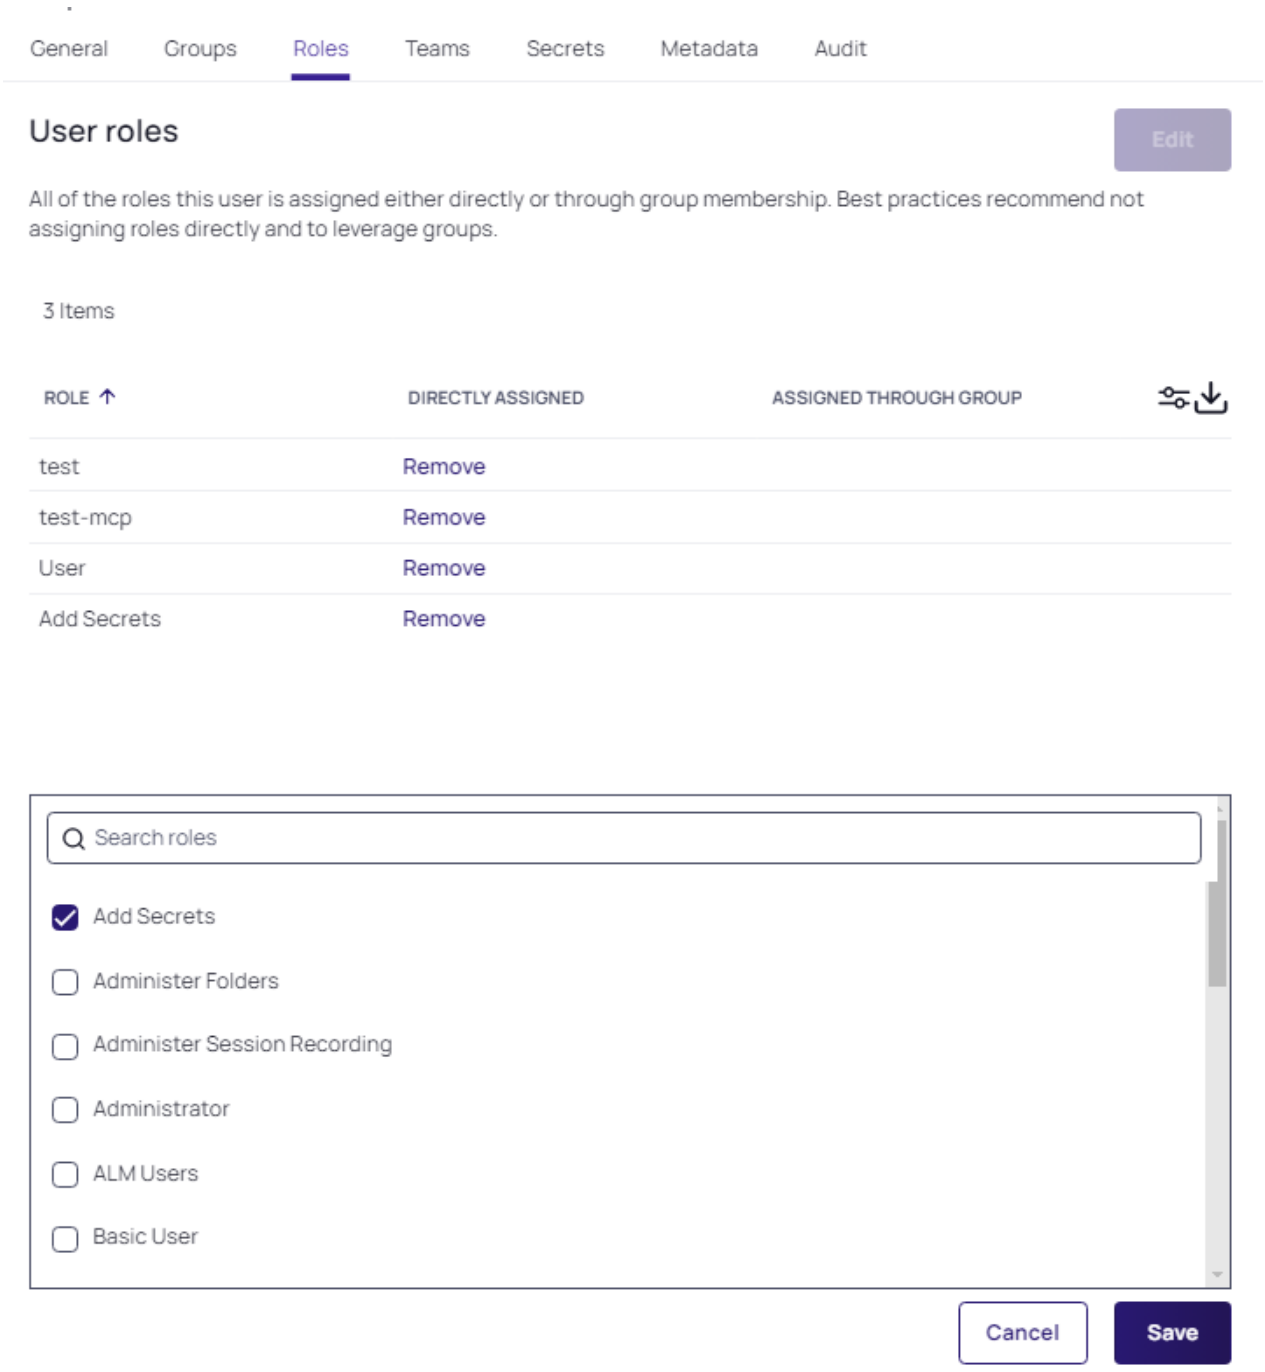
Assigning Roles to a User

Choose one of three methods to assign roles to users or groups:

- **Via the Roles Assignment tab**
  1. Search for **Roles**.
  2. Choose or create the role to assign.
  3. In the **Assignment** tab, click **Edit** to add or remove groups and users to this role.
  4. Change the **Scope** option to **Unassigned** to display the groups and users you can choose from.
  5. To remove a user or group, change the **Scope** option to **Assigned** and deselect the checkbox next to the user:

  6. Click **Save** to apply the changes.

- **Via the Users Roles tab**
  1. Search for **Users**.
  2. Choose or create the user you wish to modify.
  3. In the **Roles** tab, click **Edit**.
  4. In the search bar, type the roles you wish to add or remove for this user.
  5. Select the checkbox next to each role you wish to add and **Save**:

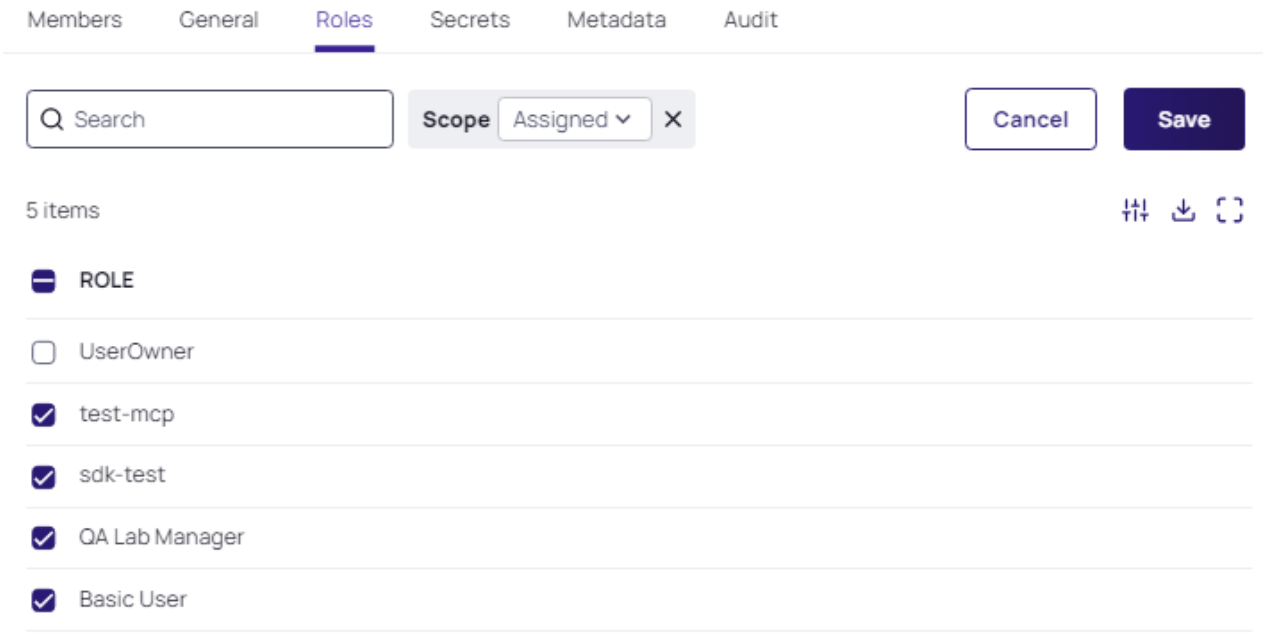


For the roles already assigned, deselect the checkbox next to their name in the search list. Alternatively, click **Remove** from the assigned role list to remove a role.

- **Via the Groups Roles tab**

1. To assign multiple roles to a single group, Search for **Groups**.
2. Click on the existing group you want to modify or create one.
3. In the **Roles** tab, click **Edit**.
4. Change the **Scope** option to **Unassigned**.
5. From the list that appears, select the checkbox for each role you wish to add.
6. Click **Save** to apply the changes.

   Optionally, change the **Scope** option to **Assigned** and deselect the checkbox next any role you wish to remove, before clicking **Save**:



Creating Roles

You can create roles from the Roles page. To get to the Roles page, Search for **Roles**. Click the **Create Role** button to add the role.

Editing Role Permissions

To add or remove Delinea permissions to an existing role, click the role name of the role you wish to edit.

Select the Permissions tab which lists all of the current role permissions that are currently assigned to this role. Add or remove role permissions by clicking edit. Once in edit mode you can remove roles by unchecking them when viewing "Assigned" or add new role permissions by checking them when viewing "Unassigned." Chips will indicate pending changes and once you are done modifying the role permissions click save.

Secret Server Role Permissions List

Overview

Secret Server uses role-based access control (RBAC) to regulate Delinea permissions. The roles are assigned to users or groups. A complete list of the permissions available to roles appears below:

> To see the built-in roles and what Delinea permissions they possess, click the desired role link on the Roles page.

Adding a jumpbox route to a target secret: A user must have owner permissions on a secret to assign, change, or remove that secret's jump server route. Additionally, users are only able to pick from a list of routes where they have at least list permission on the first jump route server. Editing Jumpbox Routes: Users must have the "Administer Jumpbox Route" permission to create, edit, or deactivate jump server routes. Users with the "View Jumpbox Route" permission can view the details of all jump server routes in the Admin Jumpbox Route page, but they cannot make any changes.

Complete List

Access Offline Secrets on Mobile

Allows a user to cache their Secrets in the Secret Server mobile application for offline use. This permission does not automatically come with the Administrator role.

Add from External Directory

Add users from external directory. Cloud only.

Add Secret

Allows a user to create new Secrets. The Add permission no longer include the role permission View Secret.

Add Secret Custom Audit

Allows a user to make a custom audit entry when accessing a Secret using the web services API.

Administer Active Directory

Allows a user to view domains, edit existing domains, delete domains, and add new domains. Also allows a user to force synchronization or set the synchronization interval.

Administer Automatic Export

The user can do everything the other automatic export permissions allow *and* edit the automatic export configuration.

Administer Backup

Allows a user to view and configure automated backups for Secret Server. Users with this role permission can change the backup path, disable backups, and set the backup schedule. On-Premises only.

Administer Configuration

Allows a user to view and edit general configuration options. For example, a user with this role permission can turn on "Force HTTPS/SSL" and disable "Allow Remember Me".

Administer Configuration Proxying

Allows a user to view and edit SSH Proxy settings.

Administer Configuration SAML

Allows a user to view and edit SAML integration settings on the Login tab of Configuration settings.

Administer Configuration Security

Formerly "Administer Security Configuration," allows a user to view and edit security configuration options in Secret Server. Currently, these include enabling FIPS compliance mode and protecting the encryption key.

Administer Configuration Session Recording

Allows a user to view and edit session recording settings on the Session Recording tab of Configuration settings.

Administer Configuration Two Factor

Allows a user to change the configuration settings of the two factor authentication that are available for users logging into Secret Server.

Administer Configuration Unlimited Vault Access

Formerly "Unlimited administrator," allows a user to turn on Unlimited Vault Access Mode. When this mode is enabled, users with the "Unlimited Vault Access" role permission can view and edit all Secrets in the system, regardless of Delinea permissions. Note that you can assign "Administer Unlimited Vault Access Configuration" to one user and "Unlimited Vault Access" to another user. This would require one user to turn on the mode and another user to view and edit secrets.

Administer ConnectWise Integration

Allows a user to view and edit configuration options for synchronizing with ConnectWise. This can be accessed through the "Folder Synchronization" link on the Administration page. Note that you need at least view access on the sync folder in order to set up or edit the ConnectWise integration.

Administer Create Application Accounts

Formerly "Create Application Account", allows a user to create application user accounts to be used exclusively for accessing Secret Server via the API. This permission allows for creating user accounts without the Administer Users or Administer Create Users permissions.

Administer Create Users

Allows a user to create new local users in Secret Server, but not edit them once created.

Administer Custom Password Requirements

Allows a user to view and edit custom password requirements that can be configured under the Security tab for individual Secrets.

Administer Data Retention

Can manage audit data retention, such as editing and running now. This permission does not automatically come with the Administrator role.

Administer DevOps Secrets Vault Tenants

Add, remove, and edit DSV tenants that automatically synchronize with Secret Server on a schedule.

Administer Disaster Recovery

Allows a user to configure instances as data sources or replicas for Disaster Recovery. Also allows user to initiate or test Data Replication and view related logs and audits.

Administer Discovery

Allows a user to view and import computers and accounts that are found by Discovery.

Administer Distributed Engine Configuration

Allows a user to update the Distributed Engine configuration.

Administer DoubleLock Keys

Allows a user to view, edit, create, and disable DoubleLock and QuantumLock keys. A DoubleLock or QuantumLock key acts as a separate encryption key to protect your most sensitive secrets. This option allows users to access and use the DoubleLocks/QuantumLocks link on the Administration page.

Administer Dual Control

Allows a user to view, edit, create, and disable Dual Control settings for reports and recorded sessions.

Administer Event Subscriptions

Allows a user to view, edit and create event subscriptions.

Administer Export

Allows a user to view the export log. Also allows users to export Secrets to which they have access to a clear text, CSV file.

Administer Folders

Allows a user to view, edit, create, move, and delete folders. Users still need the relevant view, edit, and owner permissions on the folders to perform these tasks.

Administer Groups

Allows a user to view, edit, create, and disable groups. Also allows users to assign users to groups and remove users from groups.

Administer HSM

Allows a user to change configuration or disable the use of a Hardware Security Module (HSM). On-Premise only.

Administer Inbox

Administer notification settings for the inbox.

Administer IP Addresses

Allows a user to create, edit, and delete IP Address Ranges. These ranges are used to restrict certain users to specific IP Addresses.

Administer Jumpbox Route

Allows a user to create, edit, or deactivate jump server routes.

Administer Key Management

Allows a user to enable, change, or disable the Key Management (Secret Server Cloud only).

Administer Languages

Allows a user to change the default language of Secret Server.

Administer Licenses

Allows a user to view, edit, install, and delete licenses.

Administer Lists

Allows a user to add, remove, and modify lists and list contents in Admin > Lists.

Administer Maintenance Mode

Allows a user to run maintenance mode.

Administer Metadata

Manage metadata fields and sections added to secrets and users in Secret Server.

Administer Nodes

Allows a user to view and edit server nodes and clustering settings. On-Premise only.

Administer OpenID Connect

Allows a user to manage OpenID connections.

Administer Password Requirements

Allows a user to view and edit character sets and password requirements.

Administer Pipelines

Allows a user to create, edit, and remove event pipelines and event pipeline policies.

Administer Platform Integration

Allows a user to manage the Secret Server connection to the Delinea platform.

Administer Remote Password Changing

Allows a user to turn Heartbeat and Remote Password Changing on and off globally. Also allows users to create new password changers and install password changing agents on remote machines.

Administer Reports

Allows a user to view, edit, delete, and create reports. Also allows users to customize report categories.

Administer Role Assignment

Allows a user to view which users and groups are assigned to which roles. Also allows users to assign users and groups to different roles.

Administer Role Permissions

Allows a user to view, edit, create and delete roles. Also allows users to assign different permissions to each role.

Administer Scripts

Allows a user to view and edit PowerShell, SQL, and SSH scripts on the Scripts Administration page.

Administer Search Indexer

Allows a user to view and edit search indexer options. These options control how searching in Secret Server works. For example, a user with this role permission could enable search indexing, which allows users to search on fields within a secret.

Administer Secret Policy

Allows a user to create and edit Secret Policies.'

Administer Secret Templates

Allows a user to view, edit, disable, and create Secret Templates.

Administer Security Analytics

Allows a user to view and edit the settings for Privilege Behavior Analytics.

Administer Session Monitoring

Allows a user to view and terminate active launcher sessions.

Administer SSH Cipher Suite

Allows a user to manipulate SSH cipher suite settings.

Administer SSH Menus

Allows a user to edit and create SSH Menus, used in allowlisting commands that can be used on a SSH session.

Administer System Log

Allows users to view and clear the System Log, which shows general diagnostics information for Secret Server.

Administer Teams

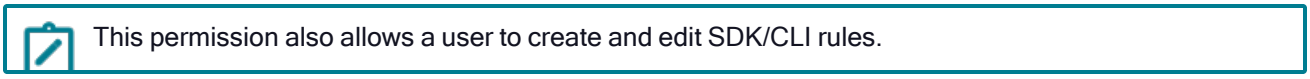
Users can create, delete, and view all teams.

Administer Template Custom Columns

Allows a user to enable the "Expose for Display" setting of a Secret template field to make it available for use in Dashboard custom columns.

Administer Users

Allows a user to create, disable, and edit users in the system.



Administer Workflows

Allows users to manage workflows (advanced access management).

Advanced Import

Allows a user to import Secrets from an XML file. Users with the this permission can import groups, folders, site connectors, sites, and secret templates, without having to create a secret. Users must have the Secret Server permissions needed for the objects listed in the XML.

Allow Access Challenge

Allows a user be challenged by Privileged Behavior Analytics if their behavior deviates from their normal behavior and meets certain requirements set by Privileged Behavior Analytics. Administrators do not have this permission by default.

Allow List Secret Access for Assigning Policy

This permission grants ability to assign a secret policy to a folder or secret if the user only has list access to the privileged account. This permission only applies to restrictions on the privileged accounts of the secret policy.

Without this permission, the user must have view access on the privileged account or will be unable to assign the secret policy.

There are security concerns for assigning a policy with a privileged account the user does not have view access on since the policy will allow an internal threat actor to create a secret with this policy to gain access to resets by the privileged account, rendering them inherit access to the privileged account.

Users must also have the View Secret Audit permission to effectively utilize the features associated with this permission while limiting the amount of Delinea permissions assigned to the user.

Approve via Duo Push

Allow a user to approve access requests via Duo push notifications. Administrators do not have this permission by default.

Assign Pipelines

Allows the user to assign an event pipeline policy to secret policies, or folders.

Assign Secret Policy

Allows a user to assign Secret Policies to folders and secrets.

Browse Reports

The "Browse Reports" role allows access to reports restricted by Delinea permissions. These Delinea permissions are configurable at the category and report levels and share a similar inheritance model to secrets and folders. You can define users or groups with "view" or "edit" Delinea permissions for each category or report.

Users with the existing "view reports" and "edit reports" roles are not restricted by the Delinea permissions set.

Bypass Direct API Authentication Restriction

Allows users to ignore the PreventDirectApiAuthentication advanced setting and log in via the API with a non-application account.

Bypass SAML Login

Allows a user to login with local account without using SAML.

Copy Secret

Allows a user to copy secrets when that user also has Own Secret role permission.

Create Root Folders

Allows a user to create new folders at the root level of the folder structure.

Deactivate Secret

Allows a user to mark secrets as deactivated.

Deactivate Secrets from Reports

Allows a user to run the deactivate Secrets action from a report.

Download Automatic Export

The user can view all of the automatic export tabs *and* download exports from cloud storage (cloud customers only).

Edit Secret

Allows a user to edit secrets. Note that they still require the "Edit" or "Owner" Delinea permissions on the individual secrets they are editing.

Erase Secret

Allows a user to permanently erase (as opposed to deactivate, which is reversible) a secret.

Expire Secrets from Reports

Allows a user to expire Secrets listed in a report.'

Force Check In

Allows a user to force a secret that is checked out by another user to be checked in.

Migrate Data to Platform

This Delinea permission will be automatically applied to roles that contain both the Administer Users and Administer Platform Integration role permissions. This Delinea permission allows a user to migrate certain information to the connected Delinea Platform instance. Without a connected Delinea Platform instance the Delinea permission has no effect.

Own Group

Allows a user to be an owner of a group. This Delinea permission is in the default Group Owner role, which is automatically assigned when that user is set as owner of a group.

Own Secret

Formerly "Share Secret", allows a user to share secrets with other users. Also allows users to perform more advanced tasks on secrets of which they are "Owners", such as configuring expiration schedules, configuring the web launcher, converting secret template, and copying secrets (when a user also have the Copy Secret role permission.)

Own User

Allows the user to become a user owner, used to configure specific users without the Administer Users permission.

Personal Folders

Allows a user to have personal folder when the global personal folders configuration options is enabled.

Privilege Manager Administrator

Allows the user to have the "Administrator" role for Privilege Manager, giving full access to the system.

Privilege Manager Helpdesk User

Allows the user to have the "Help Desk" role for Privilege Manager, giving full access to approve or deny escalation requests.

Privilege Manager MacOS Admin

Allows the user to have the MacOS "Administrator" role for Privilege Manager, giving full access to the system.

Privilege Manager Unix/Linux Admin

Allows the user to have management permissions to Unix/Linux policies and machines.

Privilege Manager User

Allows the user to have the "User" role for Privilege Manager, giving read and write permissions to most items, but not rights to modify security Delinea permissions. Administrators do not have this Delinea permission by default.

Privilege Manager Windows Administrator

Allows the user to have the Windows "Administrator" role for Privilege Manager, giving full access to the system.

Rotate Encryption Keys

Allows a user to start a process that rotates the Secret encryption keys.

Run Automatic Export

The user can view all of the automatic export tabs and run the export manually by clicking the Run Export button.

Run Disaster Recovery Data Replication

Allows user to initiate or test Data Replication.

Run Scripts

Separates privileges in script management. Holders of the "View Scripts" role permission cannot execute test runs of scripts, and this permission must be assigned to perform this task.

Administer Scripts remains unchanged and allows view, edit, and run permissions.

Secret Launch

Dictates whether or not a user can launch a secret. Previously, a user could launch a secret if their user's role had the "View Secret" permission. As of Version 11.5, a user needs this permission to launch. A user will also need the

"Secret Launch Remote Access (Platform)" permission to be able to launch a Remote Session with (RAS)

Secret Launch Remote Access (Platform)

Dictates whether or not a user can launch a secret. Previously, a user could launch a secret if their user's role had the "View Secret" permission. As of Version 11.5, a user needs this permission to launch a remote session with RAS.

Session Recording Auditor

Grants access to the session recording of a secret to a user with at least "List Access" permission on the secret. Administrators do not have this permission by default.

Users also need the "View Session Monitoring" permission to view the recordings in Secret Server.

Unlimited Vault Access

Allows a user to view and edit all secrets in the system, regardless of permissions, when Unlimited Vault Access Mode is on. Note that another user with the "Administer Configuration Unlimited Vault Access" role permission would still need to turn this mode on. See "Unlimited Vault Access" on page 283.

Unrestricted by Teams

Users can view all users, groups, and sites, regardless of team affiliation. Essentially, teams do not exist for the users with this permission, and the Teams page is not available to them. The default user role has this permission.

User Audit Expire Secrets

Allows a user to view the "User Audit" report, which shows all secrets that have been accessed by a particular user in a specified date range. Also allows the user to force expiration on all these secrets, which would make Secret Server automatically change the password.

View About

Allows a user to view the "About" page from the Help menu, which links to external resources such as Technical Support and the Delinea blog.

View Active Directory

Allows a user to view, but not edit, the Active Directory settings in the system.

View Advanced Dashboard

Allows a user to view advanced dashboard. Without this permission, users will only be able to view basic dashboard.

View Advanced Secret Options

Allows a user to view the Remote Password Changing, Security, and Dependency tabs on a Secret they have access to. Users must be able to successfully edit TOTP codes to view advanced secret options.

View All Session Recordings

Allows a user to view recorded sessions within Secret Server.

View Automatic Export

The user can view all of the automatic export tabs.

View Backup

Allows a user to view, but not edit, the automated backup settings. On-Premises only.

View Configuration

Allows a user to view, but not edit, general configuration settings.

View Configuration Proxying

Allows a user to view, but not edit, SSH Proxy settings.

View Configuration SAML

Allows a user to view SAML integration settings on the Login tab of Configuration settings.

View Configuration Security

Formerly "View Security Configuration," allows a user to view the security configuration of Secret Server.

View Configuration Session Recording

Allows a user to view session recording settings on the Session Recording tab of Configuration settings.

View Configuration Two Factor

Allows a user to view the configuration settings of the two factor authentication that are available for users logging into Secret Server.

View Configuration Unlimited Vault Access

Formerly "View Configuration Unlimited Admin" Unlimited Vault Access Configuration," allows a user to view the Unlimited Vault Access Mode configuration. Also allows a user to view the Unlimited Vault Access Mode audit log.

View ConnectWise Integration

Allows a user to view, but not edit, the ConnectWise integration settings.

View Data Retention

Can view retained audit data. This permission does not automatically come with the Administrator role.

View DevOps Secrets Vault Tenants

View (not edit) the DSV tenants set to synchronize with Secret Server.

View Disaster Recovery

Allows a user to view configuration, logs and audits for Disaster Recovery.

View Discovery

Allows a user to view, but not edit, computers and accounts that are found by Discovery.

View Distributed Engine Configuration

Allows a user to view the Distributed Engine configuration.

View DoubleLock Keys

Allows a user to view which DoubleLock or QuantumLock keys exist in the system.

View Dual Control

Allows a user to view configured Dual Control settings for reports and Secret sessions.

View Event Subscriptions

Allows a user to view event subscriptions.

View Enterprise Objects

Allows a user to view user and secret metadata.

View Export

Allows a user to view the export log of the system to see when users exported secrets. Does not allow a user to export.

View Folders

Allows a user to view, but not edit, folders in the system.

View Group Roles

Allows a user to see which groups and users are assigned to which roles. Does not allow a user to change these assignments.

View Groups

Allows a user to see which groups exist in the system. Also allows a user to see which users belong to each group.

View HSM

Allows a user to view the Hardware Security Module (HSM) configuration settings. On-premises only.

View Inactive Secrets

Allows a user to view Secrets that have been deactivated in the system. This does not allow viewing of erased secrets, which are permanently gone.

View IP Addresses

Allows a user to view IP Address Ranges that have been created to restrict access. Does not allow a user to edit these ranges.

View Jumpbox Route

Allows a user to view the details of all jump server routes in the Admin Jumpbox Route page but not make any changes.

View Key Management

Allows a user to view the Key Management settings (Secret Server Cloud only).

View Launcher Password

Allows a user to unmask the password on the view screen of secrets with a launcher. Typically, this includes Web Passwords, Active Directory accounts, Local Windows accounts, and Linux accounts.

View Licenses

Allows a user to view, but not edit, the licenses in the system.

View Lists

View lists and list contents in Admin > Lists.

View Nodes

Allows a user to view, but not edit, the Secret Server web server nodes. On-premises only.

View OpenID Connect

View OpenID Connect integration settings in the Configuration Login tab. This replaces the Delinea One equivalent.

View Own Session Recordings

Restricts a user to only viewing the recordings that user initiated. If the user with this permission clicks on a recording initiated and owned by another user, he or she will get an Access Denied window.

View Password Requirements

Allows a user to view character sets and password requirements.

View Pipelines

Allows a user to view event pipeline policies and policy activities.

View Platform Integration

Allows a user to view the Secret Server connection to the Delinea platform.

View Remote Password Changing

Allows a user to view, but not edit, Heartbeat and Remote Password Changing settings.

View Reports

Allows a user to view, but not edit, reports. See "Browse Reports."

View Roles

Allows a user to view roles in the system. Also allows a user to see which groups are assigned to which roles.

View Scripts

Allows a user to view PowerShell, SQL, and SSH scripts on the Scripts Administration page.

View Search Indexer

Allows a user to view, but not edit, search indexer settings.

View Secret

Allows a user to only view which Secrets exist in the system.

Note: Prior to version 11.4, this controlled if a user could launch a secret. It has been supplanted with Secret Launch and Secret Launch Remote Access (Platform) for launching.

View Secret Audit

Allows a user to view Secret Audit.

View Secret Password and Private Key History

Allows a user to see the history of passwords, private keys, or passphrases in both old and new UI.

View Secret Policy

Allows a user to view, but not edit, Secret Policies.

View Secret Templates

Allows a user to view, but not edit, Secret Templates.

View Security Analytics

Allows a user to view, but not edit, settings for Privilege Behavior Analytics.

View Security Hardening Report

Allows a user to view the Security Hardening Report.

View Session Monitoring

Allows a user to view active launcher sessions.

View Session Recording Audit

Allow a user to view audits of recorded sessions.

View SSH Menus

Allows a user to view existing SSH Menus, used in allow-listing commands that can be used on a SSH session.

View SSH Cipher Suite

Allows a user to view SSH cipher suite settings.

View System Log

Allows a user to only view the System Log, which shows general diagnostics information for Secret Server.

View Teams

Users can view all teams. This is essentially a read-only Administer Teams.

View User Audit Report

Allows a user to view, but not edit, the User Audit Report.

View Users

Allows a user to view which users exist in the system.

View Workflows

View (not edit) workflows used for multi-tier secret-access approvals and secret erase requests.

Web Services Impersonate

Allows a user to send an approval request to act as another user within their organization when accessing Secret Server programmatically. Administrators do not have this permission by default.

Overview of Users, Roles, User Groups, and User Teams

Users

Users in Secret Server represent individual people, each with a unique username and other attributes. Users are assigned to groups, and roles are assigned to them either directly or via groups. This setup allows for granular control over what each user can access and perform within the system.

Delinea Roles and Role Permissions

Roles

Secret Server uses a role-based access control (RBAC) mechanism to regulate system access. Each user and group must be assigned to a role. Secret Server ships with three default roles: Administrator, User, and Read-Only User. Each role contains various Delinea permissions to match the job function of the user. Roles can be customized by assigning multiple Delinea permissions to a role, which can then be assigned to a user or group.

The Unlimited Vault Access Delinea permission allows the user to have Unlimited Vault Access rights when Unlimited Vault Access is enabled in the configuration. By default, it is disabled.

To see the built-in roles and what Delinea permissions they possess, click the desired role link on the **Admin > Roles page**.

Delinea Role Permissions

Delinea role permissions in Secret Server are granular and can be assigned to roles to control what actions users can perform. Some examples of Delinea role permissions include:

- **View Active Directory**: Allows a user to view, but not edit, Active Directory settings.
- **View Configuration**: Allows a user to view, but not edit, general configuration settings.
- **View Secret**: Allows a user to view which secrets exist in the system.
- **Administer Teams**: Allows a user to create, edit, and view all teams.

For a comprehensive list of Delinea role permissions, visit the "Secret Server Role Permissions List" on page 1288.

User Groups

User groups in Secret Server allow administrators to manage users collectively. Users can belong to different groups and inherit the sharing Delinea permissions and roles attributed to those groups. This simplifies the management of Delinea permissions and roles that can be assigned to a user. Groups can also be synchronized with Active Directory to further streamline management.

For a comparison of user groups and teams, see "User Teams Overview" on page 1317.

User Teams

User teams in Secret Server are special groups created to restrict what users can see. A team bundles users and groups to assign them the same rules regarding visibility of other users and sites. This is particularly useful for managed service providers or large companies that need to isolate users by department or customer.

Team-related Delinea permissions include:

- **Administer Teams**: Users can create, edit, and view all teams.
- **Unrestricted by Teams**: Users can view all users, groups, and sites, regardless of team affiliation.
- **View Teams**: Users can view all teams.

> For a more in-depth overview, including a comparison of user groups and teams, see "User Teams Overview" on page 1317.

Bulk Operations on Users

Bulk operations on users can also be performed from the **Users** page. Select one or more users using the check boxes beside the **Username** column, or select all or none by toggling the check box in the header row. Once the appropriate users have been selected, use the Bulk Operation list at the top of the grid to select an action. Bulk operations on users currently include enabling or disabling user access, as well as configuring users for email or RADIUS two-factor authentication.

Configuring Users

User settings can be modified by clicking the username in the **Username** column on the **Users** page. Search for users using the search bar at the top of the grid. To show users that are marked inactive, search for users using the search bar at the top of the grid. You can filter your search by domain, search text and active status.

Creating Users

To manually create a user, do the following:

1. Search for**Users**to get to the Users page.
2. Select **Create User**. The Add User pop-up appears.
3. Fill in the following fields:
   - **Username**: The username used to log in.
   - **Display name**: A friendly name for this user.
   - **Domain**: The domain to which this user belongs. This cannot be modified after creation.
   - **New password**: This field is only applicable if you selected the Local domain.
   - **Confirm password**: This field is only applicable if you selected the Local domain.
   - **Email**: The email address for this user.
   - **Application Account**: select this checkbox if you want this user to act as an application account.

     > Application accounts have limited functionality and are intended for application integrations where this user can call the API services but not log into the application.

   - **Multifactor authentication**: Select which type of MFA you need for this user, if any.
   - **Enabled**: Make sure this checkbox is selected.
4. Select **Add User** to save your changes.

To add many users from your Active Directory setup, you can use Active Directory synchronization (see "Active Directory and Secret Server Overview" on page 509).

Deleting Users

You cannot delete users per se because of auditing requirements; however, deactivating the user from the "User Settings" on page 1311 accomplishes the same thing. See "Removing Deactivated User PII" on the next page for eliminating all traces of a deactivated user.

Password Settings

The following settings are found in the **Administration > Configuration** page, inside the **Local User Passwords** tab. These settings apply to users that were created manually, not users brought into Secret Server through Active Directory synchronization:

- **Allow Users to Reset Forgotten Passwords:** If enabled, the "Forgot your password?" link appears on all users' login screens. Clicking on this link prompts the user to enter the email address that is associated with the user's Secret Server account. If the email address is found, then an email containing a link for password reset is sent. Note that this only works for local user accounts and not for Active Directory accounts. Secret Server
- **Enable Local User Password Expiration:** When enabled, Secret Server forces a password change for a user after a set interval. After the interval time has elapsed, the next time the user attempts to log in, they are prompted for the old password, a new password, and a confirmation of the new password. The new password is validated against all the password requirements. Newly created local users are also be prompted to change their password upon logging into Secret Server for the first time when this setting is enabled.
- **Enable Local User Password History:** If enabled, this prevents a user from reusing a password. For example, if set to "20 Passwords", this would prevent the user from using a password they have used the previous 20 times. This in conjunction with "Enable Minimum Local Password Age" helps ensure that users are using a new and unique password frequently rather than recycling old passwords.
- **Enable Minimum Local User Password Age:** If enabled, the value for this setting reflects the minimum amount of time that needs to elapse before a password can be changed. This prevents a user from changing their password too frequently, which allows them to quickly re-use old passwords.
- **Local User Password is valid for:** If enabled, this is the interval that a local user password is valid before it must be changed (see "Enable Local User Password Expiration" setting for details). If this setting is disabled, the entered value displays as "Unlimited".
- **Lowercase Letters Required for Passwords:** Force all user Secret Server login passwords to contain at least one lowercase letter.
- **Minimum Password Length:** Force all user Secret Server login passwords to contain a set minimum number of characters.

  The maximum number of characters is 1024.

- **Numbers Required for Passwords:** Force all user Secret Server login passwords to contain at least one number.

- **Symbols Required for Passwords:** Force all user Secret Server login passwords to contain at least one symbol, such as `!@#$%^&*`.
- **Uppercase Letters Required for Passwords:** Force all user Secret Server login passwords to contain at least one uppercase letter.

Removing Deactivated User PII

Overview

General Data Protection Regulation (GDPR) adherence raises the possibility that Secret Server users may make a data removal claim against a Secret Server administrator. This requires removing any personally identifiable information (PII) in Secret Server for that individual.

To address this, Secret Server has a button that automatically removes most PII for any deactivated user.

Removing the PII

1. Remove the user from Active Directory (AD). See Active Directory Considerations below.
2. In Secret Server, Search for **User Management** and select the **Users** tab.
3. Click the user name link for the desired user. The View User Page appears.
4. Click the **Remove Personally Identifiable Information** button. A confirmation dialog box appears.

   > Once you confirm, the user cannot log on to Secret Server. Click the Cancel button if you are not positive this is what you want to do.

   Clicking the **OK** button will change these to random values or set them to null:

   - Username
   - Display name
   - Password
   - Personal folder name
   - Personal group name
   - RADIUS username

   In addition:

   - The user's AD GUID is cleared
   - The user's email address is removed from their record
   - The user's name is replaced with "<redacted>" in event audits where it can be clearly identified.
   - The PII removal is recorded in the user's audit
5. Click the **OK** button. The removal begins. Once complete, the Remove PII button disappears for that user.
6. (Optional) Run a query that scans the entire Secret Server database for the removed strings. You may want to do this because the process cannot find *all* potential instances of USER PII throughout Secret Server, such as that in secret names or notes.

You can create an Event Subscription to "remove user PII" events.

Active Directory Considerations

We recommend removing the user from AD before removing the PII. If you remove the PII without first removing the user from AD, the user is reintroduced into Secret Server on subsequent AD synchs. This creates a new user account in Secret Server, which might require you to disable this new user account and remove its PII too (after removing the AD user).

Sorting and Searching for Users

Parameters

You can sort and sometimes search users based on a number of parameters, including:

- Application account
- Created date
- Domain
- Email address
- Enabled status
- Last login date
- Locked out status
- Login failures
- Name
- OpenID Connect enabled status
- Platform integration status
- Two factor authentication method
- Username

Viewing or Hiding Columns

Each of these items can appear in a column in the Users table. To enable or disable a column:

1. Search for **User Management**.
2. Ensure the **Users** tab is selected.
3. Click the icon. The Display Columns popup appears.
4. Click to select or deselect the columns you want to appear in the users table.
5. Click the **Save** button. The table updates to reflect your choices.

Sorting by Columns

To sort by a column, click the column heading you wish to sort by. Click the column heading again to reverse the sort order.

Searching for Users

1. Search for **User Management**.
2. Ensure the **Users** tab is selected.
3. Click the **Domains** dropdown list to limit the search to a listed domain.
4. Click the **Active Users** dropdown list to limit the search to active or inactive users.
5. Type the desired term to search for in the **Search** text box. You can search by:
   - Email address
   - Name
   - Username
6. Press **<Enter>**. The search results appear.

Unlocking Local Accounts

If a user fails their login too many times (specified in the **Local User Passwords** section of the configuration page), their account is locked out and they are not be able to log in.

To unlock the account:

1. Log on as an administrator.
2. Search for **User Management** and select the **Users** tab.
3. Click on the user who is locked out.
4. Click **Edit**.
5. Click to deselect the **Locked out** check box.
6. Click **Save**.

User Login Settings

Secret Server users can be set up with many different login requirements. For example, you can force strong Login passwords by requiring a minimum length and the use of various character sets.

The following settings are available on the **Login settings** page:

"Allow Autocomplete" is now permanently on.

- **Allow Remember Me:** This option enables the Remember Me checkbox on the Login screen. When a user chooses to use remember me, an encrypted cookie is set in their browser. This enables the user to revisit Secret Server without the need to log in. This cookie is no longer be valid when the remember me period has expired. They then have to enter their login information again. This option allows users to remain logged in for up to a

specific period (specified in the "Remember Me Is Valid for" setting mentioned below). This option can be a security concern as it does not require re-entry of credentials to gain access to Secret Server.

> "Remember me" is only visible if the "Allow Remember Me" setting is enabled. This is the period that the remember me cookie mentioned above is valid. For example: if set to one day, then users taking advantage of "remember me" have to log in at least once a day. To set a time value (minutes, hours, or days), uncheck the Unlimited checkbox.

- **Remember me is unlimited:** Allows to set Remember me for the unlimited time.
- **Cache AD credentials for when engines are offline:** Allows cached credentials to be used when Distributed Engine is unable to connect to Active Directory.
- **Default login domain:** Select the related default login domain from the dropdown.
- **Enable domain selector:** Display the domain selector at login - select Show Domain Label, Show Domain Dropdown, or Hide Domain Information.
- **Enable login failure CAPTCHA:** When this option is on, the user will only have to complete a CAPTCHA if their login credentials are entered incorrectly a certain number of times.
- **Maximum login failures before CAPTCHA:** The number of login failures before CAPTCHA.
- **Maximum Concurrent Logins Per User:** This setting allows a user to log into Secret Server from multiple locations at once without logging out their sessions at other locations.
- **Maximum Login Failures:** Set the number of login attempts allowed before a user is locked out of their account. Once locked out, they need a Secret Server administrator to reset their password and enable their account. For details on how to reset a locked account, see "Creating Users" on page 1304.
- **User lockout time (minutes):** Number of minutes a User will be locked out for.
- **Visual Encrypted Keyboard Enabled:** This setting enables a visual keyboard for logins.
- **Visual Encrypted Keyboard Required:** This setting requires a visual keyboard for logins.

User Owners

User Administrators can also set another group or user as the *user owner* for a Secret Server local user. User owners can manage and edit just that user. For example, a developer might need to unlock or reset the password for an application account but should not have access to all users. Set **Managed by to User Owners** on a user and then select **Groups** or **Users**. Note that Unlimited Vault Access mode can still be used to manage groups with user owners assigned.

User Preferences

> Users can set their preferences by clicking on their profile icon in the top right and selecting User Preferences.

General Tab

The following settings are available for users under the General tab:

- **API Token:** allows creating API Tokens for use in scripts. Click on the **Generate API Token and Copy to Clipboard** link to generate a token and copy it to clipboard automatically. This token will follow the Web Services Session Timeout settings that can be found in theSecret Server application settings.
- **General Information:** contains general information about your user account within your organization's framework. The information in this section cannot be edited on this page. To update your display name, username, or email, please contact your administrator.
- **Password Settings** allows changing your local user password used to log in to Secret Server, or making changes to your user account's DoubleLock password. Click **Create DoubleLock Password**, in the pop-up enter and confirm a new password, and click **Create**.

Settings Tab

The following configuration settings are available for users under the Settings tab:

Preferences: personal user preferences associated to your account that control how the application looks, works, and displays data.

- **Color Mode:** select Light or Dark mode.
- **Communication Time Zone:** select time zone that will be used for dates when receiving communications.
- **Date Format:** select date format displayed for a user in Secret Server.
- **Language:** select language. Your browser language is set by default. See "Browsers Supported By Secret Server" on page 93 for a list of supported languages.
- **Login Home:** select the default home page after logging in if no redirect URL is specified.
- **Time Format:** select time format displayed for a user in Secret Server.

Email Settings: select what you would like to be notified about, based on the Secret events. Set the toggles to on or off to enable or disable the related settings.

- **Send Email When Dependencies Fail to Update:** enables emails to be sent when dependencies fail to update.
- **Send Email When Secrets are Changed:** enables emails to be sent on all changes of any secret that the user has view permission. There is a limit of one mail per five minutes per edit of the same user. For example, if user "User1" edits the secret twice within this grace period, only one email is sent.
- **Send Email When Heartbeat Fails for Secrets:** when enabled, the user is emailed when a heartbeat fails for any secret the user has view permission to.
- **Send Email When Secrets are Viewed:** enables emails to be sent on all views of any secret that the user has view permission. There is a limit of one email per five minutes per view of the same user. For example, if user "User1" views the secret twice within this grace period, only one email is sent.

Launcher Settings: allow setting launchers to fit the workstation needs. The settings will apply to all launchers you use where applicable. Set the toggles to on or off to enable or disable the related settings.

- **Allow Access to Printers:** enable access to printers when using the launcher.
- **Allow Access to Drivers:** enable access to drivers when using the launcher.
- **Allow Access to Clipboard:** enable access to clipboard when using the launcher.

- **Allow Access to Smart Cards:** enable access to smart cards when using the launcher.
- **Connect to Console:** allows connecting to remote machines using the Remote Desktop launcher and connecting as an administrator. This is the equivalent of using the `/admin` or `/console` switch when launching Remote Desktop.
- **Use Custom Window Size:** enable displaying Width and Height text boxes for the user to specify a custom window size for an RDP launcher.

Public SSH Keys: view the public SSH keys associated with your user account. Public SSH keys are used to authenticate to Secret Server through the SSH Terminal (CLI) interface. Only the public portion of each key is stored, and these keys are not used for authentication to external systems or servers. For more information, see SSH Terminal Administration.

Security Tab

User Sessions listed under the Security tab provide a record of known login sessions from this user account. User Sessions can be terminated which will perform a log out upon that session. To terminate a session, select it from the list, and click Terminate in the pop-up.

User Restriction Settings

The following restriction settings are available:

- **Enable Login Policy:** If enabled, this simply displays the policy. See Enabling Login Banners for details.
- **Force Inactivity Timeout:** This setting is the time limit on idle Secret Server sessions. Once a session expires, the user must login again with their username and password. See Configuring Session Timeouts section in Configuring Authentication and Login for details.
- **Force Login Policy:** This setting forces the checking of the "I accept these terms" checkbox before allowing the user to login to SS. See Enabling Login Banners for details.
- **IP Restrictions:** This setting can be entered by searching for **IP address restrictions**. In there, you can enter the IP ranges you wish your users to use. To configure a user to use the ranges, navigate to the **User View** page and click the **Change IP Restrictions** button. In the subsequent page, you can add all the ranges you want your user to use. See Restricting IP Addresses for more details.

User Settings

Search for**Users**to get to the Users page, and select the related user from the list to view its settings under the General tab. Below is a brief explanation of each text-entry field or control:

- **Username**: The username used to log in.
- **Display Name**: Text that is used throughout the user interface, such as in audits. A friendly name for this user.
- **Domain**: If a drop-down list is visible, selecting a domain from the list is one way to set the expected domain of the user. However, a more dynamic way to have this text-entry field (and all the other text-entry fields) set is through Active Directory synchronization.
- **Email**: Email address used for Request Access, email two-factor authentication, and the like.

- **Slack ID**: The Slack ID for this user.
- **Application Account**: Application accounts have limited functionality and are intended for application integrations where this user can call the API services but not log in to the application.
- **Multifactor Authentication**: Multifactor authentication for new users. See "Email Authentication" on page 450 for details. Available multifactor types:
  - **FIDO2**: Passwordless authentication using security keys or biometrics, offering strong, phishing-resistant security.
  - **TOTP Authenticator**: Generates time-limited passcodes via apps like Google Authenticator for two-factor authentication.
  - **Duo**: Cloud-based MFA solution offering various methods like push notifications and passcodes for enhanced security.
  - **Radius**: Protocol for centralized authentication and access management, commonly used for network and VPN access.
  - **Email**: Sends a one-time passcode or link to the user's email for secondary authentication.
- **Enabled**: Disabling this control removes the user from the system. Effectively, this is the way to delete a user. Secret Serverdoes not allow complete deletion of users due to auditing requirements. To re-enable a user, search for**Users**, select the **Include disabled** in the status field, and edit the user to mark them enabled (see "Configuring Users" on page 1304).
- **Status**: A locked out account is unable to log in until the account is unlocked by an administrator.
- **Restricted By Team**: Indicates whether or not the user has the role permission Unrestricted By Teams.
- **User managed by**: Allows specific users to manage this user that are not neccessarily user admins. Can be set to a specific user or All Users with Administer Users Role Permission.
- **IP address restrictions**: IP Address restrictions allow you to choose what IP Address range this user can use to access the application. When one or more IP Address ranges are enabled, this user will only be able to access the application from the enabled IP Address Range(s).

User Groups

Secret Server allows administrators to manage users through *user groups*. Users can belong to different groups and receive the sharing permissions, as well as roles, attributed to those groups. This setup simplifies the management of the permissions and roles that can be assigned to a user. Additionally, groups can be synchronized with Active Directory to further simplify management.

Group Types

Secret Server supports several types of user groups:

- **Local Groups**: Groups created and managed directly in Secret Server. See Creating User Groups.
- **Active Directory Groups**: Groups synchronized from Active Directory. Membership is managed in AD and synchronized to Secret Server. See Active Directory and Secret Server.

- **Platform Groups**: When Secret Server is integrated with Delinea Platform, Platform groups can be synchronized to Secret Server. These groups are managed in Platform and synchronized automatically. See Platform Groups Sync.

Assigning Group Owners

Group Administrators can also set another group or user as the group owners for a Secret Server local group. Group owners can manage membership just for that group. To assign the group owner:

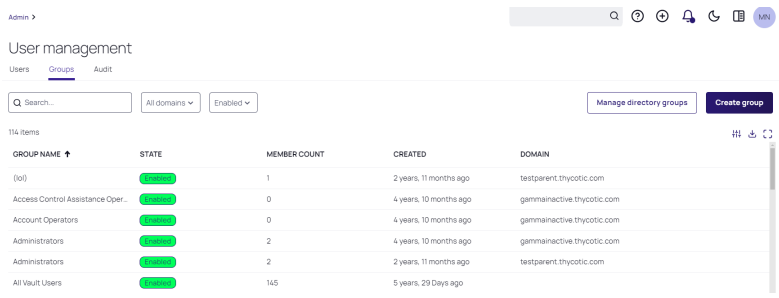
1. Search for **Groups**, and click the desired group in the list. The Group's page appears.
2. Under the **General** tab, click **Edit** in the **Group management** section.
3. Click the **Managed By** dropdown list to select the owner.
4. Click **Save**.

> Very commonly, the group owner is managed by Active Directory, not Secret Server:

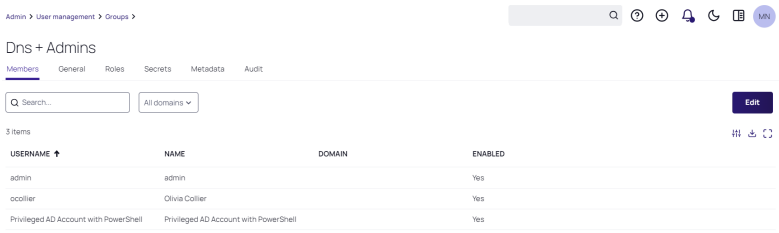
Assigning Users to Groups

On the Group Assignment page, users can be added and removed from the group.

1. Navigate to **Admin** > **Groups**:

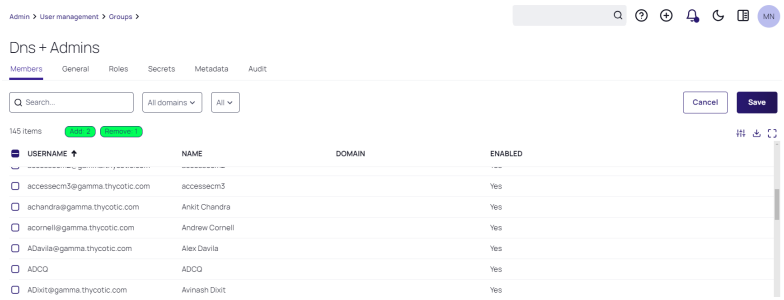


2. Select a group and click **Edit**.



3. Select the related user domains (or all domains) from the dropdown to be displayed in the list. Select Assigned, Unassigned, or All users to be displayed in the list. Check to select users to be added, or uncheck users to be

removed from the group. When done, click **Save**.



If the group was created using Active Directory synchronization, this group is not be editable. See "Active Directory and Secret Server Overview" on page 509.

Creating User Groups

You can create and edit groups from the Groups page. You can get to the Groups page by navigating to **Admin > Groups.**

By either selecting an already existing group from the list, or clicking **Create Group**, you can modify or add the group.

To add groups and the users inside them from your Active Directory setup, you can use Active Directory synchronization (see "Active Directory and Secret Server Overview" on page 509).

Platform Groups Sync

When Secret Server is integrated with Delinea Platform, Platform groups can be synchronized to Secret Server. These groups can be used to assign permissions, roles, and sharing just like any other group type.

Overview

Platform groups are managed in Delinea Platform and synchronized automatically to Secret Serverr. Unlike local groups, you cannot manually manage membership for Platform groups in Secret Server - membership is controlled entirely in Delinea Platform.

Platform groups appear in Secret Server group lists and can be used throughout Secret Server to:

- Assign permissions to secrets and folders
- Assign roles
- Share secrets with groups
- Control access to Secret Server features

Accessing Platform Groups Sync

Search for **Platform groups sync** to manage Platform group synchronization.

The Platform groups sync page contains four tabs:

- **Configuration**: Configure platform integration settings. The Configuration tab displays platform integration settings including:
  - Connection endpoints - URLs that Secret Server uses to communicate with Platform (Reply URL, Login URL, Logout URL).
  - Authentication credentials - Client ID and Client Secret used to authenticate Secret Server with Platform.
  - Synchronization interval - How frequently Platform groups are automatically synchronized to Secret Server (configured in days and hours).
  - Integration options - Additional features such as audit integration (forwards Secret Server audit events to Platform) and inventory forwarding (sends discovery data to Platform Inventory).
- **Groups**: View and manage synchronized Platform groups. The Groups tab displays:
  - Last sync finished - Timestamp of last synchronization.
  - Enabled platform groups - List of synchronized Platform groups.
  - Filter groups - Search box to filter groups. These groups can be used to assign permissions, roles, and sharing throughout Secret Server.
- **Synchronization logs**: View synchronization history with exact synchronization time and message. Use search box and Date time range filter to find the related events.
- **Audit**: View audit logs for integration changes by date, user, action, and notes.

User Mapping

The User mapping dropdown button is available at the top right to access to the primary user mapping features. To map Platform users, click **User mapping**, and select from the dropdown:

- **Map a Platform user**: Manually map a Platform user to a Secret Server user (see below).
- **Reset user mappings**: Clear all existing user mappings (see below).

Manually Mapping a Platform User

Use manual mapping when automatic mapping cannot find a match between Platform and Secret Server users. The user mapping process will restore a missing connection between a Platform user and a Secret Server user.

To map a Platform user:

1. Click **User mapping > Map a Platform user**

2. A 3-step Map a Platform user wizard opens:

- Step 1: Next to Secret Server user click on the No Secret Server user selected link.

Select a Secret Server user. This user will be mapped to the Platform user you select in the next step.

Click **Next**.

- Step 2: Select a Platform user. The Platform user selected in this step will be linked to the Secret Server user selected in the previous step.

Next to Platform user click on the No Platform user selected link, and select a Platform user from the list.

The list displays available Platform users with their mapping status. Users already mapped show a "Mapped" badge in the State column.

Select the Platform user to map to the Secret Server user, and click **Next**.

- Step 3: Confirm and map users

Review the mapping and complete the wizard.

The mapping is created immediately and will be used in the next synchronization.

Resetting User Mappings

Use reset when group synchronization is removing users from groups or you receive mapping errors.

To reset user mappings:

1. Click **User mapping > Reset user mappings**.

2. In the Reset user mappings popup, confirm the action.

Warning: This clears all existing user mappings. Users will need to log in to Platform again to recreate automatic mappings.

Using Platform Groups in Secret Server

Once Platform groups are synchronized, they work like any other group in Secret Server:

- Assigning Permissions - you can assign Platform groups to secrets and folders with View, Edit, or Owner permissions.
- Assigning Roles - you can assign Platform groups to roles to grant permissions to all group members.
- Sharing Secrets - you can share secrets with Platform groups.
- Group Membership - is read-only in Secret Server. To add or remove users, make changes in Platform and wait for synchronization to run.

Synchronizing Groups

Platform groups synchronize automatically based on the interval configured on the Configuration tab (default: every 1 hour).

To manually trigger synchronization:

1. Search for **Groups** tab.

2. Click the **Sync now** button.

Synchronization updates Group memberships, User mappings, and Group metadata.

Editing Enabled Groups

To modify which Platform groups are synchronized:

1. On the Groups tab, click **Edit**.

2. Each group displays a **Remove** link.

3. Click Remove next to the related group to stop synchronizing.

4. **Save** the changes.

Note: Removing a group from synchronization does not delete the group from Secret Server - it only stops future synchronization of that group's membership.

User Teams Overview

Purpose of User Teams

With Secret Server teams, administrators can create special groups called *teams* to restrict what users can see. A team bundles users and groups to assign them the same rules as to what other users and sites are visible to them. For example, a managed service provider could isolate their customers from seeing other customer's user accounts or a large company could "firewall" their users by department. Site visibility can also be restricted by teams.

Teams are designed for shared secrets and do not apply to Secret Server administration as a whole.

Users *without* any team-related Delinea permissions are subject to team restrictions. The Unrestricted by Teams permission must be present to remove them. That is why the User role comes with that permission by default. See Team-Related Permissions.

Team restrictions are designed for regular users so granting additional administrative Delinea permissions can override the restriction. This applies to group owners, so if a user is assigned as a group owner, that user will be able to see all users when assigning members.

Team-Related Permissions

Team visibility and management are controlled by user roles. Those roles, and by extension users, are governed by the following team-related role permissions:

- **Administer Teams:** Users can create, edit, and view all teams.
- **No Teams-related Permissions:** Users can only view other users within their team.
- **Unrestricted by Teams:** Users can view all users, groups, and sites, regardless of Team affiliation. Essentially, teams do not exist for the users with this permission, and the Teams page is not available to them. The default user role has this permission.
- **View Teams:** Users can view all teams. This is essentially a read-only Administer Teams.

User Teams Versus User Groups

User teams and user groups in Secret Server serve different purposes and offer distinct functions. Here is a detailed comparison to highlight their differences and why user teams cannot be fully replaced by user groups and vice versa:

User Groups

- **Purpose**: User groups are primarily used to manage users collectively and simplify the assignment of permissions and roles.
- **Functionality**:
  - Users can belong to multiple groups.
  - Groups can be synchronized with Active Directory.
  - Permissions and roles assigned to a group are inherited by all users within that group.
- **Use Case**: Ideal for managing permissions and roles for a set of users who need similar access rights and capabilities within Secret Server.

User Teams

- **Purpose**: User teams are designed to restrict what users can see, particularly useful for isolating visibility of users and sites.
- **Functionality**:
  - Teams bundle users and groups to assign them the same visibility rules.
  - Teams can restrict site visibility, ensuring that users in one team cannot see users or sites assigned to another team.
  - Team-related permissions control visibility and management of teams.
- **Use Case**: Ideal for scenarios where visibility needs to be restricted, such as isolating departments within a large company or separating customers in a managed service provider setup.

Key Differences

Visibility Control

- **User Groups**: Primarily manage permissions and roles but do not inherently restrict visibility of other users or sites.
- **User Teams**: Specifically designed to control and restrict visibility of users and sites, ensuring isolation between different teams.

Granularity

- **User Groups**: Focus on collective management of permissions and roles.
- **User Teams**: Focus on visibility restrictions, which can be more granular and specific to organizational needs.

Use Case Suitability

- **User Groups**: Suitable for managing access rights and permissions across users who need similar capabilities.
- **User Teams**: Suitable for scenarios requiring strict visibility controls and isolation between different sets of users.

Conclusion

While user groups are effective for managing Delinea permissions and roles, they do not offer the same level of visibility control as user teams. User teams provide a more granular approach to restricting what users can see, which is essential for certain organizational structures and security requirements.

Configuring Teams Management

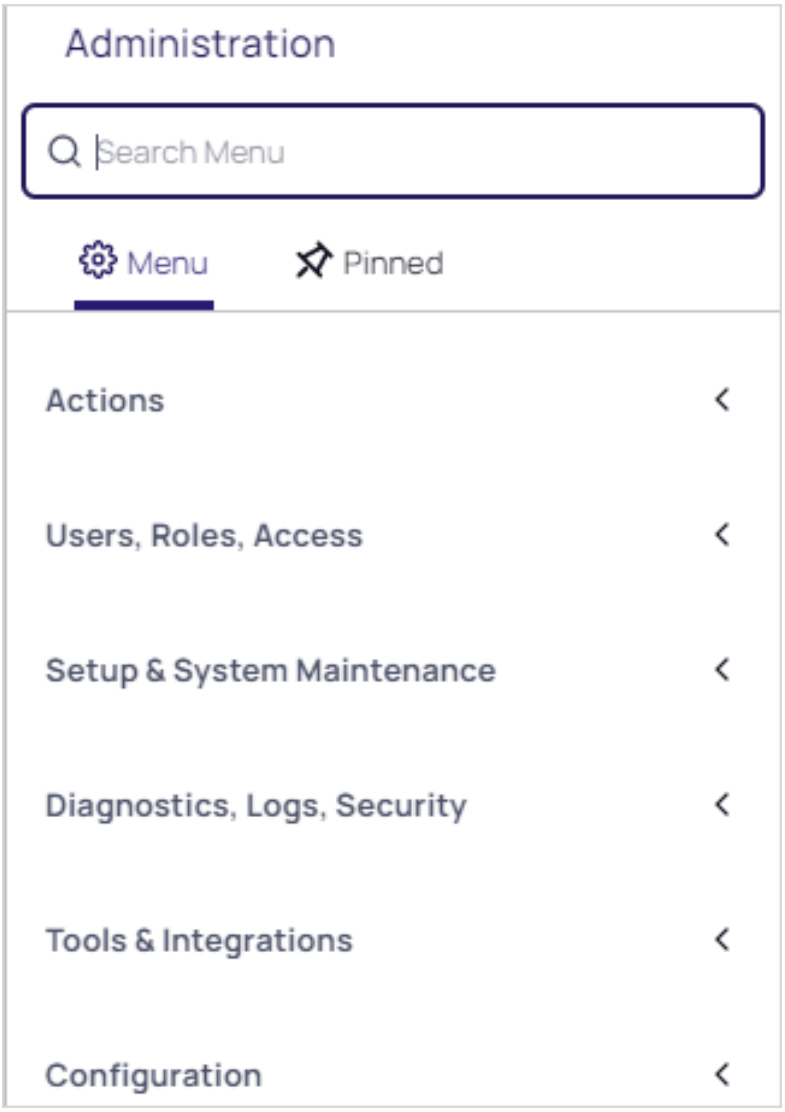
To set up Secret Server to use the team management feature:

1. Create a new role called *Team Limited User*.
2. Assign all role permissions of the standard user role except *Unrestricted by Teams*.
3. Assign users you want restricted by teams to this role.
4. Remove the User role from their account.

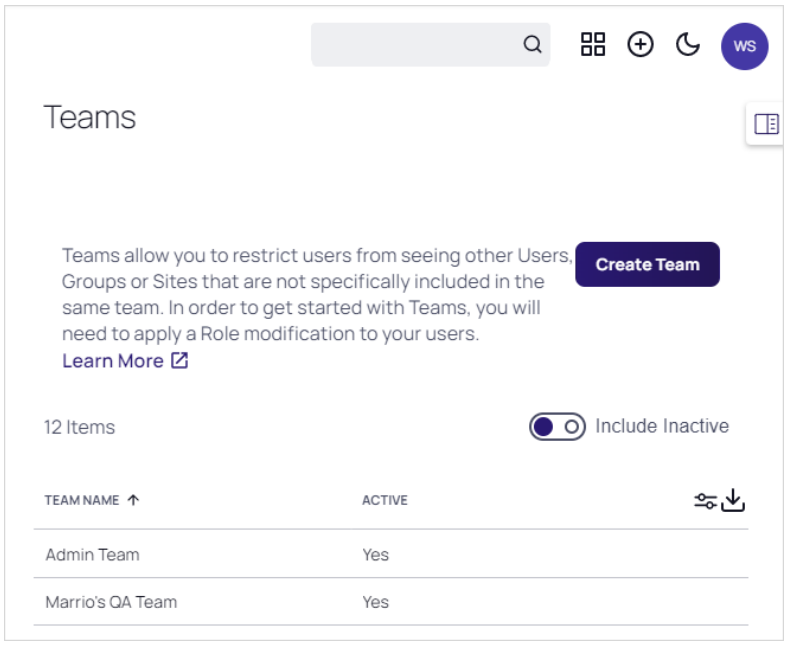
> **Note:** If you want all new users restricted by team, you can configure Secret Server to assign the Team Limited User role as the default upon creation of a new user.

Creating Teams

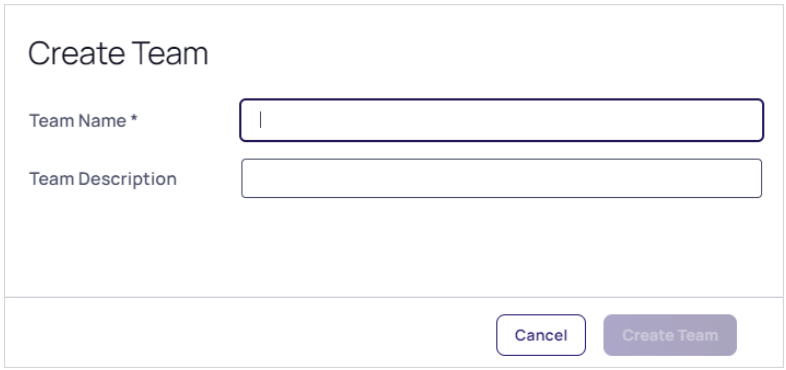
1. Navigate to **Administration**. The Admin Side Panel appears:



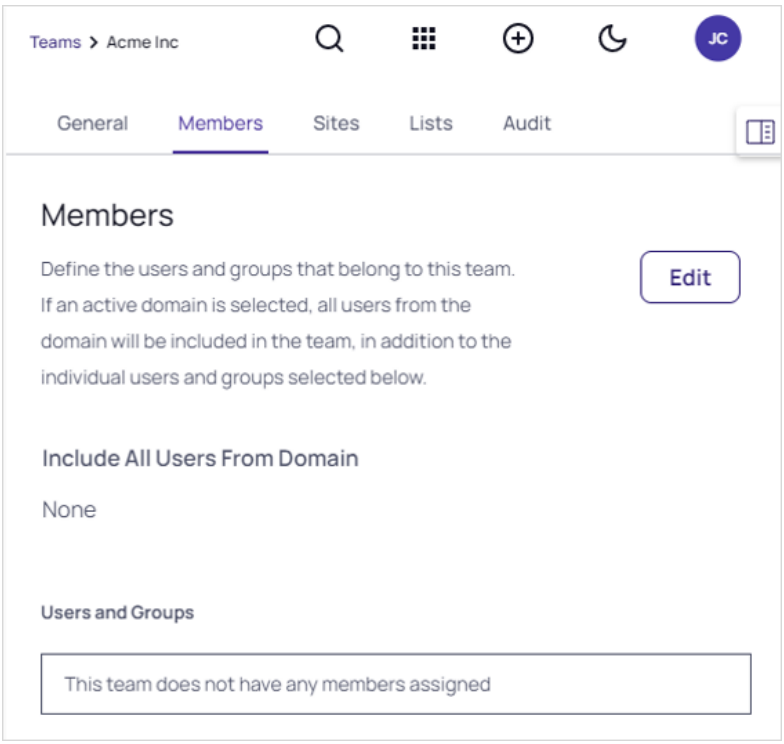
2. Click **Users, Roles, Access** and select **Teams** in the list. The Teams page appears:



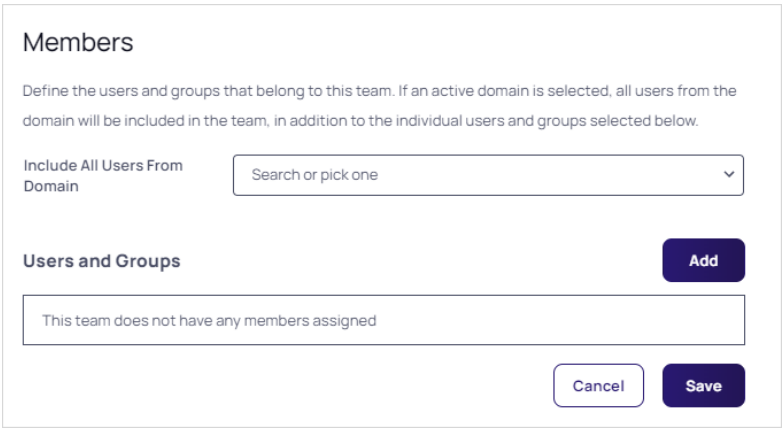
3. Click the **Create Team** button. The Create Team popup page appears:



4. Type the name for the new team in the **Team Name** text box.
5. (Optional) Type a description in the **Team Description** text box.
6. Click the **Create Team** button. The new team's Members tab appears:



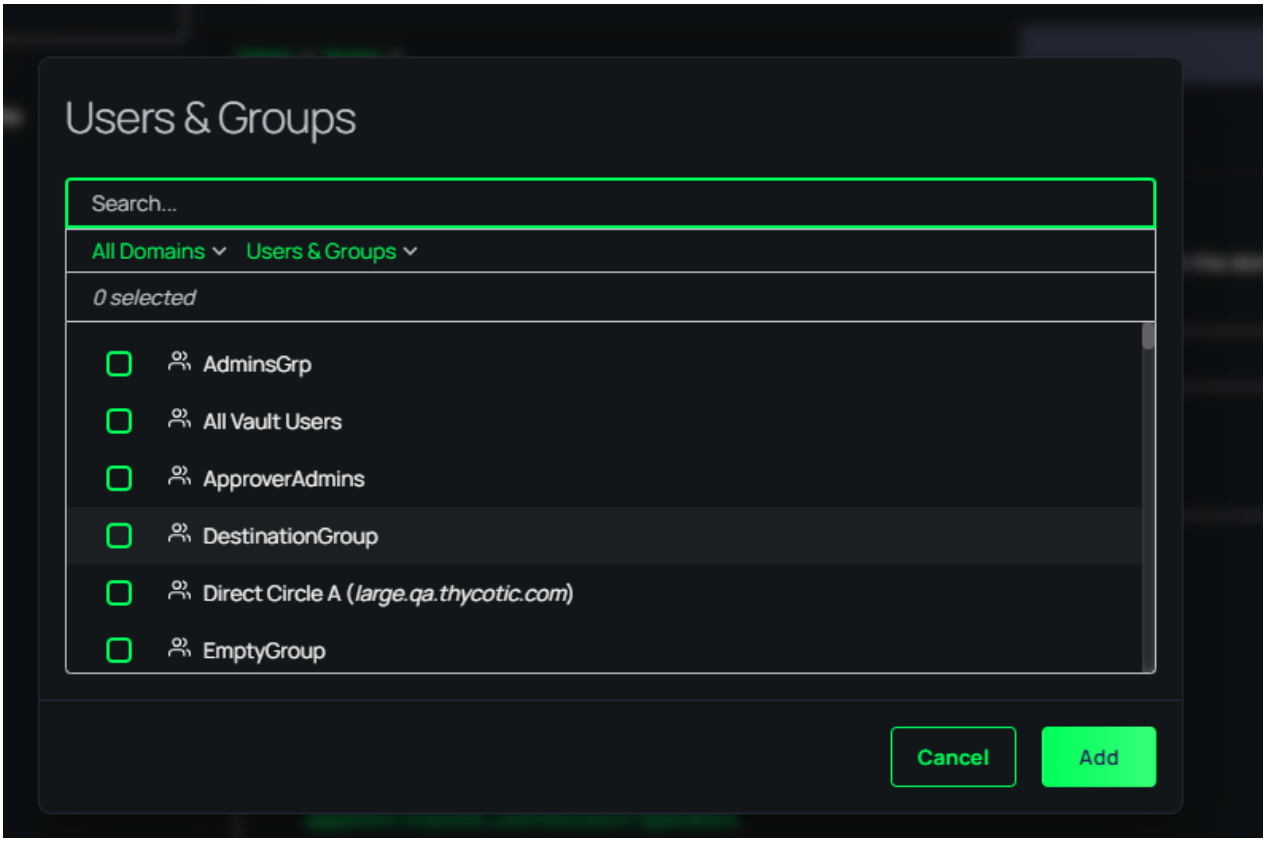
7. Click the **Edit** button. An Add Groups / Users section appears:



8. **Either** to include all users in a domain, click the first **Include All Users from Domain** dropdown list to select a domain. This only appears if you have domains available.

   Or to add individual users:

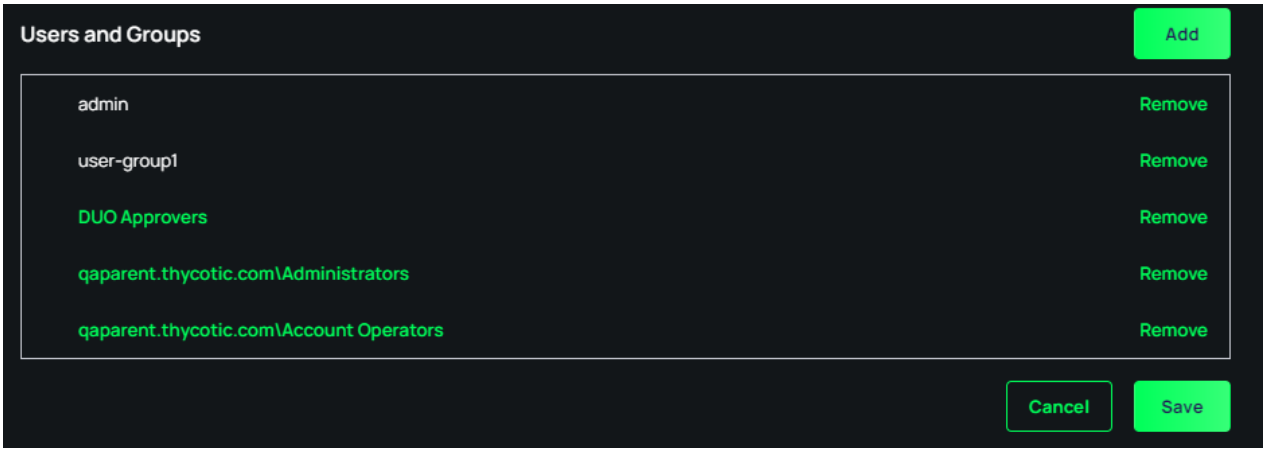
a. Click the **Add** button. The Users and Groups popup appears:



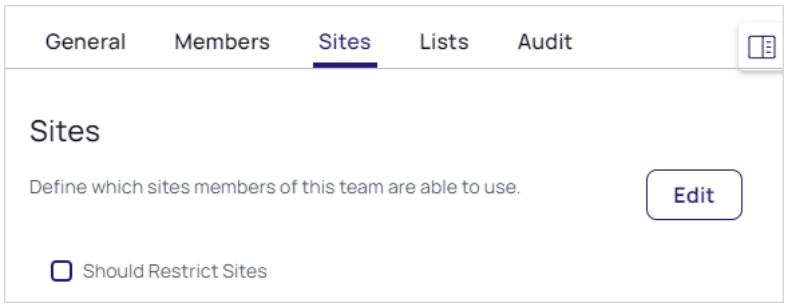
b. If needed, type the name of desired users or groups in the search box.

c. Click to select the check boxes for the desired users or groups.

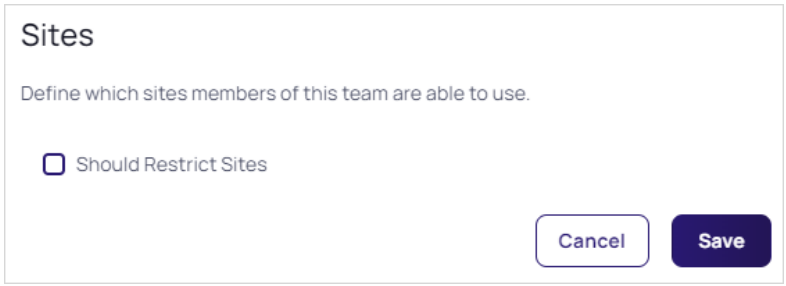
d. Click the **Add** button. The popup disappears, and your choices appear in the Users and Groups box:



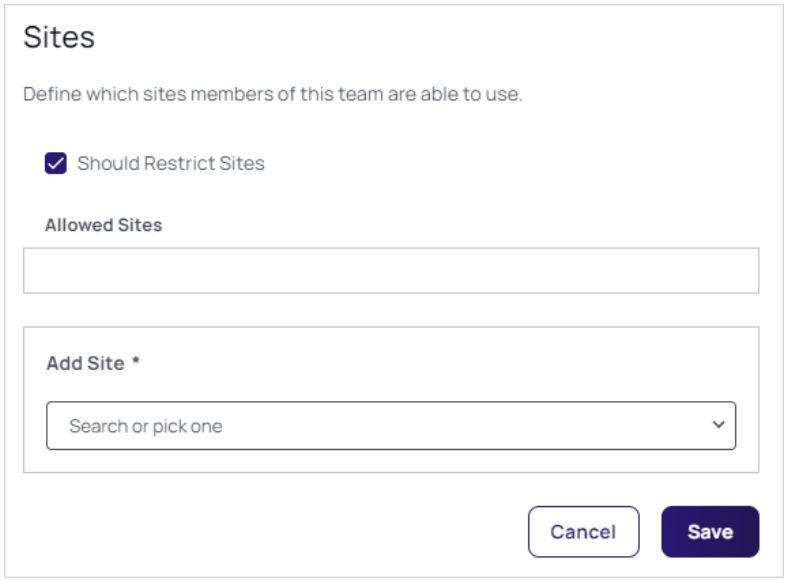
9. Click the **Save** button.
10. Click the **Sites** tab:



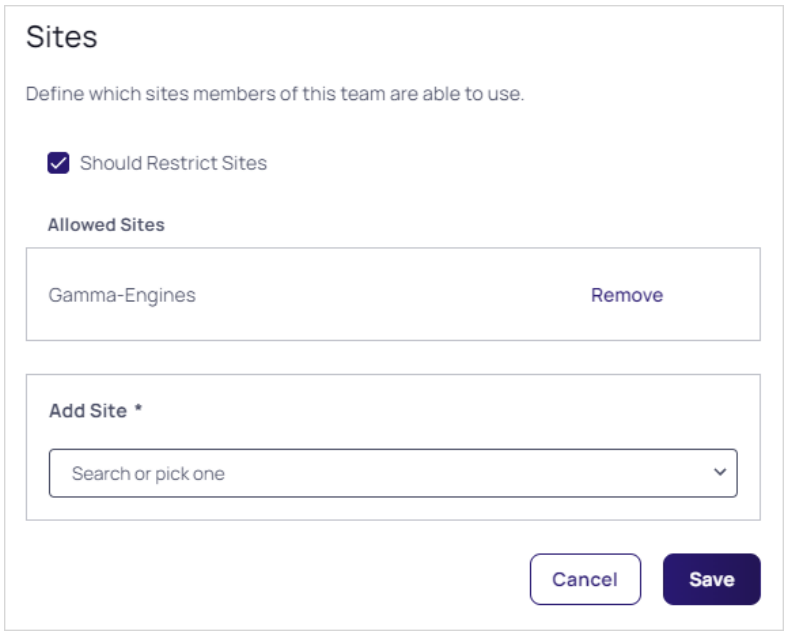
11. Click the **Edit** button. The page becomes editable:



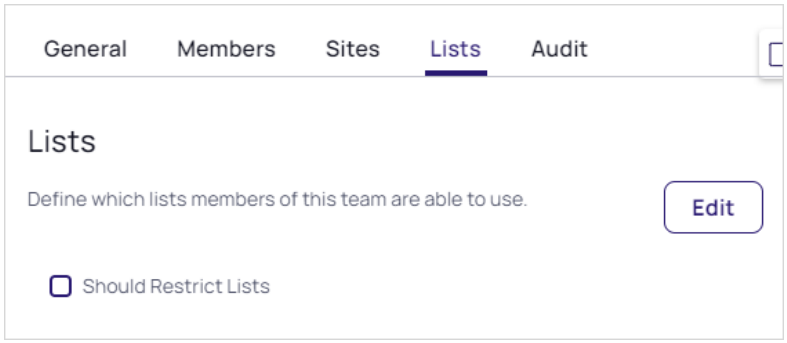
12. Click to select the **Should Restrict Sites** check box. A Site dropdown list appears:



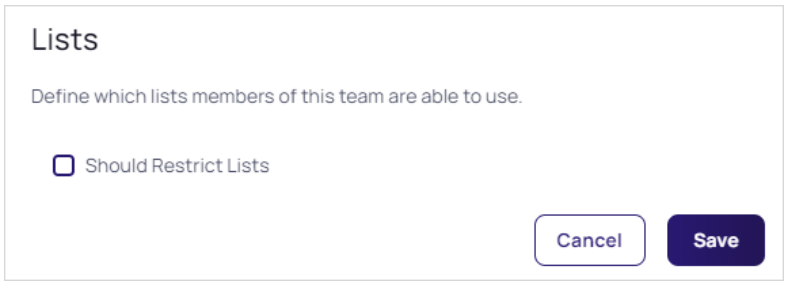
13. Click the **Add Site** list to select a site to restrict the team to. The selected site appears in the Allowed Sites box:



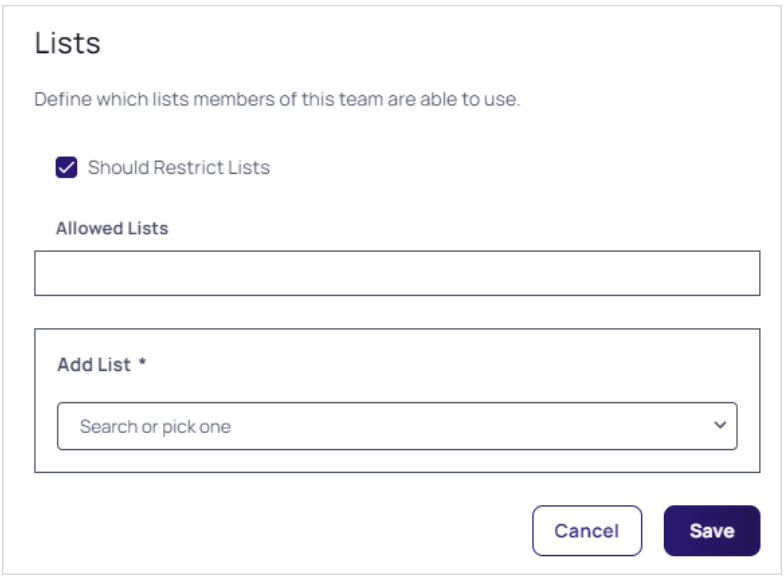
14. Click the **Save** button.
15. Click the **Lists** tab:



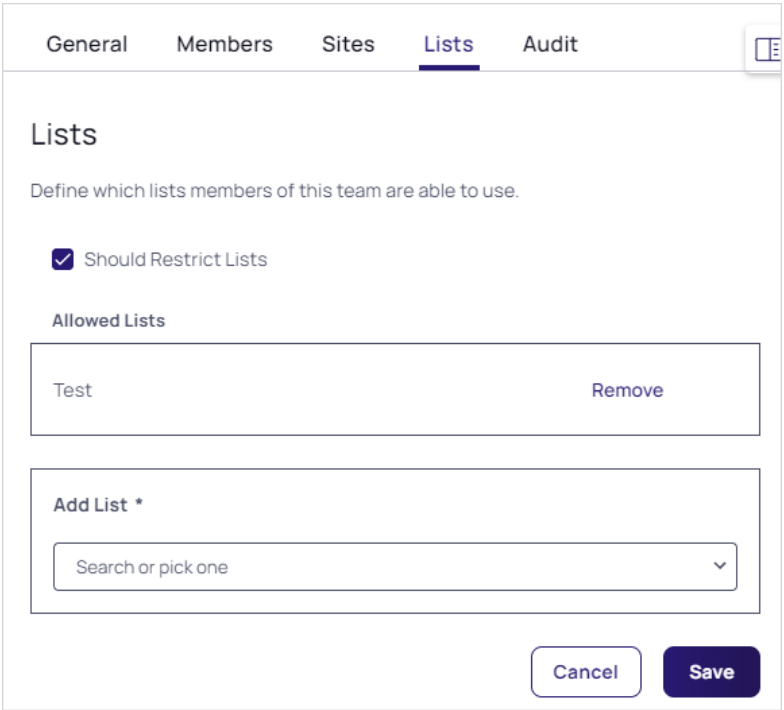
16. Click the **Edit** link. The page becomes editable:



17. Click the **Should Restrict Lists** check box.



18. Click the **Add List** dropdown list to select what lists the team members have access to. The chosen list appears in the Allowed Lists box:

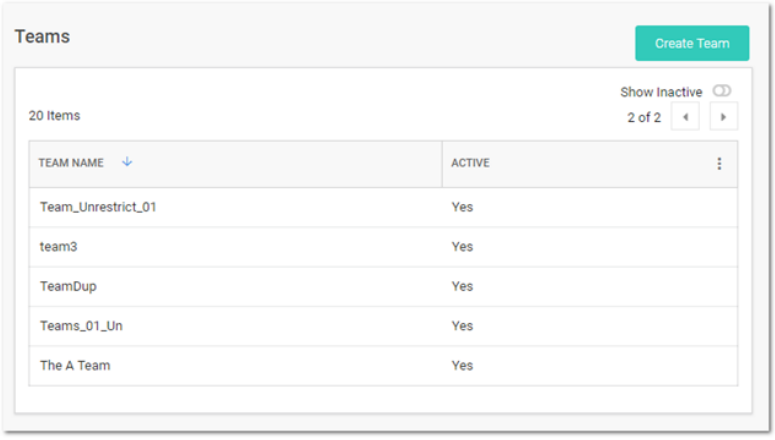


19. Repeat the process for any additional lists.
20. Click the **Save** button.

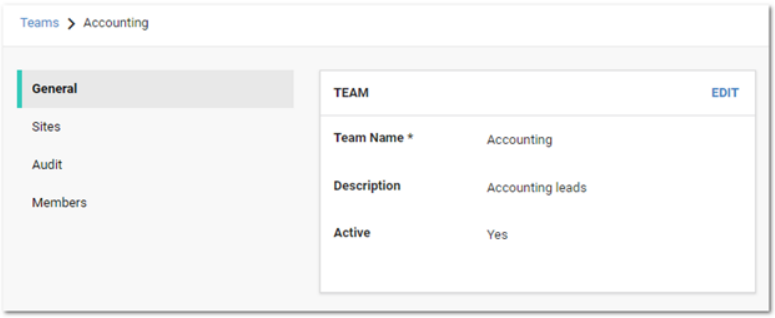
Deactivating Teams

You cannot delete teams because of auditing restrictions.

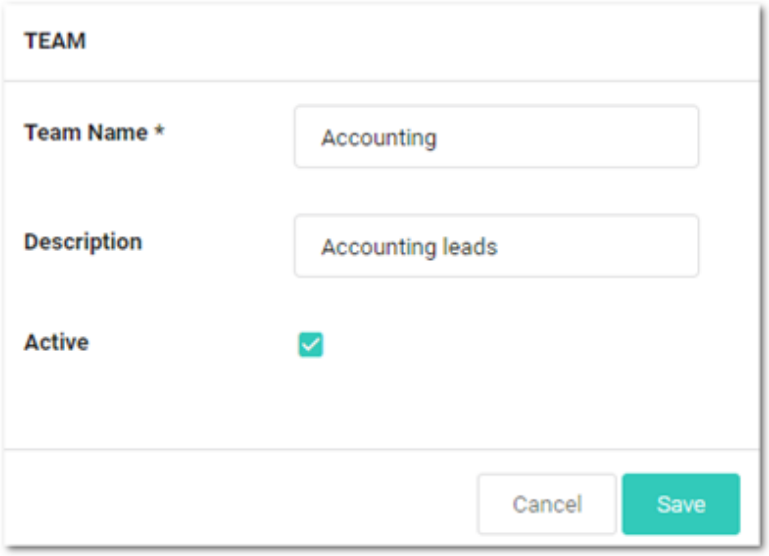
1. In Secret Server, click the **Admin** menu item. The Administration page appears.
2. Click the **Teams** button in the list. The Teams page appears:



3. Click the table row for the desired team. That team's page appears:



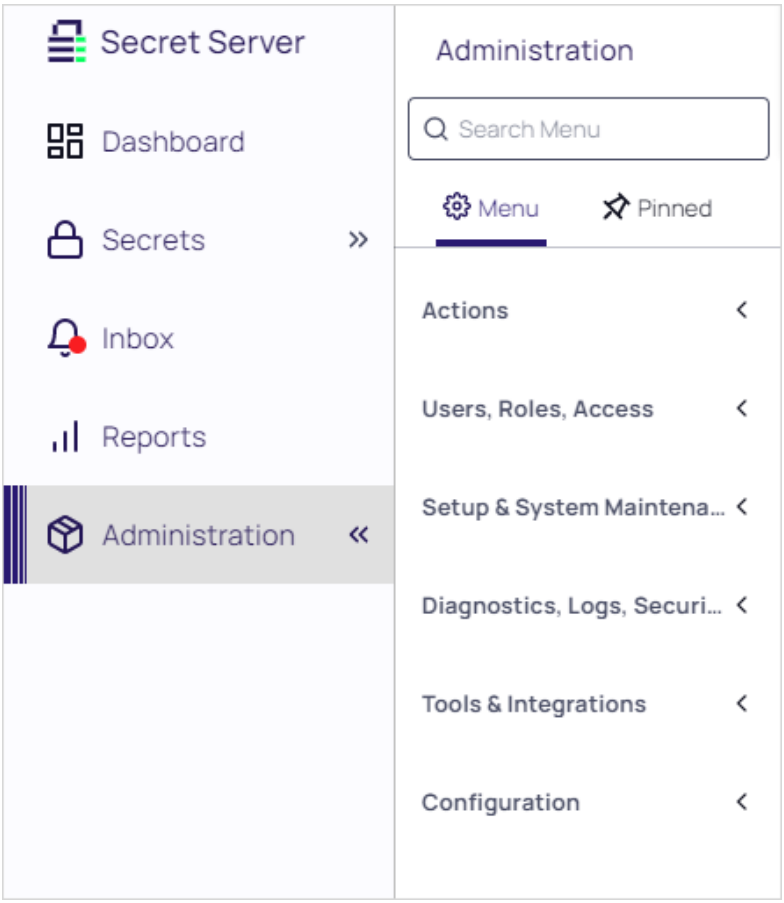
4. On the **General** page, click the **Edit** button. The tab becomes editable:



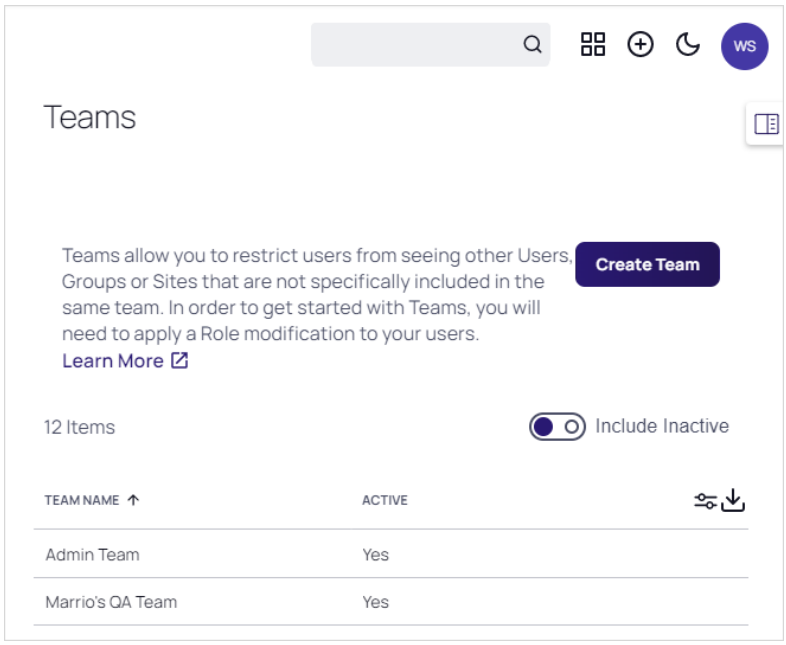
5. Click the **Active** check box to deselect it.
6. Click the **Save** button. The team is deactivated.

Editing Teams

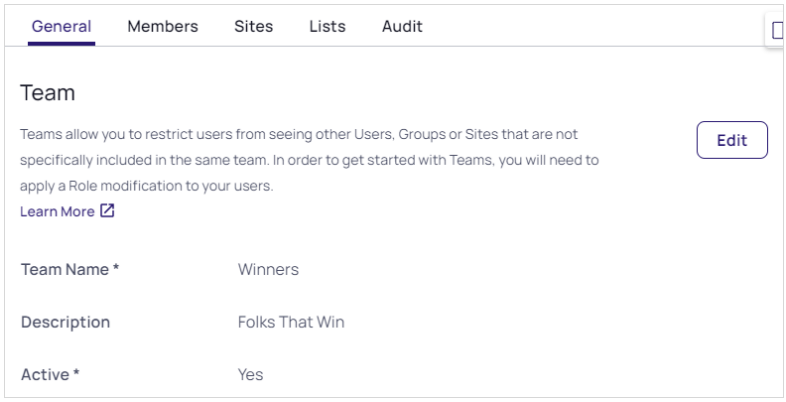
1. Navigate to **Administration**. The Admin Side Panel appears:



2. Click **Users, Roles, Access** and select **Teams** in the list. The Teams page appears:

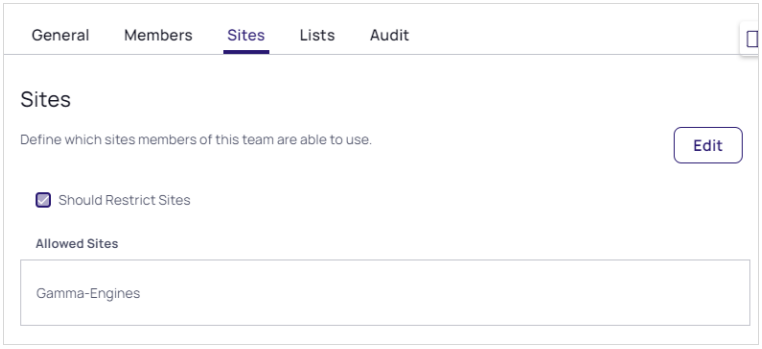


3. Click the table row for the desired team. That team's page appears on the General tab:

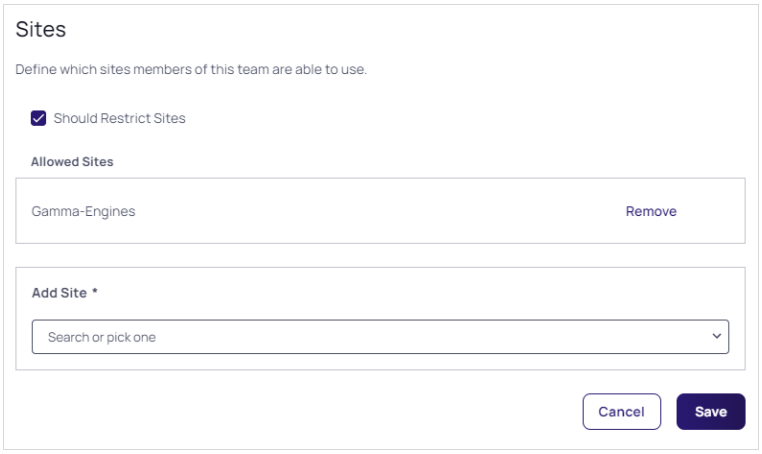


4. Click the **Edit** button to change:
   - The team name
   - The team's description
   - The team's status
5. To restrict the visible sites:

a. Click the **Sites** tab:



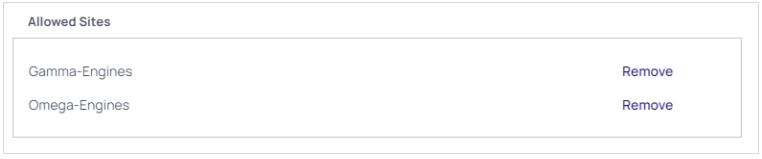
b. Click the **Edit** button. The page becomes editable:



c. If necessary, click to select the **Should Restrict Sites** check box.

d. Click the **Remove** button next to any sites you want to remove.

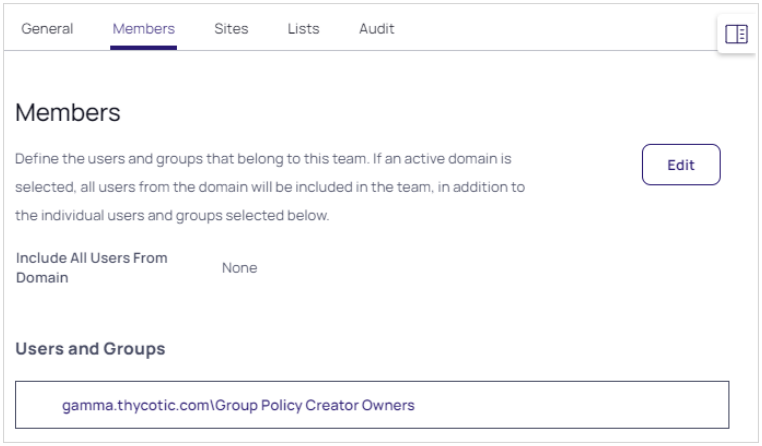
e. Click the **Add Site** dropdown list to select sites you desire to add. The selected site appears in the Allowed Sites table:



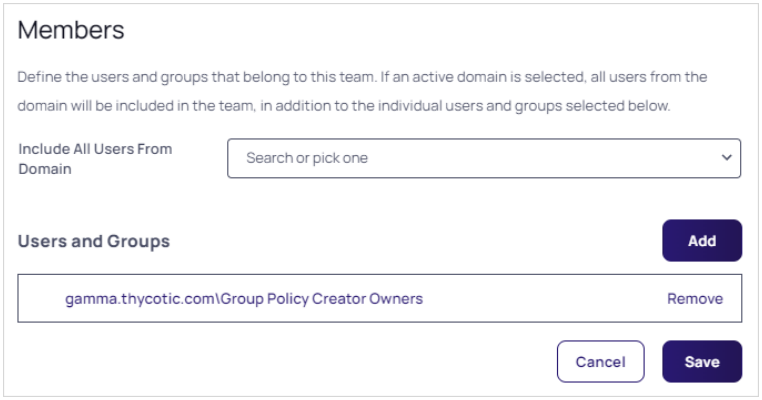
f. Click the **Save** button.

6. To edit the team's member users or groups:

a. Click the **Members** tab:



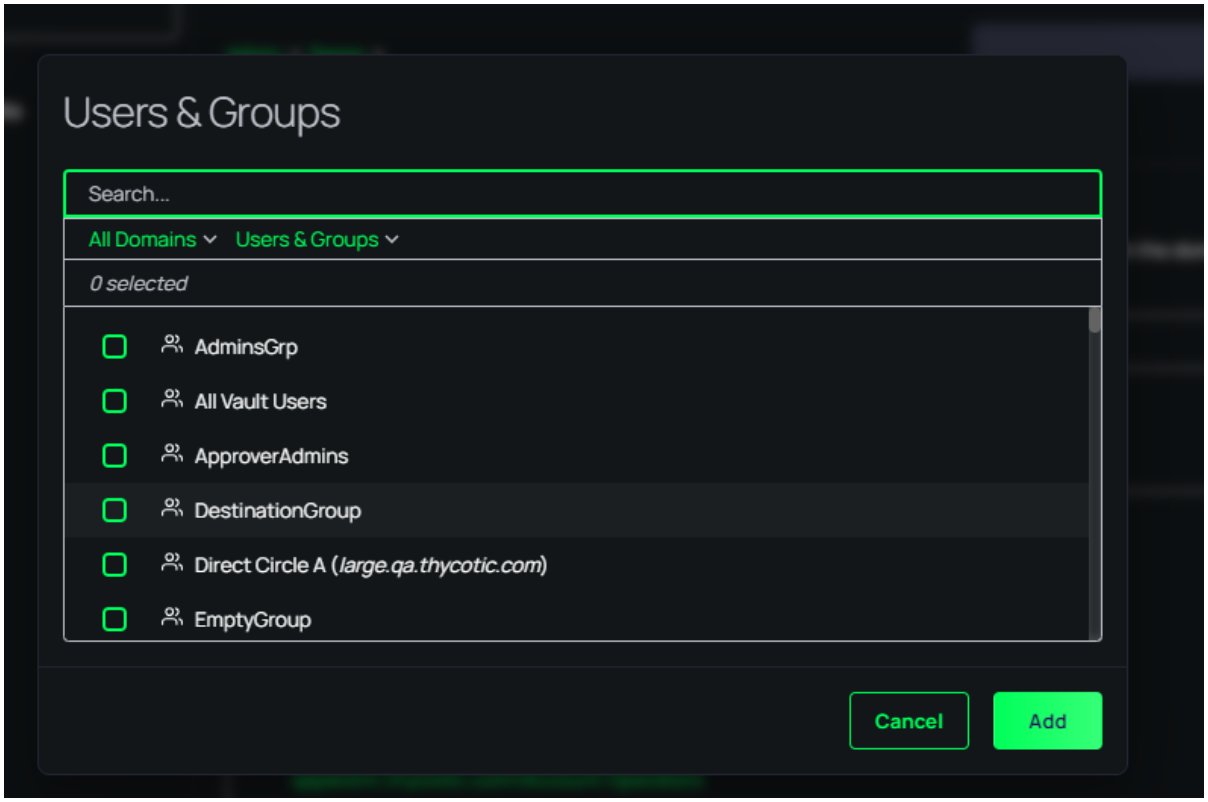
b. Click the **Edit** button. The page becomes editable:



c. **Either** to include all users in a domain, click the first **Include All Users from Domain** dropdown list to select a domain. This only appears if you have domains available.

   Or to add individual users:

i. Click the **Add** button. The Users and Groups popup appears:

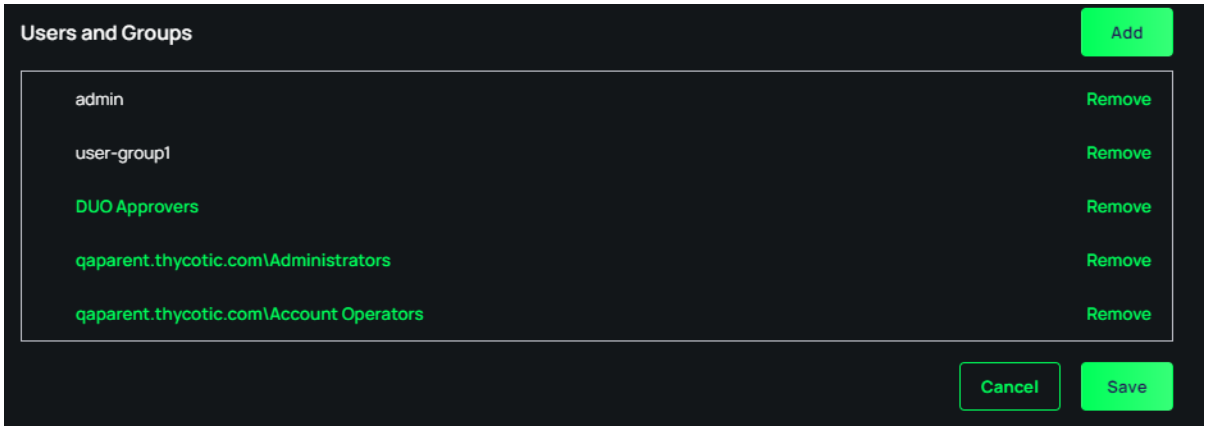


ii. Click the unlabeled domains dropdown list to select the desired domain.

iii. If needed, type the name of desired users or groups in the search box.

iv. Click to select the check boxes for the desired users or groups.

v. Click the **Add** button. The popup disappears, and your choices appear in the Users and Groups box:



vi. Click the **Save** button.

vii. Repeat the process for additional users and groups to add.

viii. Click the **Remove** button next to a user or group to delete it.

ix. Click the **Save** button.

7. View events for the team using its audit trail:

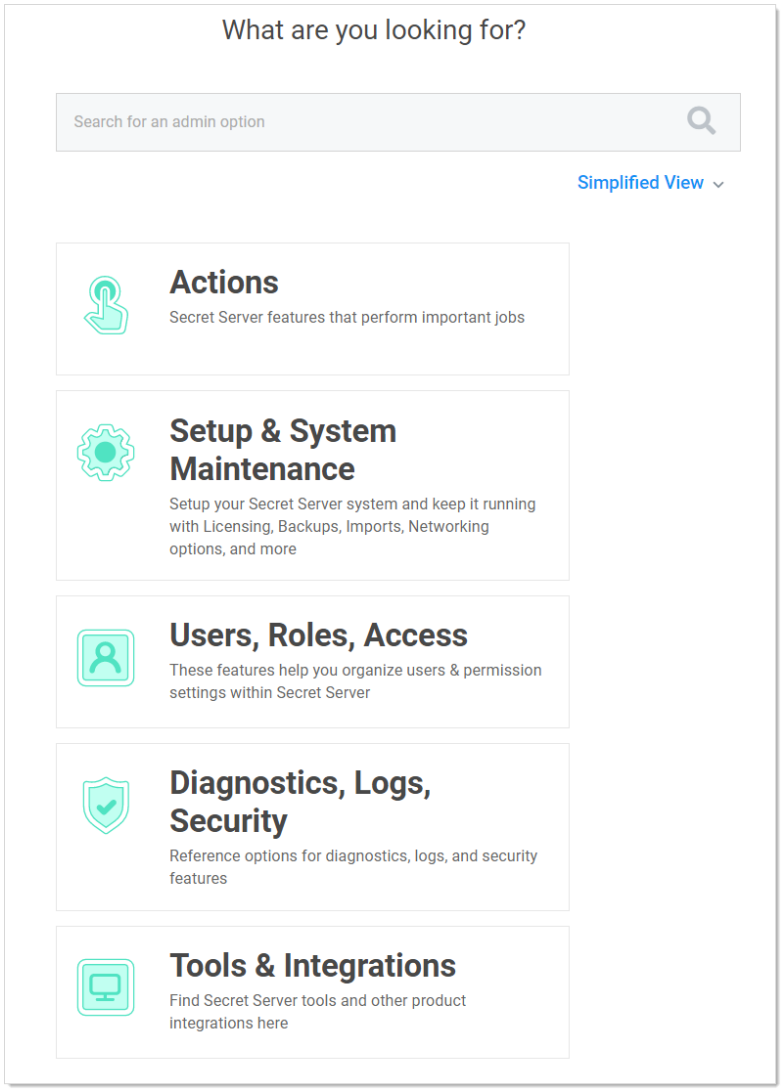
   a. Click the **Audit** tab:

   b. Audit events occur when:

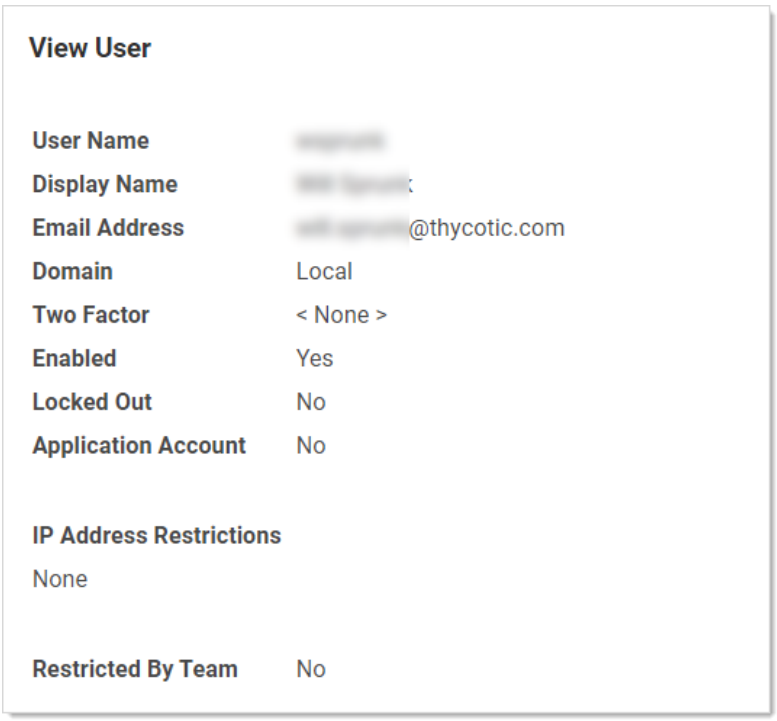
      - The team is created
      - General tab: name, description, or active status is changed
      - Sites tab: restrictions are added, removed, or changed
      - Members: users or groups are added or removed

Viewing a User's Teams

1. Search for **See All**. The Administration page appears:



2. Type and then click **Users** in the search text box. The View User page appears:



You can see if the user belongs to a team, and if so, what teams the user belongs to. If the Restricted by Team line says *No*, it means the user has been granted the Unrestricted by Teams permission, which means the user can view all users, groups, and sites.

Troubleshooting Teams

Users can view other users not in their teams if that user already had a connection, such as a shared secret, with the other user prior to setting up the team restrictions.

The API does not restrict who can be assigned if they use the known group ID of a user or group not in their team. This is designed so secret permissions can be saved across teams without removing the permissions of another team.

Security Compliance Standards

The Federal Information Processing Standard 140-1 (FIPS 140-1) and its successor (FIPS 140-2) are United States Government standards that provide a benchmark for implementing cryptographic software. has been tested within environments that are FIPS compliant. FIPS 140-2 compliance is built-in to Secret Server Cloud and is always on. For instructions to enabling FIPS in Secret Server On-Premises, see "Enabling FIPS Compliance in Secret Server On-Premises" on the next page.

Advanced Encryption Standard

The AES encryption algorithm provides a high security level for sensitive data. The National Institute of Standards and Technology (NIST) and National Security Agency (NSA) search for a replacement for the Data Encryption

Standard (DES), which had numerous issues, namely small key size and efficiency, and finally settled on AES.

> Encryption algorithms use keys to obfuscate the data. While DES only had a key size of 56 bits, AES can have a key size of 128, 192 or 256 bits. Larger keys provide more security as their size makes brute force attacks infeasible.

> To address concerns from the cryptographic community, NIST embarked on a transparent selection process. During the selection process NIST solicited designs from the global cryptographic community and voted for a winner from within fifteen finalists. The eventual winner was a team of Belgian cryptographers with their submission of the Rijndael encryption method, which became AES. For more information about the technical specifications of AES, please see the official standard.

Enabling FIPS Compliance in Secret Server On-Premises

The Federal Information Processing Standard 140-1 (FIPS 140-1) and its successor FIPS 140-2 are United States Government standards that provide a benchmark for implementing cryptographic software. Secret Server was tested and operates correctly in FIPS-compliant environments. FIPS 140-2 compliance is built-in to Secret Server Cloud and is always on.

> The Microsoft .NET implementations of AES and SHA are not FIPS certified so Secret Server uses the Windows API versions for encryption functionality which *are* FIPS certified.

See FIPS 140-2 Validation for the FIPS certificate numbers for the Windows operating systems, including the algorithm implementations that we use. Supported operating systems include Windows Server 2008 R2 and above.

Site-Specific FIPS Configuration

Individual sites are configurable for FIPS compatibility. The setting is available in the Engine Default Settings dialog box. All engines on a site will use this setting, overriding the global setting, which is configured at **Administration > Configuration > Security**.

Procedure

To enable FIPS compliance in Secret Server On-Premises:

Task 1: Enable FIPS in Secret Server On-Premises

> Secret Server is unavailable and may give errors (such as "Parser Error Message: This implementation is not part of the Windows Platform FIPS validated cryptographic algorithms") until all the steps are completed.

> During Secret Server installation, if FIPS compliance for Windows has already been enabled 'InvalidOperationException' error messages may result. To resolve the issue, please contact support for assistance.

> If FIPS is enabled as part of a domain group policy, it must be disabled before the option can be enabled in Secret Server, otherwise an error may occur. It can be re-enabled using group policy once the feature has been enabled in the application.

1. In Secret Server, Search for **FIPS**.
2. Click **Edit**, then click to enable the **Enable FIPS Compliance** check box.
3. Click **Save**.

Task 2: Enable FIPS in Windows

1. At the Windows command prompt, run `secpol.msc`. The Local Security Policy application appears.
2. In the left pane, drill down to **Security Settings > Local Policies > Security Options**.
3. In the right pane double-click the **System Cryptography: Use FIPS Compliant algorithms for encryption, hashing, and signing** policy. Its properties appear.
4. Click to enable the **Enabled** selection button on the **Local Security Setting** tab.
5. Click the **OK** button.
6. Close the **Local Security Policy** application.

Task 3: Reset the IIS Server

Run `iisreset` from the Windows command prompt. IIS resets.

> When using FIPS compliance mode in Secret Server, we use the NIST-certified encryption algorithms within the Windows Operating System.

Troubleshooting

If you have an endpoint that requires FIPS compliance, and Secret Server On-Premises is not configured for FIPS, you cannot establish a connection with that endpoint.

FIPS enforcement is dictated by the target machine. If the target requires FIPS compliance but the initiating system is unaware of this requirement, the initiating system might attempt to secure the connection using non-FIPS algorithms. Such attempts are rejected by the target endpoint.

Conversely, if Secret Server On-Premises is configured for FIPS compliance, it will successfully connect to target systems that do not require FIPS. The only exception to this is if the target endpoint specifically rejects a FIPS-approved algorithm that the Secret Server engine is trying to use.

Enabling FIPS compliance in Secret Server On-Premises restricts the cryptographic algorithms to FIPS-approved options during the initial handshake when connecting to the target. If the target does not support these FIPS-approved algorithms, the handshake fails, preventing a successful connection.

Thus, when troubleshooting FIPS-related connectivity, you might want to identify the algorithms supported by the target and ensure that the SSH algorithms configured in Secret Server match at least one of the target's supported algorithms.

Related Information

- NIST Cryptographic Module Validation Program Information
- FIPS information for Windows

Supported Versions of Secret Server Ancillary Tools

Below list is an overview of the supported versions for various ancillary tools and components that integrate with Secret Server. Keeping these tools updated ensures compatibility and optimal performance.

Database Support

Microsoft SQL Server

- Supported Versions: SQL Server 2014 Express, 2016, 2017, 2019, 2022.
- Notes: SQL Server 2014 Express is not recommended for production environments due to performance limitations.

See Installing and Configuring SQL Server for more details.

Web Browsers

Supported Browsers

- Chrome: Version 10.8 and later
- Edge: Version 10.8 and later
- Firefox: Version 10.8 and later
- Safari: Version 10.8 and later
- Opera: Version 10.8 and later
- Internet Explorer: Not supported

Operating Systems

Windows Server

- Supported Versions: Windows Server 2016, 2019, 2022.

See System Requirements for Secret Server for more details.

Protocol Handlers

Protocol Handler

- Protocol Handler Version 6.0.0.23 or higher is supported for managing multiple Secret Server instances. This version allows disabling the protocol handler auto-update function for forward and backward compatibility. See Managing Multiple Secret Server Instances with Protocol Handlers and Launchers for details.

- Protocol Handler Version 6.0.3.27 is the latest version as of the Secret Server 11.6.000025 release. This version includes changes to core internal functionality and requires manual redeployment or installation to end-user machines. Secret Server 11.6.000025 GA Release Notes for details.

Remote Desktop Services (RDS)

RDS Server

- Supported Windows Server Versions: 2012, 2016.
- Notes: Ensure compliance with Microsoft licensing requirements.

Scripting and APIs

PowerShell

- Supported Versions: PowerShell 5.1 and later.
- Ensure compatibility with REST API and scripting features.

REST API

- Supported Protocols: TLS 1.2 and later.
- Ensure web services are enabled for API access.

Additional Tools

RabbitMQ

- Supported Versions: Latest versions recommended.
- Use RabbitMQ Helper for installation.

.NET Framework

- Supported Versions: .NET 4.8 and later.

Best Practices

- Regular Updates: Keep all ancillary tools updated to the latest supported versions to ensure security and compatibility.
- Testing: Test updates in a staging environment before deploying to production.
- Documentation: Refer to the official documentation for each tool for detailed installation and configuration instructions.

Secret Server Security Model

This topic only applies to **Secret Server On-Premises**.

Delinea's Secret Server is a password vault that holds the keys to the kingdom. It is therefore critical that you understand the security model of Secret Server.

What the Security Model Covers

What Is Covered

The following are part of Secret Server's security model:

- Access to data must be authenticated and authorized.
- Access to or modification of data must have auditing for accountability.
- Data is confidential and secured at rest.
- Data is confidential and secured in transit.
- The system can be highly available.

What Is Not Covered

The following are not a part of Secret Server's security model:

- Protecting against the leakage of the existence of secret data. An attacker that can read from storage will be able to tell that secret data exists, even if it is encrypted at rest.
- Protecting against memory dumps. For example, an attacker with privileged access on the web server of an distributed engine can inspect the memory of the application and potentially compromise the confidentiality of the protected data.
- Protecting against control of the web server or database server. An attacker who can manipulate the web server or database can undermine the system's security. For example, a database administrator could delete all data, and Secret Server would not be able to recover unless restored from a backup.

Confidentiality

As of August 31, 2025, Microsoft retired TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net now requires TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

Data is secured in transit and at rest. You should secure communications between a client and the application using Transport Layer Security (TLS). TLS sets up a secure channel for communication between the client and application and protects data in transit and against eavesdroppers. Access to the Secret Server's web interface and APIs should both be secured with TLS. Our database storage at rest secures sensitive data with AES encryption in CBC mode. Communication with the database storage can be further secured by using Microsoft's SQL Server's TLS capabilities.

> Transport Layer Security (TLS) is a cryptographic protocol used to provide secure communication between web browsers and servers, ensuring the integrity and confidentiality of data exchanged over the internet. TLS is the successor to Secure Sockets Layer (SSL) and is widely used to secure online transactions, communication, and data transfer, protecting against eavesdropping, tampering, and man-in-the-middle attacks. TLS is typically used in conjunction with HTTPS (Hypertext Transfer Protocol Secure) to provide a secure and trusted connection between clients and servers.

Availability

Secret Server can operate within a highly available configuration. You can deploy multiple web server nodes such that traffic is load balanced across them. If a web server fails, then the system relies on nodes that are still available. Likewise, you can deploy multiple distributed engines for any given site to distribute workload.

Accountability

Access to and modification of data is audited, enforcing accountability for a user attempting to access or modify sensitive data.

Authentication

Access to the web interface and APIs require authentication. Users must provide their login credentials and, if applicable, their two-factor authentication, to access the system. Without authentication, the client is unable to access any data. Authentication should be protected against eavesdroppers using TLS.

Authorization

Secret Server uses authorization to protect sensitive data that is shared in the vault. It specifically allows for RBAC (Role-Based Access Controls) that provides fine grained control over the data and controls that users have access to and ability to modify. Administrators must review the Delinea permissions that they are assigning to their users to protect against internal threats from users who have unnecessary permissions in the system. You should always use a least privilege model to assign Delinea permissions.

> Role-Based Access Control (RBAC) is a security framework that regulates access to computer resources based on a user's role within an organization, rather than by their individual identity. Users are assigned to roles, and each role is granted specific privileges and access to resources. This approach simplifies user management, improves security, and reduces the risk of unauthorized access. RBAC enables organizations to enforce least privilege access, separation of duties, and accountability, making it a widely adopted model for managing access control in enterprise environments.

Hardening Guides

> This topic only applies to **Secret Server On-Premises**.

This section discusses three hardening guides:

- Common Criteria Hardening
- Distributed Engine Hardening
- Security Hardening

Overview of the Common Criteria Hardening Guide in Secret Server

The Common Criteria Hardening Guide for Secret Server provides detailed instructions for configuring Secret Server to comply with the Common Criteria (CC) for Information Technology Security Evaluation (ISO/IEC 15408). This international standard ensures that security attributes of the evaluated product are independently verified in a specific environment. Below are the key aspects covered in the guide.

> This document and all related information are legacy entries. It is the user's responsibility to test everything before making changes in a production environment.

Introduction

- Purpose: The guide is designed to help administrators configure Secret Server in compliance with Common Criteria standards.
- Audience: Intended for administrators responsible for installing, configuring, and operating enterprise infrastructure.
- Common Criteria: An international standard for security certification of computer systems, networks, and application software.

Security Hardening Checklist

- Reports: Navigate to **Reports > Security Hardening** in Secret Server to follow the checklist for securing your environment.

Configuring TLS

- TLS Requirement: Common Criteria certification requires enabling Transport Security Layer (TLS).
- Disabling TLS 1.0: TLS 1.0 must be disabled as it is no longer considered secure.
- Diffie-Hellman Hardening: Configure servers with stronger Ephemeral Diffie-Hellman settings.
- Restricting Cipher Suites: Only specific cipher suites are allowed for TLS communication.
- IIS Crypto Tool: Use the IIS Crypto tool to change cipher suites.
- HTTPS/SSL: All connections to the Secret Server web page must use HTTPS/SSL.
- TLS Auditing: Enable auditing for TLS connections and failures.
- Active Directory: Ensure TLS is configured with Active Directory.
- Syslog: Configure TLS with Syslog for secure logging.

Additional Common Criteria Configurations

- X.509v3 Certificates: Install and configure certificates following the X.509v3 standard.
- DPAPI: Enable the Windows Data Protection API (DPAPI) to protect the master encryption key file.
- FIPS Mode: Enable Federal Information Processing Standard (FIPS) mode in Secret Server On-Premises for cryptographic functionality.
- Zero Information Disclosure: Configure Secret Server to hide unnecessary information, such as detailed error messages and application version numbers.
- Login Banner: Configure a login banner to display the user policy agreement.
- Account Lockout: Implement account lockouts to prevent repeated unsuccessful login attempts.
- Disabling "Remember Me": Disable the "Remember Me" login function for security reasons.
- SQL Server Configuration: Install Microsoft SQL Server on the same machine as Secret Server and use Windows authentication mode.
- Service Account: Create a service account to run the Secret Server IIS Application Pool and configure necessary permissions.

Enabling Common Criteria Security Hardening

This document and the information contained in it are confidential and proprietary to Delinea and provided in strict confidence for the sole internal use of Delinea and authorized agents and may not be disclosed to any third party or used for any other purpose without express prior written permission of Delinea.

The PDF version of this online document is automatically generated and thus may have minor formatting anomalies.

This document is not updated with every Secret Server release–some minor releases do not affect the guide's contents and thus do not warrant a document update.

Introduction

This document is closely associated with the Security Hardening Report in Secret Server (Click **Reports > Security Hardening**) and with the "Security Hardening Guide" on page 1419, which provides information on security hardening beyond Common Criteria. We recommend having those available while reading this document.

Overview

Secret Server made several security enhancements to achieve Common Criteria (CC) certification. These features are available in all versions of Secret Server 10.4 and later. Due to their stringency and need for additional user configuration, not all these features are enabled by default by our standard installer.

This guide provides the information an administrator needs to configure Secret Server 10.4 and above in compliance with the Common Criteria evaluated configuration. Follow this guide in its entirety to ensure each parameter setting matches those evaluated and certified as secure by Common Criteria standards.

Audience

This document is for administrators who are responsible for installing, configuring, and operating enterprise infrastructure for their organization. To use this guide, you must have knowledge of your organization's network infrastructure and applicable policies. In addition, you must have administrative access to configure your operational environment.

What Is Common Criteria?

The Common Criteria for Information Technology Security Evaluation (ISO/IEC 15408), known as "Common Criteria," is an international standard for security certification of computer systems, networks, and application software. The certification ensures that claims about the security attributes of the evaluated product were independently verified in the evaluated configuration in the same specific environment. The certification assumes a specific evaluated configuration and does not validate any security claims when the product is used outside of that configuration.

Consider using the following general best practices, aligned with ISO 15408:

- Documenting and evaluate Security Functional Requirements (SFRs) and Security Assurance Requirements (SARs) to meet security profiles.
- Performing regular security audits, vulnerability assessments, and penetration tests to maintain compliance.
- Implementing robust logging and monitoring for both application and database activities.

Procedures

Security Hardening Checklist

After installing Secret Server, navigate to the **Reports > Security Hardening** tab, and follow the checklist to ensure your environment is as secure as possible:

Note: See the "Security Hardening Guide" on page 1419 for details.

Configuring TLS

To achieve Common Criteria certification on Secret Server, you must enable Transport Security Layer (TLS).

.

Manually Disabling TLS Version 1.0

TLS 1.0 is no longer considered secure, so it is important to disable this version of the protocol on Secret Server. To do this, follow the instructions in the "Manually Disabling TLS v1.0" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

TLS Diffie-Hellman Hardening Overview

For information on configuring your servers with stronger Ephemeral Diffie-Hellman hardening, see the "TLS Diffie-Hellman Hardening Overview" in the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Restricting Server Cipher Suites for TLS

Allowed Suites

Common Criteria certification requires restricting the cipher suites configured on your server to the following:

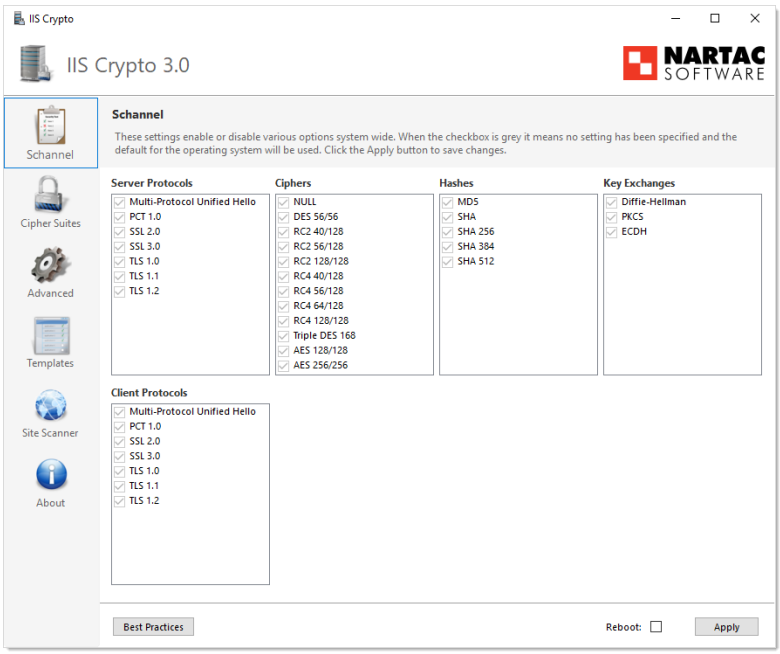
- TLS_RSA_WITH_AES_128_CBC_SHA as defined in RFC 5246.
- TLS_RSA_WITH_AES_128_CBC_SHA256 as defined in RFC 5246.
- TLS_RSA_WITH_AES_256_CBC_SHA256 as defined in RFC 5246.
- TLS_RSA_WITH_AES_256_GCM_SHA384 as defined in RFC 5288.
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256 as defined in RFC 5246.
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256 as defined in RFC 5246.
- TLS_DHE_RSA_WITH_AES_256_GCM_SHA384 as defined in RFC 5288.
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256 as defined in RFC 5289.
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 as defined in RFC 5289.
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384 as defined in RFC 5289.
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 as defined in RFC 5289.
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 as defined in RFC 5289.
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 as defined in RFC 5289.
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 as defined in RFC 5289.
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 as defined in RFC 5289.

Restricting them can cause communication issues with other servers if they are unable to communicate using any of the above ciphers. In that case, you need to modify those servers to include these cipher suites to securely communicate according to Common Criteria guidelines.

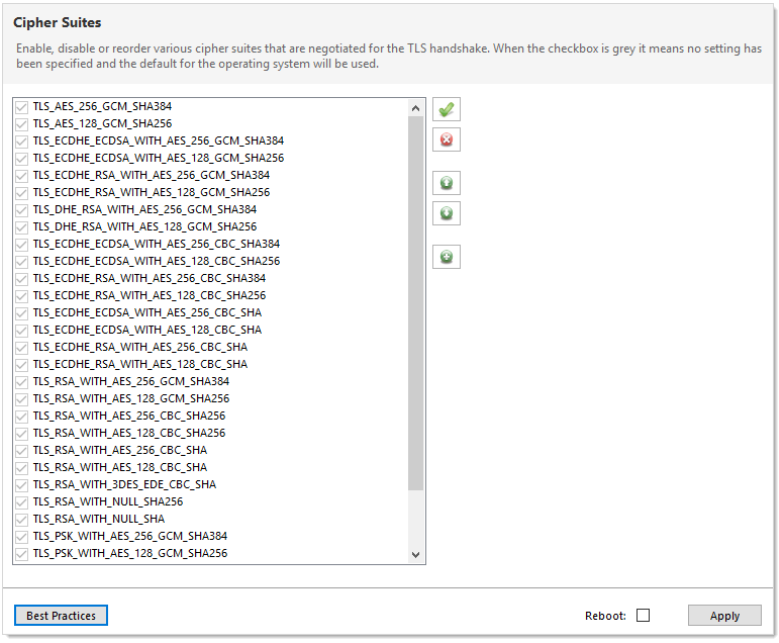
Changing Cipher Suites with the IIS Crypto Tool

One way to change the cipher suites on a computer is to use the free IIS Crypto tool:

1. Download the GUI version of the tool at: https://www.nartac.com/Products/IISCrypto/Download
2. Run the tool:



3. Click **Cipher Suites** button on the left. The Cipher Suites window appears:



4. Click the **Uncheck All** button to uncheck all cipher suites.
5. Find and click to select the suites in the list above.
6. Click the **Apply** button.

Configuring TLS with IIS

Common Criteria certification requires using HTTPS/SSL for all connections to the Secret Server Web page. To do this, follow the instructions in the "TLS Configuration with IIS" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Enabling TLS Auditing

To have Secret Server audit TLS connections and connection failures, follow the instructions in the "Configuring Auditing for TLS Connections" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Configuring TLS with Active Directory

To ensure that TLS is configured with Active Directory Follow the instructions in the "Configuring TLS with Active Directory" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Note: If you have any existing domains configured in Secret Server, you must edit them and enable LDAPS on each one.

Configuring TLS with Syslog

To configure TLS with Syslog, follow the steps in the "Configuring Syslog/CEF External Audit Server" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Additional Common Criteria Configurations

Configuring X.509v3 Certificates

See the "Configuring X.509v3 Certificates" section of the Common Criteria Hardening Guide for instructions on installing and configuring certificates on the Secret Server Web servers.

Enabling DPAPI

The Windows Data Protection API (DPAPI) is a pair of functions that allow access to operating-system-level data protection services to protect the master encryption key file, encryption.config.

To enable DPAPI, follow the instructions in the "Verify DPAPI Setting Is Enabled" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Enabling FIPS Mode

To configure your server and Secret Server to use the Federal Information Processing Standard (FIPS), follow the instructions in the "Verify FIPS Mode Is Enabled" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Note: Also see: "Enabling FIPS Compliance in Secret Server On-Premises" on page 1337

Ensuring Zero Information Disclosure

To comply with Common Criteria requirements, you must configure Secret Server to not display any unnecessary information. This applies to unhandled errors as well as the application version number.

Configuring Custom Error Messages

To hide detailed error messages and display a custom message when an unhandled error occurs:

1. Open `https://<your_secret_server_url>/ConfigurationAdvanced.aspx` in your browser.
2. Scroll to the bottom of the page and click the **Edit** button.
3. Type the message you want displayed to users in the **Zero Information Disclosure Message** text box.
4. Click the **Save** button.

Hiding the Application Version Number

To hide the application version number in the application header and footer:

1. Search for **Webservices**, and click **Edit**.
2. Check to enable **Hide Secret Server Version Numbers**.
3. Click **Save**.

> For diagnostic purposes, the application version number is still displayed on the Diagnostics page. Make sure that Delinea permissions to this page is limited to employees that may need to access this page when contacting Delinea technical support.

Configuring the Login Banner

For Common Criteria compliance, when a user first logs in, the login banner must reveal the user policy agreement and force that user to agree to the policy before logging into Secret Server. To configure the Login Banner according to Common Criteria guidelines, follow the instructions in the "Configuring the Login Banner" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Configuring Account Lockout

To access Secret Server, users must login with local or domain credentials. To comply with Common Criteria, Secret Server must use "account lockouts" to prevent repeated unsuccessful login attempts. Configurable by an Secret Server admin, an account becomes inaccessible after a defined number of unsuccessful authentication attempts until an admin unlocks the user's account.

To configure settings for account lockouts:

1. Search for **Login Settings** and click **Edit**.
2. Adjust the number in the **Maximum Login Failures** text box. The default is five attempts.

To Unlock a user's account:

1. Search for **Users**.
2. Select the related user from the list and click **Edit**.
3. Click to deselect the **Locked Out** check box.
4. Click the **Save** button.

Disabling "Remember Me" Logins

A browser's "remember me" login function stores the user's login name and password so the user does not need to enter it again on that browser, which is both convenient and insecure. To disable "Allow Remember Me" during logins, follow the instructions in the "How to Disable Allow Remember Me during Logins" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Configuring SQL Server

To meet Common Criteria requirements, Microsoft SQL Server must be installed on the local machine–the same as the Secret Server Web server. During the install process for MS SQL, ensure that you use Windows authentication mode.

If you have an installed instance of Secret Server that does not meet this requirement, you can migrate the remote database to the server hosting Secret Server. If MS SQL Server is not installed and configured on the Secret Server, you must install it. The server must be configured with enough RAM, storage space, and processors to support running MS SQL Server and the Web site simultaneously. After copying the database, you can Search for **Database** to point Secret Server to the new database location.

> Because the database must be installed locally with the Secret Server Web application for Common Criteria compliance, Secret Server is not fully compliant when running multiple nodes.

ISO 15408 emphasizes securing the database against unauthorized access, misuse, or compromise, without specifying its physical or logical location. Key aspects include access control, data integrity, and confidentiality. Therefore, we recommend the following Microsoft Windows Considerations:

- Placing the database in a secure network segment (e.g., DMZ or private subnet).
- Using role-based access controls (RBAC) to restrict database access.
- Implementing encryption for data at rest and in transit to safeguard sensitive information.

Location of the Application

Applications must enforce security policies, securely communicate with the database, authenticate users, and protect sensitive operations.

- Applications can reside locally (on the same server as the database) or remotely (on a separate server), depending on performance and security needs.
- Ensure secure communication between the application and database (e.g., using TLS/SSL).
- In multi-tenant environments, isolate applications using Windows features like AppLocker or virtualization.

Application-to-Database Authentication

The authentication mechanism must establish mutual trust between the application and database while preventing unauthorized access. Therefore, we recommend the following Microsoft Windows considerations:

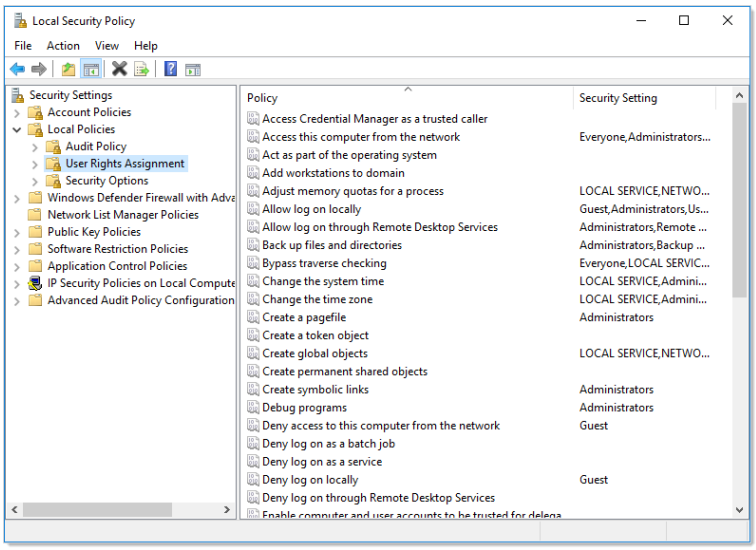
- Using Windows Authentication with Active Directory for centralized, secure credential management.
- Using Integrated Security (Kerberos or NTLM) for database connections to avoid embedding credentials in code.
- Applying the principle of least privilege, ensuring the application has only the required database permissions.
- Rotating credentials regularly and store them securely (e.g., using Windows Credential Manager or Azure Key Vault).

Running the IIS Application Pool with a Service Account

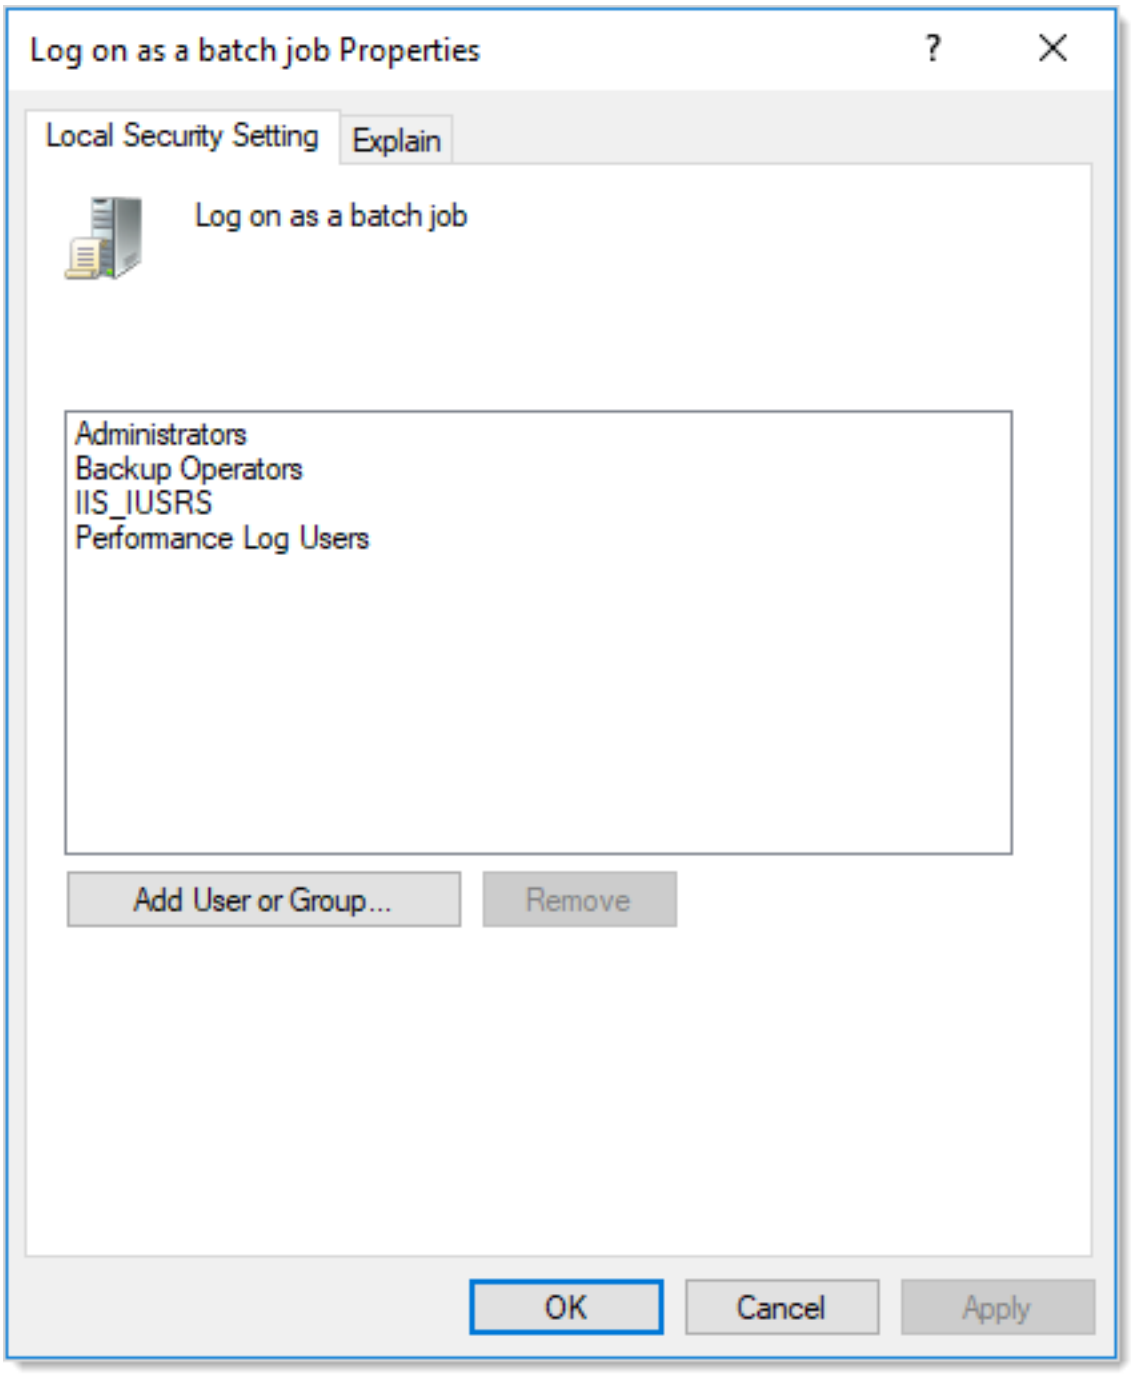
To use Windows authentication to access the SQL database, you should create a service account. To run the Secret Server IIS Application Pool with a service account:

1. Open a command prompt window, change the directory to your .NET framework installation directory (usually `C:\Windows\Microsoft.NET\Framework…`) using the `cd` command.
2. Type `.\aspnet_regiis -ga <user_name>` and press **<Enter>**. The username is from the MS SQL Server user account.
3. Give your service account "modify" access to `C:\Windows\TEMP`.
4. Open the Local Security Policy App from your start menu.
5. Grant batch logon Windows permissions to your service account:
   a. Open the Local Security Policy Console (search for and open `secpol.msc`):

   b. Expand the **Local Policies** folder (not shown).
   c. Click to select the **User Rights Assignment** folder.



d. Right-click **Log on as a batch job** in the right panel and select **Properties**.



e. Click the **Add User or Group** button.

f. Add your service account.

g. Click the **OK** button.

> If you use group policy to enforce "Log on as a batch job" and have group-managed service accounts, that will overwrite any local permissions to "Log on as a batch job" on all computers that have the policy applied. Using the local security policy is a safer option if you are not sure about your usage across your domain.

5. Grant "Impersonate a client after authentication" Windows permission to the service account under **User Rights Assignment** the same way "Log on as a batch job" was assigned above.
6. If you now get a "Service Unavailable" error after applying "Log on as a batch job" permissions:
   a. Update your group policy settings (**Start > Run > Cmd** and type `gpupdate /force`) and restart the Windows Process Activation service.

> For more information, see "Running the IIS Application Pool As a Service Account" on page 63.

Assigning Common Criteria Roles and Permissions

See the "Common Criteria Roles and Permissions" section of the Common Criteria Hardening Guide.

Managing User Passwords

See the "Managing User Passwords" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Configuring Secret Templates

To enable only the secret templates that are certified Common Criteria compliant and to set Common Criteria-compliant password policies on those templates, see the "Configuring Secret Templates" and "Configuring Password Policy for Secret Templates" sections of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Setting Authentication Strength for Non-Password Credentials

See the "Authentication Strength for Non-Password Credentials" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Configuring Remote Password Changing for SSH Key Rotation

See the "Configuring Remote Password Changing for SSH Key Rotation" section of the Common Criteria Hardening Guide.

Configuring External Auditing

Connecting to an External Audit Server

To connect to an external syslog/CEF audit server, see the "Security–Connecting to an External Audit Server" and "Configuring Syslog/CEF External Audit Server" sections of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Configuring Local Windows Event Log Auditing

See the "Configuring Local Windows Event Log Auditing" section of the "Overview of the Common Criteria Hardening Guide in Secret Server" on page 1343.

Accessing Your System

Browser Compatibility

See "Browsers Supported By Secret Server" on page 93

Web Interface

To access Secret Server, navigate to your organization's URL and login using your administrator credentials.

*For information on setting up your Secret Server Local Administrator account, see Local Admin Account Best Practices.

After enforcing the Login Policy Banner (for instructions, see Enabling Login Banners), the login screen will appear.

Once user accounts are configured, both Local accounts and Active Directory users will access Secret Server through this login screen. To configure Active Directory users, see Active Directory Integration section.

You will be directed to Secret Server's landing page for Administrator accounts.

To logout, navigate to the **profile icon** in the upper right-hand corner and select **Logout** from the dropdown list. Once user accounts are created in Secret Server from the Admin profile, users can login using user-level credentials by navigating to your organization's login URL.

More detailed information for setting up Secret Server including customizing Secret Server dashboard and creating users can be found in the related Secret Server's documentation.

Local Admin Account

To create Secret Server's Local Administrator Account you will be prompted for information through the installer (see the Installation section). Save the information you provide during this step so that you can login to the administrator account when the installer finishes setting up your instance.

Installing License Keys

After logging into Secret Server with Secret Server's local administrator account, the first thing you will need to do is install your organization's license keys. You will need three different license keys, one for the Secret Server Edition being used, one for Support, and one for Users. Install your keys by navigating to **Admin > Licenses**, click **Install New License**. To install multiple licenses at once, click the **Bulk Entry Mode** button. Add your licenses according to the example format and click **Add Multiple Licenses**, enter the required informational fields included in your trial or purchase license email and then click **Activate**.

To activate newly installed licenses, click **License Activation** to log in.

*For information on setting up your Secret Server Local Administrator account, see Local Admin Account Best Practices.

After enforcing the Login Policy Banner (for instructions, see Enabling Login Banners), the login screen will appear.

Once user accounts are configured, both Local accounts and Active Directory users will access Secret Server through this login screen. To configure Active Directory users, see Active Directory Integration section.

You will be directed to Secret Server's landing page for Administrator accounts.

To logout, navigate to the **profile icon** in the upper right-hand corner and select **Logout** from the dropdown list. Once user accounts are created in Secret Server from the Admin profile, users can login using user-level credentials by navigating to your organization's login URL.

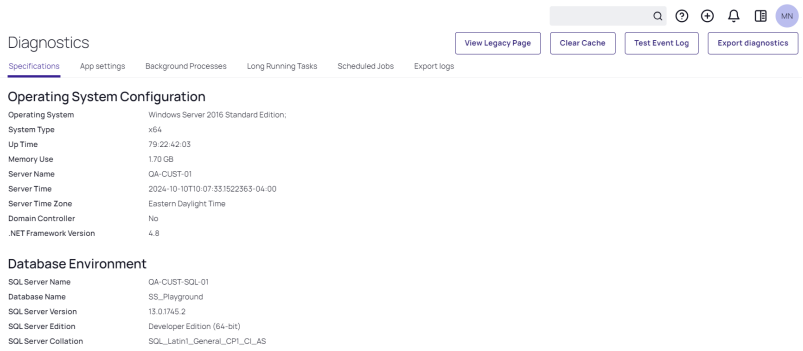
More detailed information for setting up Secret Server including customizing Secret Server your dashboard and creating users can be found in the related Secret Server's documentation.

Updating Secret Server

Checking Software Version

Verify Software Version and Components

A shorthand representation of the software version appears in the upper left-hand corner of any user screen, along with the product edition. The full software version number is listed in the **Secret Server Environment** section by navigating to **Admin > Diagnostics**:



Downloading Software Updates

By default, Secret Server is configured to notify you immediately when software updates are available. To customize this behavior, Search for **Application** from the General section, and click **Edit**, then check the box next to **Allow Automatic Checks for Updates**. This setting will create a banner at the top of your Administrator account's user screen when a new update is available for download. Disabling this feature will prevent automatic update checks and banner displays.

If your Secret Server web server has no outbound access, you can elect to receive updates through Delinea's Support Portal by logging into your Portal account at support.delinea.com, navigating to your Account Settings, and signing up for the Delinea Mailing List.

After receiving a notification for the latest software release, navigate to https://support.delinea.com/s/download-onprem to download the latest .zip file.

To perform an upgrade without outbound access, follow the steps in "Upgrading Secret Server Without Outbound Access" on page 167.

Configuring Authentication and Login

The way that Secret Server authenticates interactive users depends on the type Secret Server of authentication that your organization has configured. Secret Server can use both **Local Accounts** and/or Active Directory **Domain Accounts** for authentication into Secret Server.

Local Authentication

A local user account is stored and managed by Secret Server. To successfully authenticate a local user must login with a matching username and password. When using local login, user credentials are checked against the internal authorized users' database.

To **create**, **edit**, or **remove** a local user account you must Search for **Users** and locate any users whose Domain is listed as "Local" or **Create New** users.

Domain Authentication

A domain user account is stored and managed by Secret Server, but subject to changes made in Active Directory. To successfully authenticate a user must login with an Active Directory account that exists in Secret Server with matching Secret Server credentials. When using domain login, the TOE (Secret Server) initiates an authentication request to the external domain controller (Active Directory) using LDAP over TLS, and only allows access after receiving a successful result message.

For more information on syncing Secret Server with Active Directory credentials see section Configuring Active Directory Sync.

Account Lockout Configuration

To access any information or functionality within Secret Server, users must login with correct local or domain credentials. To comply with Common Criteria regulations, Secret Server must be configured to prevent repeated unsuccessful attempts at logging in. **Account Lockouts** are used for this purpose. Configurable by the Secret Server Administrator, an account becomes inaccessible after a limited number of unsuccessful authentication attempts until an Administrator unlocks the user's account.

To configure settings for Account Lockouts, Search for **Login Settings**, then click **Edit** and adjust the number for **Maximum Login Failures**. Default for this setting is five attempts.

To Unlock a user's account, Search for **Users**, select the related user and click **Edit**. Change the value for **Locked Out** from Yes to **No**, then click **Save**.

Lockout Window

Secret Server is programmed with a default Lockout Window of 60 minutes. This means that once a user has locked out their account, they will be able to login with the correct credentials after a period of one hour has passed. Account lockouts are designed to prevent brute force attacks.

How to Disable "Allow Remember Me" during Logins

By default, the Secret Server installer will disable the "Allow Remember Me" caching feature during logins, however, to ensure this feature is disabled, Search for **Login Settings**, and verify that the first setting **Allow Remember Me** is set to **No**. If this is set to Yes, **Edit** the page and uncheck the toggle, then **Save**.

Audits for this setting are logged under **Admin > Reports audit** tab.

Configuring the Login Banner

To configure the Login Banner, Search for **Login policy**, then click **Edit** and check the **Enable Login Policy** and **Force Login Policy** boxes.

Enabling these boxes will 1) Reveal the **User's Policy Agreement** on the Login page, and 2) Force users to **Agree** to the policy when logging into Secret Server.

How to Modify the Login Banner Messaging

To modify the display text from this **Login Policy Agreement**, go to Secret Server's Web Server and open **File Explorer**. Navigate to a text file called "**policy.txt**" (default file path location is **C:\inetpub\wwwroot\SecretServer\policy.txt**)

Open this file in Notepad and adjust the text according to your organization's policy requirements, then **Save**. The default text reads as follows:

Access to this system is restricted to authorized users. Users (authorized or unauthorized) have no explicit or implicit expectation of privacy. Any or all secrets may be modified, copied, audited, inspected, and disclosed to company management, law enforcement personnel, and other authorized individuals.

I understand that I am responsible for protecting the confidentiality of company secrets and will comply with the company Information Security Policy. Unauthorized or improper use of this system may result in administrative disciplinary action, civil and/or criminal penalties. By continuing to Login, I am indicating my awareness of and consent to these terms and conditions of use.

** *CLOSE THIS SITE IMMEDIATELY if you do not agree to these conditions* **

Alternatively, Search for **Login policy**, then click **Edit** and edit the text directly in the Login policy field. When done, click **Save**.

Configuring Session Timeouts

To configure Session Timeouts, Search for **User experience**, and click **Edit**. Check the **Force Inactivity Timeout** check box, then adjust the number of minutes of inactivity before an active session in Secret Server will timeout and force users to login again. Click **Save** to save your changes.

Configuring IP Address Restrictions

To configure IP address restrictions, Search for **IP address restrictions** and click **New IP address**. Then provide the **IP Address User/Network Name** and the **IP Address Range**, click **Save**.

To set IP address restrictions at a user-level, Search for **Users**, select the related user from the list, then click **Edit** in the IP Restrictions section, and select the checkboxes for the restrictions you would like to enable for that user. **Save** changes.

To restrict group access into Secret Server by a specific IP address or IP address range, simply configure your IP address or range as listed above, then Search for **Groups**. Select the related group. Under the General tab, in the **IP address restrictions** section click **Edit**, and check the box for your desired IP Address/Range. **Save** changes to apply. Users will now be restricted from accessing Secret Server outside of the designated IP Address Range.

Managing Local Users

Create New Local Users

To create a new local user in Secret Server, Search for **Users** and click **Create user**. Provide the requested information on the **Add User** page.

Manage Local Users

Click on the **Username** for details about a specific local user. Secret Server will provide information including **User** and **Display Names**, **email address**, **Domain** affiliated, whether the user has **Two Factor** verification set up on their account, whether the user is **Enabled**, **Locked Out** from accessing their account, or whether the account is not a User account but an **Application Account**. The **View User** page also provides information about **Groups** and **Roles** for this user.

To edit these settings, click the **Edit** button. By editing a local user you may change their **display name**, **email address**, allow **Two Factor**, **disable/enable** the account, or **lock/unlock** the account.

You also can **create a new, one-time password** for the user's account. If you change a user's password they will be prompted for a new password after logging in with the Administrator-created password.

Managing Domain Users

Configuring Active Directory Sync

Secret Server can integrate with Active Directory by allowing users to use their Active Directory credentials to login to Secret Server. According to Common Criteria compliance, Active Directory relies **on LDAPv3 (RFC 2251) protocol**, which is not configurable by users.

In order to setup Active Directory in Secret Server, you will need to:

1. **Create a Sync Secret**
2. **Specify the domain to authenticate against**
3. **Configure TLS with Active Directory**
4. **Turn on Active Directory Sync**

Secret Server relies on a primary "Sync" secret to connect to the LDAPv3 server in Active Directory. Once connection has been made to Active Directory through this secret, Secret Server needs to know which domain within Active Directory to authenticate against, and within that domain which specific Active Directory Group(s) to synchronize with. The Active Directory Sync in Secret Server targets Secret Server user account credentials from Active Directory.

> Secret Server will categorize users according to group information from Active Directory, but Secret Server does not create, delete, or alter Active Directory Group Policies.

Create a Sync Secret

Before synchronizing users, you must first create a secret to be used as the Sync Secret. This secret should contain **Domain Admin credentials** (or an account with appropriate Active Directory permissions for **Read Access** to all

your organization's AD objects).

From Secret Server's dashboard you can create this secret through the Create Secret Widget.

1. Click **Create secret**, select **Active Directory Account** from the Choose a secret template dropdown list.
2. Add a **Secret Name** and provide the **Domain Name**, **Username**, and **Password** for the Sync Secret that will be able to access Active Directory with Admin credentials. **Save**.

Specify the Domain & Enable Active Directory Integration

Specify which domains Secret Server will be able to authenticate against. Secret Server can synchronize with any number of domains.

1. Once logged into Secret Server, Search for **Directory services**.
2. Under the Configuration tab, in the Directory services section, click **Edit**. Check **Enable Directory Services** and click **Save**.
3. Under the Configuration tab, in the User Synchronization section click **Edit**. Check to select **Enable User Synchronization** and specify the following:
   - **Synchronization Interval**: How often the synchronization will run in days, hours, minutes.
   - **User Account Options**: Select **User status mirrors Active Directory (Automatic)** from the drop-down. This allows Secret Server to mirror any changes made to Active Directory automatically.
   - **Automatic User Management**: Enabling this option will disable inactive users after a specified number of months.
   - **Days to Keep Operational Logs**: Logs older than this value are removed from the system. This value is typically not modified.
   - Click **Save**
4. Under the Domains tab click **Add domain** and select **Active Directory domain** from the dropdown.
   - Provide the **Fully Qualified Domain Name**
   - Provide a **Friendly Name**
   - Ensure that the box next to **Active** is checked.
   - Select your Synchronization secret by clicking **No Selected Secret** and search for the secret created earlier.
   - Select the related **Site** - the container in which heartbeat, RPC, and other Secret activities occur.
   - Click **Validate & save**.

The Active Directory Sync Secret will be used to synchronize users and groups, **it will require permission to search and view the attributes of the users and groups. If you plan on using Discovery (NOTE: Discovery is not under Common Criteria's scope), the account will also need Windows permissions to scan computers on the network for accounts.**

Configuring TLS with Active Directory

To ensure that TLS is configured with Active Directory:

- From the **Admin > Directory services**, under the Domains tab, click **Add domain** and select **Active Directory domain** from the dropdown (continuing from previous section), after entering the requested information, check the **Use LDAPS** box to enable. Click **Validate & save** to save this domain.

**If the TLS connection to Active Directory fails, the user will be notified and the failure will be logged. Secret Server does not automatically retry to connect to TLS but will retry the next time a user attempts to connect to AD.*

More information for setting up Active Domain with LDAPS can be found at

https://blogs.msdn.microsoft.com/microsoftrservertigerteam/2017/04/10/step-by-step-guide-to-setup-ldaps-on-windows-server/**"We're no longer updating this content regularly."**

Managing Domain Credentials

Updating Domain Credentials

Updating Active Directory (AD) Credentials and passwords happens directly through Active Directory and syncs with Secret Server according to a schedule. You can synchronize your Active Directory accounts at any time by navigating to **Admin > Directory services** and clicking the **Sync now** button. *You cannot add or edit Active Directory credentials through Secret Server directly*.

When a user logs into Secret Server using Active Directory credentials or uses an AD account to launch a session, the credentials are sent to the Domain Controller in real time for authentication verification. Therefore, if an AD user account has been updated or removed, changes will be reflected immediately in Secret Server.

Failed Domain Authentication

If the connection between Secret Server and the AD domain breaks, domain users Secret Server will fail to authenticate into Secret Server until the connection is re-established. Secret Server will log all failed authentication attempts by users.

To find these audit logs, Search for **Users >** select a user and select the **Audit** tab.

Common Criteria Roles and Permissions

User Roles can be edited by navigating to **Admin > Roles** and choosing **Assign Roles**, then **Edit**. On the Role Assignment page you will be able to select which users should be assigned to which role.

The **User Roles** that comply with Common Criteria standards are:

- **Administrator**
- **User**
- **Read Only User**

By default, Administrators have all possible Role Permissions. To view the list of role permissions and security attributes that associate to each User Role, Search for **Roles** and select each role to view the list of permissions. Each user session will be limited by the Role Permissions assigned to that user.

Each can be associated with individual user identities, or can be associated with either a local Group or an Active Directory Group. To assign a Role to a User or Group, Search for **Roles**, select a role and click Edit, then select the related User or Group from the list below.

To administer configurations required for Common Criteria standards, an Administrator requires the default role permissions that are included for the Administrator Role.

Assigning Roles to Users

The default role assignment for new users is set by navigating to **Admin > User Experience** section (scroll to bottom). To ensure that no new users are created or imported with any extra privileges, make sure that this setting is set to None.

To edit this default setting, click **Edit** and select **None** from the dropdown list next to Default New User Role. Then click **Save**.

To assign users to Roles that are compliant with Common Criteria standards to specific users or groups, Search for **Users**, select the related user, under the Roles tab click Edit, and select the related roles from the dropdown below. Alternatively, Search for **Roles**, select the related role from the list, click Edit, and select the related users from the list below.

Management Functions Based On Role

This section describes management activities and corresponding roles of the evaluated security functionality.

Role	Management Functions
Read-only User	Search and list Secrets
User	Use Secret/Launch session
User	Request access to Secret
Administrator	Create, view, expire, edit, and assign Secrets
Administrator	Perform bulk operations on Secrets
Administrator	Create and manage groups
Administrator	Create and manage roles, assign roles to users
Administrator	Create and manage containers (folders)
Administrator	Create and manage Secret policy
Administrator	Configure TOE SF (see Table 5)
Administrator	Create, manage, and unlock local accounts
Administrator	Configure IIS, SQL, syslog
Administrator	Update TOE

Table 1: Management Functions and Roles

By default each User Role is attached to Permission Sets. To view the specific permissions that each role is attached to, Search for **Roles** and click into the user roles listed to see the list of permissions.

Organizations can tailor these user roles to maintain whatever permissions settings are required for your specific user environment.

The following table specifies the user role required to allow each management activity listed according to Common Criteria Standards.

Requirement	Management Activities	Role
ESM_EAU.2	Management of authentication data for both interactive users and authorized IT entities (if managed by the TSF)	Administrator
ESM_EID.2	Management of authentication data for both interactive users and authorized IT entities (if managed by the TSF)	Administrator
ESM_ICD.1	Definition of identity and credential data that can be associated with users (activate, suspend, revoke credential, etc.)	Administrator
	Management of credential status	Administrator
	Enrollment of users into repository	Administrator
ESM_ICT.1	Configuration of circumstances in which transmission of identity and credential data (and object attributes, if applicable) is performed	Administrator
FAU_STG_ EXT.1	Configuration of external audit storage location	Administrator
FIA_AFL.1	Management of the threshold for unsuccessful authentication attempts	Administrator
	Management of actions to be taken in the event of an authentication failure	Administrator
FIA_USB.1	Definition of default subject security attributes, modification of subject security attributes	Administrator
FMT_MOF.1	Management of sets of users that can interact with security functions	Administrator
FMT_SMR.1	Management of the users that belong to a particular role	Administrator
FTA_SSL.3	Configuration of the inactivity period for session termination	Administrator
FTA_TAB.1	Maintenance of the banner	Administrator
FTP_ITC.1	Configuration of actions that require trusted channel (if applicable)	Administrator
FTP_TRP.1	Configuration of actions that require trusted path (if applicable)	Administrator

Table 2: Management Functions and Roles by Common Criteria Requirement

Managing User Passwords

Password Requirements for User Authentication

The Secret Server password policy for your user accounts is determined either through Active Directory or through Local User Passwords settings. To configure settings for Local User Passwords, Search for **Local User Password** and click **Edit**.

To meet Common Criteria Compliance regulations, passwords must be a **minimum of 16 characters** and include any subset of the following requirements (as demonstrated below):

- **Upper case letters**
- **Lower case letters**
- **Numbers**
- **These Special Characters: ! @ # $ % ^ & * ( )**

Passwords in Secret Server are randomly generated according to admin-defined password complexity policies. By default the generator requires at least one upper case letter, one lower case letter, one number, and one symbol. The number of each type of character can be modified, and custom character sets can be created and used in password policies.

Resetting User Authentication

To reset an Active Directory user account password, you must go *through Active Directory*.

To reset a Local User Password, follow these steps:

1. Search for **Users**.
2. Select the user who needs a reset.
3. Select **Edit**.
4. Type a new password twice. This is a *temporary password* that you must provide to the user. Immediately after the user logs into Secret Server they will be prompted to change their password.

If you are locked out of the Secret Server Local administrator account and you cannot request a reset through a linked administrator email account, contact the Delinea Support Team to request a password reset, and have your organization's **security pin code** at hand.

Setting Local User Password History Requirements

Ensure that local users cannot re-use old passwords to an administrator-settable number of past passwords used by that user.

1. Search for **Local User Passwords**.
2. Click **Edit**.
3. Check the toggle box next to **Enable Local User Password History**.
4. Set the number of historic passwords you would like to block for Secret Server Users.

5. Click the toggle next to **All** to block users from ever re-using any previous password.
6. Click **Save** to save changes.

Managing Secrets

Creating Secrets

Each object that is stored within Secret Server is referred to as a **Secret**. Usually, a Secret will be a username and password combination. Other examples of Secrets can include SSH keys, contact information, or safe combinations.

To create a Secret, use the Create Secret widget.

Select the type of Secret you want to create.

Enter the data for the Secret you want to save, and make sure to choose the Folder that the Secret will be saved into. Click **Save**, and your Secret has been created.

Configuring Secret Templates

Secret Server manages privileged account credentials through a highly configurable system of secrets. **Secret Templates** are used to create secrets and define object attributes for secrets. Templates can be configured according to account requirements.

The following is a list of Secret Templates that are compliant with Common Criteria standards available in the Government edition of Secret Server:

- **Active Directory Account**
- **Bank Account**
- **Combination Lock**
- **Contact**
- **Credit Card**
- **Password**
- **Pin**
- **Product License Key**
- **Security Alarm Code**
- **Social Security Number**
- **Unix Account (SSH Key Rotation)**

To follow Common Criteria standards, navigate to **Admin | Secret Templates** and click the **Active Templates** button. Ensure that only the templates listed above are selected in the Active column. Then **Save**. Users only can create Secrets using templates marked as Active.

To view object attribute data in a template from the dropdown list of Active Templates, **select a template** from the dropdown list and then click **Edit**.

Each of the listed templates below only hold object attribute data that are defined locally by Secret Server. The objects, secrets, and templates are as follows:

Object

Attribute

Objects in Secret Server are defined by attribute data. All object attribute data is locally defined by Secret Server.

Secret

Attributes Inherited from Template

Secret templates dictate the fields each secret contains, the launchers for each secret, and the remote password changer used. They also provide a default expiration, which can be changed on a per-secret basis.

Command Restrictions

Command restrictions are limited to SSH sessions and allow administrators to create multiple-choice command menus that users can follow. If SSH command menus are enabled, users cannot issue commands directly to the target system.

Field Data

Each field in a secret template is either “Text,” “Password,” or “Notes.” Password fields can be hidden from users and are updated when a password change has occurred on that secret’s account. Text fields are the standard field type and may include information such as “Domain” or “Username.”

Folder

Folders in Secret Server store individual secrets. Permissions applied to folders dictate which users can view the secrets inside that folder and which users can see the folders.

Password Requirements Rule Override

Password requirements can optionally be enforced on a per-template basis. If the password requirement is not enforced, users can manually type any password they want and will be notified if they enter a weak password that does not meet the password requirements. If the requirements are enforced, users cannot save the new password until it meets the requirements.

Policy Identifier

Secret policies are a collection of security and password settings that are applied to individual secrets or folders. Each setting of a secret policy can be configured as either default or enforced. Default allows users to later change the setting. Enforced locks the settings and cannot be modified on a per-secret basis unless the secret is moved out of the folder that has the secret policy attached. Secret policy settings include items such as “Remote Password Changing Auto Change,” and “Requires Approval for Access.”

Subject Identifier

The secret template of each secret identifies the type of store password or other data. This allows users to see the intended usage of each template.

Secret Name

The secret name is the label or title that describes the content of each secret. When Secret Server creates secrets automatically, the default naming convention is “host/account,” or “domain/account.”

Template

Field Parameters

Field parameters include username, password, and type. Secrets include a combination of field parameters that vary with user input. Secret type is defined by the template for each secret, such as “Bank Account” or “Active Directory Account.” The number of field parameters also are defined at the secret template level.

Password Change Policy

Password rotation is enabled or disabled on a per-secret or per-template basis.Password rotation frequency depends entirely on the expiration period for each secret. The default expiration time is 30 days for all secret templates.

Password Strength Policy

A password policy is a set of instructions on how each new password is created.Administrators must choose a minimum and maximum password length, which character sets are used, and how many characters from each set are required. See section 9.0 for details on setting password requirements.

Secret Expiration Policy

When a secret reaches its expiration date, it is flagged as “Expired.” If automatic password rotation is enabled for that secret, expiration triggers a remote password change. Expiration can be changed on each secret, but the default expiration period is set at the secret template level.

Secret Name Pattern

When Secret Server names a secret via the discovery import process, it uses the naming convention “hostname/username,” or “domain/username.” This is not enforced, so users can name secrets whatever they want.

Template Description

Secret template descriptions allow administrators to describe the purpose of a template when they create a new template, which is a best practice to avoid confusion.

Template Name

The secret template name is what users see in the drop-down menu when they create a new secret. It is also on the Secret Browse page so that users can see which secret template is associated with each secret.

Template Status

Like secrets, users can disable secret templates to make them invisible to users, unless they chose to view inactive templates. The status is either “enabled” or “disabled.”

Secret Access Policy

If users have view (or greater) rights, they can see whether a secret exists and can open the secret to view its data. If a user does not have view rights, the secret is invisible.

Secret Modification Policy

Each secret carries individual access permissions that are typically inherited from the secret's folder. These permissions determine which users can view the secret and which users can edit the secret's data. A user can have view, edit, or owner permission. With the view permission, a user can view but not modify a secret. The edit permission allows the user to modify field data. The owner permission allows users to grant or revoke access to other users.

Configuring Password Policy for Secret Templates

When creating and rotating passwords for secrets inside of Secret Server, it is important to uphold strong requirements and to use Secret Server to manage changing requirements effectively.

For example, Secret Server allows administrators to set the minimum password length to 6 characters, observe that a 7-character password and a 16-character password are both accepted, then change the minimum length to 8, observe that a 7-character password is then rejected but that a 16-character password is accepted.

In Secret Server password requirements can be set and applied *at the Secret Template level*. To adjust requirements:

1. Search for **Secret Templates**.
2. Select the **Password Requirements** tab.
   - To edit *all* your organization's default password requirements on secret templates, select the **Default** password requirement from the list.
   - To create a new password requirement specific to this template, click **Create**.
3. Adjust the **Password Length** and **Character Set** requirements to the needs of your organization. You may assign your new requirement to any Secret Template or templates.

Password Requirements set for these templates will be enforced for both human-generated and auto-generated secrets.

Authentication Strength for Non-Password Credentials

Secret Server uses RSA keys of 2048 bits or higher for secure authentication. These SSH keys are non-password credentials that can be managed by Secret Server. To ensure that these are maintained up to encryption standards, make sure that your **Unix Account (SSH Key Rotation)** Template is configured with an SSH Key Bit Size of 2048 or higher.

By default, the Government Edition of Secret Server will set this Template setting to 2048.

To adjust the bit size:

1. Search for **Secret Templates**.
2. Select **Unix Account (SSH Key Rotation)** from the dropdown list.
3. Click the **Edit** button.
4. From the Secret Template Designer page, click **Edit** to adjust settings. You can increase the bit size to 4096 from the default setting of 2048 if you choose, but do *not* lower this setting to 1024.

To create, store, and manage SSH keys in Secret Server, users must engage this Unix Account (SSH Key Rotation) Template. That means an SSH key will be created only when a standard encryption is enforced.

Configuring Remote Password Changing for SSH Key Rotation

Security Overview for SSH Key Rotation and PuTTY Launcher

SSH Key Rotation allows you to manage your Unix account private keys and passphrases as well as their passwords. The public/private key pair is regenerated and the private key is encrypted with a new passphrase any time a secret's password changes, either manually or automatically. The public key is then updated on the Unix machine referenced on the secret.

To use default SSH Key Rotation commands, the machine being managed must meet the following minimum requirements:

- SSH Key logins in OpenSSH format should be enabled on the target using keys. A secret can be created with keys in PuTTY format but they will be converted to OpenSSH when the key is rotated.
- Public keys should be stored in [~userhome]/.ssh/authorized_keys (not authorized_keys2).
- Grep and Sed should be installed on the target.
- If doing a privileged SSH Key Rotation, where a privileged user sets the key for another user, the privileged user must have sudo permissions that do not prompt for a password, as well as permissions to edit the user's authorized keys file with sudo.

If a system does not meet these requirements it may still be possible to do key rotation by modifying the key rotation command sets.

Creating a Unix Account (SSH Key Rotation) Secret

Under Secret Server's Common Criteria compliance standards, you can set up Secret Server to rotate SSH Keys for Unix Accounts.

To setup a Launcher, you will need a **Unix Account (SSH Key Rotation)** Secret that is connected to a remote machine

To create a Unix Account (SSH Key Rotation) Secret:

1. From the **Home** Dashboard select the **Unix Account (SSH Key Rotation)** Template from the **Create Secret** widget.
2. Enter a **Secret Name**, **Machine Name**, **Username**, and **Password** for the Unix/Linux Account.
3. Select the SSH **Private Key** by browsing to it on your machine.
4. Enter the **Private Key Passphrase** for the SSH Key. If there is a corresponding Public Key, upload that as well.

5. Specify which Secret Server folder you want to store the Key in if it differs from the default folder path. Likewise, determine what secret policies you want to assign to this SSH key, if any.

To automatically rotate the private and public SSH key pairing upon clicking **Save**, click **Generate New SSH Key**. This action is a security measure to ensure that no one can access your SSH key unless they are doing so through Secret Server's vault.

Enabling the Launcher

By default, the Launcher is enabled.

To verify this, click on **Admin > Launchers**, select the related launcher from the list, click **Edit** and ensure that this is set to **Yes**.

Using the Launcher

Note: SSL Certificates must be properly configured or the Launcher will fail to connect. So when you try to connect to Secret Server you receive a certificate error such as host name mismatch, you must resolve the cause of the error before the putty launcher will function. To directions on setting up certificates, see section **CREATE AN INTERNAL LINK** 11.2 Configuring X.509v3 Certificates.

1. From your Home screen, click the SSH secret
2. Click **View Secret**.
3. Click the **PuTTY Launcher** icon.

> The first time you perform this task you will receive a "**Protocol Handler Failed to Launch**" message. Select the type of launcher you need and **Run** the .msi file. Secret Server will download a very small process called a Protocol Handler that facilitates the connection between your machine and the endpoint. Once the Protocol Handler is downloaded, close out the "Failed to Launch" window and *refresh your browser page*.

4. Click the launcher icon on the secret, and provide the machine name if prompted. The credentials will be passed along to the launcher and will open the appropriate launcher PuTTY session.

Enable Remote Password Changing

> To maintain compliance with Common Criteria regulations, Remote Password Changing is applicable for SSH Key Rotation ONLY.

1. Search for **Remote Password Changing**.
2. Click **Edit**.
3. Check to select **Enable Remote Password Changing**.
4. Click **Save**.

Rotate SSH Key Remotely

1. Navigate back to the SSH Key Rotation Secret page.
2. At the bottom of the screen, click the **Change Password Remotely** button.
3. From the Change Password Remotely screen, **Generate** a new Password and Passphrase for your new SSH Key.
4. Next to Generate New SSH Key, leave the toggle checked.
5. Click **Change**. You will be directed to a **Password Scheduled for Change** screen.
6. Click **Back** to return to your secret's Remote Password Changing tab.
7. Navigate to the **General** tab.
8. Verify that a new password is listed. In the screenshot below you can see the previous passwords listed in the Notes section, confirming that the rotation was effective.
9. Click the **PuTTY Launcher** icon to confirm that Secret Server can still connect to the unix/linux machine using the newly rotated SSH Key.

Secret Expiration

A core feature of Secret Server is Secret expiration. Any template can be set to expire within a fixed time interval. For a Secret to expire, a field must be selected as the target of the expiration. For example, a Secret template for Active Directory accounts might require a change on the password field every 90 days. If the password remains unchanged past the length of time specified, that Secret is considered expired and will appear in the **Expired Secrets** panel on either the Dashboard's Expired Secrets widget or the Home page.

Secret expiration provides additional security by reminding users when sensitive data requires review. This can assist in meeting compliance requirements that mandate certain passwords be changed on a regular basis. When expiration is combined with Remote Password Changing, Secret Server can completely automate the process of regularly changing entire sets of passwords to meet security needs.

Setting up Secret Expiration for the Secret template

To set up expiration on a Secret, you must first enable expiration on the template from which the Secret is created.

To enable Secret expiration for a Secret template, Search for **Secret Templates**. In the Manage Secret templates page, select the template from the dropdown list and click the **Edit** button. In the Secret template Designer page, click on the Change link. On this subsequent page, check the **Expiration Enabled?** box. You can now enter the expiration interval (every x number of days) as well as the field on the Secret you wish to expire and require to be changed. The interval setting can be overridden for each individual Secret.

Enabling expiration for a template will enable expiration for all the Secrets that were created using this template.

Setting up Secret Expiration for the Secret

Now that expiration has been enabled for the template, Secret expiration is enabled for the Secrets that were created using that template as well as Secrets created in the future. The Expiration tab will appear on the Secret View page and requires the user to have Owner permission on the Secret. If you would prefer to set a custom expiration at the Secret level, you can adjust the interval of expiration for the Secret by clicking the **Expiration** tab in

the Secret View page. In the Expiration tab, you can set the Secret to expire using the template settings (default), a custom interval, or a specific date in the future.

Forcing Expiration

To force expiration, navigate to the **Secret View** page. From there, click **Expire Now**. This will force the Secret to expire immediately regardless of the interval setting. The expiration date will read "Expiration Forced".

Resetting an Expired Secret

To reset an expired Secret, you will need to change the field that has expired and is required to change. For example, if the field set to expire is the Password field and the current Password is "asdf", then a change to "jklh" will reset the expiration interval and thus remove the expiration text on the Secret View page.

If you do not know which field is set to expire, you will need to go to the Secret template that the Secret was created from. Search for **Secret Template** and select the template. Click the **Edit** button and then on the next page, click the "**Change**" link. In the "Change Required On" textbox you will see the field that is set to expire.

AutoChanging an Expired Secret

Remote Password Changing (RPC) is enabled under the Administration, Remote Password Changing page. Click **Edit** to enable Remote Password Changing, Secret Heartbeat, and Secret Checkout. Once enabled, all Secret templates with RPC configured will be available to use RPC.

The Remote Password Changing tab contains the settings for configuring RPC on an individual Secret. Enabling AutoChange on a Secret will allow Secret Server to Remotely Change the Password when it expires. The user must have Owner permission on the Secret to enable AutoChange. When editing on the RPC tab, the Next Password field can be set. If left blank an auto-generated password will be used.

To auto-change passwords based on secret expiration leave the AutoChange schedule set to "**None**."

If the password change fails, Secret Server will flag the Secret as Out of Sync and continue to retry until it is successful. If the Secret cannot be corrected or brought In Sync, manually disabling AutoChange will stop the Secret from being retried.

Setting the Password Change Retry Interval

Secret Server checks for expired secrets once every minute. However, if a previous password change attempt failed, Secret Server will not immediately try to change that password again the next time expired secrets are checked. Each secret template has a "Retry Interval" that it uses to determine how often to attempt retries of failed password changes. This exists to prevent unavailable machines or network connection issues from overwhelming the server or network with potentially thousands of password change requests at once. The default retry interval is one hour. To change the default, Search for **Secret Templates**, select the template you wish to change from the dropdown menu, and click **Edit**.

At the bottom of the **Secret Template Designer** page, click **Configure Password Changing**

On the **Secret Template Edit Password Changing** page, click **Edit**. Adjust the **Days**, **Hours**, and **Minutes** values of the **Retry Interval**. You can also adjust the **Maximum Attempts** if you want Secret Server to stop attempting to change the password after a specified number of failures. Click **Save** when done.

Configuring Common Criteria

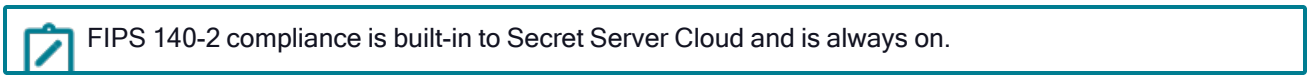
Verify Settings in Government Edition

Verify DPAPI Setting is Enabled

The Delinea Government Edition Installer will automatically set encryption in Secret Server to use DPAPI. To verify that DPAPI is in use, Search for **DPAPI** and ensure that DPAPI is enabled by checking the existence of the **Decrypt Key to not Use DPAPI** button.

If DPAPI is not enabled in your Secret Server installation, this button will say "**Encrypt Key to Use DPAPI**." To maintain compliance with Common Criteria standards do not decrypt the Secret Server key.

Verify FIPS Mode in Secret Server On-Premises is Enabled



Common Criteria evaluations rely on FIPS 140 validations to provide assurance that cryptographic functionality is implemented properly. The Secret Server Government Edition Installer checks for FIPS encryption security standards on the Windows local server and enables FIPS mode by default in Secret Server. To check this setting, Search for **FIPS** and ensure that the **Enable FIPS Compliance** line is set to **Yes**.

Manually Enabling FIPS in Secret Server On-Premises on Windows Local Servers

The **Secret Server Government Edition Installer** ensures that FIPS Compliance is automatically enabled in Windows on your local server. To verify or do this manually:

1. Go to **Windows Local Security Policy editor** (secpol.msc)
2. Navigate on your left pane to **Security Settings > Local Policies > Security Options**
3. Find and go to the property of **System Cryptography: Use FIPS Compliant algorithms for encryption, hashing, and signing...**
4. Choose **Enable** and click **OK**.
5. Restart your Server with **iisreset**.

The Microsoft .NET implementations of AES and SHA are not FIPS certified so Secret Server uses the Windows API versions for encryption functionality which *are* FIPS certified. **More information on the FIPS certificate numbers for the Windows operating systems, including the algorithm implementations that we use can be found at:**http://technet.microsoft.com/en-us/library/cc750357.aspx

Manually Disabling TLS v1.0

To disable the TLS 1.0 protocol so that IIS does not try to negotiate using the TLS 1.0 protocol, follow these steps:

1. Click **Start**, click **Run**, type regedt32 or type regedit, and then click **OK**.
2. In Registry Editor, locate the following registry key:

HKey_Local_Machine\System\CurrentControlSet\Control\SecurityProviders \SCHANNEL\Protocols\TLS 1.0\Server

If the subkeys “Server” or “Client” do not exist, create them under the TLS 1.0 key.

3. On the **Edit** menu for each subkey, click **Add Value**.
4. In the **Data Type** list for each subkey, click **DWORD**.
5. In the **Value Name** box for each subkey, type “**Enabled**,” and then click **OK**.

   *Note If this value is present, double-click the value to edit its current value.
6. Type **00000000** in Binary Editor to set the value of the new key equal to "0".
7. Click **OK**. Restart the Windows Server.

More information can be found at https://support.microsoft.com/en-us/help/187498/how-to-disable-pct-1-0-ssl-2-0-ssl-3-0-or-tls-1-0-in-internet-informat

Microsoft Cryptographic Engine

Secret Server relies on Windows Server 2016 Standard Edition or later to provide protocol and cryptographic functionality. Windows Server 2016 Standard Edition implements a FIPS certified (CMVP #2937) Cryptographic Primitives Library.

More information on the FIPS 140 certificate numbers for the Windows operating systems, including the algorithm implementations that we use can be found at: http://technet.microsoft.com/en-us/library/cc750357.aspx

The use of other cryptographic engines was not evaluated nor supported in the Common Criteria configuration.

Configuring X.509v3 Certificates

In order to maintain compliance with Common Criteria standards, the following installed certificates must follow the standard X.509v3 digital certificate structure.

**Do not use self-signed certificates in production environments.*

Installing Certificate in Trust Store

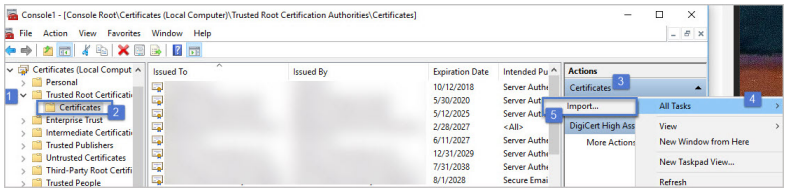
To best protect the users of your Secret Server website, use an SSL certificate from a trusted root authority and install it on your **web server(s)**.

- It is possible to use a self-signed certificate in demo or sandbox environments as long as **all other machines** used to access Secret Serverare also configured to trust the certificate. Otherwise, users will receive warnings about it being invalid and unsafe to navigate to your Secret Server URL.
- Local machines either need to Import your **public certificate** into the **Trusted People** certificate store if you used IIS to create it, or If you used OpenSSL and set up a **custom Root CA** to sign your web server certificate, the Root CA must be imported into the **Trusted Root Certification Authorities** store.
- If a **custom Intermediary CA** is created, this must also be imported into the **Intermediate Certification Authorities** store.

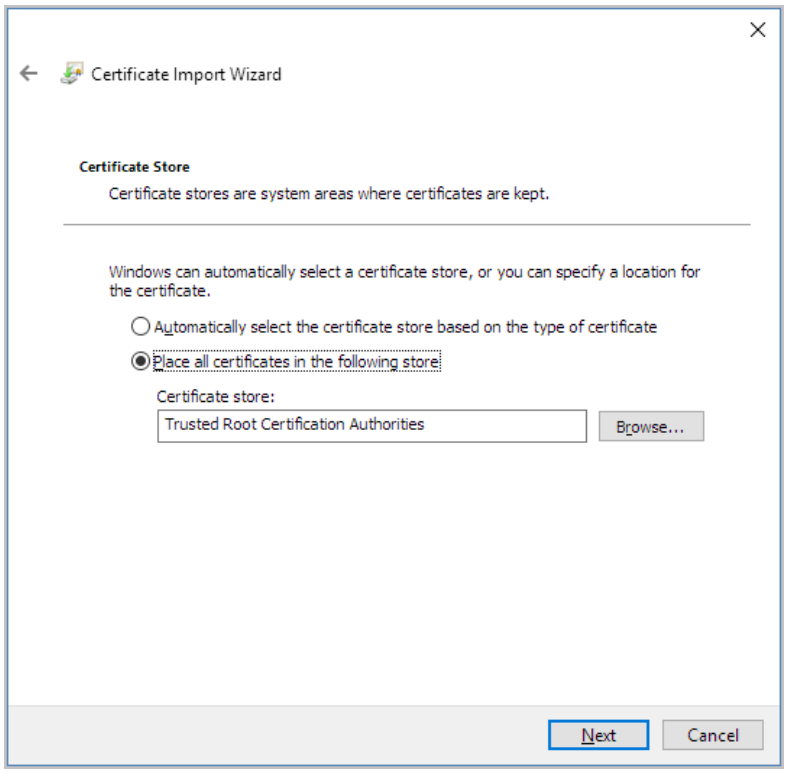
If Secret Server will be communicating with any remote server using TLS, any Root CAs and Intermediate CAs in the trust chains of the certificates presented by those remote servers must be added to the **Trusted Root Certification Authorities** and **Intermediate Certification Authorities** stores respectively. This includes syslog and LDAPS servers.

Follow the steps below to install a certificate in the Trusted Root CA store:

1. On your local machine open **mmc.exe**, select **File**, then **Add/Remove Snap-In…**
2. Next choose **Certificates** and then **Add**. Select **Computer Account**, then **Local Computer**. Click **Finish**.
3. Open **Certificates (Local Computer)**, then expand the **Trusted Root Certification Authorities** store/folder from the left pane and select **Certificates**, then in the right-side **Actions** pane select **More Actions**, **All Tasks**, and **Import…**



4. Click **Next** then select the certificate to import. This is usually a file with a file extension of .cer, .crt, .pem, or .pfx and click **Next**.
5. If prompted, enter the certificate's password and click **Next**.
6. Leave the selected options at the **Certificate Store** step and click **Next**.



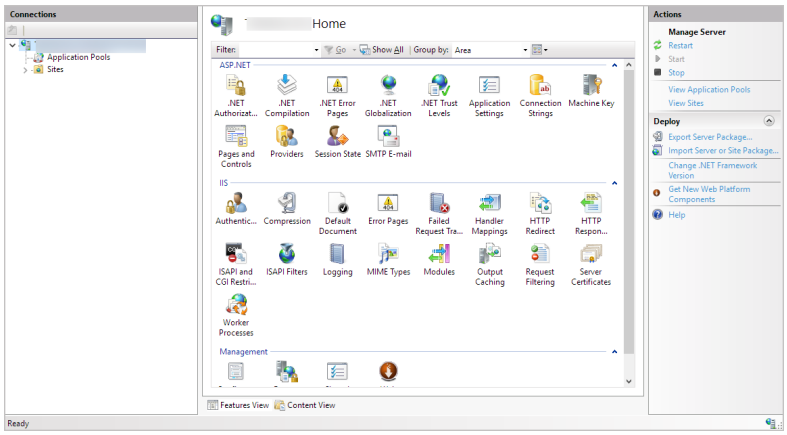
7. Click **Finish** to import the certificate

To import and Intermediate Certificate Authority follow the same steps for a Root Certificate Authority but select **Intermediate Certification Authorities** in step 3 instead of **Trusted Root Certification Authorities**. In step 6, the selected certificate store should also say **Intermediate Certification Authorities**.

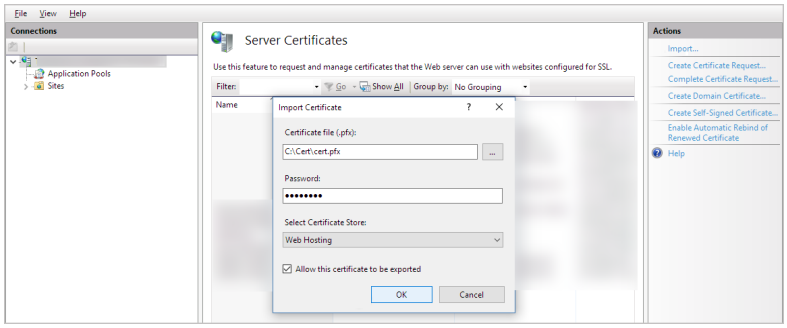
Configuring Web Certificate

To install a web certificate for use by IIS:

1. Open IIS Manager by clicking **Start**, clicking **Run**, typing in "**inetmgr**", and clicking **OK**.
2. Click on the server node (one of the root nodes) in the left panel, and double click on **Server Certificates**.



3. Click **Import...** in the right-hand **Actions** panel



4. Select the certificate to use, enter the password, select “Web Hosting” in **Select Certificate Store**, and click **OK**.

Alternatively, to create a self-signed certificate, click **Create Self-Signed Certificate** on the right panel and type in a Friendly Name.

> Note, using Self-Signed certificates is not compliant with Common Criteria standards. If using a self-signed certificate you must also export and install it on every user machine that connects to the Secret Server website.

Now that your certificate is installed, IIS must be configured to use it.

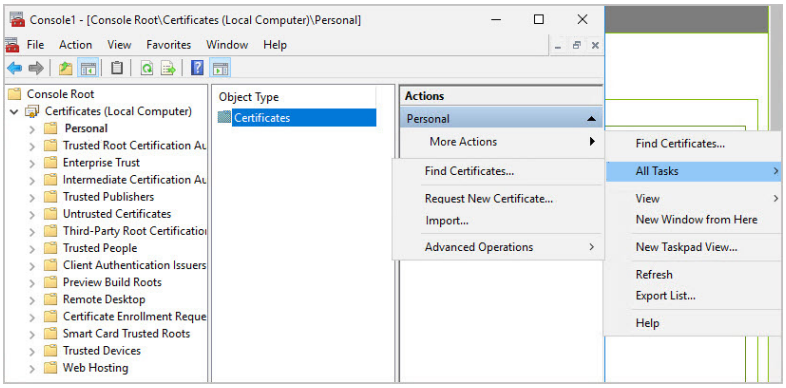
- In IIS Manager, click on your website in the left panel, then click **Bindings** on the right panel.
- If https is not already listed, click **Add**, select **https**, select the correct certificate, and click **OK**.
- If https was already listed, select it, click **Edit**, and select the correct certificate.

Configuring Client Certificates

Client Certificates can be used for **LDAPS** connections and for **Secure TCP** Syslog connections if your LDAPS or Secure TCP Syslog server requires one to be used.

You will need to install a Client Certificate on your **web server(s)** in the Local Computer’s **Web Hosting** (used by newer versions of IIS) or **Personal** Stores:

1. On your local machine open **mmc.exe**, select **File**, then **Add/Remove Snap-In…**
2. Next choose **Certificates** and then **Add**. Select **Computer Account**, then **Local Computer**. Click **Finish**.
3. Open **Certificates (Local Computer)**, then import your certificate by selecting the **Personal** or **Web Hosting** store/folder from the left pane, then **All Tasks**, and **Import…**

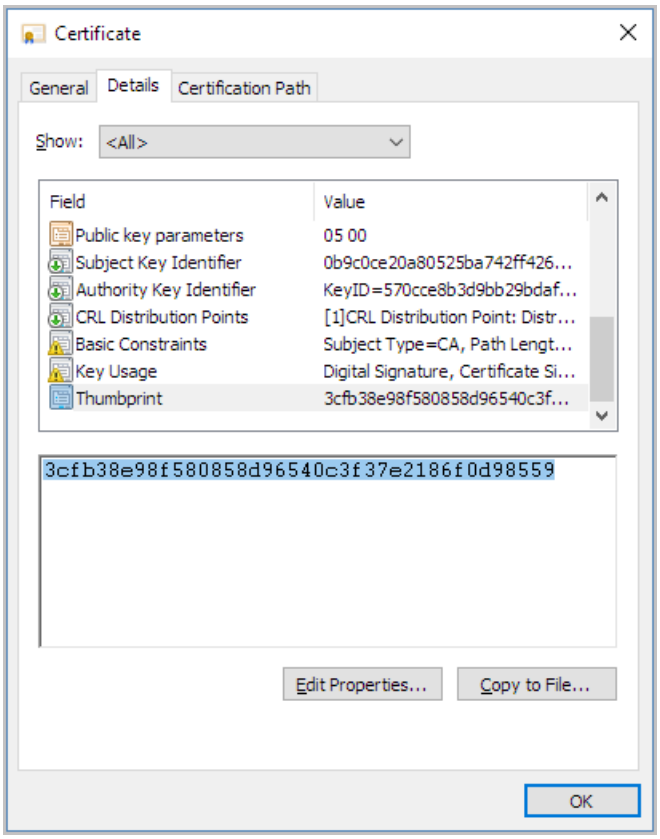


4. Follow the Import Wizard to complete the installation of the client certificate.If you are using an older version of IIS, or IIS is not installed on your machine, the Web Hosting store will not exist. In that case, import into the Personal store.

To enable Secret Server to send the client certificate to remote servers, you must first get the certificate thumbprint. This thumbprint will be added to Secret Server and used to identify which certificate to send when a client certificate is requested.

To get the certificate thumbprint:

1. Right-click on the certificate file in Windows Explorer or the certificate listed in MMC and select **Open**.
2. Select the **Details** tab.
3. Scroll down in the list of fields until you find **Thumbprint**. Select it. The value will be displayed in the box below the field list.



4. Select the text in this box and copy it by pressing **Ctrl+V**.

Now that you have the thumbprint copied to the clipboard, you can add it to Secret Server:

1. In Secret Server, select **Admin > TLS auditing**. The additional fields appear.
2. Paste the thumbprint in the **Client Certificate Thumbprint(s)** field. If you need to use more than one client certificate (for example, if you havemultiple Secret Server nodes with different client certificates), you can paste multiple thumbprints in this field.
3. Click **Save** when done.

Certificate Identifiers Overview

Certificates used for server authentication are verified by Secret Server using the verification provided by Microsoft Windows' Schannel. A certificate must contain a reference identifier that the client can use to verify that the server is presenting a matching certificate. This identifier can be contained in either the certificate **Subject** or **Subject Alternative Name (SAN)**. In order for the Subject to be verified as valid for a given server, it must contain a CN entry that contains the **Fully-Qualified Domain Name (FQDN)** of the server. If a certificate needs to be valid for more than one reference identifier, the certificate can contain a SAN that contains multiple entries. These entries can include both DNS names and IP addresses. If a certificate contains a SAN, the CN in the subject is ignored and only the entries in the SAN are used to validate the certificate against the server.

Configuring Transport Layer Security (TLS)

Common Criteria users must configure TLS in Secret Server. To enable TLS, follow the steps in the below sections:

TLS Configuration with AD

To configure TLS with Active Directory, follow the steps in section Configuring TLS with Active Directory.

TLS Configuration with IIS

According to Common Criteria security standards, you must force Secret Server through HTTPS/SSL for all website connections, ensure you are using an https URL in your Secret Server browser, then Search for **SSL**, click **Edit** and then check the **Force HTTPS/SSL** checkbox, followed by the **Enable HSTS**. We recommend adjusting the Maximum Age (in seconds) to a high number, for example for approximately six months, but we recommend up to one year. **Save** changes.

For more information on HSTS, see "Securing Traffic with HTTP Strict Transport Security" on page 784

Local Auditing

Understanding Local Audit Records and Reports

By design, Secret Server locally audits all actions taken within Secret Server. Secret Server's auditing capacity is not configurable. See **Auditable Events** for details on Secret Server items that are audited and corresponding user permissions required for accessing audit records.

Various User Permissions are tailored for specific kinds of audits, listed below. To adjust user permissions, Search for **Roles** and create a new role or click an existing role to edit the permissions on it. You can assign roles to individual users by going to **Admin > Users** and assigning roles.

- **Add Secret Custom Audit**
  Allows a user to make a custom audit entry when accessing a Secret using the web services API.
- **User Audit Expire Secrets**
  Allows a user to view the User Audit report, which shows all secrets that have been accessed by a particular user in a specified date range. Also allows the user to force expiration on all these secrets, which would make Secret Server automatically change the password.
- **View Configuration Unlimited Admin**
  Formerly "View Unlimited Vault Access Configuration," allows a user to view the Unlimited Vault Access Mode configuration. Also allows a user to view the Unlimited Vault Access Mode audit log.
- **View Secret Audit**
  Allows a user to view Secret Audit.
- **View User Audit Report**
  Allows a user to view, but not edit, the User Audit Report.

Accessing Local Reports

To view a list of out of the box reports, Search for **Security hardening**.

For customized reports and creation, see the **Audit** tab.

Administrator actions have audit trails inside Secret Server, these are generally found as a **View Audit** button on any landing page under the **Admin** tab.

For User Audits, navigate to **Reports > User Audit** tab, then select a user and time period to view the audit of all actions taken by that user in Secret Server.

Configuring Local Windows Event Log Auditing

Outside of Secret Server, you can also send audit logs as EVT records to your Windows Server's Windows Event Log locally**.**

Note that the Windows Event Log is tied to the syslog implementation, because of this, disabling syslog will disable Windows Event Logs as well. If Syslog/CEF Logging is not yet enabled within Secret Server, go to **Admin | Configuration** and **Edit** the General tab to check **Enable Syslog/CEF Logging** followed by **Write Syslogs As Windows Events**. *Syslog/CEF Logging configuration also detailed in section 13.3 Configuring Auditing for TLS Connections*

The following steps walk you through how to grant required permissions to the Application Pool outside of Secret Server to successfully write audits to the Windows Event Log:

Granting Application Pool Access to Windows Event Log

When the database becomes inaccessible, Secret Server will try to log errors to the Windows Event Log. By default, however, Network Service and standard service accounts will not have permissions to the Event Log. *Permissions must be manually added to the Application Pool for specific Event Log registry keys*.

> Changes made to the Windows registry happen immediately, no ***backup is created automatically. Do not edit the Windows registry unless youare confident about doing so. Using Registry Editor incorrectly can causeserious, system-wide problems that may require you to re-install Windows tocorrect them. Microsoft cannot guarantee that any problems resulting from*** the use of Registry Editor can be solved. Use this tool at your own risk.

Required Registry Permissions

The following permissions are required for the Identity configured on the Secret Server Application Pool in IIS (Network Service, IIS APPPOOL\SecretServer, etc.).

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog

Applies to "This key and subkeys".

- Read
  - Query Value
  - Enumerate Subkeys
  - Notify
  - Read Control
- Set Value
- Create Subkey

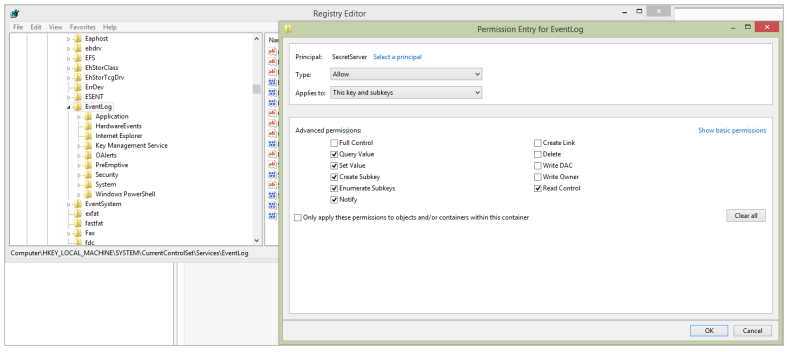
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog\Security

Applies to "This key and subkeys".

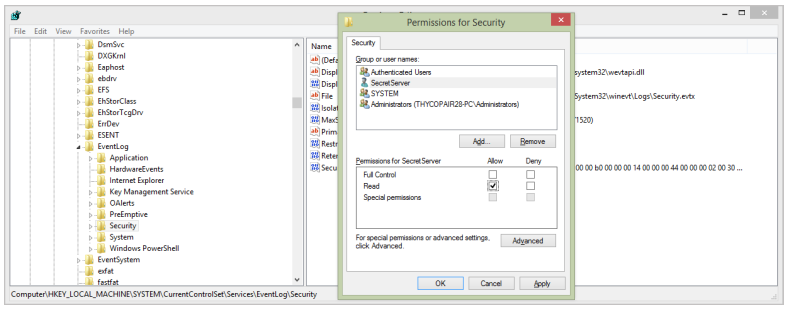
- Read
  - Query Value
  - Enumerate Subkeys
  - Notify
  - Read Control

How to Apply Windows Event Log Permissions

1. Determine the account that is running Secret Server. This can be done by Secret Server. logging in to Secret Server, **Admin > Diagnostics**. Select the **Background Processes** tab. Look for any of the "Thread Identity" labels. These will contain the identity of Secret Server (often NT AUTHORITY\NETWORK SERVICE or IIS APPPOOL\SecretServer).
2. Open the **Registry Editor** on the machine running Secret Server (**Start > run-regedit**, depending on OS)
3. On the left, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog**
4. Right click on the **EventLog** folder in your registry editor and select **Permissions**, then click the **Advanced** button
5. On the Permissions tab, Click **Add**
6. Click **Select a principal**.
7. Enter the name of your app pool's account (see step 1, for example: "IIS APPPOOL\SecretServer") in the box listed under **Enter the object name to select (examples).** Click **Check Names**, Once "SecretServer" (or the name of your Secret Server app pool) is listed in the box and underlined, click **OK**
8. Under **Basic permissions:**, check **Read**.
9. Click **Show advanced permissions**, then check **Set Value** and **Create Subkey** under **Advanced permissions:**.



10. Click **OK** on the remaining dialogs and **Apply** the permissions. You should be back on the main Registry Editor window.
11. Navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog\Security**, right-click and select **Permissions...**
12. Click **Add...**, find the account running Secret Server (like in step 7), then click **OK**.
13. Check **Read** in the **Allow** column, then click **OK** to apply the permission.

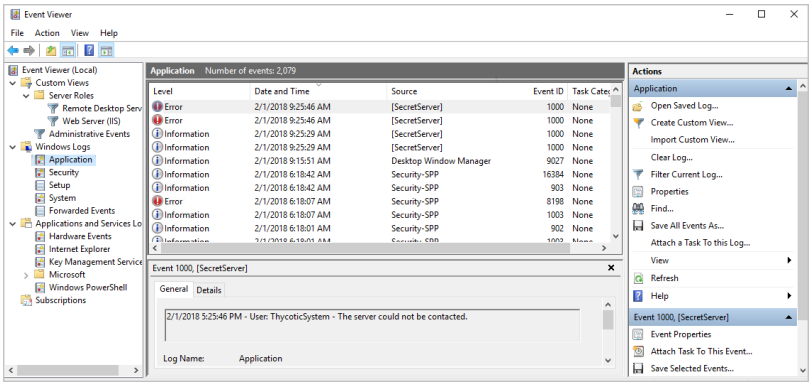


14. In Secret Server, Search for **General** tab to verify that the Application Setting **Write Syslogs as Windows Events** is set to **Yes**.

Accessing Windows Event Logs

After setting up Windows Event Logs to consume Secret Server logs you can access logs for local auditing and troubleshooting purposes through the **Windows Event Log Event Viewer** on Secret Server's local server.

To find the Windows Event Log, open the Windows **Event Viewer** from the local server and navigate to **Windows Logs | Application**. Event Logs for Secret Server will be listed as **[SecretServer]** under the **Source** column:



External Auditing

Security—Connecting to an External Audit Server

Using the **Secure TCP** Syslog/CEF Protocol will make Secret Server try to establish a secure connection to your external audit server. Secret Server will only use TLS v1.2 or v1.1 for security reasons.

If your audit server requires Client Certificates, see **Configuring Client Certificates**. If configured, Secret Server will pass the Secret Server certificate to the external audit server when it connects, so the audit server can validate the Secret Server machine.

If the connection between Secret Server and the external audit server is disconnected or cannot be established, Secret Server will log an internal error and automatically try to re-send any missed audit messages later. For more information, see **Determining Status of a Remote Audit Server**.

For a connection to be successfully established using Secure TCP protocol, Secret Server must trust the SSL certificates being used by the audit server. If the audit server is using a self-signed certificate, the Certificate

Authorities that created it must be installed on the Secret Server machine. If Secret Server has issues trusting the certificate, details will be logged internally.

More information on creating your own Certificate Authorities can be found at the OpenSSL Certificate Authority.

Configuring Syslog/CEF External Audit Server

Compatible Audit Servers

- syslog-ng
- Any Audit server that accepts TLS encrypted messages using the BSD Syslog Protocol

Configuring Your External Audit Server

1. Search for **Application**, then click **Edit**.
2. Check to enable **Enable Syslog/CEF Logging**.

> Syslog/CEF may require an additional license key. To install licenses, Search for **Licenses** and select **Install New License**. Once installed, you will need to activate your license. Contact your Delinea Sales Representative if you have questions about your licensing.

- **Syslog/CEF Server.** Configure the Syslog/CEF IP address for the IIS Server hosting the Syslog/CEF web application.
- **Syslog/CEF Port.** Next, configure the port number where the logging information will be passed for the **Syslog/CEF Port.** 6514 is the default port for Secure TCP Syslog. Secret Server requires outbound access to this server and port so communication can pass freely.
- **Syslog/CEF Protocol**. Set the Syslog/CEF Protocol to **Secure TCP**. This setting will accept either TLS v1.2 or v1.1 for added security, because other versions of SSL (i.e. SSL v3 and TLS v 1.0) have known weaknesses.
- **Syslog/CEF Time Zone**. Lastly set Syslog/CEF Time Zone to **UTC Time** or **Server Time** depending on your preference.

> The standard for Syslog is ISO timestamps; however, some still use the legacy format. Syslog is the default for upgrades to allow current configurations to retain their behavior, and ISO format is the default in new instances. Syslog format: Jun 23 2022 11:22:33. ISO 8601 format: 2022-06-23T11:22:33.000. You must enable the configuration preview to modify this setting.

Caching Syslog Audits

Once secure logging is enabled in Secret Server, if the connection breaks between the external Syslog server and Secret Server, failed syslog messages will be cached in the Secret Server database and re-sent at regular intervals until the connection between the syslog server and Secret Server is reestablished.

Compatibility Notes Related to Using Client Certificates

If you are using a Client Certificate, Secret Server's IIS AppPool must be granted access to use the certificate using the Windows HTTP Services Certificate Configuration Tool (WinHttpCertCfg.exe). Otherwise if Secret Server is configured to use a Client Certificate, and IIS doesn't have permission, you will see errors like this in the logs:

TLS Error Detected (Authentication Error connecting to IP:PORT) - The credentials supplied to the package were not recognized.

Example usage:
cd C:\Program Files (x86)\Windows Resource Kits\Toolswinhttpcertcfg.exe -g -c LOCAL_MACHINE\MY -s "CertificateSubject" -a "HOSTNAME\IIS APPPOOL\SecretServer"

Download the Windows HTTP Services Certificate Configuration Tool (WinHttpCertCfg.exe).

If you are using a Client Certificate and a Syslog-NG logging server, you may occasionally see this message in the main Syslog-NG log file:

SSL error while reading stream; tls_error='SSL routines:ssl_get_prev_session:session id context uninitialized'

On the Secret Server side, it shows up like this:

TLS Error Detected (Authentication Error connecting to IP:PORT) - Authentication failed because the remote party has closed the transport stream.

This error is caused because Windows tries to cache secure connections when client certificates are in use, but because Syslog-NG has not configured their OpenSSL "session id context", OpenSSL gives this error when it tries to resume a previous session.

Secret Server will automatically reconnect and resend any missed messages, so these errors really should cause no impact. However if you would like, you can disable Window's secure connection caching, by adding the ClientCacheTime setting set to 0 (zero) in the Registry, and then doing a reboot. This did not cause any significant performance impact in our internal testing, but your mileage may vary.

If Syslog-NG configures their OpenSSL session ID context, this error message correction will no longer be needed.

Configuring Auditing for TLS Connections

To track problems with TLS connections including whenever the connection might fail, enable the TLS Certificate Chain Policy and Error Auditing in Secret Server by navigating to **Admin > Configuration > Security** tab, then scrolling down to the TLS Auditing section.

- Ensure that the **Apply TLS Certificate Chain Policy and Error Auditing** is set to **Yes.** If not set to yes, Client Certificates cannot be used.
- Ensure that the **Enable TLS Debugging and Connection Tracking** is set to **Yes**. When set to yes, Secret Server will send information logs to your audit server about when TLS connections are opened or closed. If debug logging is enabled in "web-log4net.config" detailed information about X509 certificate chain validation will also be logged. Note that this setting may create a lot of extra messages in your log files.

To Edit click the **Edit** button and **check** the setting you want to turn on or uncheck the setting you want to turn off.

If the TLS connection breaks, an error message will be logged in the local audit trail and Secret Server will keep trying every 60 seconds to reestablish the TLS connection to the syslog server.

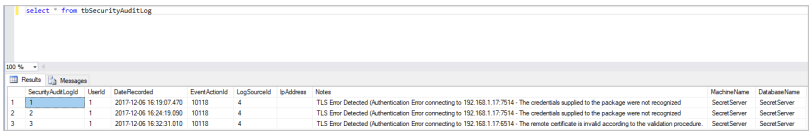
If Secure TCP is used for the Syslog/CEF Protocol, and there are one or more Client Certificate Thumbprints entered, Secret Server will check the Local Computer's Web Hosting and Personal certificate store and use the first one it finds. For more information see **Configuring Client Certificates**.

To add Client Certificate Thumbprints, you can copy and paste a list in bulk after clicking Edit, then Advanced (not required). Separate each SSL Certificate SHA1 Thumbprint (40 characters each) with a semicolon (up to ten total are allowed).

Determining Status of a Remote Audit Server

To view the logs for any TLS-Connection related errors:

- Open **Microsoft SQL Server Management Studio**, navigate to your SecretServer database (**DBMachineName > Databases > SecretServer**) and run a **New Query**.
- Type **select * from tbSecurityAuditLog** to view the events from your TLS Audit:



For more detailed troubleshooting reporting, refer to the logs in File Explorer on Secret Server's web server C:\inetpub\wwwroot\SecretServer\log) including ss.log, ss-BSSR.log (Background Scheduler), ss-BSWR.log (Background Worker) for any errors that might crop up.

Management Functions

This section describes management activities and corresponding roles of the evaluated security functionality

Roles and Management Functions

Role	Management Functions
Read-only User	Search and list Secrets
User	Use Secret/Launch session
User	Request access to Secret
Administrator	Create, view, expire, edit, and assign Secrets
Administrator	Perform bulk operations on Secrets
Administrator	Create and manage groups
Administrator	Create and manage roles, assign roles to users
Administrator	Create and manage containers (folders)

Role	Management Functions
Administrator	Create and manage Secret policy
Administrator	Configure TOE SF (see Table 16)
Administrator	Create, manage, and unlock local accounts
Administrator	Configure IIS, SQL, syslog
Administrator	Update TOE

By default each User Role is attached to various Permission Sets. To view the specific Delinea permissions that each role is attached to, Search for **Roles** and click into the user roles listed to see the list of Delinea permissions.

Organizations can tailor these user roles to maintain whatever Delinea permissions settings are required for your specific user environment.

The following table specifies the specific user roles required to allow each management activity listed.

Requirement	Management Activities	Role
ESM_EAU.2	Management of authentication data for both interactive users and authorized IT entities (if managed by the TSF)	Administrator
ESM_EID.2	Management of authentication data for both interactive users and authorized IT entities (if managed by the TSF)	Administrator
ESM_ICD.1	Definition of identity and credential data that can be associated with users (activate, suspend, revoke credential, etc.)	Administrator
	Management of credential status	Administrator
	Enrollment of users into repository	Administrator
ESM_ICT.1	Configuration of circumstances in which transmission of identity and credential data (and object attributes, if applicable) is performed	Administrator
FAU_STG_ EXT.1	Configuration of external audit storage location	Administrator
FIA_AFL.1	Management of the threshold for unsuccessful authentication attempts	Administrator
	Management of actions to be taken in the event of an authentication failure	Administrator
FIA_USB.1	Definition of default subject security attributes, modification of subject security attributes	Administrator

Requirement	Management Activities	Role
FMT_MOF.1	Management of sets of users that can interact with security functions	Administrator
FMT_SMR.1	Management of the users that belong to a particular role	Administrator
FTA_SSL.3	Configuration of the inactivity period for session termination	Administrator
FTA_TAB.1	Maintenance of the banner	Administrator
FTP_ITC.1	Configuration of actions that require trusted channel (if applicable)	Administrator
FTP_TRP.1	Configuration of actions that require trusted path (if applicable)	Administrator

Distributed Engine Hardening

Introduction

This topic discusses best practices for hardening Secret Server distributed engine servers.

If attackers compromise one of the DE servers, they would have access to all critical DBs, applications, and network devices at the network level. DEs do not store any passwords, PII, or user data in any configuration files.

Due to their intrinsic nature, some PowerShell script run by DEs may expose API usernames or passwords in the PowerShell log.

General Hardening Steps

Restrict RDP Connections

- Limit RDP connections to all PAM Server, except for PAM admins and some users from the hosting team.
- If there is no firewall segmentation in LAN network, you can accomplish this with the Windows OS firewall.

Restrict Incoming Port Access to All DE Servers

- Allow only RDP port access from some internal IPs.
- Allow a SSH proxy port coming from the user's LAN.
- Block all other incoming ports.

Remove Unnecessary User Groups

For administrator and Remote Desktop user groups:

- Remove default domain admins, administrator and some common groups.
- Create one group that is going to have access these servers.
- Disable the built-in local administrator user.

Rename Default Accounts

- Change the names of both the administrator and guest accounts to names that do not indicate their account permissions.
- Create a new locked and unprivileged "administrator" user name as bait.

Disable Services

Disable these services:

- Routing and remote access
- Smart card
- Smart card removal policy
- SNMP trap
- Special administration console helper
- Windows error reporting service
- WinHTTP Web proxy auto-discovery service

Restrict Network Protocols

Keep these:

- Client for Microsoft network
- File and printer sharing for Microsoft network
- Internet protocol version 4 (TCP/IPv4)

Remove these:

- QoS packet scheduler
- Link-layer topology discovery mapper IO driver
- Link-layer topology discovery responder

Validate Server Roles

Ensure only the minimum roles and features that are required are defined on the DE Servers. Remove all unnecessary roles and features.

The following roles are removal candidates, not ones to keep.

Roles

Application Server

- TCP port sharing
- Windows process activation service support

- Named pipe activation
- TCP activation

Remote Access

- Direct access and VPN (RAS)
- Routing
- Web application proxy (with dependent features)

Web Server (IIS)

- Web server
- Health and diagnostic
- Logging tools
- Tracing

Security

- Centralized SSL certificate support
- Client certificate mapping authentication
- Digest authentication
- IIS client certificate mapping authentication
- IP and domain restrictions
- URL authentication

Application Development

- Server side includes
- Web socket protocols
- Windows deployment services (with dependent features), including all child roles

Features

- Group policy management
- IIS hostable Web core
- Ink and handwriting services
- Media foundation
- RAS connection manager administration kit (CMAK)
- Remote server administration tools, including all child features.
- Windows internal database
- SMB 1.0/CIFS file sharing support

SSL/TLS Settings

Keep your server SSL/TLS settings up to date. Among other settings, the different protocols and cipher suites can be vulnerable to different attacks on SSL/TLS.

- Disable SSL 2.0
- Disable SSL 3.0
- Disable TLS 1.0
- Disable TLS 1.1
- Enable TLS 1.2

GPO Hardening

The following are recommended settings for Microsoft Group Policy Objects (GPO).

User Configuration > Policies > Administrative Templates > Control Panel/Personalization

Vulnerability:

There is no protection against a user with physical and remote desktop access to the server.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Enable screen saver	Enabled
Force specific screen saver	Enabled
Password protect the screen saver	Enabled
Screen saver timeout	Enabled Seconds: 600

Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies /Security Options

This setting enables advanced auditing in the operating system.

Policy	Recommended Value
Audit: Force audit policy subcategory settings to override audit policy category settings	Enabled

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Logon Account

Vulnerability:

Lack of information on unauthorized user login attempt. Lack of this type of information prevents identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Credential Validation	Success, Fail
Other Account Logon Event	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Account Management

Vulnerability:

Lack of information on user management in the system (addition and removal of users). Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Application Group Management	Success, Fail
Computer Account Management	Success, Fail
Distribution Group Management	Success, Fail
Other Account Management Events	Success, Fail
Security Group Management	Success, Fail
User Account Management	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Logon\Logoff

Vulnerability:

Lack of information on unauthorized user login attempt. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Account Lockout	Success, Fail
Logoff	Success, Fail
Logon	Success, Fail
Network Policy Server	Success, Fail
Other Logon\Logoff Event	Success, Fail
Special Logon	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Object Access

Vulnerability:

Lack of information on access to sensitive files and folders in the system. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

Applying Auditing for Success can overload the system. In case an overload is created, it is recommended to apply the auditing for Failure only.

Policy	Recommended Value
Application Generated	Success, Fail
Certification Services	Success, Fail
Detailed File Share	Fail
File Share	Success, Fail
File System	Success, Fail
Kernel Object	Success, Fail

Policy	Recommended Value
Registry	Success, Fail
Removable Storage	Success
SAM	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Policy Change

Vulnerability:

Lack of information on changes in the policy. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Audit Policy Change	Success, Fail
Authentication Policy Change	Success, Fail
Authorization Policy Change	Success, Fail
Filtering Platform Policy Change	Success, Fail
MPSSVC Rule-Level Policy Change	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > Privilege Use

Vulnerability:

Lack of information on the use of system authorizations. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Non Sensitive Privilege Use	Success, Fail
Sensitive Privilege Use	Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Advance Audit Policy Configuration > System

Vulnerability:

Lack of information on system start-up, shutdown and system changes. Lack of this type of information will prevent identification of intruders to the system, as well as inability to check access to the server or its resources.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Other System Events	Success, Fail
Security State Change	Success, Fail
Security System Extension	Success, Fail
System Integrity	Success, Fail

Computer Configuration > Policies > Windows Settings > Security Settings > Event Log

Vulnerability:

There is a risk that many log records will not be saved due to the file's size.

Severity of the damage:

Medium

Operational aspects:

None

Policy	Recommended Value
Maximum application log size	100032 KB
Maximum security log size	100032 KB
Maximum system log size	100032 KB

Policy	Recommended Value
Prevent local guests group from accessing application log	Enabled
Prevent local guests group from accessing security log	Enabled
Prevent local guests group from accessing system log	Enabled
Retention method for application log	As needed
Retention method for security log	As needed
Retention method for system log	As needed

Computer Configuration > Policies > Windows Settings > Security Settings > Registry

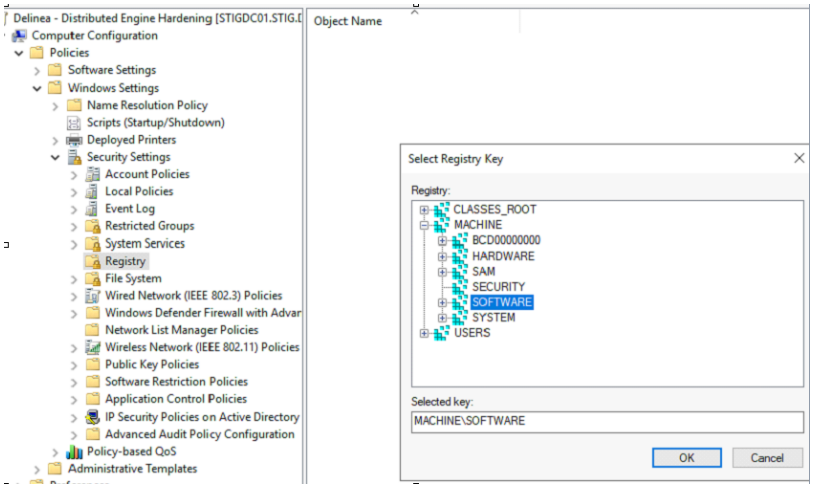
The purpose of this GPO setting is to add auditing to the following registry keys:

- HKLM\SYSTEM
- HKLM\SOFTWARE

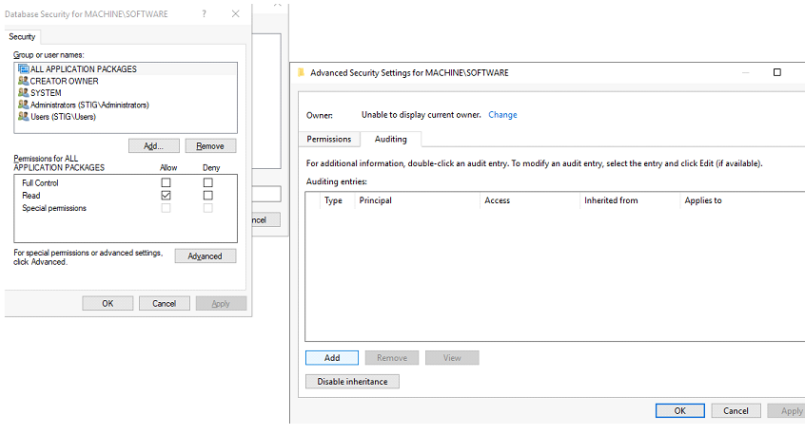
Auditing should be applied according to the following parameters:

- Audit - Success only: Set Value
- Audit - All: Create Subkey, Create Link, Delete, Read Permissions, Change Permissions

1. Right click on Registry, select Add Key, then select MACHINE\SOFTWARE.

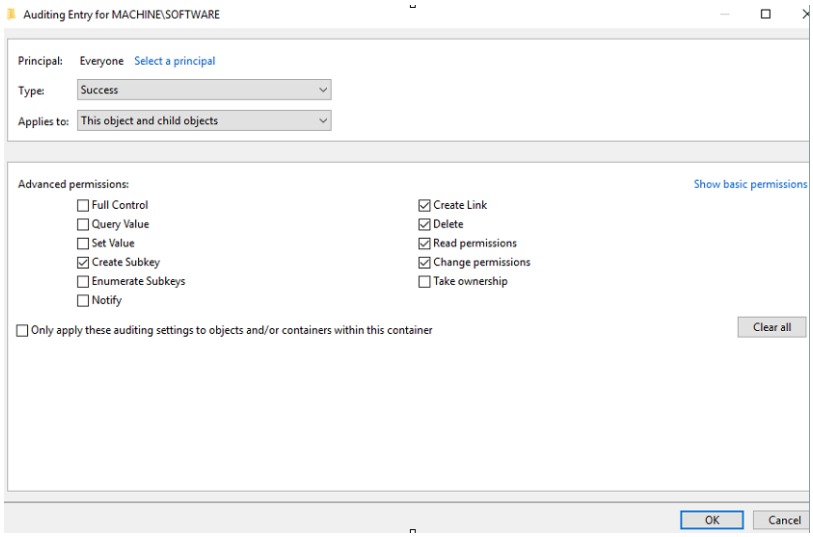


2. Click Advanced, select Auditing tab, click Add.

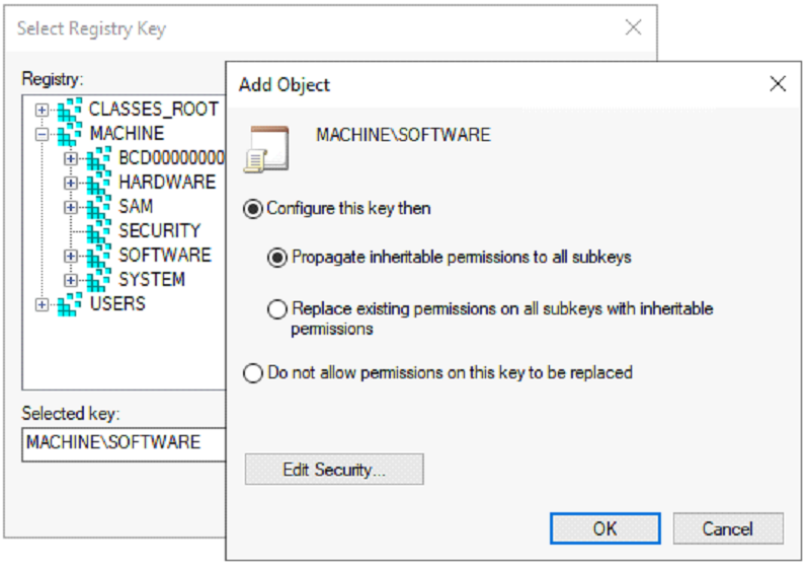


3. Change Principal to Everyone, select Show Advanced Permissions, select the following boxes:

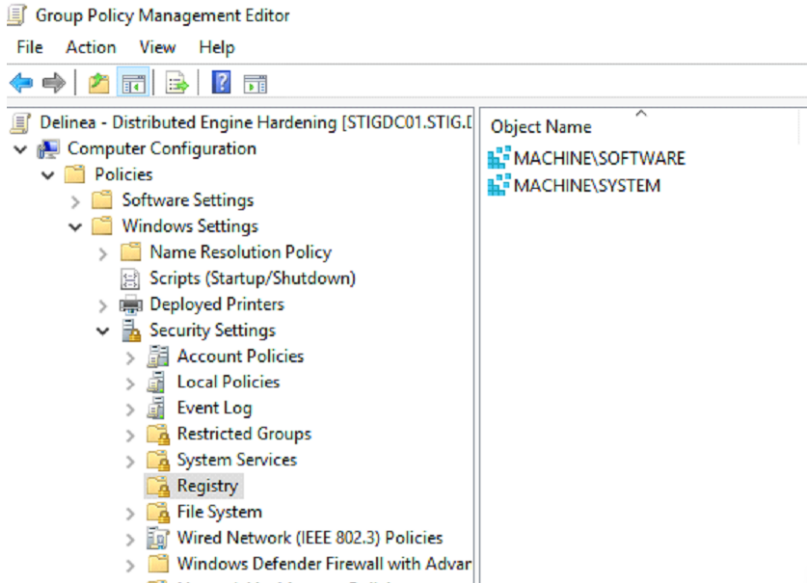
- Create Subkey
- Create Link
- Delete
- Read Permissions
- Change Permissions



4. Click OK, then click Apply Settings.



5. Perform the same steps above for MACHINE\SYSTEM.



Computer Configuration > Policies > Windows Settings > Security Settings > File System

The purpose of this GPO setting is to add auditing to the following directories:

- `%SystemRoot%\System32\Config`
- `%SystemRoot%\System32\Config \RegBack`

Vulnerability:

Lack of information on delete, change of authorizations, gain ownership of sensitive files, or any attempt to do so, will prevent the ability to identify unauthorized access and therefore will make it difficult to prevent such attempts.

Severity of the damage:

Medium

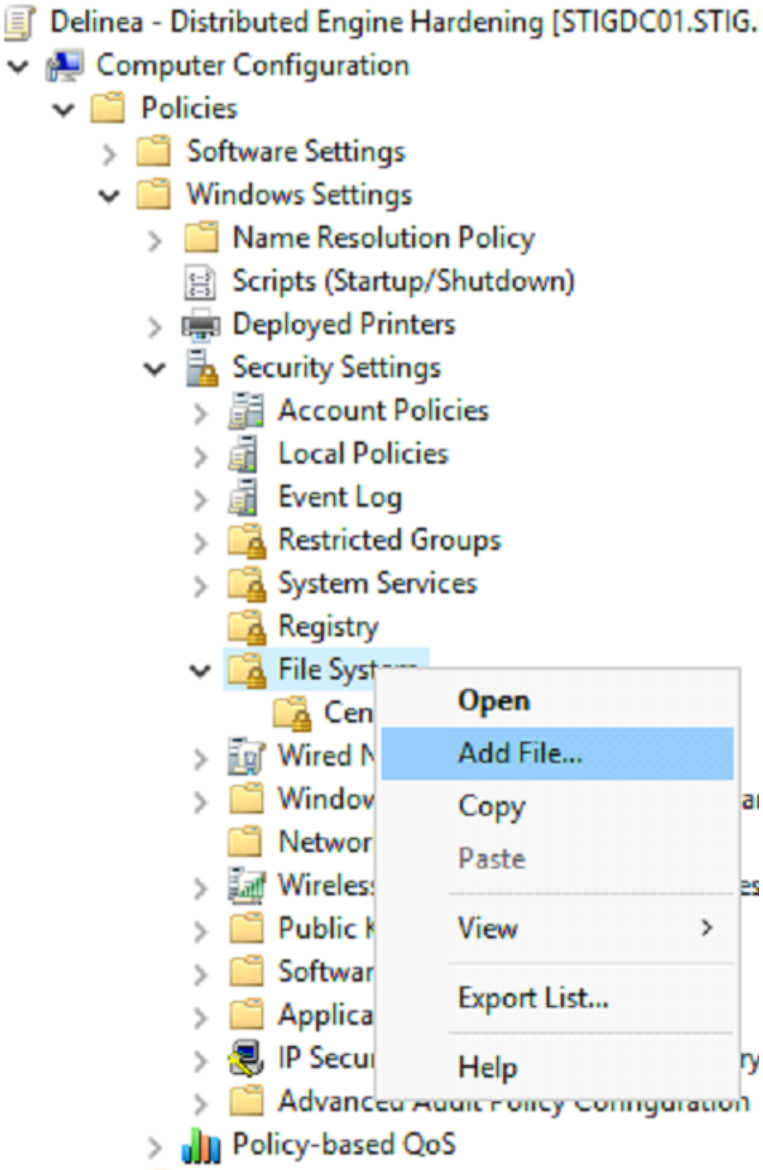
Operational aspects:

None

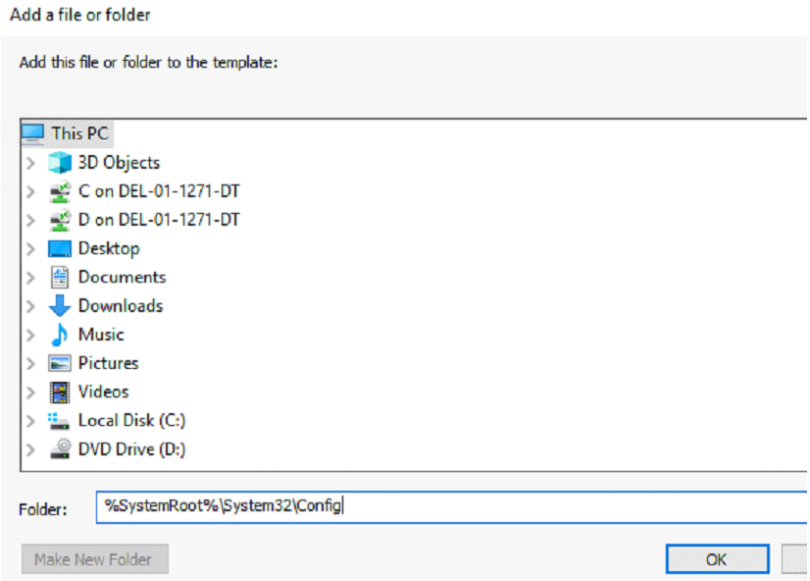
Windows permissions and auditing should be applied according to the following parameters:

- Audit-Failure only: Traverse Folder\ Execute File, List Folder\ Read Data, Read Attributes, Read Extended Attribute.
- Audit - All: Create Files\ Write Data, Create Folders\ Append Data, Write Attributes, Write Extended Attributes, Delete Subfolders And Files, Delete, Change Permissions, Take Ownership.
- Permissions: Administrator, System - Full

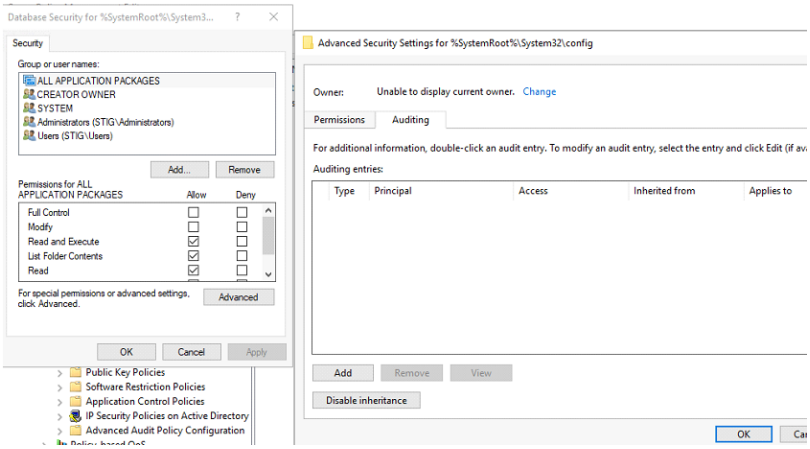
1. Right click File System, click Add File.



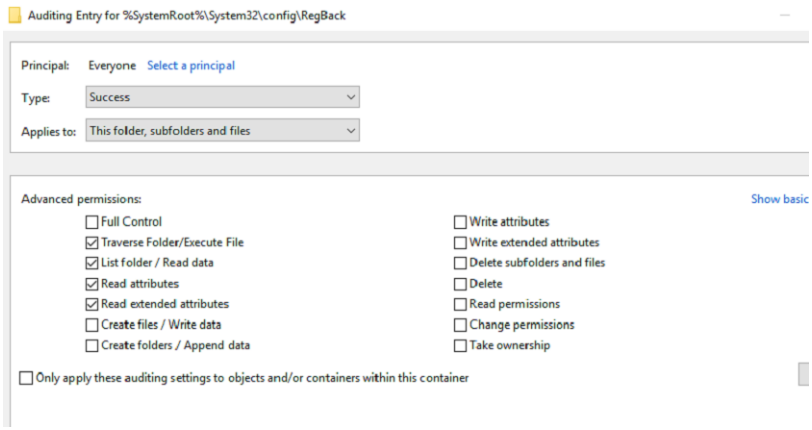
2. Add the folder path *%SystemRoot%\System32\Config*



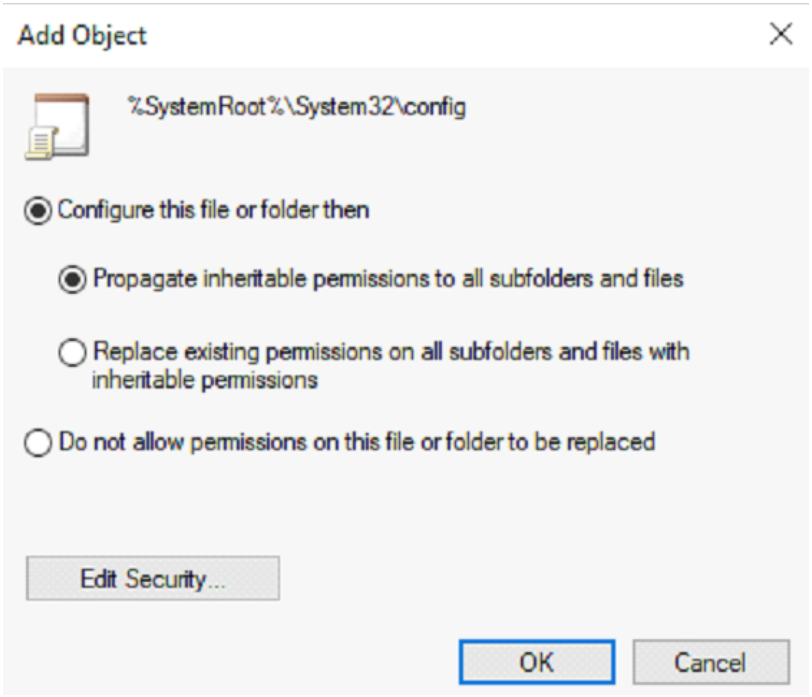
3. Click Advanced, then click Auditing tab, and click Add.



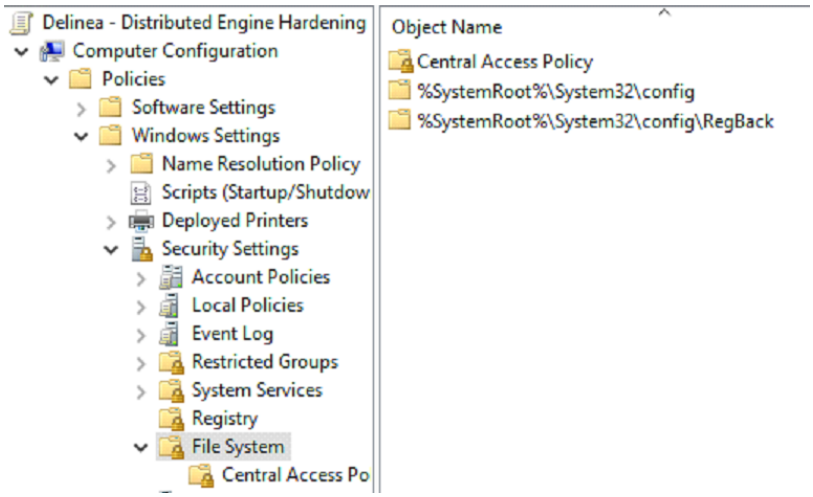
- Change Principal to Everyone, select Show Advanced Permissions, and select the following boxes:
- Traverse Folder\ Execute File
- List folder\ Read data
- Read attributes
- Read extended attribute



4. Click OK, then click Apply Settings.



5. Perform the same steps above for *SystemRoot%\System32\Config\RegBack*



Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies/Security Options

Policy	Recommended Value	Comment or Vulnerability
Accounts: Administrator account status	Enabled	
Accounts: Guest account status	Disabled	
Accounts: Limit local account use of blank passwords to console logon only	Enabled	
Accounts: Rename administrator account	It is recommended to change both the Administrator and the guest names to a name that will not testify about their Windows permissions, and also to create a new locked and unprivileged user name Administrator as bate	Comment: Apply this parameter according to the organization security policy. Vulnerability: The administrators default name is known as a high privilege user. This user is a target for hacking attempts. Severity of the damage: Medium Operational aspects: None
Audit: Audit the use of Backup and Restore privilege.	Enabled	Vulnerability: The system does not monitor backup and restore activities of files, therefore it does not allow exposing unusual activities in this area. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Devices: Allowed to format and eject removable media	Administrator	Vulnerability: Users may be able to move data on removable disks to a different computer where they have administrative privileges. The user could then take ownership of any file, grant themselves full control, and view or modify any file. The fact that most removable storage devices will eject media by pressing a mechanical button diminishes the advantage of this policy setting. Severity of the damage: Low Operational aspects: None
Devices: Prevent users from installing printer drivers	Enabled	Vulnerability: A malicious user could install inappropriate printer drivers in a deliberate attempt to damage the computer, or a user might accidentally install malicious software that masquerades as a printer driver. Severity of the damage: Low Operational aspects: None
Domain member: Disable machine account password changes	Disabled	Vulnerability: Computers that cannot automatically change their account password are at risk from an attacker who could determine the password for the computer's domain account. Severity of the damage: Low Operational aspects: None
Domain member: Maximum machine account password age	30 days	Vulnerability: Setting this parameter to 0 will allow an attacker to execute Brute Force attacks to find the computer account password. Severity of the damage: Low Operational aspects: None
Domain member: Require strong (Windows 2000 or later) session key	Enabled	Vulnerability: Session keys that are used to establish secure channel communications between domain controllers and member computers are much stronger in Windows 2000 than they were in previous Windows operating systems. Severity of the damage: Low Operational aspects: None
Interactive logon: Do not display last user name	Enabled	Vulnerability: An attacker with access to the console (for example, someone with physical access or someone who is able to connect to the server through Remote Desktop Services, also known as Terminal Services) could view the name of the last user who logged on to the server. The attacker could then try to guess the password, use a dictionary, or use a brute force attack to try to log on. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Interactive logon: Do not require CTRL+ALT+DEL	Disabled	Vulnerability: If users are not required to press CTRL+ALT+DEL, they are susceptible to attacks that attempt to intercept their passwords, If this setting is enabled, an attacker could install a Trojan horse program that looks like the standard logon dialog box in the Windows operating system, and capture the user's password. Severity of the damage: Low Operational aspects: None
Interactive logon: Number of previous logons to cache (in case domain controller is not available).	0	Vulnerability: Users who access the server console will have their logon credentials cached on that server. An attacker who is able to access the file system of the server could locate this cached information and use a brute force attack to attempt to determine user passwords. Severity of the damage: Medium Operational aspects: The local Administrator password should be known in case of DC unavailability.

Policy	Recommended Value	Comment or Vulnerability
Interactive logon: Require Domain Controller authentication to unlock workstation	Enabled	Vulnerability: By default, the computer caches in memory the credentials of any users who are authenticated locally. The computer uses these cached credentials to authenticate anyone who attempts to unlock the console. When cached credentials are used, any changes that have recently been made to the account-such as user rights assignments, account lockout, or the account being disabled-are not considered or applied after the account is authenticated. User privileges are not updated, and (more important) disabled accounts are still able to unlock the console of the computer. Severity of the damage: Medium Operational aspects: The local Administrator password should be known in case of DC unavailability
Microsoft network client: Send unencrypted password to third-party SMB servers.	Disabled	Vulnerability: The server can transmit passwords in plaintext across the network to other computers that offer SMB services. These other computers might not use any of the SMB security mechanisms that are included with Windows Server 2003 and above. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Microsoft network server: Amount of idle time required before suspending session	15 minutes	Vulnerability: Each SMB session consumes server resources, and numerous null sessions will slow the server or possibly cause it to fail. An attacker could repeatedly establish SMB sessions until the server's SMB services become slow or unresponsive. Severity of the damage: Medium Operational aspects: None
Microsoft network server: Attempt S4U2Self to obtain claim information	Disabled	Vulnerability: Enabling this policy setting allows you take advantage of features in Windows Server 2012 and Windows 8 for specific scenarios to use claims-enabled tokens to access files or folders that have claim-based access control policy applied on Windows operating systems prior to Windows Server 2012 and Windows 8. Severity of the damage: Medium Operational aspects: None
Microsoft network server: Server SPN target name validation level	Off	Vulnerability: This policy setting controls the level of validation that a server with shared folders or printers performs on the service principal name (SPN) that is provided by the client computer when the client computer establishes a session by using the SMB protocol. The level of validation can help prevent a class of attacks against SMB servers (referred to as SMB relay attacks). This setting will affect both SMB1 and SMB2. Severity of the damage: Low Operational aspects: None
Network access: Do not allow anonymous enumeration of SAM accounts	Enabled	Vulnerability: An unauthorized user could anonymously list account names and shared resources and use the information to attempt to guess passwords or perform social engineering attacks. Severity of the damage: Medium Operational aspects: None
Network access: Do not allow anonymous enumeration of SAM accounts and shares	Enabled	Vulnerability: An unauthorized user could anonymously list account names and shared resources and use the information to attempt to guess passwords or perform social-engineering attacks. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Network access: Do not allow storage of passwords and credentials for network authentication.	Enabled	Vulnerability: Passwords that are cached can be accessed by the user when logged on to the computer. Although this information may sound obvious, a problem can arise if the user unknowingly runs malicious software that reads the passwords and forwards them to another, unauthorized user. Severity of the damage: Medium Operational aspects: This parameter could affect windows schedule task services
Network access: Let Everyone permissions apply to anonymous users	Disabled	Vulnerability: The system will allow all users, including users who have not identified themselves in the Domain, perform operations of reading information related to user accounts and the names of the shares. Severity of the damage: Medium Operational aspects: None
Network access: Named Pipes that can be accessed anonymously	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: Ability to remotely access data on the system by an unauthorized user. Severity of the damage: Low Operational aspects: None
Network access: Remotely accessible registry paths	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: An attacker could use information in the registry to facilitate unauthorized activities. To reduce the risk of such an attack, suitable ACLs are assigned throughout the registry to help protect it from access by unauthorized users. Severity of the damage: Low Operational aspects: None
Network access: Remotely accessible registry paths and subpaths	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: An attacker could use information in the registry to facilitate unauthorized activities. To reduce the risk of such an attack, suitable ACLs are assigned throughout the registry to help protect it from access by unauthorized users. Severity of the damage: Low Operational aspects: None
Network access: Restrict anonymous access to Named Pipes and Shares.	Enabled	Vulnerability: Null sessions are a weakness that can be exploited through shared folders on computers environment. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Network access: Shares that can be accessed anonymously	List has been deleted	The policy was enabled and the existing list was deleted. Vulnerability: Any shared folders that are listed can be accessed by any network user, which could lead to the exposure or corruption of sensitive data. Severity of the damage: Medium Operational aspects: None
Network access: Sharing and security model for local accounts	Classic - Local users authenticate as themselves	Vulnerability: With the Guest only model, any user who can authenticate to the server over the network does so with guest privileges, which means that they will not have write access to shared resources on that server. Although this restriction does increase security, it makes it more difficult for authorized users to access shared resources on the server because ACLs on those resources must include access control entries (ACEs) for the Guest account. With the Classic model, local accounts should be password protected. Otherwise, if Guest access is enabled, anyone can use those user accounts to access shared system resources. Severity of the damage: Low Operational aspects: None
Network security: Do not store LAN Manager hash value on next password change	Enabled	Vulnerability: The SAM file can be targeted by attackers who seek access to user name and password hashes. Such attacks use special tools to discover passwords, which can then be used to impersonate users and gain access to resources on your network. Severity of the damage: Medium Operational aspects: None
Network security: Force logoff when logon hours expire	Enabled	Vulnerability: Users can remain connected to the computer outside of their allotted logon hours. Severity of the damage: Low Operational aspects: None
Network security: LAN Manager authentication level	Send NTLMv2 Responses Only/Refuse LM & NTLM	Vulnerability: The system allows identification of users in the old LM and NTLM protocols. The old identification protocols are vulnerable to attacks. Severity of the damage: Medium Operational aspects: These parameters could effect on legacy system if the system don't support NTLMv2

Policy	Recommended Value	Comment or Vulnerability
Network security: Minimum session security for NTLM SSP based (including secure RPC) clients	Require NTLMv2 session security Require 128-bit encryption	Vulnerability: Network traffic that uses the NTLM Security Support Provider (NTLM SSP) might be exposed such that an attacker who has gained access to the network can create man-in-the-middle attacks. Severity of the damage: Medium Operational aspects: None
Network security: Minimum session security for NTLM SSP based (including secure RPC) servers	Require NTLMv2 session security Require 128-bit encryption	Vulnerability: Network traffic that uses the NTLM Security Support Provider (NTLM SSP) might be exposed such that an attacker who has gained access to the network can create man-in-the-middle attacks. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Recovery console: Allow automatic administrative logon	Disabled	Vulnerability: The Recovery Console can be very useful when you need to troubleshoot and repair computers that do not start. However, it is dangerous to allow automatic logon to the console. Anyone could walk up to the server, disconnect the power to shut it down, restart it, select Recover Console from the Restart menu, and then assume full control of the server. Severity of the damage: Medium Operational aspects: None
Recovery console: Allow floppy copy and access to all drives and all folders	Disabled	Vulnerability: An attacker who can cause the system to restart into the Recovery Console could steal sensitive data and leave no audit or access trail. Severity of the damage: Low Operational aspects: None
Shutdown: Allow system to be shut down without having to log on	Disabled	Vulnerability: Users who can access the console locally could shut down the computer. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Shutdown: Clear virtual memory pagefile	Enabled	Vulnerability: Important information that is kept in real memory may be written periodically to the paging file to help the operating system handle multitasking functions. An attacker who has physical access to a server that has been shut down could view the contents of the paging file. The attacker could move the system volume into a different computer and then analyze the contents of the paging file. Although this process is time consuming, it could expose data that is cached from random access memory (RAM) to the paging file. Severity of the damage: Low Operational aspects: It takes longer to shut down and restart the computer, especially on computers with large paging files.
System Settings: Optional subsystems	No one	Enable the policy and delete the existing list of users that will be populated by default. Vulnerability: The POSIX subsystem introduces a security risk that relates to processes that can potentially persist across logons. If a user starts a process and then logs out, there is a potential that the next user who logs on to the computer could access the previous user's process. This would allow the second user to take actions on the process by using the privileges of the first user. Severity of the damage: Low Operational aspects: None
System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies	Enable	Vulnerability: Without the use of software restriction policies, users and computers might be exposed to the running of unauthorized software, such as viruses and Trojans horses. Severity of the damage: Medium Operational aspects: None
User Account Control: Use Admin Approval Mode for the built-in Administrator account	Enable	Vulnerability: Malicious software running under elevated credentials without the user or administrator being aware of its activity. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
User Account Control: Allow UIAccess applications to prompt for elevation without using the secure desktop	Disable	Vulnerability: Without the use of software restriction policies, users and computers might be exposed to the running of unauthorized software, such as viruses and Trojans horses. Severity of the damage: Medium Operational aspects: None
User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode	Prompt for consent for non-Windows binaries	Vulnerability: Malicious programs running under elevated credentials without the user or administrator being aware of their activity. This setting raises awareness to the user that a program requires the use of elevated privilege operations and requires that the user be able to supply administrative credentials in order for the program to run. Severity of the damage: Medium Operational aspects: None
User Account Control: Behavior of the elevation prompt for standard users	Prompt for credentials on the secure desktop	Vulnerability: Malicious programs running under elevated credentials without the user or administrator being aware of their activity. This setting raises awareness to the user that a program requires the use of elevated privilege operations and requires that the user be able to supply administrative credentials in order for the program to run. Severity of the damage: Low Operational aspects: None
User Account Control: Run all administrator in admin approval mode	Enable	Vulnerability: This is the setting that turns on or off UAC. If this setting is disabled, UAC will not be used and any security benefits and risk mitigations that are dependent on UAC will not be present on the system. Severity of the damage: Medium Operational aspects: None
User Account Control: Switch to the secure desktop when prompting for elevation	Enable	Vulnerability: Elevation prompt dialog boxes can be spoofed, causing users to disclose their passwords to malicious software. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
User Account Control: Virtualize file and registry write failures to per-user locations	Enable	Severity of the damage: Low Operational aspects: None

Computer Configuration > Administrative Templates > Windows Components > Security Settings > Remote Desktop Services

Vulnerability:

An unlimited number of open connections can cause denial of Service attack on the Remote Desktop services, also known as Terminal Services.

If a disconnected session kept alive that can lead a session hijacking by an attacker.

Clipboard mapping enables the client to transfer a virus or a malicious application to the server as well as copy configuration or sensitive data from the server back to the client machine. There is a risk of infecting to the whole network or damaging the system.

Severity of the damage:

Medium

Operational aspects:

None

Path	Policy	Recommended Value
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Connections	Automatic reconnection	Disabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Connections	Configure keep-alive connection interval	Enabled Keep-Alive interval:1
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Connections	Deny logoff of an administrator logged in to the console session	Enabled

Path	Policy	Recommended Value
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Device and Resource Redirection	Do not allow Clipboard redirection	Disabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Device and Resource Redirection	Do not allow supported Plug and Play device redirection	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Device and Resource Redirection	Do not allow COM port redirection	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Device and Resource Redirection	Do not allow LPT port redirection	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Device and Resource Redirection	Do not allow drive redirection	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Security	Do not allow local administrators to customize Windows permissions	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Temporary Folders	Do not delete temp folders upon exit	Disabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Temporary Folders	Do not use temporary folders per session	Disabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Session Time Limits	End session when time limits are reached	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Remote Session Environment	Remove "Disconnect" option from Shut Down dialog	Enabled

Path	Policy	Recommended Value
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Remote Session Environment	Remove Windows Security item from Start menu	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Security	Require secure RPC communication	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Security	Set client connection encryption level	Enabled Encryption Level: High Level
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Connections	Set rules for remote control of Remote Desktop Services user sessions	Enabled View Session without user's permission
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Session Time Limits	Set time limit for active but idle Remote Desktop Services sessions	Enabled
Computer Configuration > Policies > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Session Time Limits	Set time limit for disconnected sessions	Enabled 15 minutes

Computer Configuration > Policies > Windows Settings > Security Settings > User Rights Assignment

Policy	Recommended Value	Comment
Access Credential Manager as a trusted caller		Vulnerability: If an account is given this right, the user of the account can create an application that calls into Credential Manager and is then provided the credentials for another user. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Access this computer from the network	BUILTIN\Administrators	Vulnerability: This right allows the users to use the SMB communications protocol in front of the server. This protocol allows access to the operating resources, such as: sharing and remote system administration using the operating system's built-in tools. Severity of the damage: Medium Operational aspects: None
Act as part of the operating system		Vulnerability: Users with the Act as part of the operating system user right can take complete control of the computer and erase evidence of their activities. Severity of the damage: Medium Operational aspects: None
Adjust memory quotas for a process	NT AUTHORITY\NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE, BUILTIN\Administrators	Vulnerability: A user with the Adjust memory quotas for a process user right can reduce the amount of memory that is available to any process, which could cause business-critical network applications to become slow or to fail. This privilege could be used to start a denial-of-service (DoS) attack. Severity of the damage: Medium Operational aspects: None
Allow log on locally	BUILTIN\Administrators	Vulnerability: Any account with the Allow log on locally user right can log on at the console of the computer. If you do not restrict this user right to legitimate users who must log on to the console of the computer, unauthorized users could download and run malicious software to elevate their privileges. Severity of the damage: Medium Operational aspects: None
Allow log on through Remote Desktop Services	BUILTIN\Administrators	Vulnerability: Any account with the Allow log on through Remote Desktop Services user right can log on to the remote console of the computer. If you do not restrict this user right to legitimate users who must log on to the console of the computer, unauthorized users could download and run malicious software to elevate their privileges. Severity of the damage: Medium Operational aspects: None
Back up files and directories	BUILTIN\Administrators	Vulnerability: Users who can back up data from a computer could take the backup media to a non-domain computer on which they have administrative privileges and restore the data. They could take ownership of the files and view any unencrypted data that is contained within the backup set. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Bypass traverse checking	NT AUTHORITY\ NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE, NT AUTHORITY\Authenticated Users, BUILTIN\Administrators	Vulnerability: This right allows the user to access files and partitions although he is not authorized to view files and change them. Severity of the damage: Medium Operational aspects: None
Change the system time	BUILTIN\Administrators, NT AUTHORITY\LOCAL SERVICE	Vulnerability: Users who can change the time on a computer could cause several problems. For example, time stamps on event log entries could be made inaccurate, an attacker who changes a computer's time may cause that computer to be unable to obtain or grant Kerberos protocol tickets. Severity of the damage: Medium Operational aspects: None
Change the time zone	BUILTIN\Administrator	Vulnerability: Changing the time zone represents little vulnerability because the system time is not affected. This setting merely enables users to display their preferred time zone while being synchronized with domain controllers in different time zones. Severity of the damage: Low Operational aspects: None
Create a token object		Vulnerability: A user account that is given this user right has complete control over the system, and it can lead to the system being compromised. Severity of the damage: High operational aspects: None
Create global objects	NT AUTHORITY\SERVICE, NT AUTHORITY\NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE, BUILTIN\Administrators	Vulnerability: Users who can create global objects could affect processes that run under other users' sessions. This capability could lead to a variety of problems, such as application failure or data corruption. Severity of the damage: Medium Operational aspects: None
Create permanent shared objects		Vulnerability: Users who have the Create permanent shared objects user right could create new shared objects and expose sensitive data to the network. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Create symbolic links	Administrators	Vulnerability: Users who have the Create symbolic links user right could inadvertently or maliciously expose your system to symbolic link attacks. Symbolic link attacks can be used to change the permissions on a file, to corrupt data, to destroy data, or as a DoS attack. Severity of the damage: Low Operational aspects: None
Debug programs	BUILTIN\Administrator	Vulnerability: The Debug programs user right can be exploited to capture sensitive computer information from system memory or to access and modify kernel or application structures. Some attack tools exploit this user right to extract hashed passwords and other private security information or to insert rootkit code. Severity of the damage: Low Operational aspects: None
Deny access to this computer from the network	BUILTIN\Guests	Vulnerability: Users who can log on to the computer over the network can enumerate lists of account names, group names, and shared resources. Users with permission to access shared folders and files can connect over the network and possibly view or modify data. Severity of the damage: Medium Operational aspects: None
Deny log on as a batch job	BUILTIN\Guests	Vulnerability: Accounts that have the Deny log on as a batch job user right could be used to schedule jobs that could consume excessive computer resources and cause a DoS condition. Severity of the damage: Medium Operational aspects: None
Deny log on as a service	BUILTIN\Guests	Vulnerability: Accounts that can log on as a service could be used to configure and start new unauthorized services, such as a keylogger or other malicious software. Severity of the damage: Medium Operational aspects: None
Deny log on locally	BUILTIN\Guests	Vulnerability: Any account with the ability to log on locally could be used to log on at the console of the computer. If this user right is not restricted to legitimate users who must log on to the console of the computer, unauthorized users might download and run malicious software that elevates their privileges. Severity of the damage: Medium Operational aspects: None

Policy	Recommended Value	Comment
Deny log on through Remote Desktop Services	BUILTIN\Guests	Vulnerability: Any account with the right to log on through Remote Desktop Services could be used to log on to the remote console of the computer. If this user right is not restricted to legitimate users who need to log on to the console of the computer, malicious users might download and run software that elevates their privileges. Severity of the damage: Medium Operational aspects: None
Enable computer and user accounts to be trusted for delegation	BUILTIN\Administrators	Vulnerability: Misuse of the Enable computer and user accounts to be trusted for delegation user right could allow unauthorized users to impersonate other users on the network. An attacker could exploit this privilege to gain access to network resources and make it difficult to determine what has happened after a security incident. Severity of the damage: Medium Operational aspects: None
Force shutdown from a remote system	BUILTIN\Administrators	Vulnerability: Any user who can shut down a computer could cause a DoS condition to occur. Therefore, this user right should be tightly restricted. Severity of the damage: Low Operational aspects: None
Generate security audits	NT AUTHORITY\NETWORK SERVICE, NT AUTHORITY\LOCAL SERVICE	Vulnerability: Accounts that can write to the Security log could be used by an attacker to fill that log with meaningless events. If the computer is configured to overwrite events as needed, attackers could use this method to remove evidence of their unauthorized activities. If the computer is configured to shut down when it is unable to write to the Security log and it is not configured to automatically back up the log files, this method could be used to create a DoS condition. Severity of the damage: Low Operational aspects: None
Increase scheduling priority	BUILTIN\Administrators	Vulnerability: Increasing the working set size for a process decreases the amount of physical memory that is available to the rest of the system. Severity of the damage: Low Operational aspects: None
Load and unload device drivers	BUILTIN\Administrators	Vulnerability: Device drivers run as highly privileged code. A user who has the Load and unload device drivers user right could unintentionally install malicious software that masquerades as a device driver. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Lock pages in memory	BUILTIN\Administrators	Vulnerability: Users with the Lock pages in memory user right could assign physical memory to several processes, which could leave little or no RAM for other processes and result in a DoS condition. Severity of the damage: Low Operational aspects: None
Manage auditing and security log	BUILTIN\Administrators	Vulnerability: Anyone with the Manage auditing and security log user right can clear the Security log to erase important evidence of unauthorized activity. Severity of the damage: Medium Operational aspects: None
Modify an object label		Vulnerability: Anyone with the Modify an object label user right can change the integrity level of a file or process so that it becomes elevated or decreased to a point where it can be deleted by lower-level processes. Either of these states effectively circumvents the protection offered by Windows Integrity Controls and makes your system vulnerable to attacks by malicious software. Severity of the damage: Low Operational aspects: None
Modify firmware environment values	BUILTIN\Administrators	Vulnerability: Anyone who is assigned the Modify firmware environment values user right could configure the settings of a hardware component to cause it to fail, which could lead to data corruption or a DoS condition. Severity of the damage: Medium Operational aspects: None
Perform volume maintenance tasks	BUILTIN\Administrators	Vulnerability: A user who is assigned the Perform volume maintenance tasks user right could delete a volume, which could result in the loss of data or a DoS condition. Also, disk maintenance tasks can be used to modify data on the disk such as user rights assignments that might lead to escalation of privileges. Severity of the damage: Low Operational aspects: None
Profile single process	BUILTIN\Administrators	Vulnerability: The Profile single process user right presents a moderate vulnerability. Attackers with this user right could monitor a computer's performance to help identify critical processes that they might want to attack directly. Attackers may be able to determine what processes run on the computer so that they could identify countermeasures that they may need to avoid, such as antivirus software or an intrusion-detection system. They could also identify other users who are logged on to a computer. Severity of the damage: Low Operational aspects: None

Policy	Recommended Value	Comment or Vulnerability
Restore files and directories	BUILTIN\Administrators	Vulnerability: An attacker with the Restore files and directories user right could restore sensitive data to a computer and overwrite data that is more recent, which could lead to loss of important data, data corruption, or a denial-of-service condition. Attackers could overwrite executable files that are used by legitimate administrators or system services with versions that include malicious software to grant themselves elevated privileges, compromise data, or install programs that provide continued access to the computer. Severity of the damage: Medium Operational aspects: None
Shut down the system	BUILTIN\Administrators	Vulnerability: The ability to shut down the server should be limited to a very small number of trusted administrators. Severity of the damage: Low Operational aspects: None
Take ownership of files or other objects	BUILTIN\Administrators	Vulnerability: Any users with the Take ownership of files or other objects user right can take control of any object, regardless of the permissions on that object, and then make any changes that they want to make that object. Such changes could result in exposure of data, corruption of data, or a DoS condition. Severity of the damage: High Operational aspects: None

Security Hardening Guide

This topic only applies to **Secret Server On-Premises**.

Introduction

This document outlines security hardening for securing your Secret Server instance, whether it be installed on a single server or in a multi-clustered environment.

Throughout this guide, many references are made to "configuration" settings. Unless otherwise specified, this refers to the settings found by selecting **Configuration** from the **Admin** menu in Secret Server.

Overview

It is critical to secure your Secret Server implementation. That needs to include a layered approach to security (defense in depth), including the operating system, software updates, physical access, protocols, system settings, backups, and personnel procedures. This section of the guide links to other sections containing more details.

Best Practices

General

- **Keep Windows up-to-date:** Microsoft regularly releases security patches that resolve vulnerabilities in Windows operating systems.
- **Backup at least daily:** Consider your disaster recovery plan. See "Backup, Disaster Recovery, and Glass Break" on page 467.
- **Review system log for errors:** Periodically check the system log (Admin > System Log) for recurring errors. Also do so after any upgrades.
- **Whole-disk encryption:** Use whole disk encryption, such as BitLocker, with a trusted platform module (TPM) to prevent those with physical access from removing disks to gain access to your Secret Server application by circumventing OS and application authentication.
- **Security Hardening Standards:** Consider security hardening standards that apply to either the operating system or applications, such as IIS or Microsoft SQL. Secret Server is compatible with CIS Level 1 and CIS Level 2 hardening and has STIG compatibility.

> Attaining full security-hardening standards compatibility is a Delinea priority.

Active Directory

On Active Directory domain controllers, there is a set of unsafe default configurations for LDAP channel binding that allow LDAP clients to communicate with them without ensuring LDAP channel binding and LDAP signing. This can open the controllers to privilege vulnerabilities. See 2020 LDAP channel binding and LDAP signing requirements for Windows for details.

Database

- **Limit access to your Secret Server database:** When you create your Secret Server database, limit access to as few users as possible. We recommend you disable the "sa" account in the SQL instance that contains Secret Server.
- **Limit access to other databases:** When you create a database account for SS, you should ensure it only has access to the Secret Server database.
- **Use Windows Authentication for database access:** Windows authentication is much more secure than SQL authentication. See Choose an Authentication Mode (TechNet article) for details. To use Windows authentication in SS, you need to create a service account. See the "Accessing MS SQL Server with IWA" on page 1436 for details.
- **Limit access to your database backups:** Database backups are critical for disaster recovery, but they also carry a risk if someone gains access. The Secret Server database is encrypted, but you should still limit access to ensure maximum security. Limit access to database backups to as few users as possible.
- **Don't share a SQL instance with less secure databases:** Putting the database on a server with less-secure database instances can expose vulnerabilities. For example, an attacker could use SQL injection on another application to access your private Secret Server database. If you intend to put Secret Server on a shared SQL

instance, ensure that the other databases are classified internally as sensitive as Secret Server and have similar security controls in place.

- **Review Microsoft's recommendations for SQL security:** See the Securing SQL Server article in Microsoft's documentation.

> Secret Server also supports SQL Server Transparent Data Encryption (TDE) for further protection of the database files. This can have a slight performance impact on the environment and can increase the complexity of the database configuration. Please review this page for more information: Transparent Data Encryption (TDE).

Application Server

- **Use SSL (HTTPS):** We require using Secure Sockets Layer (SSL) encryption to ensure that all communication between the Web browser and Secret Server is secure. We recommend you install a third-party certificate, domain certificate, or self-signed certificate on your website. For information on creating and installing a self-signed certificate, please see "Installing Self-Signed SSL Certificates" on page 443.
- **Force SSL (HTTPS):** Even after you install an SSL certificate, users may still be able to access Secret Server through regular HTTP. To that, enable the "Force HTTPS/SSL" option in Secret Server at Admin > Configuration on the **Security** tab.
- **Limit access to your Secret Server directory**. This contains the Secret Server encryption key, as well as the database connection information (these values are encrypted but remember "defense in depth." Try to grant access to as few users as possible).
- **Limit logon rights to the application server**. Administrators accessing the Application Server directly could attempt to monitor memory in use on the server. Secret Server does several things to protect application memory but the best safeguard is to limit access to the Application Server to as few users as possible.
- **Protect your encryption key**. The encryption key for Secret Server is contained in the encryption.config file, which resides in your Secret Server directory. This file is obfuscated and encrypted, but "defense in depth" would require limiting access to the file. Using DPAPI to encrypt your encryption.config file is one option. This will use machine-specific encryption to encrypt the file. Make sure you back up the original file before enabling this option. To further protect the file, you can enable EFS encryption. EFS (Encrypting File System) is a Microsoft technology that allows a user or service account to encrypt files with login passwords. For more details, read Protecting Your Encryption Key Using EFS in this same article. The most secure option is to use a Hardware Security Module (HSM) to protect the Secret Server encryption key. For more information, see "Using Hardware Security Modules" on page 1461.

Application Settings

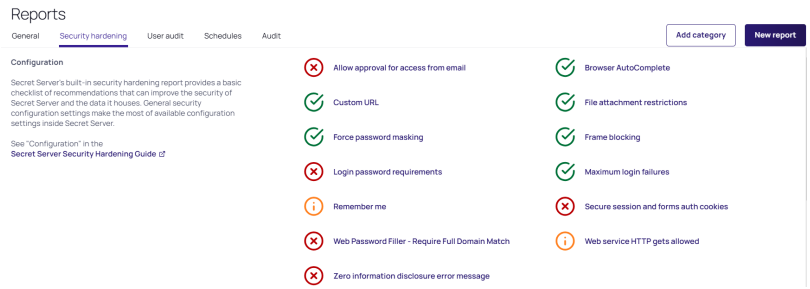
- **Use doublelock for your most sensitive secrets:** DoubleLock is a feature in Secret Server that allows secrets to be protected with additional AES256 encryption keys. Each user gets their own public and private key set when using doublelock. Their private key is protected by an additional password (user-specific, not a shared password) that each user must enter when using doublelock. DoubleLock protects from situations where you accidentally assign someone to the wrong AD group or an attacker gains full access to both your database and Web server - they still will not be able to access doublelocked secrets. For more information, refer to "QuantumLock Overview" on page 1093.

- **Secure the local admin account:** When you create the first user in SS, it is a privileged admin account that you can use when your domain is down. We recommend that you choose a non-obvious name for this account and protect it with a very strong password. This password should be stored in a physical safe with limited access (there is no need to use this account except in emergencies where other accounts are not working if AD is down or some other reason).
- **Review activity reports:** It is a good practice to regularly review the activity and secret permissions reports. This can help find anomalies in secret permissions and login failures.
- **Use event subscriptions or SIEM to notify of any security anomalies:** Use event subscriptions to send email alerts on various events in the system, and syslog can send events to a SIEM tool for correlation. For example, this could be used to notify administrators if there are failed login attempts or if certain secrets are viewed.

Security Hardening Report

Secret Server contains a built-in security hardening report to provide a basic checklist of recommendations that can improve the security of Secret Server and the data it houses. The items in this report range from common tasks, such as ensuring SSL is configured, to more advanced options like DPAPI encryption of the encryption key. To find this report, click the **Reports** on the dartboard, and then select the **Security Hardening** tab.

Figure: Security Harding Report:



An X denotes a failure, and a checkmark denotes a pass. An exclamation point is a warning. Typically, Secret Server could not detect a setting or all aspects of a check were not completed. For example, TLS 1.0 was disabled but TLS 1.1 was not.

You will find the following items in the report:

> The individual items below are in alphabetical order, not the order they are in the Hardening Report. The sections are in the same order as the report. This was because the report name does not always match the name of the corresponding label on the configuration UI control. In addition, the controls are not in the same order in the UI as their equivalents in the report.

Configuration Section

Allow Approval for Access from Email

Recommendation: Off

Allow Approval For Access from Email is a convenience option that allows users to approve or deny a secret access request by clicking a link in the request email sent by Secret Server. Allow Approval From Email does not require a

user to authenticate with Secret Server when approving access to a secret. This can be a security concern if the approver's email account becomes compromised, which could allow an attacker to mitigate MFA in some cases to complete an approval. Turn Allow Approval From Email off to get a pass result.

To disable this setting, find the **Permission Options** section of the **Configuration Settings** page and disable **Allow Approval for Access from Email**.

Custom URL

Recommendation: On

The Custom URL sets a definitive URL for Secret Server. Without it, certain features in Secret Server which need to build a link back to the server must construct the link using the host value on the request, which is susceptible to manipulation.

To disable this setting, Search for **Security hardening**. Under the **Security hardening** tab, select **Custom URL**.

File Attachment Restrictions

Recommendation: On

Labeled **Enable File Restrictions** in the UI.

File attachment restrictions allows administrators to configure what kind of file attachments can be uploaded to secrets. This helps protect users from being tricked into downloading a malicious secret attachment. The file extension and maximum file size can be specified, such as:

```
*.7z, *.bmp, *.ca-bundle, *.cer, *.config, *.crt, *.csr, *.csv, *.dat, *.doc, *.docx,
*.gif, *.gz, *.id-rsa, *.jpeg, *.jpg, *.json, *.key, *.lic, *.p7b, *.pcf, *.pdf, *.pem,
*.pfx, *.pkey, *.png, *.ppk, *.pub, *.tar, *.tif, *.tiff, *.tpm, *.txt, *.vdx, *.vsd,
*.vsdx, *.xls, *.xlsx, *.xml, *.zip
```

This security check will fail if the file attachment restrictions is not enabled. This check will return warnings if a potentially dangerous file extension is allowed, maximum file size is not specified, or maximum file size is greater than 30 MB.

Search for **File Restrictions section** to change these settings.

Frame Blocking

Recommendation: On

Labeled **Enable Frame Blocking** in the UI.

Do not allow Secret Server to be opened in a `<iframe>` HTML tag on another, potentially malicious, site. This adds the HTTP header `X-Frame-Options: DENY`. This deters clickjacking and spreading potential XSS vulnerabilities.

Search for **Frame Blocking** to change this setting.

Login Password Requirements

Passwords used by local users to log onto Secret Server can be strengthened by requiring a minimum length and using a variety of character sets. We recommend a minimum password length of eight characters. In addition, all character sets (lowercase, uppercase, numbers, and symbols) are required to get a pass result.

Turn on these login password settings on the **Local User Passwords** tab of the **Configuration Settings** page.

Maximum Login Failures

Recommendation: Reference the lockout policy for your organization. Most often, this setting will mirror the AD GPO lockout policy.

The maximum number of login failures is the number of attempts that can be made to log into Secret Server as a user before that user's account is locked. A user with the administer users role permission will then be required to unlock the user's account. The maximum failures allowed should be set to five or less to get a pass result.

Change the **Maximum Login Failures** setting on the **Login** tab of the **Configuration** settings.

Remember Me

Recommendation: Off

Labeled **Allow Remember Me** in the UI.

"Remember Me" is a convenience option that allows users to remain logged onto Secret Server for up for a specific period. This setting can be a security concern because it does not require re-entry of credentials to gain access to Secret Server.

Disable **Allow Remember Me** on the **Login** tab of the **Configuration** page to get a pass result. It must be set to be valid for 1 day or less to not get a fail result.

Closing a browser completely (all tabs) will log the user out of Secret Server, regardless of this setting.

Secure Session and Forms Auth Cookies

Secure Session and Forms *Authentication* Cookies.

Recommendation: See KBA

Cookies contain potentially sensitive information that can allow users to log onto application. By default, cookies are not marked with the secure attribute. That is, **they are transmitted unencrypted when a user accesses Secret Server through HTTP instead of HTTPS**.

For more information about how to secure your cookies, see "Securing ASP Cookies" on page 1478.

Web Service HTTP Gets Allowed (SOAP and REST-style)

Labeled **Allow HTTP Get** in the UI.

Recommendation: Off

Web service HTTP GET requests are allowed, which can be used for both SOAP and REST-style calls to many Secret Server Web service methods. This can be a security concern as a malicious user could create a link to the Web service that, when clicked, would execute the request. It is recommended to disable this feature to enhance security.

To mitigate security risks, disable the **Allow HTTP Get** option - Search for **Webservices**, click **Edit**, uncheck **Allow HTTP GET** and click **Save**. This will prevent both SOAP and REST-style HTTP GET requests from being executed.

Zero Information Disclosure Error Message

Recommendation: On

Replace all error messages with a custom "contact your admin" message. Error messages can be very helpful when diagnosing installation and configuration issues. However, having errors displayed to a potential attacker can provide him or her with the critical information they need to perform a successful attack.

To hide error messages from the business user, add the `ZeroInformationDisclosureMessage` application setting to the `web-appSettings.config` file. This file is located in directory containing the Secret Server application files. Add the key below to this file in between the `<appSettings>` tags. The contents of that tag is displayed as a message that appears to the user whenever an error occurs in the system. For example:

```
<add key="ZeroInformationDisclosureMessage" value="An error occurred in the application.
Please contact your administrator." />
```

This setting is enabled by default in Secret Server 10.7.26+.

Database Section

SQL Account Using Least Permissions

Use the fewest Secret Server permissions as possible in the SQL Account used to access the database. We recommend using a least permission approach where the account only has dbOwner. See "SQL Server 2016 Standard Edition Installation" on page 128.

SQL Server Authentication Password Strength and Username

This section addresses two separate but closely related settings: "SQL Server Authentication Password Strength" and "SQL Server Authentication Username."

Recommendation: Change settings as needed

SQL Server authentication requires a username and a strong password. Strong passwords are eight characters or longer and contain lowercase and uppercase letters, numbers, and symbols. In addition, the SQL Server authentication username should not be obvious.

You can change the credentials of a local SQL account through SQL Server Management Studio, where the Secret Server database is located. The SQL Server authentication credentials used by the application can then be changed by going to the installer `installer.aspx` page and changing them on step three. Using Windows authentication to authenticate to SQL Server is allowed.

For details about creating or modifying a SQL account for Secret Server, see "SQL Server and Secret Server" on page 121

Windows Authentication to Database

Recommendation: Configure

> If the SQL instance is *solely* using Windows authentication, this check will pass. If using mixed mode, it will fail—even you are using both Windows authentication plus SQL authentication.

Windows authentication takes advantage of Windows security to provide secure authentication to SQL Server. The SQL Server authentication options can be changed by going to the installer (installer.aspx) and changing them.

Environment Section

Application Pool Identity

Recommendation: Check configuration

The Application Pool identity appears to be a member of the administrators group on the system. This puts the system at risk by giving more access than necessary.

Check the identity of the application pool used by Secret Server in IIS. The Application Pool should be configured to use a service account and not be given unrestricted access to the server or domain.

DPAPI or HSM Encryption of Encryption Key

Recommendation: On

Encrypt your Secret Server encryption key, and limit decryption to that same server. Data Protection API (DPAPI) is an encryption library that is built into Windows operating systems. It allows encryption of data and configuration files based on the machine key. Enabling DPAPI Encryption in Secret Server protects the Secret Server encryption key by using DPAPI, so even getting access to the Secret Server encryption key is not enough to be useful—the machine key is required. If you enable this option, back up your encryption key first, as a DPAPI encrypted file can only be used by the machine it was encrypted on.

To enable DPAPI encryption, to **Admin > Configuration > Security tab** and click the **Encrypt Key Using DPAPI** button.

> This check also passes if Hardware Security Module (HSM) integration is enabled.

SSL Section

Require SMTP SSL

Recommendation: On

> Labeled **Use SSL** (on the Email tab) in the UI.

> We strongly recommend enabling this setting.

SMTP SSL is required to ensure that all communication between Secret Server and the email server is encrypted. Enable the "Use SSL" option in Secret Server to get a pass result.

Search for **Use SSL** to enable the setting.

Require SSL

> Labeled **Force HTTPS/SSL** in the UI.

Recommendation: On

> We **strongly** recommend using SSL for Secret Server.

Only use SSL (HTTPS) for Secret Server access. Secure Sockets Layer (SSL) is required to ensure that all communication between the Web browser and Secret Server is encrypted. To do so, you need an SSL certificate. You may use an existing wildcard certificate, create your own domain certificate, or purchase a third-party SSL certificate for the Secret Server website. For testing, you can use a self-signed certificate. See "Securing ASP Cookies" on page 1478 for more information.

Once the SSL certificate is installed, enable **Force HTTPS/SSL** on the **Security** tab of the **Configuration** page to force users to only access Secret Server over HTTPS and to receive a pass in the report.

SSL/TLS Hash

Recommendation: Confirm or remediate

Check the digest algorithm of the certificate. If the algorithm is SHA1, this check returns a warning because SHA1 is being phased out. If the digest algorithm is MD2, MD4, or MD5, the check will fail because they are not secure. SHA256, SHA384, and SHA512 will pass. This check fails if Secret Server cannot be loaded over HTTPS.

Example warning:

"The digest algorithm is sha1RSA, which is considered weak. The algorithm is being phased out and should be replaced with a better algorithm when it comes time to renew the SSL certificate."

Go to the browser's certificate information when logged onto Secret Server. This is usually a button next to the URL text box.

SSL/TLS Key

Recommendation: Confirm or remediate

Check the key size of the HTTPS certificate used. If it is RSA or DSA, the key must be at least 2048-bit to pass. If the signature algorithm of the certificate is ECDSA, the key size must be at least 256-bit to pass. If the algorithm of the certificate is unknown, the result shows "unknown. This check fails if Secret Server cannot be loaded over HTTPS.

Go to the browser's certificate information when logged onto Secret Server. This is usually a button next to the URL text box.

SSL/TLS Protocols

> As of August 31, 2025, Microsoft retired TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net now requires TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

Recommendation: Confirm or remediate

Check for legacy SSL or TLS protocols, which should not be used in a secure environment. If the server accepts SSLv2 or SSLv3 connections, this check will fail. SSLv2 is not considered secure for data transport, and SSLv3 is vulnerable to the POODLE attack. If this server does not support TLSv1.1 or TLSv1.2, this check will give a warning because they are recommended. The SSL certificate used may affect what protocols can be used, even if they are enabled. This check will fail if Secret Server cannot be loaded over HTTPS.

> You can check and modify these settings in the Window registry. See Transport Layer Security (TLS) Registry Settings in Microsoft's documentation.

Example warning:

"The server supports the accepts SSLv2 or SSLv3 connections protocol, which are weak. Consider disabling these protocols."

Using HTTP Strict Transport Security

> Labeled **Enable HSTS** in the UI.

HTTP Strict Transport Security (HSTS) is an additional security layer for SSL. HSTS allows Secret Server, Password Reset Server, or Group Management Server to inform browsers that it should only be accessible over HTTPS. With this setting enabled, visitors are automatically redirected by their browser to the HTTPS-enabled site.

When the **Force HTTPS/SSL** option in enabled on the **Security** tab of the **Configuration** page, the **Enable HSTS** check box will be displayed. After the option is turned on, you can click **Advanced** to specify the maximum age in seconds for how long the policy should be in effect before re-evaluating. The default value is 31,540,000 seconds (a year)—the amount required to enable the checkmark, which assumes the site should never be accessed without TLS or SSL.

For details about this, see "Securing Traffic with HTTP Strict Transport Security" on page 784.

Security Settings Not in the Hardening Report

Apply TLS Certificate Chain Policy and Error Auditing

Recommendation: Confirm or remediate

Add audits for TLS certificate validation. Auditing will apply to all Active Directory domains using LDAPS and Syslog using TLS. Certificate policy options, including ignoring certificate revocation failures, apply to syslog using TLS

only. The default is the most strict so the certificate chain policy may need to be updated. TLS errors will be logged to Security Audit Log found on the Administration page.

Disable the **Admin >Configuration > Security tab > Apply TLS Certificate Chain Policy and Error Auditing** setting.

TLS errors are logged to the **Security Audit** log at **Admin > See All > Security Audit Log**.

Enable FIPS Compliance

Recommendation: Off

Only allow FIPS-compliant encryption schemes. FIPS (Federal Information Processing Standards) is a set of standards for government entities. It covers many things, including encryption. For businesses, FIPS can be counter productive because it restricts them from using newer or improved existing encryption methods. In addition to enabling this setting, several other tasks are required to meet this standard, including enabling it for Windows itself. For more information, see "Enabling FIPS Compliance in Secret Server On-Premises" on page 1337 for details.

Search for **FIPS Compliance** to change this setting.

Key Rotation

Recommendation: Review KBA

> Key rotation is not a setting but an activity. It is included here for completeness (the entire Configuration Security tab)

Secret key rotation changes out the encryption key for secret data and re-encrypts that data with a new key. This helps you to meet compliance requirements mandating that encryption keys are changed on a regular basis. See "Secret Key Rotation" on page 1475.

Two-Factor Authentication

Users must authenticate to Secret Server at least once using either local Secret Server credentials or their Active Directory credentials. In addition, you can protect Secret Server by enabling two-factor authentication (2FA). 2FA is an additional security layer, such as a text message PIN code sent to your smart phone. The following options are supported by Secret Server for 2FA:

SAML

Secret Server supports the Security Assertions Markup Language (SAML), which provides a more centralized method of adding 2FA to the Secret Server log on. Please see the "Configuring SAML Single Sign-on" on page 431.

Email

Using email for 2FA means that after authenticating with their password, the user receives an email containing a one-time PIN code to enter. For this to work, an SMTP server must be configured in Secret Server and each user must have a valid email address associated with their account. For Active Directory users, the email address will be synced automatically from their domain account.

Check user email addresses at **Admin > Users**.

Soft Tokens

Soft tokens using the Time-based One-time Password (TOTP) algorithm, such as Google Authenticator and Microsoft Authenticator, are supported by Secret Server 2FA. Users are prompted to enter a token displayed on their mobile device each time they log onto Secret Server. The time-based token changes on a regular interval (such as 30 seconds).

RADIUS

One option is to use a Remote Authentication Dial-In User Service (RADIUS)compliant device, such as an RSA or CryptoCard token, as the second form of authentication. The user is prompted to enter his or her RADIUS password after initial authentication is done with their Secret Server or AD password.

To set this up, you first need to configure Secret Server to integrate with your RADIUS server, and then you can enable it for individual users or for by domain.

See "Enabling RADIUS Two-Factor Authentication" on page 455 for details.

Duo Security

Using this method requires that you have an active account for Duo Security. Duo Security provides several options for 2FA. The API hostname, integration key, and secret key values are required for Secret Server to authenticate Duo users.

See for details.

Enabling Two-Factor Authentication

Enabling for Users

To enable two-factor authentication for a user or several users at once, select **Users** from the **Admin** menu and then select the users in the grid. Use the bulk operation drop-down menu to choose the type of authentication to enable.

> If prerequisite settings are not configured, the 2FA option may be disabled or will not appear as an option. See the descriptions above for information about prerequisites for each type of two-factor authentication.

Enabling per Domain

Two-factor authentication can also be enabled per domain if you are syncing users from Active Directory. To do so, select **Active Directory** from the **Admin** menu and then click **Edit Domains**. Click the domain name and then click **Advanced (not required)** to reveal the **Auto-Enable Two Factor for New Users** setting. Select this checkbox and click **Save and Validate**.

Roles

Secret Server uses role-based access control, which allows administrative and user capabilities to be partitioned by role. This can allow for granular control over which areas of the application a user has access to, for example, allowing someone the rights to manage licenses and view reports in Secret Server but nothing else.

Controlling Access to Features Using Roles

Limiting Role Access to the Export Permission

Exporting secrets from your Secret Server as text is very helpful for meeting regulations in certain industries (secrets can then be printed to paper and locked in a physical safe). It can also be used as another disaster recovery option, but access to exporting data from the Secret Server should be tightly controlled. You could create a separate role with just the export permission for anyone needing to export secrets.

Unlimited Vault Access Mode

Unlimited Vault Access (UVA) mode allows any role with the "Unlimited Vault Access" permission to see all secrets in the Secret Server. This mode is very helpful for recovering passwords in emergencies or when staff are terminated. You can tightly control access to this feature by splitting out the role permissions for Administer Configuration Unlimited Vault Access" and "Unlimited Vault Access" into two different roles. This allows you to create the "two-key effect" for access to the mode. See Using Two Roles for Access to Unlimited Vault Access Mode, below, for details.

Limiting Role Access to Secret Templates

Anyone with access to modify your secret templates can change the definitions of the data being stored, and this access should be tightly controlled. Your secret templates are unlikely to need changing once you have defined them, so limiting access to a select number of individuals is typically sufficient.

Monitoring Roles with Event Subscriptions

Another option when protecting roles is to configure event subscriptions to notify appropriate staff in the event that Roles are changed or assigned. Event subscriptions are email alerts that can be sent to users, groups or specific email addresses, based on different events in Secret Server. There are also events available around the "Unlimited Vault Access" role to further protect it from misuse.

Using Two Roles for Access to Unlimited Vault Access Mode

We recommend determining which role permissions should or should not be combined for users before assigning roles and allowing users access to the application. Part of that is planning access to the "unlimited vault access" mode. Users with the "administer configuration unlimited vault access" role permission can enable that mode. Once the system is in the mode, users with the "unlimited vault access" role permission can view all secrets in Secret Server and access all configuration settings. So a user with both Delinea permissions can enable the "unlimited vault access" mode and then view all the secrets or make any configuration change.

To prevent a single person from having that much access, the two role permissions should be given to two different roles and only those roles, and nobody should have access to both of the roles. That enforces accountability and requires the cooperation of two people to enter "unlimited vault access" mode.

A solution is to create the two roles, each containing one of the role permissions, and then take those two permissions out of the day-to-day administrator role and any other roles besides the two. You can then assign either one of those roles to trusted people with no single person having both roles.

Thus, the access procedure is:

1. User A with the role with the "administer configuration unlimited vault access" permission puts the system into "unlimited vault access" mode. Not having the correct role, user A cannot make any changes requiring the "unlimited vault access" permission.
2. User B with the role with the "unlimited vault access" permission performs any configuration or accesses secrets only available to that role.
3. When User B is finished, user A takes the system out of "unlimited vault access" mode.
4. User B can no longer make any changes requiring the "unlimited vault access" permission because roles with that permission can only be accessed in "unlimited vault access" mode. User A cannot make any changes either because User A does not a the role with the "unlimited vault access" permission.

Additional safeguards included:

- Enabling or disabling "unlimited vault access" mode is audited, and a comment should be provided each time it is enabled.
- When "unlimited vault access" mode is enabled, a banner appears at the top of every Secret Server page notifying users that their secrets can currently be viewed by an a user with unlimited vault access.
- Event subscription notifications should be set up to send an email to a specified user, group of users, or other email address whenever "unlimited vault access" mode is enabled or disabled.
- All actions that are normally audited, such as secret views, edits, or permissions changes, are still audited while "unlimited vault access" mode is enabled.

Encryption

DPAPI Encryption

Overview

The Data Protection API (DPAPI) is an option that provides an additional layer of security for the Secret Server encryption key. The Secret Server encryption key is contained within a file that is decrypted and used by the application to encrypt or decrypt the sensitive data that is stored in the Secret Server database. Using the DPAPI option in Secret Server ensures that the encryption key file is also encrypted with a key that only Windows knows and is only be usable on same server it was encrypted on. Anybody trying to configure Secret Server on another server using that DPAPI-encrypted key is blocked from doing so.

> The encryption key file, `encryption.config`, should be backed up and stored in a secure location before turning on DPAPI encryption. This allows you to restore a backup of the application on another server in a DR scenario. The file is in the Secret Server application directory.

> In order to encrypt the `encryption.config` file, the App Pool identity account needs Windows NTFS permissions on the file.

Enabling and Disabling DPAPI

To turn on DPAPI encryption of the file, select **Configuration** from the **Admin** menu. Select the **Security** tab, click **Encrypt Key Using DPAPI**, and then type your password and acknowledge the warning before clicking **Confirm**. To

decrypt the key, navigate to the same tab and click **Decrypt Key to not Use DPAPI**.

Using Clustering with DPAPI

You can use DPAPI while clustering is enabled for Secret Server, however there are a few things to take into consideration:

- Backup the encryption key before using this option, otherwise disaster recovery could prove impossible, should the server fail.
- You must initially transfer the un-encrypted key that DPAPI will encrypt to each Secret Server node. Secret Server
- You must enable DPAPI for Secret Server by accessing each server locally (browse to Secret Server while on the server it is installed on, and then enable DPAPI encryption).
- During upgrades, to avoid turning off DPAPI, you can copy all files over to secondary nodes *except* for `database.config` and `encryption.config`.

For more information about clustering see Secret Server Clustering.

Protecting Your Encryption Key Using EFS

Encrypting File System (EFS) is a Microsoft technology that allows a user to encrypt files with their password. This means that only the user who encrypted the file will be able to access it, even if it is assigned to other users. If an administrator resets the password on this account and the account does not change its own password, then the file is not recoverable.

You can use EFS to protect your Secret Server encryption key. This allows only a single service account to access the file, and no other user can read the key unless they know the service account password. Below are the steps for encrypting your `encryption.config` and `database.config` files with EFS:

1. Backup your `encryption.config` and `database.config` files to a secure location. This is very important for DR recovery purposes.

   Important: This step is critical–If you lose access to your service account or the server fails, you will be unable to recover your secrets without these backup files.
2. Create a new service account or select an existing one. The service account should initially have privileges to log on a computer.
3. If you have already installed Secret Server and are using Windows authentication for database access, make sure the service account has access to the database.
4. Run the Secret Server application pool as this service account. See "Running the IIS Application Pool As a Service Account" on page 63 .
5. Give the service account full access to your Secret Server directory through Windows Explorer if it does not have it already.
6. Log on your server as the service account.
7. For both the `encryption.config` and `database.config files` (this instruction uses the former):

a. Locate the `encryption.config` file in your Secret Server directory (usually `C:\inetpub\wwwroot\SecretServer`).
b. Right-click the file and select **Properties**.
c. Click the **General** tab.
d. Click the **Advanced** button.
e. Click to select the **Encrypt contents to secure data** check box.
f. Click the **OK** button.
g. Click the **Apply** button.
h. If prompted, select the **Encrypt the file only** option.
i. Click the **OK** button.

8. Log out of Windows and log back in as an administrator.
9. Confirm that the application still works by performing an IIS Reset (`IISReset` command at the command prompt) or recycling the application pool.
10. Ensure you can still log in and view your secrets.

SSL (TLS) and HSTS

We strongly recommend employing SSL (TLS) for Secret Server. Taking SSL a step further, Secret Server also supports HTTP Strict Transport Security (HSTS). HSTS is supported by modern browsers and tells the browser that a site is only accessible by SSL with a valid certificate, period. Even if there is a man-in-the-middle attack with a trusted, but different, SSL certificate, the browser will reject the SSL certificate. Consequently, this setting is very useful for protecting against forged SSL certificates or man-in-the-middle attacks.

For more information about configuring SSL certificates, see the . You can view additional information about HSTS in Securing with HTTP Strict Transport Security (HSTS).

SSH Key Validation

Host SSH Key verification is supported for use with heartbeat, proxied launchers, password changers, and discovery. Host SSH key verification can help ensure that the machine you are connecting to is a trusted host. Host SSH key verification will not pass credentials to the target machine unless the public key digest matches the SHA1 digest that Secret Server has on file. This helps prevent man-in-the-middle attacks.

Mapping an SHA1 Digest to Secrets

To configure host SSH key verification:

1. Navigate to **Secret Templates** from the **Admin** menu.
2. And add a field for the host's SSH key digest.
3. Click **Configure Extended Mappings**.
4. Add a **Server SSH Key** mapping to your newly created SSH key digest field.
5. On your secrets, add the SSH key digest of the hosts to your digest field. Verification takes effect the next time you connect to the host.

Validating SHA1 Digests for Unix Account Discovery

To validate SHA1 server digests for Unix account discovery, create a file named `KeyDigests.txt` in the root of the Secret Server website. Each line should contain an IP address or other computer identifier, a comma, and the SHA1 digest, for example:

```
192.168.1.5,7E:24:0D:E7:4F:B1:ED:08:FA:08:D3:80:63:F6:A6:A9:14:62:A8:15
apollo,7A:25:AB:38:3C:DD:32:D1:EA:86:6E:1C:A8:C8:37:8C:A6:48:F9:7B
```

When the file exists and has data, all scanned machines must match one of the SHA1 hashes in the file before scanning. Any computers that do not match will still show up on the "Discovery Network View" page, but authenticated scanning will not take place. That is, no credentials will be passed to the machine, and accounts will not be retrieved from the machine.

Disabling IIS HTTP Headers

Introduction

This section describes plugging some potential, minor but significant, information leaks by the Secret Server Web server. Web applications, such as Secret Server, may unintentionally disclose information about their underlying technologies through headers, error messages, version numbers, or other identifying information. An attacker can use that information to research vulnerabilities in those technologies to attack the application to breach the system.

Procedure

First, **hide the IIS version**. The HTTP header "X-Powered-By" reveals the version of IIS used on the server. To stop this, remove the header:

1. Open the IIS Manager.
2. In the **Connections** tree, select the website that Secret Server is running under.
3. Click the **HTTP Response Headers** button on the right. The HTTP Response Headers panel appears.
4. Click to select the **X-Powered-By** HTTP header.
5. Click the **Remove** button in the **Actions** panel. The header disappears.

Second, **hide the ASP.NET version**. The HTTP header "X-ASPNET-VERSION" reveals the version of ASP.NET being used by the Secret Server application pool. To stop this, remove the header:

1. Open the `web.config` file for Secret Server, which is located in the root directory for the website.
2. Inside the `<system.web>` tag, add the tag `<httpRuntime enableVersionHeader="false"/>`.
3. Save the file.

Third, **hide the server type**. The header line `Server: Microsoft-HTTPAPI/2.0` is added to the header by the .NET framework. To remove that information, you must update the Windows Registry:

> Do not simply remove the Server header variable—it will cause parts of Secret Server to malfunction.

1. Open the Windows Registry Editor.
2. Navigate to `Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\HTTP\Parameters`.

3. Change the `DisableServerHeader` (REG_DWORD type) registry key from `0` to `1`.

> There are other ways to hide the server type. We strongly recommend this one.

Adjusting CORS Policy Headers

By default, Secret Server only allows Cross-Origin Resource Sharing (CORS) to unauthenticated resources. CORS allows a restricted resource on a Web page to be requested from a different domain from that resource. To adjust this behavior, either hardening (such as blocking all CORS calls) or relaxing it, follow these instructions:

1. In the Secret Server installation folder, open the `web-appsettings.config` file in a text editor.
2. In the **appSettings** section add: `<add key="UseWebConfigCORS" value="true"></add>`
3. Save the file.
4. In the same folder, also open the `web.config` file in the text editor.
5. In the **system.webServer/httpProtocol/customHeaders** section, add: `<add name="Access-Control-Allow-Origin" value="[customer URL here]" /><add name="Access-Control-Allow-Headers" value="Content-Type" /><add name="Access-Control-Allow-Methods" value="GET, POST, PUT, DELETE, OPTIONS" />`
6. Save the file.

Accessing MS SQL Server with IWA

> This topic only applies to **Secret Server On-Premises**.

> Please see "Running the IIS Application Pool As a Service Account" on page 63 for additional information.

Introduction

Integrated Windows Authentication (IWA) requires:

- Installing a SQL Server instance
- Creating a new domain service account
- Granting access to SQL Server database
- Registering a service account to run IIS and ASP.NET
- Assigning an account as an application pool identity

> **Note:** For instructions on Creating the SQL account or Installing SQL Server see "Installing and Configuring SQL Server" on page 123

Creating a Domain Service Account

The account needs access to the application server and database server. Ensure password expiration is not enabled or the account could lock you out of Secret Server.

Granting Access to SQL Server database

1. Connect to the Database instance using SQL Management Studio.
2. Right click on the Security node (ensure this is the top most security node under the instance and not under the database name itself) and select **New > Login**.
3. Enter the Login name as `Domain\Username`.
4. Ensure **Windows Authentication** radio button is selected.
5. If you have already created the database, then under **User Mappings** select the database and grant dbOwner permission. Otherwise, if you plan to have the Database created for you, under **Server Roles** select dbCreator.
6. Click the **Ok** button.

Assigning Account as Identity of Application Pool

1. Open IIS (Run command inetmgr).
2. Click the Application Pool node.
3. Select Secret Server's Application Pool (default is SecretServerAppPool).
4. On the Right panel, Click .
5. Scroll down to the **Identity** row under **Process Model**.
6. In the popup, select **Custom Account > Set**.
7. Type the user as domain\username.
8. Type the password.
9. Click the **Ok** button.
10. Recycle the application pool by clicking the **Recycle..** button under the **Application Pool** tasks.

Considerations for an Externally Accessible Secret Server

This topic only applies to **Secret Server On-Premises**.

Secret Server can be hosted externally, like any other IIS website. We recommend using all security measures for Secret Server that you would use for any server directly accessible to the internet. We also recommend the measures described below.

Limiting the Attack Surface

- The Secret Server application should reside on a dedicated server in a DMZ.
- Secret Server and its database should reside on separate servers. If a hole for SQL connections can be opened in the DMZ firewall, the database can reside on the other side of the DMZ firewall.

Using Secure Connections

- Use HTTPS to access to the website.
- Use SSL to connect to the Secret Server database.
- Use LDAPS to connect the web server to Active Directory.

Setting Up Remote Password Changing

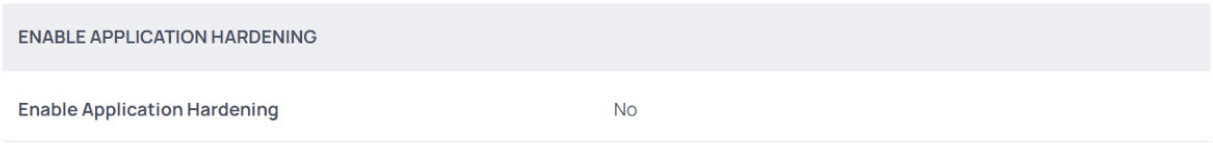
By default, Secret Server changes passwords on devices and accounts directly from the web server where it is installed, but when Secret Server is installed in a DMZ zone, it does not have direct network connections to these devices and accounts.

However, you can enable Secret Server to change passwords throughout your network over a specified port using distributed engines. See "Distributed Engine Overview" on page 718 for more information on setting up and using Secret Server Distributed Engines.

Enabling Application Hardening

This topic only applies to **Secret Server On-Premises**.

Application Hardening can be found in the **Admin > Configuration > Security tab**.



When this feature is enabled, extra checks are done to make sure user records have not been tampered with. If a user's record has been found to have been modified by someone other than Secret Server itself, they will not be able to log in. New Event Subscriptions have also been added to send alerts if tampering is detected. This feature is only available in Secret Server on-premise.

This feature is a configurable setting designed to modify the system so that a database administrator cannot effectively modify or create a User Record through the database directly—this action needs to happen in the application itself. This includes:

- Resetting a password
- Disabling or changing Two-Factor Authentication
- Creating a brand-new record with a known password

Encryption FAQ

This topic provides answers to frequently asked questions about encryption in Secret Server.

General

Is Secret Server source code available for review?

Secret Server is currently closed source and is not available for review.

What is the cryptographic library used by Secret Server?

Secret Server uses the Microsoft CNG namespace of the .NET Framework library for encryption, which uses the ncrypt and bcrypt Microsoft libraries. FIPS mode can be enabled in Secret Server to ensure that only FIPS-validated algorithms are used.

Password Storage

Can we enforce a password policy that requires eight characters or more?

Yes, the password policy can require longer than 8 characters. To configure this:

1. Search for **Configuration**.
2. Click the **Local User Passwords** tab.
3. Set the minimum password length to 9 or higher.

To control passwords stored in secrets rather than login passwords, you can define Password Requirements under **Admin > Secret Templates**.

How are login passwords stored?

Local user passwords are hashed using PBKDF2-SHA256 with 100,000 iterations to a fixed character length digest (hexadecimal from the bytes).

Password fields on secrets are encrypted using AES-256 since the system must be able to retrieve them to perform password changing, heartbeat, and session launching.

Secret Server enforces rules on secret passwords using Password Requirements by Secret Template. You can also enforce requirements on local login passwords if you don't use AD authentication to get into Secret Server. If you use AD to authenticate to Secret Server, then you can set your password policy in AD and the password is not stored in Secret Server.

How is PBKDF2-SHA256 used to hash passwords?

Secret Server uses the Microsoft CNG API for PBKDF2-SHA256 with a user-specific randomized salt and 100,000 iterations for local user passwords.

How is the salt stored?

The salt is stored on the tbUser.Password column as the first 32 characters of the value. There is no pipe or other separation value. Secret Server knows to use the first 32 characters as the salt.

How and where are salts stored for encrypted data?

Salts are stored as prepended values in the same database column as the hashed (for hashed passwords) or encrypted value (for secret data that is salted/entropied before encryption to avoid duplicate encrypted values).

Authentication

Is another authentication supported, such as Active Directory?

Yes. Active Directory, SAML, and RADIUS authentication are all supported.

Is Mutual HTTPS authentication supported?

IIS can be configured to require client certificates before granting access to the website. Secret Server also has other means to ensure the identity of the client:

- **IP address restrictions**: Restrict the IP address ranges from which a user can access Secret Server.
- **RADIUS-based authentication**: Allows authentication through RSA tokens or any RADIUS-compatible authentication.
- **Two-factor authentication**: Using pin-codes via email, OATH authenticators, and Duo Security to ensure the user has access to a secondary device or their email account.

Encryption

What is the HTTPS cipher suite?

The HTTPS cipher suite is controlled by IIS and can be configured through the IIS Manager.

What is the AES-256 block cipher mode of operation?

Secret Server uses the CBC cipher mode of operation for all AES-256 encryption operations. All secret items are encrypted using AES-256.

How are initialization vectors managed?

Initialization vectors (IVs) are managed in the same way that encryption keys are managed. Each secret item has its own random unique IV.

Would two or more different passwords be separately encrypted using the same cryptographic key and IV?

No. All secret data is encrypted with a secret-level AES-256 key, and each item has a unique IV.

What is the random number generator for the cryptographic keys?

Secret Server uses the Microsoft CNG Random Number Generator.

Cryptographic Keys

How are cryptographic keys generated, stored, and protected in Secret Server?

Cryptographic keys are randomly generated during installation and encrypted using a heavily obfuscated encryption key. They are then stored in the `encryption.config` file, which exists in the Secret Server directory. This file is required for decrypting database information, so we recommend that you do not give the same user account access to both the `encryption.config` file and the database. Each encryption key is unique per installation.

When using an HSM, the top-level master key is an RSA 2048 or 4096 key managed by the HSM rather than a key in the `encryption.config` file.

If not using an HSM, you can enforce DPAPI or EFS protection on the `encryption.config` file for additional security.

The top-level key (either the `encryption.config` or RSA key managed by the HSM) encrypts the secret keys, which are intermediate AES-256 keys. The intermediate keys can be rotated in the administration menu.

For more information on rotating the master encryption key, see "Master Encryption Key Rotation" on page 1471.

Is there support for using an HSM to store the cryptographic keys?

Yes. Secret Server supports any HSM with a CNG provider or PKCS #11 support. For more information, see "Hardware Security Module Overview" on page 1460.

QuantumLock

QuantumLock was previously called DoubleLock.

Where are the QuantumLock key pairs stored?

The QuantumLock IV is stored in the database table tbDoubleLock. The QuantumLock key is stored in the database table tbEncryptor per user that is assigned to that QuantumLock. Note that the QuantumLock is a symmetric 256-bit key used for AES encryption.

Does Unlimited Administrator Mode allow access to QuantumLock-protected passwords?

No. This would not be possible since the person would not have the necessary information to decrypt the QuantumLock keys, which are then needed to decrypt the secret data.

What public key cryptography standards, algorithms, and key lengths are used by QuantumLock?

Each user has an RSA public and private key pair. The private key is encrypted using their QuantumLock password as a key.

With the QuantumLock feature enabled, you can optionally use a quantum-safe algorithm for encapsulation to protect the private key, specifically CRYSTALS Kyber-1024, which is designed to counter the potential threat from quantum computers to current encryption methods.

For more information on QuantumLock, including the comparison between RSA-2048 and Kyber-1024, see "QuantumLock Overview" on page 1093.

Is the RSA key pair generated according to any standard, such as PKCS#1?

Secret Server uses System.Security.Cryptography.RSACryptoServiceProvider to create the RSA key pair using a key size of 2048.

How is the QuantumLock password used as a key?

Yes, there is a key derivation function. Secret Server uses Rfc2898DeriveBytes (PBKDF2) with a fixed salt and 1000 iterations to derive a 32-byte (256-bit) AES key from the QuantumLock password.

Is a standard such as PKCS#1 used to RSA encrypt the QuantumLock symmetric AES key?

Yes. Secret Server uses PKCS#1-based RSA encryption using OAEP padding.

What RSA key size is used during QuantumLock?

The key size used for the RSA key is 2048. The generation and use of the 2048 key does not take any noticeable time when using the user interface.

Hardening RDS Hosts for Session Connector

This topic only applies to **Secret Server On-Premises**

Overview

Delinea Secret Server offers a variety of session launching methods, including the use of Microsoft Remote Desktop Services (RDS) in conjunction with Secret Server Session Connector. This setup allows users to initiate privileged sessions via an RDS host without needing additional installations on client devices. All that's required is a Remote Desktop Protocol (RDP) client capable of opening RDP files furnished by Secret Server. Given the integral role of RDS hosts in this configuration, it is essential to harden them.

Prerequisites

Complete and validate the installation, setup, and functionality of Secret Server Session Connector before proceeding with the hardening process. If the RDS host is already in production, ensure a full backup of the RDS host and its configurations are available.

The Issue

RDS hosts offer access to a published application. Even though users will connect with unique, non-privileged, and randomly generated credentials on the RDS host, they can still interact extensively with the OS. For example, using the <CTR>-<ALT>-<END> command in the published application accesses the task manager on the RDS host, letting the user initiate additional programs and view the host's local file system. This could potentially allow the user to start additional unauthorized applications.

The Solution

Limit user access, reduce the attack surface, and ensure secure session handling through a combination of OS-level settings, GPOs, and application configurations.

Operating System Hardening

- **Patching**: Regularly update the OS to patch known vulnerabilities.
- **Unnecessary Services**: Disable services and applications that are not required for the server's role.
- **Antivirus/Antimalware**: Install and regularly update antivirus software.
- **Limit User Access**: Only grant least-privilege access rights.

Network Hardening

- **Firewalls**: Ensure a firewall is in place to filter unwanted inbound and outbound traffic. Only allow the necessary ports (for example, 3389 for RDP).
- **Virtual Private Network (VPN):** Avoid directly exposing the RDS server to the internet. Employ a VPN to facilitate secure remote connectivity.
- **Strategic Network Segmentation:** Position the RDS server within a distinct VLAN, ensuring optimal traffic isolation and mitigating risks associated with broader network vulnerabilities.
- **Intrusion Detection:** Deploy an Intrusion Detection System (IDS) to continuously oversee and promptly address any unusual or potentially harmful network behavior.

Local User Hardening via PowerShell Script

For these local user adjustments, you can use the provided PowerShell script. The following settings are deployed into the default user profile via the PowerShell script:

- **Hide Local Drives:** Prevent users from viewing the RDS host's local drives.
- **Lock CTRL-ALT-DEL Screen:** Restrict users from locking the system, altering passwords, or launching the task manager.
- **Remove Shutdown Button:** Although standard users lack the permission to shut down the RDS host, it is best to hide the shutdown buttons to avoid confusion.
- **Disable Screensaver and Lock Screen:** Users do not know the password for the randomly generated user. Configure the system to prevent screensaver activation or session lockouts.
- **Lock Internet Explorer Settings:** Even if Internet Explorer is not in active use, configure its settings to enhance security.

PowerShell Script

Overview

The script performs the following actions:

- Sets the execution policy to RemoteSigned.
- Creates a backup of the default user's `ntuser.dat` file.
- Loads the default user profile registry hive for editing.
- Hides local drives of the RDS Server.
- Disables local drive viewing.
- Adjusts <CTRL>-<ALT>-<DEL> options.
- Disables Task Manager, Change Password, and Lock.
- Disables Internet Explorer context menu.
- Disables Screensaver and Lock Screen.
- Disables Developer mode on Internet Explorer.
- Removes shutdown buttons.
- Blocks access to Control Panel and PC Settings.
- Disables Windows Store.
- Checks and verifies the changes made to the registry settings.
- Unloads the default user profile registry hive after edit.

Download

Access the script via the box below.

Deployment

To ensure smooth execution of this PowerShell script:

- Run the script before applying hardening group policies to the RDS host.
- Right click and select **Run as administrator**.

By default, the script will only hides C and D drives. If you wish to hide additional drives, please change the prospective registry values in the following sections prior to running the script:

See How-to: Hide drive letters from Windows Explorer for details on calculating and setting the desired values.

```
# Hide Drive Setting
```

Current value is 12 (C + D)

```
# No View Drive Setting
```

Current value is 12 (C + D)

The script is designed to provide visual feedback on the status of each setting:

- Green: Denotes settings that are correctly configured and aligned with security and operational standards.
- Red: Denotes settings that are not found within the system registry.
- Yellow: Denotes settings that are present but have a value mismatch, meaning the current configuration does not align with the expected standard.

```
<#
.SYNOPSIS
This script is designed to harden the default user profile on a system.
.DESCRIPTION
This script performs the following actions:
- Sets the execution policy to RemoteSigned
- Creates a backup of the default user's ntuser.dat file.
- Loads the default user profile registry hive for editing.
- Hides local drives of the RDS Server.
- Disables viewing of local drives.
- Adjusts CTRL-ALT-DEL options.
- Disables Task Manager, Change Password, and Lock.
- Disables Internet Explorer context menu.
- Disables Screensaver and Lock Screen.
- Disables Developer mode on Internet Explorer.
- Removes Shutdown Buttons.
- Blocks access to Control Panel and PC Settings.
- Disables Windows Store.
- Checks and verifies the changes made to the registry settings.
- Unloads the default user profile registry hive after editing.
- Reverts the execution policy back to its original state.
Note: This script needs to be run as an administrator.
#>
# User Confirmation
$confirmation = Read-Host "This script will make changes to system settings. Do you
want to continue? (Y/N)"

Restoring from Backup

If the hardening script causes issues and you need to restore the NTUSER.DAT backup:

> Note: NTUSER.DAT is a protected system file that is locked when any user profile is loaded. Restoration requires Safe Mode access or booting from recovery media.

To restore the backup:

1. Boot into Safe Mode:

- Restart the server and press F8 during startup (or use `` `shutdown /r /o /f /t 00` `` from an elevated command prompt to access advanced startup options).
- Select **Troubleshoot > Advanced Options > Startup Settings > Restart**.
- Press 4 or F4 to enable Safe Mode.

2. Locate the backup file:

The backup file is created in the same directory where you ran the script with a timestamped filename: `` `ntuser.dat-backup-YYYY_MM_DD_HH_mm_ss` ``

3. Restore the backup:

- Open an elevated command prompt in Safe Mode.
- Navigate to the directory containing the backup file.
- Run the following commands:

```
cd C:\users\default
takeown /f ntuser.dat
icacls ntuser.dat /grant administrators:F
copy /Y "path\to\ntuser.dat-backup-YYYY_MM_DD_HH_mm_ss" ntuser.dat
```

Replace `path\to\ntuser.dat-backup-YYYY_MM_DD_HH_mm_ss` with the actual path and filename of your backup.

4. Reboot normally:

- Restart the server to exit Safe Mode: `` `shutdown /r /t 0` ``

Alternative method using Recovery Environment:

If you cannot access Safe Mode, you can restore from Windows Recovery Environment (WinRE) by booting from Windows installation media and accessing the command prompt from the repair options.

> Important: Test the restoration procedure in a non-production environment before relying on it in production scenarios. Always maintain a full system backup before running the hardening script.

Machine Hardening via Group Policy Objects (GPO)

The CIS (Center for Internet Security) Benchmark is an invaluable tool, offering a solid foundation for system configurations. Serving a wide range of entities from commercial sectors to government agencies, it provides detailed guidelines, ensuring robust system hardening. Similarly, the STIG (Security Technical Implementation Guide) framework is revered for its comprehensive approach, especially tailored to fortify systems entrusted with national security and classified data.

Integrating Our Custom Hardening GPO

Overview

Our custom hardening GPO can be easily integrated into your Active Directory environment. While the policy comes with a default configuration based on our insights and some industry best practices, you can modify it to better fit your organization's specific requirements.

> If you are currently implementing STIG policies, we advise against integrating our GPO. The overlap and potential conflicts may compromise system integrity and result in a decreased STIG compliance score. For detailed guidance on this, please refer to the relevant section on “STIG Compliance with Session Connector Functionality”.

Adding the Custom GPO to Your AD Environment

Download

Download the Hardening RDS Hosts for Session Connector .

Deploying the GPO File

> We recommend applying the GPO exclusively to the RDS host being used in conjunction with the session connector.

1. Extract the contents of the zip file to your desired location
2. Open the Group Policy Management Console (GPMC).
3. Create a new GPO.
4. Right click the new GPO and select **Import Settings**. An Import Settings Wizard appears.
5. Click the **Next >** button to skip backing up the GPO.
6. Populate the **Backup folder** text box on the **Backup location** page with the location you unzipped the file to, and click the **Next >** button.
7. On the **Source GPO** page click the GPO you just added in the **Backed up GPOs** list, and click the **Next >** button.
8. On the **Migrating References** page, click to select the **Copying them identically from the source** selection button, and click the **Next >** button.
9. On the **Completing the Import Settings Wizard** page, click the **Finish** button.

Applying Custom GPOs to a Chrome Browser

This section describes how to configure Google Chrome ADM/ADMX templates to use custom GPOs:

1. Download the Google Chrome Enterprise Browser. This includes the ADM/ADMX templates and Google updater ADMX template update.

2. ADMX Deployment:

   For a central store deployment, place the `.admx` files here:

   `\\<domain>\SYSVOL\<domain>\Policies\PolicyDefinitions`

   Without a central store, place the `.admx` files here:

   `%systemroot%\PolicyDefinitions`

3. ADML Deployment:

   For a central store deployment, place the `.adml` files here (adjusting the language tag):

   `\\<domain>\SYSVOL\<domain>\Policies\PolicyDefinitions\en-US`

   Without a central store, place the `.adml` files here (adjusting the language tag):

   `%systemroot%\PolicyDefinitions\en-US`

> As a best practice, always pilot any new GPO within a controlled setting prior to a full-scale deployment on your production systems.

STIG Compliance with Session Connector Functionality

Overview

While the Security Technical Implementation Guide (STIG) provides a robust framework for system security, some functional requirements, such as those of the session connector for RDP sessions, may necessitate deviations from STIG policies that might marginally lower your STIG compliance score.

The following policy configurations optimize session connector functionality on your RDS host. These recommendations offer a balance between operational necessities and security best practices. If you are employing the session connector for RDP, ensure that these policies are applied across your target systems as well.

User Rights Assignments

Configuration Path

Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies > User Rights Assignments

Policies

Allow local login:

- Users
- Administrators

Allow login through terminal services:

- Remote Desktop Users
- Administrators

Deny login through terminal services:

- Guests
- <NETBIOS>\Domain Admins
- <NETBIOS>\Enterprise Admins

Remote Desktop Session Host Security Configurations

Configuration Path

Computer Configuration > Administrative Templates > Windows Components > Remote Desktop Services > Remote Desktop Session Host > Security

Policies

Always prompt for password upon connection: disabled

> It is imperative to validate these configurations in a controlled environment before deploying them in production, ensuring both compliance and operational integrity. Also, coordinate with IT governance or compliance teams to ensure alignment with organizational guidelines.

Application Lockdown

- An application white listing strategy is instrumental in elevating the security posture of an organization.
- By permitting only approved applications to execute, the risk of malicious software execution and potential security breaches is significantly reduced.
- Consider tools such as Microsoft AppLocker for application control solutions.

Application Hardening via AppLocker

You can easily integrate our custom AppLocker GPOs into your Active Directory environment. While these policies come bundled with two different AppLocker configuration files based on our insights, you can choose the one that best aligns with your objectives and modify it as needed.

Session Connector Considerations

For the seamless operation of Session Connector launchers, the following executables must be explicitly allowed to run within your policies:

- rdpwin.exe
- rdpwin.bootstrapper.exe
- rdpwin.rdpclient.exe
- rdpwin.watchdog.exe

These executables are crucial for the proper functioning of session connector launchers as they perform various roles from launching the applications and managing RDP client sessions, to monitoring the health of the launcher. Ensuring these are allowed to run is vital for maintaining operational integrity and ensuring users can initiate and maintain their sessions without interruption.

AppLocker Policies

Both policies target the “Remote Desktop Users” group on the RDS host and will apply deny rules to prevent these users from accessing software. When launching an application, the Session Connector will grant logon rights by creating an ephemeral local user and adding this user to the “Remote Desktop Users” group.

During the installation of Remote Desktop Services (RDS), if you elected to associate the session collection with the default “Domain Users” group, the restrictions of these policies will apply to **all** domain users. RDS nests the “Domain Users” security group within the “Remote Desktop Users” group.

This integration is critical if you plan to run an application in the context of a specific domain user and wish for the AppLocker policies to be enforced.

If “Domain Users” is nested within “Remote Desktop Users,”, we recommend assigning your administrative user a new primary group in Active Directory Users & Computers (ADUC) and remove the administrative user from the “Domain Users” security group. This allows your administrative user to perform administrative tasks on the RDS host.

StrictAppLockerPolicy.xml

This policy restricts members of the “Remote Desktop Users” group from launching all applications, scripts, windows installers, files, and packaged apps, regardless of their path, unless explicitly defined in the exceptions.

Here is a list of the exceptions, which are primarily required for basic session connector functionality:

If you elect to use this policy, you should manually edit the AppLocker rule "Deny All (Remote Desktop Users)" and explicitly add exceptions here for your approved applications.

- conhost.exe: Handles console windows, providing the user interface for console applications.
- csrss.exe: Critical for system functionality, handling console windows, and the shutdown process.
- dllhost.exe: Hosts DLLs on behalf of other applications, potentially for COM components or other DLLs.
- dwm.exe: Manages graphical effects in the user interface.
- explorer.exe: The main shell of Windows, providing the desktop environment, taskbar, and Start menu.
- lsass.exe: Handles authentication and password policies, managing user login.
- osk.exe: Provides an on-screen keyboard for accessibility.
- rdpclip.exe, rdpinit.exe: Allows for clipboard sharing between the local machine and the RDP session.
- rdpinit.exe: Initializes an RDP session.
- rdpsa.exe, rdpsaproxy.exe: System executables that support the proper functionality of Remote Desktop Services.
- rdpshell.exe: Provides a shell or user interface for the RDP session.
- runonce.exe: Runs commands or scripts when a user logs on to the system for the first time after a restart.
- screenmagnifier.exe: Accessibility feature for screen magnification.

- sethc.exe: Related to Sticky Keys, a part of accessibility features.
- sihost.exe: Shows various user interface elements, such as system information on the secure desktop.
- smss.exe: Initializes the user session during Windows startup.
- svchost.exe: Hosts various Windows services.
- taskhostw.exe: A generic host process for running DLL-based services.
- tsthemes.exe: Related to RDP theme and appearance settings.
- userinit.exe: Initializes user settings and launches the user shell after log on.
- wermgr.exe: Involved in error reporting and solutions.
- winlogon.exe: Handles the login and logout procedures.
- rdpwin.exe, rdpwin.bootstrapper.exe, rdpwin.rdpclient.exe, rdpwin.watchdog.exe: Delinea files required for session connector functionality.

DefaultAppLockerPolicy.xml

This is a less restrictive policy and only restricts members of the “Remote Desktop Users” group from launching the following applications within the Windows directory:

> If you elect to use this policy you should manually edit the AppLocker Executable Rules and explicitly add or remove denied applications here based on your organization’s requirements.

- at.exe: Schedules commands at a specific time.
- bcdedit.exe: Manages Boot Configuration Data.
- bitsadmin.exe: Creates download or upload jobs, facilitating unauthorized data transfer or malware delivery.
- cacls.exe: Changes file and directory Windows NTFS permissions, which could modify system security settings.
- certreq.exe: Performs various certification authority (CA) certificate functions.
- certutil.exe: Manages CA certificates.
- cipher.exe: Alters the encryption of directories and files on NTFS partitions.
- cmd.exe: Allows arbitrary command execution.
- cmstp.exe: Installs or removes Connection Manager service profiles, which can be misused for arbitrary code execution.
- compmgmtlauncher.exe: Launches the Computer Management console.
- control.exe: Accesses Control Panel items.
- cscript.exe/wscript.exe: Executes VBScript or JScript.
- csvde.exe: Imports and exports Active Directory data in a comma-separated format.
- dcomcnfg.exe: Manages DCOM settings. Unauthorized modifications can lead to unauthorized remote control or data access.
- dism.exe: Services Windows images and could be misused to alter them.

- diskpart.exe: Manages disk partitions.
- dnscmd.exe: Manages DNS servers from the command line, which can be misused to change DNS configurations.
- driverquery.exe: Lists installed device drivers, which can be used for system reconnaissance.
- dsdbutil.exe: A command-line tool that can be used to manage Active Directory databases.
- dsquery.exe: Searches for objects in the directory from the command line.
- eventcreate.exe: Creates custom events in specified event logs.
- eventvwr.exe: Views system logs, which can be exploited for "bait and switch" attacks.
- expand.exe: Expands compressed files, which can be misused for bypassing software restriction policies.
- extrac32.exe: Extracts .cab files from the command line, similar to expand.exe.
- findstr.exe: Searches for strings in files, which can be used for data reconnaissance.
- finger.exe: Displays information about remote users on older systems.
- forfiles.exe: Executes commands on a set of files.
- fsutil.exe: Manages FAT and NTFS file systems, which could tamper with file systems.
- ftp.exe: FTP client.
- getmac.exe: Displays MAC addresses of network adapters.
- gpresult.exe: Displays group policy information for remote users.
- infdefaultinstall.exe: Installs driver packages.
- klist.exe: Manages Kerberos tickets, misuse of which can lead to unauthorized access.
- lodctr.exe: Updates performance counter-related registry values, which can be misused.
- makecab.exe: Creates .cab files, potentially misused for file obfuscation.
- mavinject.exe: Injects DLLs, which can be misused for privilege escalation.
- mmc.exe: Microsoft Management Console, which hosts various management snap-ins.
- msconfig.exe: Modifies system startup items.
- mshta.exe: Executes HTML applications, which can be misused for unauthorized script or payload execution.
- msiexec.exe: Installs software packages.
- msinfo32.exe: Retrieves detailed system information.
- net.exe: Manages users, groups, and more.
- netsh.exe: Modifies network configurations.
- nltest.exe: Provides network diagnostics, which can be used for reconnaissance.
- odbcad32.exe: Manages database connections.
- openfiles.exe: Displays files opened by remote users, which can be used for reconnaissance.
- pathping.exe: A network diagnostic tool, which is useful for reconnaissance.

- perfmon.exe: Monitors system performance.
- powershell.exe: PowerShell, a powerful scripting environment.
- printbrmui.exe: Manages printer migrations.
- query.exe: Provides information on user sessions, processes, and more, which is useful for reconnaissance.
- quser.exe: Displays information about logged-on users, which can be used for reconnaissance.
- rasdial.exe: Manages network connections, which can be misused to establish unauthorized connections.
- reg.exe: Edits the registry from the command line.
- regedit.exe, regedt32.exe: Modifies the Windows registry.
- robocopy.exe: A file copy tool, which can be misused to transfer data.
- schtasks.exe: Manages scheduled tasks.
- sc.exe: Manages services.
- secedit.exe: Configures and analyzes system security by comparing it to a template.
- shutdown.exe: Shuts down or restarts the system.
- sdbinst.exe: Installs custom database files, which can be misused for unauthorized binary execution.
- sysprep.exe: Prepares systems for cloning, which can remove security settings.
- takeown.exe: Regains file access by taking ownership, which can be misused to modify system files.
- taskmgr.exe: Manages processes and views performance stats.
- telnet.exe: Telnet client.
- tzutil.exe: Time zone utility, which can be misused in specific contexts.
- vssadmin.exe: Manages volume shadow copies.
- wevtutil.exe: Manages event logs, which can be misused to clear them.
- werfault.exe: Windows Error Reporting tool, which has been misused for malicious intent in some scenarios.
- whoami.exe: Displays information about the current user.
- winrs.exe: Runs commands on remote computers.
- wmic.exe: Windows Management Instrumentation command line, which can be used for reconnaissance or administration.
- wsmprovhost.exe: Hosts Windows Remote Management, which can be misused in specific contexts.
- wusa.exe: Installs Windows updates, which can be misused to install malicious updates.
- xwizard.exe: Extensible Wizard Framework, which has been used in UAC bypass techniques.

Integrating Our Custom AppLocker Policies

These steps enhance security by restricting the execution of potentially harmful or unauthorized applications.

Download

Access the GPO and AppLocker policies via the Hardening RDS Hosts for Session Connector

Deployment

> We recommend applying this GPO exclusively to the RDS host being used in conjunction with session connector.

1. Extract contents of the zip file to your desired location.
2. Follow “Guidelines for Machine Hardening via GPO” for instructions on how to import a GPO.
3. Edit the new GPO and import the desired AppLocker policy:
   a. Navigate to the following path in the GPO editor: Computer Configuration > Policies > Windows Settings > Security Settings > Application Control Policies > AppLocker.
   b. Right click and select **Import Policy**
   c. Select the desired policy.
   d. Click the **Open** button. An Import Policy dialog box appears.
   e. Click the **Yes** button. An AppLocker dialog box appears.
   f. Click the **OK** button. The dialog box disappears.
   g. Ensure the new rules appear in the GPO editor.

AppLocker Diagnostic Procedures

Running in Audit Only Mode

If you experience issues with applications executing, we recommend switching AppLocker’s operational mode from “Enforce rules” to “Audit only.” This adjustment enables a comprehensive audit while ensuring uninterrupted application functionality. To switch the mode:

1. Navigate to the following path in the AppLocker GPO: Computer Configuration > Policies > Windows Settings > Security Settings > Application Control Policies > AppLocker.
2. Right click and select **Properties**
3. Set the **Executable rules** dropdown list to **Audit only**.

Using AppLocker Audit Logs

Procedure

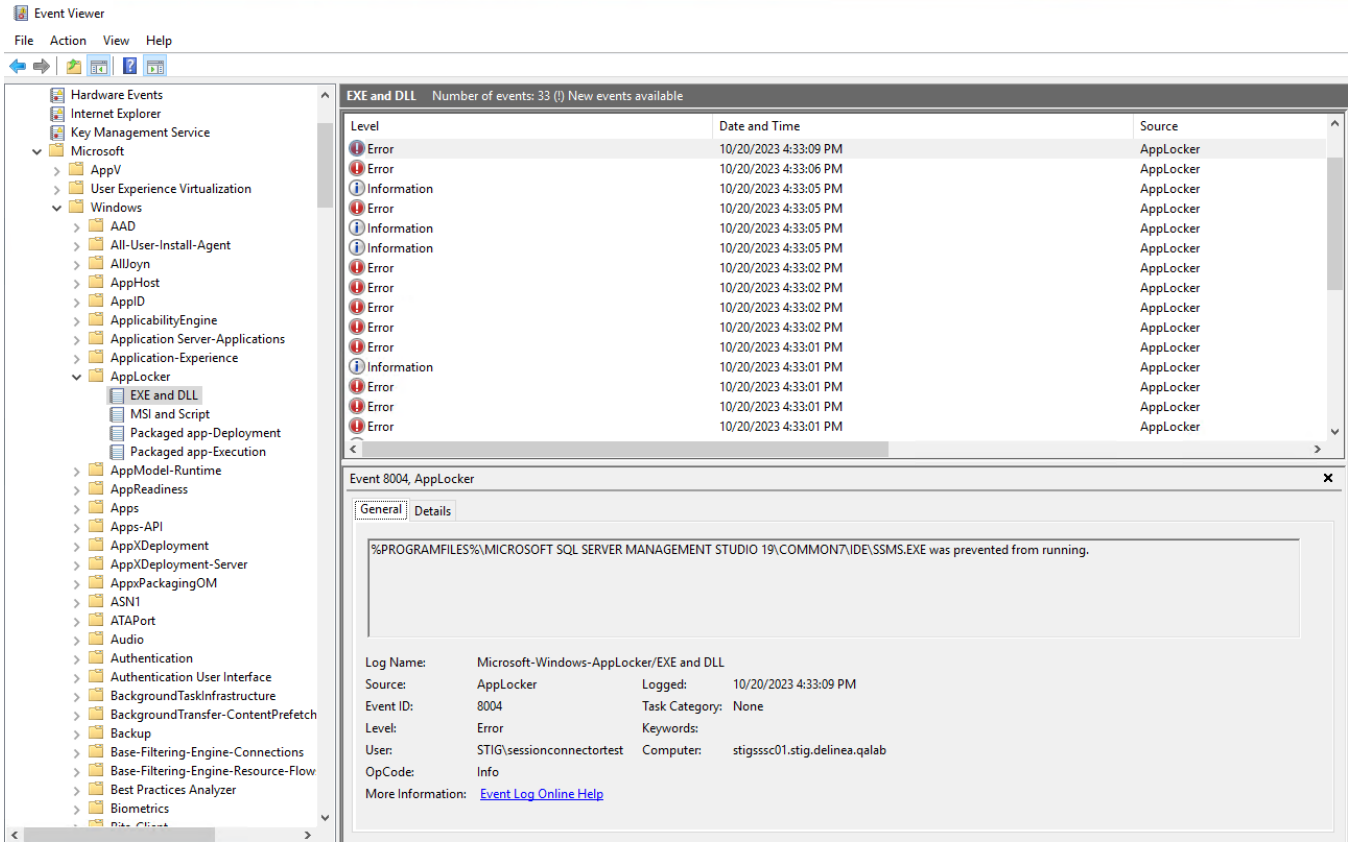
The AppLocker audit logs provide invaluable insights and are instrumental for troubleshooting:

1. **Access Event Viewer**: Press Windows Key + R, type `eventvwr.msc`, and press **<Enter>**.
2. **Navigate to AppLocker Logs**: Go to Applications and Services Logs > Microsoft > Windows > AppLocker.
3. **Select Log Files**: Click on the log categories such as EXE and DLL to view events.
4. **Filter Audit Events**: Use **Filter Current Log** on the right panel, and specify event levels or IDs to isolate audit results.

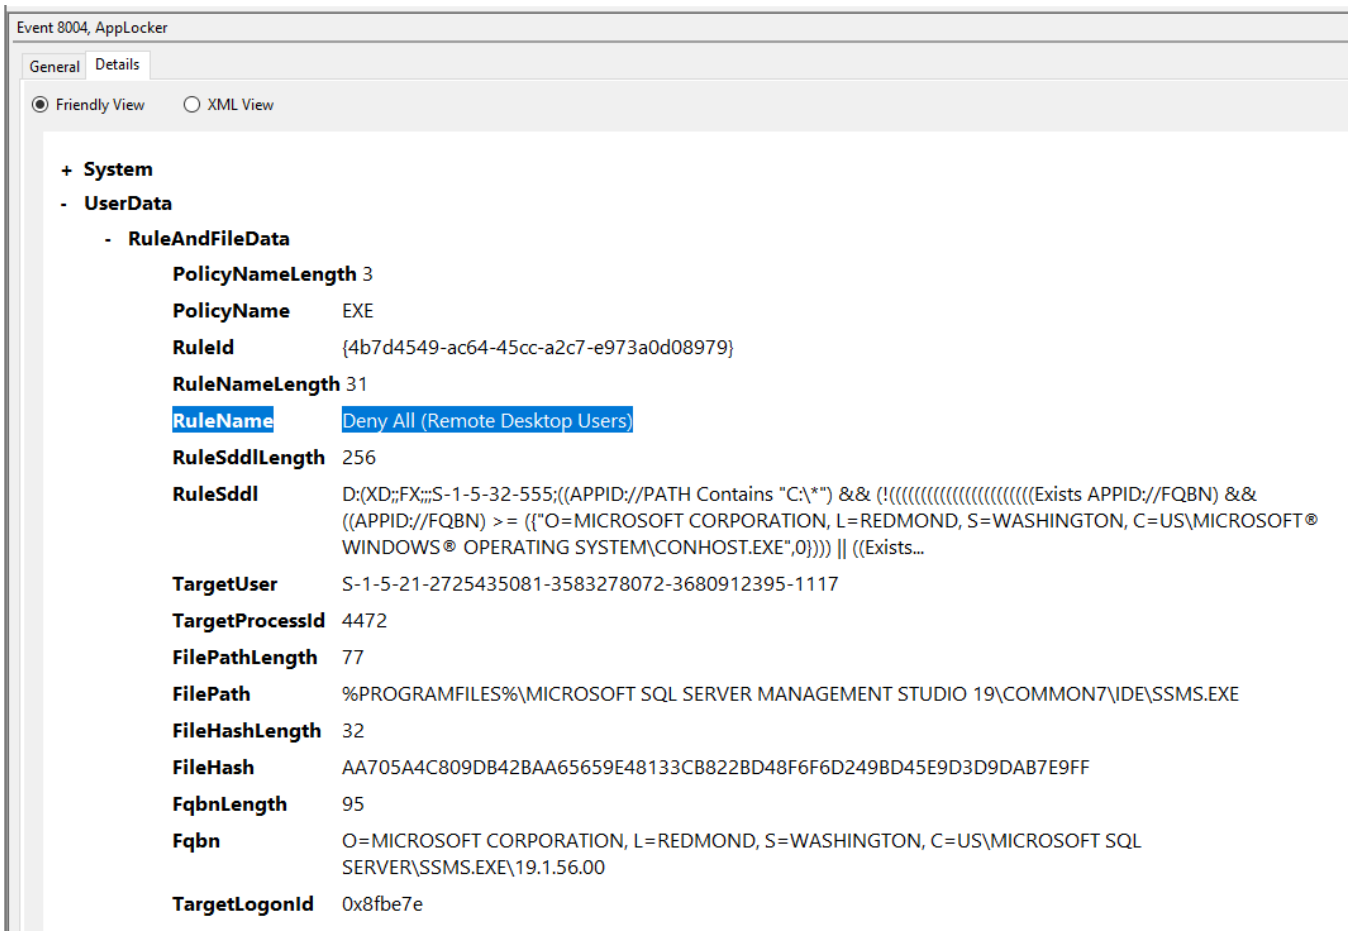
5. **Analyze Event Details**: Select events and review the **General** and **Details** tabs for information on the audited application and actions taken.
6. **Adjust Policies**: Analyze to pinpoint issues, and modify AppLocker policies as needed for resolution.

Example

SSMS.EXE will not run:



Click the details tab to display additional information regarding the rule preventing the application from launching:



Additional Suggestions

Monitoring and Logging

We recommend:

- Employing proactive system and application log analysis to detect irregularities and potential threats.
- Setting up automated alerts for critical events, notably patterns like successive failed login attempts, to ensure timely interventions.

Continuous Maintenance and Oversight

We recommend:

- Remaining informed and promptly acting on any updates or advisories from Delinea.
- Routinely assessing and refining security configurations to ensure they align with evolving best practices and organizational needs.

Remember, while hardening is essential, it is equally crucial to maintain usability and functionality for end-users. We strongly recommend thoroughly testing any security configurations in a staging environment before deploying to production.

Hardware Security Module Overview

This topic only applies to **Secret Server On-Premises**.

Hardware Security Modules (HSMs) are specialized hardware devices designed to securely manage, process, and store cryptographic keys. Integrating HSMs with Secret Server enhances the security of secret management by providing a secure environment for cryptographic operations and key management. This integration offers several benefits, including enhanced security, compliance with regulatory requirements, and optimized performance for cryptographic operations.

Secret Server integrates with hardware security modules (HSMs). When Secret Server is configured to use an HSM, the Secret Server encryption key is protected by that HSM.

HSMs offer several security features that traditional servers cannot. Depending on the model and design of the HSM, most HSMs are designed to be physically tamper-proof. HSMs may also be independent hardware on a network, which allows physically placing the HSM is a more secure location that might otherwise be too inconvenient for a server.

To provide broad support for HSMs, Secret Server supports any HSM that can be configured with Microsoft's Cryptography Next Generation (CNG) provider or Public-Key Cryptography Standards #11 (PKCS #11). CNG is a layer provided by Windows Server 2008 and later that HSM manufacturers can interface with. PKCS #11 is an API provided by each HSM vendor that Secret Server can interface with to perform cryptographic operations. If your HSM properly supports CNG or PKCS #11 and supports compatible algorithms, Secret Server can use it.

Turning off HSM (deselecting the check box) in Secret Server may cause a "Server connection unavailable" error. If this happens, a manual reset of the IIS server should take care of it.

CNG provider installation and configuration varies from HSM to HSM; however, documentation is available from each HSM vendor on how to correctly install CNG providers or set up PKCS #11.

Key Benefits of HSM Integration

1. **Enhanced Security**: HSMs significantly reduce the risk of key compromise by using a hardware-based solution for key management. They are often designed to be physically tamper-proof and can be placed in secure locations.
2. **Compliance**: HSMs meet stringent security standards and compliance requirements, helping organizations adhere to regulatory mandates.
3. **Performance**: HSMs are optimized for cryptographic operations, providing high performance and reliability.

Supported HSMs and Standards

Secret Server supports any HSM that can be configured with Microsoft's Cryptography Next Generation (CNG) provider or Public-Key Cryptography Standards #11 (PKCS #11). For a list of compatible HSMs see HSM integrations.

By integrating HSMs with Secret Server, organizations can achieve a higher level of security and compliance for their secret management processes.

Using Hardware Security Modules

HSMs are used for the Secret Server on-premise version only. For Secret Server Cloud, see AWS Key Management in Secret Server Cloud.

HSM Requirements

Each HSM must provide support for these algorithms:

For CNG:

- **RSA 4096**: Support for RSA with 4096-bit keys is required. The HSM must also support RSA for encryption and decryption, in addition to signing.
- **Padding Type**: The HSM must support one of the following for RSA encryption:
  - PKCS#1 v1.5 padding
  - OAEP padding
- **CNG API Calls**:
  - NCryptCreatePersistedKey
  - NCryptDecrypt
  - NCryptDeleteKey
  - NCryptDeriveKey
  - NCryptEncrypt
  - NCryptEnumStorageProviders
  - NCryptExportKey
  - NCryptFinalizeKey
  - NCryptFreeBuffer
  - NCryptGetProperty
  - NCryptImportKey
  - NCryptIsAlgSupported
  - NCryptOpenKey
  - NCryptOpenStorageProvider

- NCryptSecretAgreement
- NCryptSetProperty

For PKCS #11:

- **AES 256**: Support for AES 256-bit keys is required.
  - The HSM must also support a `CKM_AES_CBC_PAD` mechanism for encryption and decryption, and the slot must be a hardware slot.

Additionally, closely follow the requirements and recommendations of the HSM vendor for things such as minimum latency, redundancy, and operating environment.

> Due to its limitations, the NETWORK SERVICE account is not supported as an account for the IIS Application Pool. We recommend configuring Secret Server's application pool as a service account. In the advanced settings for the application pool, set **Load User Profile** to true.

> Certain HSM provider products interfere with each other. We recommend no more than one HSM provider be configured on a Windows installation at a time.

Compatible HSMs

Secret Server supports any HSM that can be configured with Microsoft's Cryptography Next Generation (CNG) provider or with Public-Key Cryptography Standards #11 (PKCS #11).

For details and comprehensive information on compatible HSMs see HSM integrations.

CNG is a layer provided by Windows Server 2008 and later, that HSM manufacturers can interface with. PKCS #11 is an API provided by each HSM vendor that can interface with to perform cryptographic operations. If your HSM properly supports CNG or PKCS #11 and supports the right algorithms, Secret Server can use it.

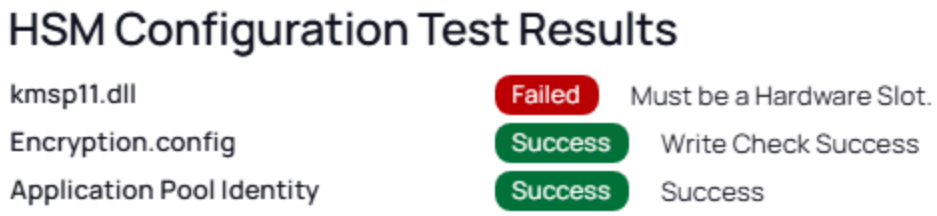
Below is a list of known HSMs that are compatible with Secret Server:

Table: Compatible HSMs

Vendor	Device	Notes
Amazon	Amazon CloudHSM (Cavium)	CNG and PKCS11 compatible with version 5.0.0 and greater. Per Amazon documentation: PKCS #11 library for AWS CloudHSM. For PKCS11 setup in Secret Server, you must enter the user pin in this format: username:password.
Entrust	nShield HSM	CNG and PKCS11 are compatible with version 12.80.4. See Entrust Integrations if you have issues with PKCS11.
Google	Google Cloud HSM	**Not supported** because it uses a single-key slot in the KMS for their HSM slots. Secret Server requires a hardware slot*.
Securosys	Primus-E20	CNG and PKCS11 compatible with version 1.46 or greater.

Vendor	Device	Notes
Thales	Luna Network HSM	CNG with firmware 7.7.0 or greater. FIPS mode requires OAEP padding type. PKCS11 is compatible with firmware 7.4 and greater.
Thales	Luna Cloud HSM (DPoD)	CNG compatible with firmware 7.7.0 and greater. FIPS mode requires OAEP padding type. PKCS11 is compatible with firmware 7.4 and greater.
Utimaco	CryptoServer	CNG and PKCS11 are compatible with version 4.10.0. Version 5.1.1.1 is **not** compatible–fails with CC mode.
Yubico	YubiHSM 2 FIPS v2.2	CNG is compatible with version 4.10.0. PKCS11 is **not** compatible with version 5.1.1.1–it does not support the AES CBC mechanism.

* Produces this error:



Silent HSM Operation

Because Secret Server is a Web application with no one physically present at the server at most times, it interacts with the HSM in "silent" mode. This prevents the HSM from attempting to interact with any users logged into the server.

Some HSM features require interaction. If the HSM is configured in a way that requires interaction, Secret Server cannot communicate with the HSM and fails during the configuration steps.

For example, Operator Card Sets (OCS) in Thales network HSMs have such a configuration. If the Thales CNG provider is configured to use an OCS for key protection instead of module protection, someone must be physically present at the HSM and the server to insert their operator card when the key is needed. If the OCS quorum is more than a single card, Secret Server cannot interact with the HSM because it requires inserting and removing the OCS cards.

In that case, we recommend that Thales' CNG provider be configured to use module protection instead of an OCS. It is possible to use an OCS with Secret Server if the quorum is exactly one card and the card is left in the HSM at all times.

Consult your HSM vendor and their documentation to ensure that the HSM and their CNG provider are able to operate in silent mode and are configured to do so.

Configuring the HSM Integration

To configure the HSM integration, go to the **Admin > HSM**.

For CNG:

You can find the list of available CNG Providers by querying for the list of registered CNG providers. Each provider must correctly report that it is a "Hardware" provider, and that it is not a Smart Card reader. If an error occurs while querying the CNG provider for its properties, it will not appear in the list. The error, however, is reported to Secret Server's system log.

If the desired CNG provider does not appear in the list of CNG providers, ensure that the provider is correctly registered and that IIS has been restarted after the CNG registration. Also check that an error is not occurring while querying the HSM by examining the system log.

For PKCS #11:

Each HSM vendor provides a cryptoki library (dll) for PKCS #11 that Secret Server can interface with to perform cryptographic operations. Please note:

- This DLL must be copied to the `c:\inetpub\wwwroot\SecretServer\pkcs11` folder for Secret Server to see it.
- This DLL must support `CKM_AES_KEY_GEN and CKM_AES_CBC_PAD` mechanisms and the slot must be a hardware slot.

Along with the DLL, a token label and the user PIN are needed for Secret Server setup. Please refer to your HSM vendor's documentation for obtaining these values.

Once the options are selected, Secret Server simulates encryption and decryption operations and verifies the results to check that they're functioning properly. Finally, Secret Server verifies the selected providers, and then enables the HSM integration.

Stopping Other Nodes in a Clustered Environment

HSMs cannot be enabled, disabled, or rotated in a clustered Secret Server environment.

Follow these steps on all nodes (except for the one running) to stop other nodes while updating the HSM configuration:

1. Open the IIS Manager on the server node.
2. Expand the server.
3. Select **Application Pools**.
4. Right-click on the Secret Server application pool.
5. Select **Stop**.

Follow these steps on the one running node:

1. Search for **Backup**.
2. Click on **Run Backup Now** at the top right. This backs up the Secret Server database and application files.
3. Search for **HSM**.

4. Click on one of these HSM options: **Enable HSM**, **Disable HSM**, or **Rotate HSM Key** and follow the previous instructions.
5. Once completed, go back to the IIS Manager and recycle the Secret Server application pool, or open a command prompt window as an administrator and perform an IIS reset.
6. Confirm that accessing secrets in Secret Server is successful.

Follow these steps on each of the other server nodes:

1. Copy the updated `encryption.config` file from the one running node to the `c:\inetpub\wwwroot\SecretServer` folder.
2. Open the IIS Manager.
3. Expand the server.
4. Select **Application Pools**.
5. Right-click on the Secret Server application pool.
6. Select **Start**.
7. Confirm that logging in and accessing secrets in Secret Server is successful.

Enabling HSM

To enable the HSM:

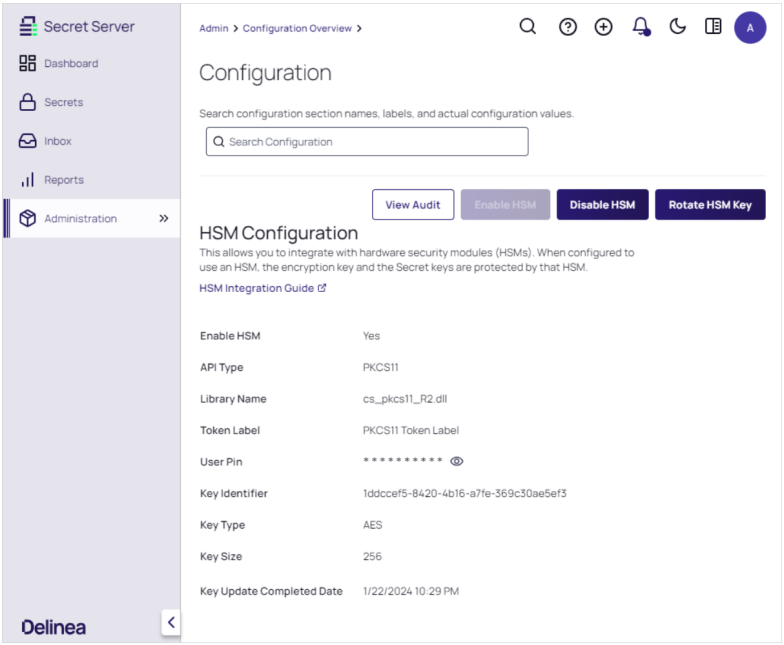
1. Search for **HSM**.
2. Click **Enable HSM** at the top right.

   > Back up the `encryption.config` file before proceeding.

3. Click the **Next** button.
4. Select the **API type** - the type of API used to access HSM:
   - For CNG, select:
     - **Persistent Provider**: The location where the encryption key will be persisted.
     - **Key Type**: The type of key.
     - **Key Size**: The size of the key in bits.
     - **Padding Type**: The padding scheme used for encryption with the RSA key.
   - For PKCS11, select:
     - **Library name**: The HSM vendor-specific cryptoki library used for PKCS#11.
     - **Token Label**: Type the token label created during PKCS#11 setup with the HSM vendor.
     - **User pin**: Type the user pin created during PKCS#11 setup with the HSM vendor.

- **Key Type**: The type of key.
- **Key Size**: The size of the key in bits.

5. Click **Next**. This performs a test to ensure the HSM can be used.
6. Click the **Next** button.
7. Verify the HSM configuration.
8. Click the **Save** button. The enabled configuration looks like this:



9. Do an IIS reset or application pool recycle. This starts the rotation.

Rotating the HSM Key

If HSM is enabled, Secret Server can now rotate the HSM key to ensure the secret keys are always protected by an HSM key. Rotating the HSM key only decrypts the secret keys and then re-encrypts them with the new HSM key. We recommend performing a secret key rotation after the HSM key has been rotated.

To rotate the HSM key:

1. Search for **HSM**.
2. Click the **Rotate HSM Key** button.

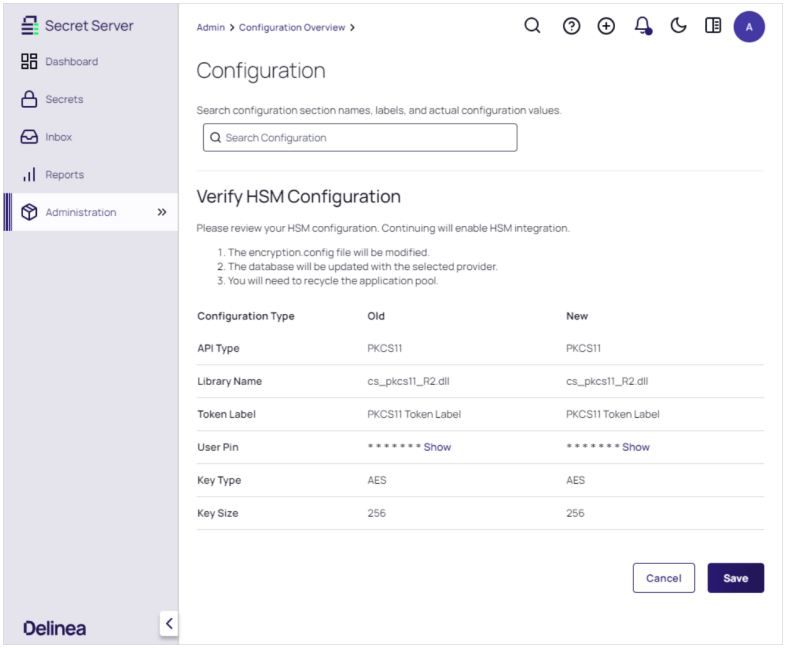
> Back up the `encryption.config` file before proceeding.

3. Click the **Next** button.
4. Select the **API type** - the type of API used to access HSM:

> Secret Server is unable to rotate to a different API type. So the selection will be the same API type as currently used.

- For CNG, select:
  - **Persistent Provider**: The location where the encryption key will be persisted.
  - **Key Type**: The type of key.
  - **Key Size**: The size of the key in bits.
  - **Padding Type**: The padding scheme used for encryption with the RSA key.
- For PKCS11, select:
  - **Library name**: The HSM vendor-specific cryptoki library used for PKCS#11.
  - **Token Label**: Type the token label created during PKCS#11 setup with the HSM vendor.
  - **User pin**: Type the user pin created during PKCS#11 setup with the HSM vendor.
  - **Key Type**: The type of key.
  - **Key Size**: The size of the key in bits.

5. Click **Next**. This performs a test to ensure the HSM can be used.
6. Verify the new HSM configuration:



7. Click **Save**.
8. Do an IIS reset or application pool recycle. This starts the rotation.

Disabling HSMs

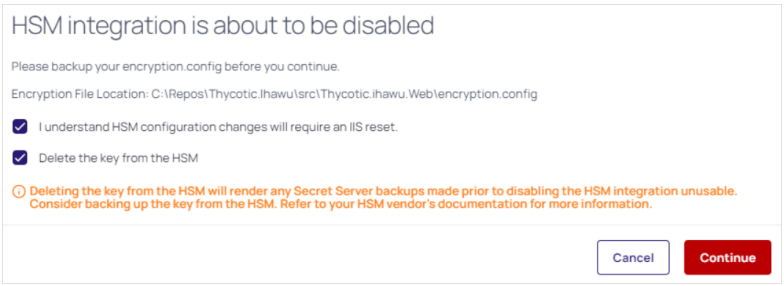
> This procedure requires an IIS reset.

To disable an HSM:

1. Search for **HSM**.

   > Back up the `encryption.config` file before proceeding.

2. Click the **Disable HSM** button. A warning popup appears:



3. Decide if you want to delete the key from the HSM.

   > Keep in mind deleting the key makes any backups using this key unusable.

4. Click **Continue**.
5. Do an IIS reset. This starts the rotation.

Securing the HSM Integration

The wizard to enable, rotate, and disable HSM integration is protected by the **Administer HSM** role permission in Secret Server. The permission should be carefully assigned–if at all. Additionally, you can create an event subscription that sends alerts when the role permission is assigned or unassigned from a role.

Configuring the HSM also has its own event subscriptions for when the HSM integration is enabled, rotated, or disabled.

You can add an application setting to Secret Server to prevent changes to HSM configuration. Enabling, rotating, and disabling this requires direct access to the file system where Secret Server is installed.

To enable this setting, edit the `web-appSettings.config` file within Secret Server to contain a key called **LockHsmConfiguration** with a value of **True** as follows:

```
<?xml version="1.0" encoding="utf-8" ?>
<appSettings>
  <add key="LockHsmConfiguration" value="True" />
</appSettings>
```

This prevents access to the HSM configuration pages, regardless of role permissions. The only way to gain access is to remove this setting, proving you, at a minimum, have access to the server where Secret Server is installed.

HSM Redundancy

HSM redundancy varies from HSM to HSM. Please refer to the vendor's documentation on how to back up the HSM. Backups are typically either made to a common file location, another HSM, or onto a smart card with the HSM's built-in smart card reader.

As long as the HSM provider is installed on the server and a key exists on the HSM with the same identifier, Secret Server will attempt to use that key.

Testing HSM CNG Configuration

Secret Server does its own testing and verification of the HSM and its CNG provider before the HSM integration can be enabled. To further diagnose any issues with the HSM, the **certutil** command line utility, which is part of Windows, can test the HSM with the **-csptest** option specified.

An example output may contain something like this:

```
Provider Name: SafeNet Key Storage Provider
   Name: SafeNet Key Storage Provider
……
Asymmetric Encryption Algorithms:
  RSA
      BCRYPT_ASYMMETRIC_ENCRYPTION_INTERFACE -- 3
      NCRYPT_ASYMMETRIC_ENCRYPTION_OPERATION -- 4
      NCRYPT_SIGNATURE_OPERATION -- 10 (16)
    NCryptCreatePersistedKey(SafeNet Key Storage Provider, RSA)
       Name: cngtest-6166f8fe-8caf-4e30-8e5c-a-24575
……
Pass
```

Examine the output of the test by looking for your CNG provider's name for your HSM and verifying the result. We recommend running this test using the same account as the application pool Secret Server is using. If the testing tool reports errors, consult your HSM's vendor or documentation for resolution.

PKCS #11 Log

The PKCS #11 logs are stored at `c:\inetpub\wwwroot\SecretServer\pkcs11\log\SSPKCS11.log`. This captures the PKCS #11 activity between Secret Server and the HSM when enabling, rotating, and disabling.

Each HSM vendor will have a way to output the PKCS #11 logging to a file. Please refer to your HSM vendor's documentation on how to set up logging.

Troubleshooting

If this error message `Thycotic.HSM.CNG.CngException: Failed to operate transformation` occurs, do the following:

1. Go to the Secret Server directory.
2. Open the `web-appSettings.config` file located at `c:\inetpub\wwwroot\SecretServer`.
3. Add the following tag in that file:

```
<?xml version="1.0" encoding="utf-8" ?>
<appSettings>
    <add key="RecycleAppPoolOnHSMError" value="true" />
</appSettings>
```

4. Restart IIS.

Enabling and Disabling HSM for Clustered Environments With Licensing Issues

> This topic only applies to **Secret Server On-Premises**.

If you are having a license issue with HSM enabled, you will need to disable HSM in order to continue to the Secret Server License page. This guide will also be helpful if you do not have a license issue, but would like to disable an HSM in Secret Server.

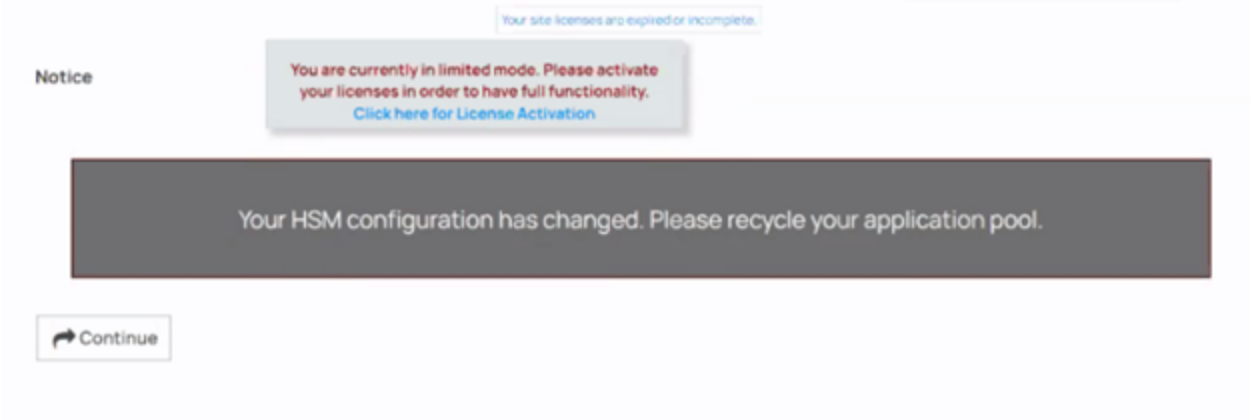
1. The first step is to backup your application folder on any of your server nodes and your database. The application folder path in *C:\Inetpub\wwroot\SecretServer*. This Secret Server folder will be the folder of the node that will not have the application pool stopped. This will be the application folder for the working node. The Secret Server folder will hold the encryption.config file. For backing up your database, you can follow the documentation from Microsoft.
2. Once the backup is completed and stored somewhere safely, please proceed and stop the Application Pools on all server nodes except for one.

   > If you have only one server node then this step can be skipped.

3. After completing step 2, please click **Disable HSM** which will give you two checkbox options: One asking you to backup the encryption.config key and one asking if you would like to clear your HSM key. Please click on Option 1 as you have completed this by backing up your Secret Server Application Folder.

   > You can choose Option 2, but this will require you to set up the HSM key again.

4. After this has completed you will get a message like in the screenshot below. This will require you to restart your application pool on the current standing node or you can run an iisreset in CMD (Run As Administrator).



5. If you are not experiencing a license issue, please skip to step 8. If you are experiencing a license issue please go to the license page.
6. At the license page, start your application pool on all application servers. If you have a single node then please disregard this step.
7. Add any new licenses to this page and make sure you click license activation to activate across all servers. Please remove any expired licenses to avoid any confusion in the future. Removing expired licenses will not effect your environment.
8. Take the backup encryption file from your working node and copy and paste it to the rest of the Application Server nodes in this file directory *C:\\Inetpub\wwroot\SecretServer*. You need to copy and replace this. Then, run an *iisreset* for each server this was replaced on.
9. Please then enable clustering if it was disabled in **Administration > Server Nodes.**
10. Please take any servers out of maintenance mode if necessary.

Master Encryption Key Rotation

Important Support Note: Rotating the master encryption key is a sensitive operation. While we have detailed the steps in this topic, we urge you to contact Support to work with a support representative before attempting any MEK rotation to ensure all prerequisites have been met. Please provide at least a five-day notice in advance of when you want to conduct the rotation.

Overview

When Secret Server is first installed, a unique random AES256 Master Encryption Key (MEK) is generated and saved in a file, `encryption.config`. The MEK protects anything sensitive in Secret Server that is not associated with a specific secret, as well as each secret's unique AES256 key when an HSM is not used.

For added security, you can rotate the MEK, re-encrypting protected data with the new key.

Geo-Replication, DPAPI, or an active secret key rotation must not be in effect when rotating the MEK.

MEK rotation fully supports using a Hardware Security Module (HSM) for Secret Server On-Premises or key management for Secret Server Cloud. This feature requires Enterprise Plus edition or the advanced encryption license. If you are using an HSM, disable it for your first MEK rotation. You can then re-enabled it, and you can run future MEK rotations without disabling it.

If the rotation button is disabled then DPAPI also needs to be disabled, otherwise it will cause the process to fail. The DPAPI needs to be disabled on all nodes.

Rotation Procedure

To perform a MEK rotation:

1. **Important:** For Secret Server on Premises, back up the current MEK file `encryption.config` in the application directory **on each node**.

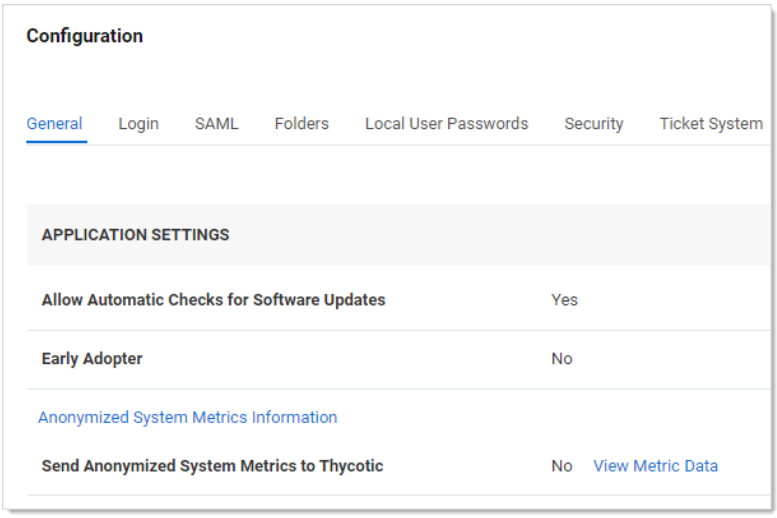
   Do not continue until you back up your encryption key. Failure to do so could cause extensive permanent data loss.

   For Secret Server on Premises, if this is the first MEK rotation, also backup any encrypted session recording videos saved to disk. They are only updated during the very first MEK rotation. Failure to do so could cause extensive **permanent data loss**.

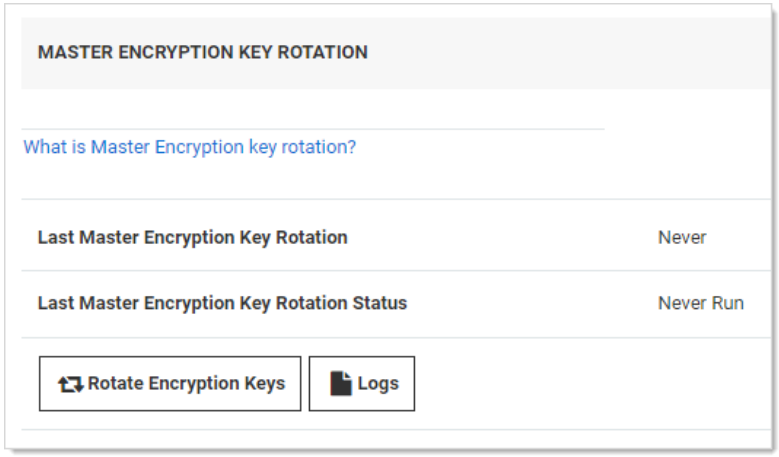
2. **Important:** For Secret Server on Premises, back up your database. See the first task on the "Moving the Microsoft SQL Server Database to Another Machine" on page 125 topic for details.

   Do not continue until you back up your database. Failure to do so could cause extensive **permanent data loss**.

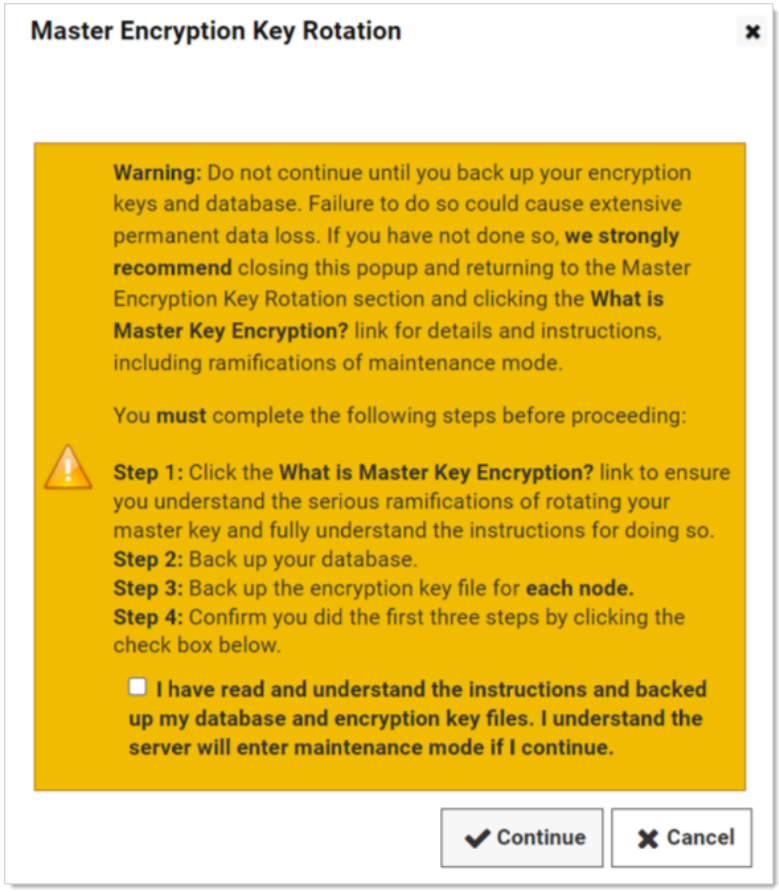
3. Search for **Security**. The Configuration page appears:



4. Click the **Security** tab.
5. Go to the **Master Encryption Key Rotation** section (*not* the Key Rotation section):



6. Click the **Rotate Encryption Keys** button. The Master Encryption Key Rotation popup appears:



7. Carefully read the text, especially for the check box itself.

8. When you are finished, click to select the check box to acknowledge having read it.
9. Click the **Continue** button. The server goes into maintenance mode to perform MEK rotation. Secrets and configuration settings cannot be updated while in maintenance mode. Secrets cannot be updated while in this mode. Processing time will vary, depending on the hardware, number of secrets, and HSM key size.
10. The rotation begins.
11. Secret Server updates the `encryption.config` file on the current server. The file now contains the new MEK, as well as the previous MEK, which is needed to re-encrypt all of the data. The `encryption.config` file is only updated on the node you are connected to when you click the **Rotate Encryption Keys** button, so, depending on whether you have clustered servers, pick one of the following procedures:

    If you are *not* running a cluster of On-Premises servers:

    a. When prompted to restart the IIS application, run `iisreset` to stop and restart the IIS server.

    b. Open Secret Server to restart it.

    If you *are* running a cluster of On-Premises servers:

    a. When prompted to restart the IIS server, run command `iisreset /stop` on all nodes in an elevated command prompt. This stops but does not restart IIS on the nodes.

    b. Copy the `encryption.config` file from the updated node to all other nodes.

    Note: If you are not sure which node performed the rotation, check the "modified time" of the `encryption.config` files.

    c. Run `iisreset /start` on all nodes. This restarts IIS on the nodes.

    d. Open Secret Server to restart it. The first Secret Server node you run continues the rotation process.
12. The new MEK takes effect, and any *new* records encrypted use the new key. Any data still using the old key continues to work until the rotation fully finishes.
13. Secret Server's background worker (Secret Server-BWSR.log) enables maintenance mode, preventing changes to secrets and other configuration settings, and continues the rotation process.
14. Secret Server marks the data needing an update in the database and begins rotating everything. A progress bar appears on the **Security** tab.
15. After all data is rotated except for session recording videos, maintenance mode is disabled.
16. Secret Server's session recording role (Secret Server-SRWSR.log) starts rotating any existing session recording videos encrypted by the MEK. The **Last Master Encryption Key Rotation Status** text changes to **Pending - Encrypting Session Data**. Depending on the number of videos, this may take some time. This only applies to the first MEK rotation–further rotations do not update the recordings again.
17. Once the process finishes, the **Last Master Encryption Key Rotation Status** text changes to **Completed - Master Encryption Keys Rotated**.

> Because we only track the current and previous MEK, the MEK rotation must be fully successful before you can run another one. A Retry button appears if the process times out or needs restarting. Monitor the rotation status and contact support if it fails to complete. Failure to do so could cause extensive **permanent data loss**.

Secret Key Rotation

Overview

Secret key rotation is a somewhat similar process to RPC by which the encryption key, used for securing secret data, is changed and that secret data is re-encrypted. Each secret receives a new, unique AES-256 key. Secret key rotation can be used to meet compliance requirements that mandate encryption keys be changed on a regular basis.

How to Perform Secret Key Rotation

> Secret key rotation requires the Rotate Encryption Keys permission.

1. Search for **Security.**
2. In the **Key Rotation** section, click the **Rotate Secret Keys** button.

Secret key rotation begins as soon as Secret Server enters maintenance mode. Because maintenance mode disables various functionality (such as secrets cannot be updated), the timing of secret key rotation merits consideration of Secret Server processing time. We recommend running secret key rotation during off-peak or non-business hours.

> To learn more about maintenance mode, see the "Maintenance Mode FAQ" on page 234.

Estimated Processing Time

Maintenance mode takes five minutes to enable before secret key rotation is started. The processing time for secret key rotation varies greatly, depending on the following factors:

- Total number of secrets
- Total number of secrets with file attachments and the size of those file attachments
- Hardware configuration:
  - Number of CPUs and cores
  - Memory size
  - Network latency
- HSM key size, if applicable

As a general guideline, use the following:

Table: Secret Key Rotation Processing Time

Configuration	Approximate Time Taken
Without HSM (default)	2,000-12,000 secrets per minute

Configuration	Approximate Time Taken
HSM with a 2048-bit key	240-600 secrets per minute
HSM with a 4096-bit key	120-300 Secrets per minute

Secret Server Telemetry

This topic only applies to Secret Server On-Premises

Overview

There are 3 reasons for Delinea products to call home–when:

- Checking for available updates
- Activating licenses
- Reporting anonymized usage metrics

Each of these communications is explained below and can be disabled or avoided.

Checking for and Downloading Updates

Frequency: Once per day

The software checks for available updates and sends the following information to Delinea's update server:

- .NET Framework version
- IP address of the installed instance
- Microsoft SQL Server version
- Microsoft Windows version
- Product version

Checking for updates and sending this information will only occur if both of the following are true:

- The server has outbound network access, which you can block at a firewall.
- The "Allow Automatic Checks for Software Updates" check box is enabled at **Admin > Configuration > Application** (see below).

No sensitive data is sent during the check. Its only purpose is to alert administrators if a software update is available. The queried website is also used to download new software versions during the upgrade process. If you wish to allowlist the specific servers involved, they are:

- `d36zgw9sidnotm.cloudfront.net:443`
- `updates.thycotic.net:443`
- `updates.thycotic.net:80`
- `tmsnuget.thycotic.com/nuget/`

Note that Secret Server would still manually check for an update if there is internet access and a manual update is triggered, even if Allow Automatic Checks for Software Updates feature is off.

License Activation

Frequency: when a new license is activated.

The software also sends contact and license-key information, provided by the administrator, to Delinea during online license activation. The same information is sent via another computer for offline activation.

Reporting Anonymized Usage Metrics

This section only applies to Secret Server and Secret Server Cloud versions 10.6 and above.

Delinea collects anonymized usage data to help guide future research and development plans so that product improvements can provide the greatest benefit to customers.

Frequency: Once per day

Secret Server returns anonymized metrics across several categories:

- A unique identifier number that allows Delinea to correlate metrics from the same server over time but does not contain any information that identifies the customer.
- License information, including edition information and the number of licensed users but not license keys or other identifying data.
- Product configuration and usage, such as number of secrets stored and product feature status, not including any identifying data.
- Product environment, including host operating system and SQL server version, not including any identifying data.

Reporting of anonymized metrics only occurs if:

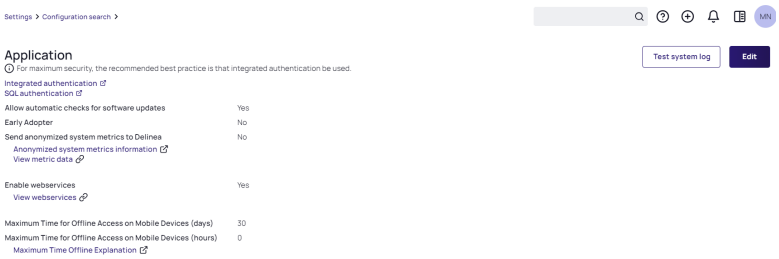
- The server has outbound network access (you can block your server at a firewall if desired)
- The "Send Anonymized System Metrics to Delinea" setting under Admin > Configuration is enabled (see below).

You can allow for the metrics reporting on your firewall by allowlisting: `https://telemetry.thycotic.net:443`.

Setting and Viewing Secret Server Telemetry

To set or view telemetry:

1. Click **Admin > Configuration search**, then select **Application** from the General section. The Applicationsettings page appears:



2. (Optional) To view the JSON file for the possible sent metrics, click the **View Metric Data** link. The file appears:

```
{
  "identifier": "cef588896e3e9718d59ccdd0f9e77568",
  "licenses": [],
  "features": [
    {
      "name": "Remote Password Changing",
      "enabled": true,
      "count": 0,
      "countDescription": "Secrets with AutoChange enabled"
    },
    {
      "name": "Heartbeat",
      "enabled": true,
      "count": 614,
      "countDescription": "Secrets with Heartbeat enabled"
    },
    {
      "name": "Checkout",
      "enabled": true,
      "count": 5,
      "countDescription": "Secrets with Checkout enabled"
    },
    {
      "name": "Checkout Change Password",
      "enabled": false,
      "count": 0,
      "countDescription": "Secrets with Checkout change password enabled"
    },
    {
      "name": "DoubleLock",
      "enabled": true,
      "count": 0,
      "countDescription": "Secrets with DoubleLock enabled"
    },
    {
      "name": "Request Access",
      "enabled": true,
      "count": 104,
      "countDescription": "Secrets with Request Access enabled"
    },
    {
      "name": "Request Access Editors need approval",
      "enabled": true,
```

3. Click **Edit**. The section changes to edit mode.
4. Click to select or deselect the **Send Anonymized System Metrics to Delinea** check box.
5. Scroll down and click the **Save** button.

Securing ASP Cookies

> This topic only applies to **Secret Server On-Premises**.

To secure your ASP session and forms authentication cookies, perform the following steps:

1. Ensure that there is an SSL certificate installed for the instance.
2. Log in to Secret Server using HTTPS.
3. Navigate to the **Admin > Configuration** page
4. Click on the **Security** tab.
5. Click the **Edit** button
6. Check the **Force HTTPS/SSL** check box
7. Click the **Save** button.
8. Open the `web-cookie.config` file in the application installation folder.
9. Set `requireSSL` to `true`.

   Save and Close the file.
10. Open the `web-auth.config`file in the application installation folder.
11. Set `requireSSL` to `true` . If the attribute does not exist, add it to the `forms` tag.

    Save and Close the file.
12. Recycle the Secret Server's application pool.

> If you later migrate Secret Server to a new server, SSL must be configured on the new server before you can log in due to these settings. If you want to log in prior to configuring SSL, reverse steps 8 through 13 and recycle the application pool.

Securing IIS Server

> This topic only applies to **Secret Server On-Premises**.

This is a list of items that IIS admin can implement to secure the IIS Web server for additional Secret Server hardening.

Accounts

- Remove unused accounts from the server.
- Disable the Windows Guest account.
- Rename the Administrator account.
- Ensure the Administrator account has a strong password.
- Ensure the IUSR_MACHINE account is disabled if it is not used by the application.
- If your applications require anonymous access, create a custom least-privileged anonymous account. Ensure the anonymous account does not have write access to Web content directories and cannot execute command-line tools.
- Ensure the ASP.NET process account is configured for least privilege. This only applies if you are not using the default ASPNET account, which is a least-privileged account.

- Ensure strong account and password policies are enforced for the server.
- Restrict remote logons–the "Access this computer from the network" user-right is removed from the Everyone group.
- Disable null sessions (anonymous logons).
- Ensure no more than two accounts are in the Administrators group.

Auditing and Logging

- Audit failed logon attempts.
- Relocate and secure IIS log files.
- Configure log files with an appropriate size, depending on the application security requirement.
- Regularly archive and analyze log files.
- Audit access to the `Metabase.bin` file.
- Configure IIS to us the W3C extended log file format for auditing.

Code Access Security

- Enable code access security on the server.
- Remove all code access security permissions from the local intranet zone.
- Remove all code access security permissions from the Internet zone.

Files and Directories

- Ensure files and directories are contained on NTFS volumes.
- Ensure Web site content is located on a non-system NTFS volume.
- Ensure log files are located on a non-system NTFS volume and not on the same volume where the Web site content resides.
- Ensure the All Vault Users group is restricted (no access to `\Windows\system32` or Web directories).
- Ensure the website root directory has deny write ACE for anonymous Internet accounts.
- Ensure content directories have deny write ACE for anonymous Internet accounts.
- Remove the Remote IIS administration application.
- Remove the Resource Kit tools, utilities, and SDKs.

IIS Metabase

- Use NTFS permissions to restrict access to the metabase (`%systemroot%\system32\inetsrv\metabase.bin`).
- Ensure IIS banner information is restricted (IP address in content location is disabled).

ISAPI Filters

Ensure unnecessary or unused ISAPI filters are removed from the server.

Machine.config

- Ensure protected resources are mapped to HttpForbiddenHandler.
- Remove unused HttpModules.
- Ensure tracing is disabled: `<trace enable="false"/>`.
- Ensure debug compiles are turned off: `<compilation debug="false" explicit="true" defaultLanguage="vb">`

Patches and Updates

- Run Microsoft Baseline Security Analyzer on a regular interval to check for latest operating system and components updates, including

  Windows, IIS server, and the .NET Framework.
- Test updates on development servers prior to deployment on production servers.
- Check the Microsoft Security Notification Service at docs.microsoft.com on a regular interval for up-to-date Microsoft technical security notifications.

Ports

- Ensure Internet-facing interfaces are restricted to port 80 (and 443 if SSL is used).
- Ensure Intranet traffic is encrypted (for example, with SSL) or restricted.

Protocols

- Disable WebDAV if not used by the application or secure it if it is required.
- Harden the TCP/IP stack.
- Ensure NetBIOS and SMB are disabled if not used (closes ports 137, 138, 139, and 445).

Registry

- Restrict remote registry access.
- Secure SAM (`HKLM\System\CurrentControlSet\Control\LSA\NoLMHash`).

Script Mappings

- Ensure extensions not used by the application are mapped to `404.dll`, including .idq, .htw, .ida, .shtml, .shtm, .stm, idc, .htr, and .printer.
- Ensure unnecessary ASP.NET file type extensions are mapped to HttpForbiddenHandler in `Machine.config`.

Server Certificates

- Ensure certificate date ranges are valid.
- Ensure certificates are used for their intended purpose (for example, the server certificate is not used for e-mail).

- Ensure the certificate's public key is valid, all the way to a trusted root authority.
- Ensure the certificate is SHA 256 or better.

Services

- Disable unnecessary Windows services.
- Ensure services are running with least-privileged accounts.
- You can disable FTP, SMTP, and NNTP services if they are not required.
- Ensure the Telnet service is disabled.
- Ensure the ASP.NET state service is disabled and is not used by your applications.

Shares

- Ensure all unnecessary shares are removed (including default administration shares).
- Restrict access to required shares (the All Vault Users group does not have access).
- Remove administrative shares (C$ and Admin$) if they are not required.

Sites and Virtual Directories

- Ensure Web sites are located on a non-system partition.
- Ensure the "Parent paths" setting is disabled.
- Remove potentially dangerous virtual directories, including IISSamples, IISAdmin, IISHelp, and Scripts.
- Remove or secure MSADC virtual directory (RDS).
- Ensure include directories do not have the "Read Web" permission.
- Restrict Write and Execute Web permissions for the anonymous account on virtual directories that allow anonymous access.
- Ensure there is script source access only on folders that support content authoring.
- Ensure there is write access only on folders that support content authoring and these folder are configured for authentication (and SSL encryption, if required).
- Remove FrontPage Server Extensions (FPSE) if not used. If they are used, ensure they are updated and access to FPSE is restricted.

Other Considerations

- Ensure server remote administration is secured and configured for encryption, low session time-outs, and account lockouts.Ensure HTTP requests are filtered.
- Use a dedicated machine as a Web server.
- Physically protect the Web server machine in a secure machine room.
- Configure a separate anonymous user account for each application, if you host multiple Web applications.
- Do not install the IIS server on a domain controller.

- Do not connect an IIS Server to the Internet until it is fully hardened.
- Do not allow anyone except the administrator to locally log on to the machine.

Securing IIS Server

> This topic only applies to **Secret Server On-Premises**.

This is a list of items that IIS admin can implement to secure the IIS Web server for additional Secret Server hardening.

Accounts

- Remove unused accounts from the server.
- Disable the Windows Guest account.
- Rename the Administrator account.
- Ensure the Administrator account has a strong password.
- Ensure the IUSR_MACHINE account is disabled if it is not used by the application.
- If your applications require anonymous access, create a custom least-privileged anonymous account. Ensure the anonymous account does not have write access to Web content directories and cannot execute command-line tools.
- Ensure the ASP.NET process account is configured for least privilege. This only applies if you are not using the default ASPNET account, which is a least-privileged account.
- Ensure strong account and password policies are enforced for the server.
- Restrict remote logons–the "Access this computer from the network" user-right is removed from the Everyone group.
- Disable null sessions (anonymous logons).
- Ensure no more than two accounts are in the Administrators group.

Auditing and Logging

- Audit failed logon attempts.
- Relocate and secure IIS log files.
- Configure log files with an appropriate size, depending on the application security requirement.
- Regularly archive and analyze log files.
- Audit access to the `Metabase.bin` file.
- Configure IIS to us the W3C extended log file format for auditing.

Code Access Security

- Enable code access security on the server.
- Remove all code access security permissions from the local intranet zone.

- Remove all code access security permissions from the Internet zone.

Files and Directories

- Ensure files and directories are contained on NTFS volumes.
- Ensure Web site content is located on a non-system NTFS volume.
- Ensure log files are located on a non-system NTFS volume and not on the same volume where the Web site content resides.
- Ensure the All Vault Users group is restricted (no access to `\Windows\system32` or Web directories).
- Ensure the website root directory has deny write ACE for anonymous Internet accounts.
- Ensure content directories have deny write ACE for anonymous Internet accounts.
- Remove the Remote IIS administration application.
- Remove the Resource Kit tools, utilities, and SDKs.

IIS Metabase

- Use NTFS permissions to restrict access to the metabase (`%systemroot%\system32\inetsrv\metabase.bin`).
- Ensure IIS banner information is restricted (IP address in content location is disabled).

ISAPI Filters

Ensure unnecessary or unused ISAPI filters are removed from the server.

Machine.config

- Ensure protected resources are mapped to HttpForbiddenHandler.
- Remove unused HttpModules.
- Ensure tracing is disabled: `<trace enable="false"/>`.
- Ensure debug compiles are turned off: `<compilation debug="false" explicit="true" defaultLanguage="vb">`

Patches and Updates

- Run Microsoft Baseline Security Analyzer on a regular interval to check for latest operating system and components updates, including

  Windows, IIS server, and the .NET Framework.
- Test updates on development servers prior to deployment on production servers.
- Check the Microsoft Security Notification Service at docs.microsoft.com on a regular interval for up-to-date Microsoft technical security notifications.

Ports

- Ensure Internet-facing interfaces are restricted to port 80 (and 443 if SSL is used).
- Ensure Intranet traffic is encrypted (for example, with SSL) or restricted.

Protocols

- Disable WebDAV if not used by the application or secure it if it is required.
- Harden the TCP/IP stack.
- Ensure NetBIOS and SMB are disabled if not used (closes ports 137, 138, 139, and 445).

Registry

- Restrict remote registry access.
- Secure SAM (`HKLM\System\CurrentControlSet\Control\LSA\NoLMHash`).

Script Mappings

- Ensure extensions not used by the application are mapped to `404.dll`, including .idq, .htw, .ida, .shtml, .shtm, .stm, idc, .htr, and .printer.
- Ensure unnecessary ASP.NET file type extensions are mapped to HttpForbiddenHandler in `Machine.config`.

Server Certificates

- Ensure certificate date ranges are valid.
- Ensure certificates are used for their intended purpose (for example, the server certificate is not used for e-mail).
- Ensure the certificate's public key is valid, all the way to a trusted root authority.
- Ensure the certificate is SHA 256 or better.

Services

- Disable unnecessary Windows services.
- Ensure services are running with least-privileged accounts.
- You can disable FTP, SMTP, and NNTP services if they are not required.
- Ensure the Telnet service is disabled.
- Ensure the ASP.NET state service is disabled and is not used by your applications.

Shares

- Ensure all unnecessary shares are removed (including default administration shares).
- Restrict access to required shares (the All Vault Users group does not have access).
- Remove administrative shares (C$ and Admin$) if they are not required.

Sites and Virtual Directories

- Ensure Web sites are located on a non-system partition.
- Ensure the "Parent paths" setting is disabled.
- Remove potentially dangerous virtual directories, including IISSamples, IISAdmin, IISHelp, and Scripts.
- Remove or secure MSADC virtual directory (RDS).
- Ensure include directories do not have the "Read Web" permission.
- Restrict Write and Execute Web permissions for the anonymous account on virtual directories that allow anonymous access.
- Ensure there is script source access only on folders that support content authoring.
- Ensure there is write access only on folders that support content authoring and these folder are configured for authentication (and SSL encryption, if required).
- Remove FrontPage Server Extensions (FPSE) if not used. If they are used, ensure they are updated and access to FPSE is restricted.

Other Considerations

- Ensure server remote administration is secured and configured for encryption, low session time-outs, and account lockouts.Ensure HTTP requests are filtered.
- Use a dedicated machine as a Web server.
- Physically protect the Web server machine in a secure machine room.
- Configure a separate anonymous user account for each application, if you host multiple Web applications.
- Do not install the IIS server on a domain controller.
- Do not connect an IIS Server to the Internet until it is fully hardened.
- Do not allow anyone except the administrator to locally log on to the machine.

Hiding HTTP Header Information

This topic only applies to **Secret Server On-Premises**.

Web applications, such as Secret Server, can leak information useful to attackers via headers, error messages, version numbers, and more. To hide HTTP header information in Secret Server, follow the procedures below.

Hide the IIS Version

To hide the version of IIS used on the server, remove the HTTP header *X-Powered-By* by following the steps below:

1. Open the IIS Manager.
2. In the Connections tree, select the website that Secret Server is running under.
3. Click the **HTTP Response Headers** button on the right. The HTTP Response Headers panel appears.

4. Click to select the **X-Powered-By HTTP** header.
5. Click the **Remove** button in the **Actions** panel.

Hide the ASP.NET Version

To hide the version of ASP.NET used by the Secret Server application pool, remove the HTTP header *X-ASPNET-VERSION* by following the steps below:

1. Open the `web.config` file for Secret Server, which is located in the root directory for the website.
2. Inside the `<system.web>` tag, add the tag `<httpRuntime enableVersionHeader="false"/>`.
3. Save the file.

Hide the Server Type

To hide the server type, remove the line, `Server: Microsoft-HTTPAPI/2.0` (added by the .NET framework) from the HTTP header using the procedure below:

> Although there are other methods for hiding the server type, we strongly recommend updating the Windows registry using the procedure below. Do not simply remove the server header variable. Doing so will cause parts of Secret Server to malfunction.

1. Navigate to **Computer > HKEY_LOCAL_MACHINE > SYSTEM > CurrentControlSet > Services > HTTP > Parameters**.
2. Change the **DisableServerHeader (REG_DWORD type)** registry key from 0 to 1.

APIs and Scripting

> This section contains general material on API access and scripting. APIs, scripts and techniques may appear elsewhere in the documentation for specific aspects of Secret Server. For example, Automatic Secret Export REST API is in the Secret Import and Export sections.

Secret Server offers a robust set of web services and APIs that enable organizations to seamlessly integrate privileged account management into their IT infrastructure and automate critical security processes. These APIs are designed to provide a secure and flexible way to interact with Secret Server programmatically, allowing for the development of custom workflows, integration with third-party applications, and enhancement of DevOps practices.

Web Services API

Secret Server's web services API includes both SOAP and RESTful interfaces, making it accessible to a wide range of programming languages and platforms. Developers can use these APIs to automate tasks such as creating, retrieving, and managing secrets, as well as configuring folders and permissions. This level of integration is crucial for maintaining a secure and efficient environment where privileged credentials are centrally managed and protected.

Key features of the Web Services API include:

- Authenticating to Secret Server
- Creating and managing folders
- Saving new secrets and editing existing ones
- Searching for secrets
- Setting permissions on secrets and folders

Learn more about API web services:

- API Web Services for Secret Server | Supports REST and SOAP

REST API Examples

Delinea provides examples and guides for using the REST API with various programming languages, such as Python and Perl. These examples demonstrate how to authenticate to Secret Server, retrieve secrets, and perform updates on secret fields and items. The REST API is particularly user-friendly, leveraging standard HTTP methods and status codes for operations, making it a preferred choice for modern web applications.

REST API capabilities include:

- Integration with scripting languages for custom automation
- Operations to manage secrets and their attributes
- Token-based authentication for secure access

REST API documentation:

- "REST API Reference Download" on page 1522

By using Secret Server's web services and APIs, organizations can ensure that their privileged account management is not only secure but also seamlessly integrated with their existing tools and workflows, enabling them to maintain a strong security posture while improving operational efficiency.

API Authentication

Script authentication in Secret Server is a critical aspect of securely automating tasks and integrating with other systems. The recommended approach is to use the Secret Server Software Development Kit (SDK) for DevOps, which provides a secure way to handle credentials and access tokens. The SDK ensures that credentials are stored securely and that tokens are used with a least-privilege approach, limiting access to only what is necessary. Additionally, it is important to avoid using admin accounts for scripts, never store passwords or tokens in plain text, and always set tokens to expire after a short period. Integrated Windows Authentication (IWA) can also be used for on-premises deployments. Following these best practices helps mitigate risks associated with automated scripts and ensures robust security.

Generating Self-Signed Certificates for Scripts

Please run the following as **Administrator**.

```
# This simply generates a self-signed certificate which will import into <Secret Server
URL />
# Requires .NET 4.5 or above
# Please Run As Administrator
### User Variables ###
# Filename of PFX
$filename = 'PFXNAMEHERE.PFX'
# Certificate Password for PFX
$pass = Read-Host -Prompt "Please Enter Password for .pfx file" -AsSecureString
# DNS name in certificate
$dnsname = Read-Host -Prompt "Please enter the server's FQDN"
###--Commands--###
# NOTE: The provider must be set in order to be compatible with .NET 4.5 newer versions of
.NET can import certs from more providers
try {
    $cert = New-SelfSignedCertificate -CertStoreLocation cert:\localmachine\my -DnsName
$dnsname -HashAlgorithm SHA256 -KeyLength 4096 -Provider "Microsoft Enhanced RSA and AES
Cryptographic Provider"
    $path = 'cert:\localmachine\my\' + $cert.thumbprint
    Export-PfxCertificate -Cert $path -FilePath $filename -Password $pass
    # remove from cert store
    Remove-Item $path
}
catch { Write-Error $_ }
```

Script Authentication Using Tokens

Overview

Manipulating the Secret Server API via scripts is very handy and powerful but also potentially dangerous, so it is critical to follow best practices to ensure robust security. This topic discusses these best practices. We recommend the Secret Server Software Development Kit for DevOps for all automated or machine-to-machine scripts. If not using the SDK, we strongly recommend creating an application account for script access and limiting Delinea permissions via both roles and the secrets themselves.

Best Practices

For security, it is critical that you:

- Do not use admin accounts.
- Use a least-privilege account, limiting role and secret access permissions.
- Never store passwords or tokens in plain text. Use secure credentials instead–see below for details.
- Use a least-privilege application account. These are restricted from logging in the UI.
- Never use domain admin credentials in an automated script.
- Create a specific service account with only the permissions needed to get the task done.
- Always expire tokens. To expire tokens, navigate to the **Admin > Application**, click **Edit**, check to enable **Session Timeout for Webservices**, and set the timeout to a short period (the default is 20 minutes).

Authentication Methods

> Entra ID authentication is not supported

Scripts Run by Automated Processes

Recommended methods:

- Secret Server Software Development Kit for DevOps (SDK). The SDK is a great way to limit access to a specific client with encrypted credentials and IP restrictions. See Using the Secret Server SDK for DevOps for more information.
- Integrated Windows Authentication (IWA).

Specific User Use Cases with Script Augmentation

Recommended methods:

- Get credentials with two-factor authentication (2FA). This is a secure way to prompt users for credentials for manually run scripts.
- Prompt with 2FA. This prompts the user for script credentials.
- IWA.

Example Credential-Access Scripts

Recommended Methods

Get-Credential with 2FA

```
$application = "<Secret Server URL>"
function Get-Token
{
    [CmdletBinding()]
    param(
        $credentials,
        [Switch] $UseTwoFactor
    )
    $creds = @{
        username = $credentials.UserName
        password = $credentials.GetNetworkCredential().Password
        grant_type = "password"
    };
    $headers = $null
    If ($UseTwoFactor) {
        $headers = @{
            "OTP" = (Read-Host -Prompt "Enter your OTP for 2FA: ")
        }
    }
    try
    {
```

```
        $response = Invoke-RestMethod "$application/oauth2/token" -Method Post -Body
$creds -Headers $headers;
        $token = $response.access_token;
        return $token;
    }
    catch
    {
        $result = $_.Exception.Response.GetResponseStream();
        $reader = New-Object System.IO.StreamReader($result);
        $reader.BaseStream.Position = 0;
        $reader.DiscardBufferedData();
        $responseBody = $reader.ReadToEnd() | ConvertFrom-Json
        Write-Host "ERROR: $($responseBody.error)"
        return;
    }
}
$token = Get-Token -credentials (Get-Credential) -UseTwoFactor
```

Prompting for Credentials with 2FA

```
$application = "<Secret Server URL>"
function Get-Token
{
    [CmdletBinding()]
    param( [Switch] $UseTwoFactor
    )
    $creds = @{
        username = Read-Host -Prompt "Enter your username: "
        password = Read-Host -Prompt "Enter your password: "
        grant_type = "password"
    };
    $headers = $null
    If ($UseTwoFactor) {
    $headers = @{
        "OTP" = (Read-Host -Prompt "Enter your OTP for 2FA: ")
       }
    }
    try
    {
        $response = Invoke-RestMethod "$application/oauth2/token" -Method Post -Body
$creds -Headers $headers;
        $token = $response.access_token;
        return $token;
    }
    catch
    {
        $result = $_.Exception.Response.GetResponseStream();
        $reader = New-Object System.IO.StreamReader($result);
        $reader.BaseStream.Position = 0;
        $reader.DiscardBufferedData();
        $responseBody = $reader.ReadToEnd() | ConvertFrom-Json
```

```
        Write-Host "ERROR: $($responseBody.error)"
        return;
    }
}
$token = Get-Token -UseTwoFactor
```

Integrated Windows Authentication

> Secret Server Cloud does not support IWA.

```
$api = "<Secret Server URL>" /winauthwebservices/api/v1"
$endpoint = "$api/secrets/3844"
$secret = Invoke-RestMethod $endpoint -UseDefaultCredentials
```

> See "Using Webservices with IWA via PowerShell" on page 400 for more information.

Downloading Example Scripts

Example Scripts:

- "REST API PowerShell Scripts" on page 1525

> For REST API Client Generation (Advanced), please see "REST API Client Generation with Swagger" on page 1517

> See "Using Webservices with IWA via PowerShell" on page 400 for more information.

Secret-based Credentials for PowerShell Scripts

Overview

You can specify a secret to provide the default credentials for running all PowerShell scripts on a site. This allows sites in different data centers to have different default credentials. This applies to remote password changing, checkout hooks, and account discovery PowerShell scripts.

> If you want a specific secret checkout hook, secret password changer, or account discovery scanner to use different credentials you can still provide credentials in those areas, which will take precedence over the one set on the site.

RunAs Secret Precedence

Remote Password Changing

The precedence order for which RunAs secret to use for remote password changing is:

1. Privileged account on the secret RPC tab
2. Secret site's RunAs secret
3. Secret

Secret Dependencies

The precedence order for which RunAs secret to use for PowerShell Secret dependencies is:

1. Privileged account on the dependency
2. RunAs secret on the dependency group's site
3. Secret site's RunAs secret
4. Secret

Checkout Hooks

The precedence order for which RunAs secret to use for checkout hooks is:

1. Privileged account on the hook
2. Secret site's RunAs secret
3. Secret

Procedures

Setting the Default PowerShell Credential for a Site

To set a default PowerShell credential for a site:

1. Search for **Distributed Engine** and select a site from the list.
2. In the **Advanced site configuration** section click **Edit**.
3. Next to the **Default PowerShell RunAs Secret** field click on the **No secret selected** link and select the related secret from the list.
4. Click **Save**.

Using the Site PowerShell Credentials for Discovery

To use the site PowerShell credentials on a discovery scanner:

1. Add a PowerShell scanner to a discovery source or edit an existing scanner:
   - Search for **Discovery** and select the **Configuration** tab.
   - Select **Extensible Discovery** from the dropdown at the top right, and select **Configure Discovery Scanners**.
   - Select a scanner from the list and click **Edit** to edit an existing scanner, or click **Create scanner** at the top right if you would like to create a new scanner.

- If creating a new scanner, specify its **Name** and **Description**, check to enable **State**, select the related **Scanner type**, and in the **Base scanner** field select **PowerShell Discovery**.
- Optionally check to enable **Allow OU** input, select the **Input template, Output template**, and **Script**.
- When done click **Save**.
- If editing an existing scanner, select a disabled scanner and set the related fields the same way its mentioned above, and click **Save**.

2. Select the scanner that you have just created or edited, click **Edit**,and check to select **Use Site RunAs Secret**.
3. Click **Save**.

> If no RunAs secret is set on the site, you will get an error message when you try to save.

Developer Resources

This topic is a one-stop resource for Secret Server developers. It points to topics, as well as legacy knowledgebase articles. See the main "APIs and Scripting" on page 1487 section too.

SOAP API

- SOAP Web Services API Guide (Legacy feature)

Scripting Overview

Scripting in Secret Server is a powerful feature that allows administrators and DevOps teams to automate complex tasks, integrate with third-party applications, and enhance security processes. Secret Server supports both SOAP and RESTful APIs, enabling seamless interaction with various programming languages such as .NET, Java, Python, Ruby, and PowerShell.

Key Features

- Automating complex tasks
- Integrating with third-party applications
- Enhancing security processes

The Secret Server Software Development Kit (SDK) provides a secure way to access the API directly from the command line, eliminating the need to hard-code credentials into scripts. Additionally, PowerShell scripts can be used for custom password changers, dependency management, and integration with ticketing systems. By leveraging these scripting capabilities, organizations can ensure efficient and secure management of privileged accounts and secrets.

Key Resources

- PowerShell Scripts: Discover how to create and use PowerShell scripts to automate tasks and integrate with Secret Server.
- Creating and Using SQL Scripts: Learn how to leverage SQL scripts for managing dependencies and automating database interactions.
- Creating and Using SSH Scripts: Explore the use of SSH scripts for secure remote operations and automation.
- Dependency Tokens: Understand how to use dependency tokens in scripts to manage and update secret dependencies efficiently.
- Using Secret Fields in Scripts: Find out how to access and manipulate secret fields within your scripts for enhanced functionality.

PowerShell Scripts Overview

PowerShell scripting in Secret Server provides a versatile and powerful way to automate tasks, manage dependencies, and integrate with various systems. By using PowerShell scripts, administrators can enhance security processes and streamline operations within their IT environments.

Key Features

- Automating complex tasks
- Managing dependencies
- Integrating with third-party applications

PowerShell scripts can be used for custom password changers, dependency management, and integration with ticketing systems. By leveraging these scripting capabilities, organizations can ensure efficient and secure management of privileged accounts and secrets.

Key Resources

Creating and Using PowerShell Scripts: Explore detailed guides on creating and utilizing PowerShell scripts to automate tasks and integrate with Secret Server.

Secret RPC Scripts: Learn advanced techniques for using PowerShell scripts to manage complex dependencies and enhance security processes.

Creating and Using PowerShell Scripts

Overview

You can use PowerShell scripts in Secret Server to automate specific tasks. These scripts are useful in several places in Secret Server, such as in creating custom remote password changers, custom dependency changers, discovery scanners, and custom ticket system integration.

Creating a PowerShell Script

1. Develop your script. See:
   - "REST API PowerShell Scripts" on page 1525
   - "Using Secret Fields in Scripts" on page 1516
   - "Dependency Token List" on page 1512

   Do not edit the script with Windows Notepad. Instead, use Notepad++, Visual Studio Code, or Atom. Windows Notepad can add invisible characters that can cause issues.

   Using PowerShell in Secret Server involves passing a parameter string to the script. This string can contain literal values as well as tokens that represent values on the object in Secret Server that the script is attached to. For example, when creating a custom password changer, you pass in values such as the user name, old password, and new password using tokens that represent these values for whichever secret is running the password change script. Similarly, dependencies have a set of tokens that represent values on the dependency and its associated secret.

2. Search for **Scripts: PowerShell, SQL, SSH**, and on the Scripts page, click **Create Script**.

> In some older versions of Secret Server, you can find the **Scripts** option under **Remote Password Changing** on the **Administration** menu bar.

3. In the New Script page, type the script name in the **Name** text box.
4. Type a description in the **Description** text box.
5. Choose to select the **Enabled** checkbox.
6. In the **Script Type** field select **PowerShell**.
7. Click the **Category** dropdown list to select the type of script. This will determine where the script resides in Secret Server and more. For instance, the Dependency choice ensures that Remote Password Changing is turned on by enabling it on the Remote Password Changing page.
8. Paste your script into the **Script** text box.
9. When done, click **Save**. The new script appears in the table on the Scripts page.

Best Practices

Debugging

Scripts may contain debug lines to help you test the script. Debug statements use the `Write-Debug` command. For example: `Write-Debug "The users name is $Username"`

Script Arguments

There are input boxes for specifying arguments in places where the PowerShell scripts are used. Argument values are specified on a single line separated by a space. Values containing spaces should be enclosed in quotes. Parameters to PowerShell scripts are referenced through the zero-based `Args` array. It is often beneficial to assign `Args` variables to other more-meaningful named variables. For example:

Arguments: "Welcome back" and "Joe"

Script:

```
$greeting = $Args[0]
$name = $Args[1]
Write-Debug "$greeting $name"
```

Output: "Welcome back Joe"

Exceptions

In situations where the script should fail, given a specific set of conditions, an exception should be explicitly thrown. When an exception is thrown, the script stops running and the failure is logged in the system log. The script is considered to have successfully run if no errors or exceptions occur while processing. For example:

```
if ($meetsCondition -eq $false)
```

```
{
  throw "Did not meet condition"
}
```

Secret RPC Scripts

You can pass values calculated with a PowerShell script. For example, you can cycle an AWS IAM token. When changed within a PowerShell script, the new token is returned from the AWS API so it may be returned as a PSObject that will be used to update the secret.

DataItems

These return values from the script are called update "DataItems." These dataitems override any existing values and bypass any next values, including Auto-change Next Password. PowerShell RPC requires that you use a privileged account if a password is one of the items passed back in the DataItems.

Example returning a DataItems for a secret:

```
#at the end of the script add this return
$dataItem = New-Object –TypeName PSObject;$dataItem | Add-Member -MemberType NoteProperty -Name "Notes" -Value "NewValue1";$dataItem | Add-Member -MemberType NoteProperty -Name "Password" -Value " NewValue2";$dataItem | Add-Member -MemberType NoteProperty -Name "Machine" -Value " NewValue3";
return $dataItem
```

In this example, the fields “Notes”, “Password”, and “Machine” on the secret are updated with a “NewValue”. In your environment, these values are typically in relation to items that were generated during the RPC.

Dependencies

PowerShell dependencies can also return DataItems that are used to update a dependency.

This requires:

- Using a dependency changer with a defined scan-item template.
- The values passed back must be scan-item template fields. There are three built-in fields: "Description," "ServiceName," and "Machine." Advanced PowerShell dependency changers that use postscripts may also pass values between themselves.

Here is an example of returning a DataItem for a dependency:

```
# At the end of the script add this return
$dataItem = New-Object –TypeName PSObject;$dataItem | Add-Member -MemberType NoteProperty -Name "Description" -Value "NewValue1";$dataItem | Add-Member -MemberType NoteProperty -Name "ServiceName" -Value " NewValue2";$dataItem | Add-Member -MemberType NoteProperty -Name "Machine" -Value " NewValue3";
return $dataItem
```

In this example, the values on the dependency are updated to match the “NewValue” that is being passed back from the PowerShell dependency changer.

Dependency Tokens

The available tokens are:

- `$UPDATED.<Token>` This give you the value the dependency script returned for the token DataItem. `<Token>` would be changed to match the field name returned that is needed in the script.
- `$SECRET.UPDATED.<Token>` This returns the value the secret password change script returned for the token DataItem.

Limitations

Files:

Files are supported but need to be returned as a string value in the DataItem. There could be encoding complications to watch out for as it uses UT8F.

Run Dependency:

- This loads the values from the current secret as DataItems.
- When running a dependency manually from the UI, which is typically done to update a dependency that was offline during the secret's password reset, DataItems that are saved on the secret as files are not supported, so the run will fail.

Test Dependency:

Tests done from the UI do not use DataItems, so they may return false positives with advanced dependencies.

Privileged Account:

A privilege account is required if changing the password of a secret.

Overview of WinRM with PowerShell

Windows Remote Management (WinRM) is a Microsoft technology that enables remote management of Windows systems over the network using various protocols and tools, including PowerShell. WinRM provides a standardized way to execute commands, transfer data, and perform remote administration tasks on Windows machines.

Using PowerShell scripts with WinRM offers several benefits and capabilities:

- Remote PowerShell Sessions: WinRM allows you to establish remote PowerShell sessions with one or more target computers. This enables you to run PowerShell commands and scripts on remote systems as if you were working directly on those machines.
- Remote Execution of Scripts: You can execute PowerShell scripts on remote computers without establishing an interactive session. This is useful for automating tasks or running scripts on multiple systems simultaneously.
- Secure Communication: WinRM supports various authentication methods, including Kerberos, Negotiate, and HTTPS/SSL, ensuring secure communication and data transfer between the local and remote systems.
- Credential Delegation: WinRM supports credential delegation, which allows you to run scripts or commands on remote systems using different credentials, enabling privilege escalation or impersonation when necessary.

- Session Configuration: WinRM provides session configurations that define the environmental settings, such as language mode, execution policies, and available modules, for remote PowerShell sessions. This ensures consistent and controlled execution environments across remote systems.
- PowerShell Remoting: PowerShell Remoting is a feature built on top of WinRM that simplifies the process of establishing remote PowerShell sessions and executing scripts or commands on remote systems.

To use PowerShell scripts with WinRM, you typically follow these steps:

1. Enable WinRM on the remote systems you want to manage.
2. Configure WinRM to allow remote PowerShell sessions and script execution.
3. Establish a remote PowerShell session using the Enter-PSSession or New-PSSession cmdlets, or execute scripts directly using the Invoke-Command cmdlet.
4. Run your PowerShell scripts on the remote systems within the established session or through direct script invocation.
5. Optionally, configure session configurations, authentication methods, and credential delegation as needed for your specific use case.

WinRM and PowerShell Remoting provide a powerful combination for remote management and automation of Windows systems. They enable IT administrators and system administrators to centrally manage and execute scripts, commands, and configurations across multiple remote machines, streamlining administrative tasks and improving operational efficiency.

Configuring WinRM for PowerShell

WinRM (Windows Remote Management) is a crucial component for enabling PowerShell communication. This configuration lays the foundation for executing PowerShell scripts remotely. Ensure that WinRM is properly configured before proceeding to CredSSP setup.

Overview

Secret Server relies on Windows Remote Management (WinRM) components to run PowerShell scripts. This requires configuration on the Secret Server Web server and any distributed engines. By default, Secret Server uses `http://localhost:5985/wsman` as the WinRM endpoint. The endpoint URI can be seen under **Admin > Distributed Engine > Local**, in the Advanced site configuration section. At the moment, we only support running PowerShell scripts on localhost. If you are new to PowerShell Remoting please review PowerShell Remoting Security Considerations.

Note that your system should be running Windows Server 2012 or later, have the Administrative access to the server, and there should be network connectivity between the client and server.

Standalone Configuration

By default WinRM uses Kerberos for authentication. Since Kerberos is not available on machines that are not joined to the domain, HTTPS is required for secured transport of the password. Only use this method if you are going to run scripts from a Secret Server Web server or distributed engine that is **not** joined to the domain.

> WinRM HTTPS requires a local computer "Server Authentication" certificate with a CN matching the hostname that is not expired, revoked, or self-signed. A certificate would need to be installed on each endpoint Secret Server or the engine manages.

To create a new listener use the command `New-WSManInstance` to create a new WSMan instance for managing remote connections.

```
New-WSManInstance - ResourceURI winrm/config/Listener -SelectorSet @{Transport=HTTPS} -
ValueSet @{Hostname="HOST";CertificateThumbprint="XXXXXXXXXX"}
```

Domain Joined Configuration

Run PowerShell as an Administrator and execute:

```
Enable-PSRemoting
```

See Enable-PSRemoting for more information.

This command performs the following steps:

- Runs the Set-WSManQuickConfig cmdlet, which performs the following tasks:
  - Starts the WinRM service
  - Sets the startup type on the WinRM service to Automatic
  - Creates a listener to accept requests on any IP address
  - Enables a firewall exception for WS-Management communications
  - Registers the Microsoft.PowerShell and Microsoft.PowerShell.Workflow session configurations, if it they are not already registered
  - Registers the Microsoft.PowerShell32 session configuration on 64-bit computers, if it is not already registered
  - Enables all session configurations
  - Changes the security descriptor of all session configurations to allow remote access.
- Restarts the WinRM service to make the preceding changes effective.

Verifying Listeners

Confirm the listener:

```
Get-WSManInstance -ResourceURI winrm/config/listener -SelectorSet @
{Address="*";Transport="http"}
```

The output should reflect the newly configured listener with **Enabled : true**

Additional Considerations

> Ensure that the account running WinRM and connecting to the target machine has the permissions to access that machine over the network. Configure the policy value for **Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment > Access this computer from the network** to include the service account or user account that will need access to this computer over the network via WinRM.

- By default two BUILTIN groups are allowed to use PowerShell Remoting as of v4.0: Administrators and Remote Management Users.

  ```
  (Get-PSSessionConfiguration -Name Microsoft.PowerShell).Permission
  ```

- Sessions are launched by Secret Server under the user's context, which means all the same security controls and policies apply within the session.
- See Tracking, Detecting, and Thwarting PowerShell-based Malware and Attacks (Trend Micro) for additional security considerations.
- Your environment may already be configured for WinRM. If your server is already configured for WinRM but it is not using the default configuration, you can change the URI to use a custom port or URLPrefix.

> Ensure that all configurations are tested in a development environment before applying to production.

> Follow the steps in the exact order to avoid configuration errors.

Configuring CredSSP for WinRM with PowerShell

Introduction

CredSSP (Credential Security Support Provider) is used for credential delegation when accessing external resources via PowerShell scripts. This setup is essential after configuring WinRM to ensure secure credential handling.

In some cases, a PowerShell script may need to access resources outside of a Secret Server machine. This requires that any credentials are delegated to the target machine. Secret Server runs PowerShell scripts using Windows Remote Management (WinRM), which does not allow credential delegation by default. To allow credential delegation, the Secret Server machine must have Credential Security Support Provider (CredSSP) enabled. CredSSP is a security support provider that allows a client to delegate credentials to a target server.

CredSSP is required for dealing with double-hop scenarios. Per Microsoft documentation:

- CredSSP authentication is intended for environments where Kerberos delegation cannot be used.
- Support for CredSSP was added to allow a user to connect to a remote server and have the ability to access a second-hop machine, such as a file share.
- The first hop we make to their DE or web node (Enter-PSSession localhost), if they are running code locally from there and then doing a remote call (e.g. testing access to a remote UNC path) it will then require the second hop.

Enabling CredSSP for WinRM in Secret Server

1. Search for **Application**.
2. Click **Edit** at the top right.
3. Click to select the **Enable CredSSP Authentication for WinRM** checkbox.
4. Click the **Save** button.

> This is the global CredSSP settings and by default will configure CredSSP and connections to come *from* the Web server. This is used when **not using distributed engines.**

> If you are using distributed engines and you enable CredSSP at the site-specific level, these settings take precedence over this global CredSSP setting. Secrets will prioritize these site-specific settings. Therefore, if you plan on using CredSSP through a distributed engine, you should consider disabling the global setting seen below and only configure it at the site-specific level.

Configuring CredSSP for WinRM on the Secret Server Machine

1. Log on to the machine running Secret Server.
2. Run Windows PowerShell as an administrator.
3. Enable client-side CredSSP by running:

   ```
   Enable-WSManCredSSP -Role Client -DelegateComputer <Secret Server fully qualified machine name>
   ```

   The `Enable-WSManCredSSP` command purpose is to enable CredSSP authentication on the server, which is essential for securely delegating credentials when accessing external resources via PowerShell scripts.

   Execute this command after configuring WinRM to ensure that CredSSP is properly set up for credential delegation.

   Use this command in environments where secure credential delegation is required, particularly when scripts need to access resources on other servers.

   For example:

   ```
   Enable-WSManCredSSP -Role Client -DelegateComputer <localhost>
   ```

   > localhost is the actual string that Secret Server uses to generate the PowerShell run space. Sometimes customers need both localhost and FQDN entries. *In theory*, those entries should be the same, thus not needing a second one.

4. Enable server-side CredSSP by running:

   ```
   Enable-WSManCredSSP -Role Server
   ```

5. The Web server always uses a specified account to run the PowerShell scripts. Considerations:

- Ensure that account is added to the "Remote Management Users" local group on each Web server.
- For RPCs with custom password changers, this would be "Change Password Using," and then select "Privileged Account."
- For PowerShell password changers in the classic UI, this would be "Run PowerShell Using" and can alternatively be configured as the "Default Privileged Account" at the template level.
- For custom dependencies using PowerShell scripts, this would be the "Run As" secret.
- If you use any form of extensible discovery, this account needs to be the first secret that is linked to the scanner. Any additional secrets linked to the scanner are typically associated with authentication to the destination system.

Configuring CredSSP for WinRM on a Distributed Engine

You can alternatively configure CredSSP and the credential delegation to occur from your distributed engines by changing this setting at the site level:

1. Search for **Distributed Engine**. The Distribute Engine Configuration page appears.
2. Select the related site from the list.
3. Scroll down to see the **Enable CredSSP Authentication for WinRM** listing in the **Advanced Site Configuration** section.
4. If it is not enabled (value set to No), log on to each of your distributed engines where CredSSP is enabled.
5. Run Windows PowerShell as an administrator.
6. Enable client-side CredSSP by running:

   ```
   Enable-WSManCredSSP -Role Client -DelegateComputer <distributed engine fully qualified machine name>
   Enable-WSManCredSSP -Role Client -DelegateComputer <localhost>
   ```

   > localhost is the actual string that the Distributed Engine is using to generate the run space. Some customers need to have both the localhost and FQDN entry. In theory, both entries above should be the same, thus not needing a second entry.

7. Enable server-side CredSSP by running:

   ```
   Enable-WSManCredSSP -Role Server
   ```

8. The distribute engine will always use a specified account to run the PowerShell scripts. Considerations:
   - Ensure that account is added to the "Remote Management Users" local group on each engine where CredSSP is enabled.
   - For RPCs with custom password changers, this would be "Change Password Using," and then select "Privileged Account".
   - For PowerShell password changers in the classic UI, this would be "Run PowerShell Using" and can alternatively be configured as the "Default Privileged Account" at the template level.
   - For custom dependencies using PowerShell scripts, this would be the "Run As" secret.

- If you use any form of extensible discovery, this account needs to be the first secret that is linked to the scanner. Any additional secrets linked to the scanner are typically associated with authentication to the destination system.

9. Ensure that the "Allow Delegating Fresh Credentials" group policy setting is enabled and is not disabled by a domain policy.
   a. Open the gpedit.msc file on your Secret Server machine or distributed engine, depending on where CredSSP is enabled
   b. Navigate to **Computer Settings > Administrative Templates > System > Credentials Delegation**.
   c. Edit the "Allow Delegating Fresh Credentials" setting.
   d. Verify that it is Enabled.
   e. Click "Show..."
   f. Verify that the list contains an entry that begins with "wsman/" and ends with the fully qualified machine name of the Secret Server machine or distributed engine.
   g. If destination systems are non-domain joined or on another domain without a trust, it may be required for you to add in an entry for **each** destination system you wish to run the script or do discovery on (as examples). Consider collecting a list of all destination FQDNs for your specific use case and adding them all in one go.
10. Depending on where CredSSP is configured (Web server or distributed engine), run the following commands:
    - View existing entries: `Get-Item WSMan:\localhost\Client\TrustedHosts`
    - Adding computers if your TrustedHosts list is empty: `Set-Item WSMan:\localhost\Client\TrustedHosts -Value <ComputerName>,[<ComputerName>]`
    - Adding computers to your existing TrustedHosts list:

      ```
      $curList = (Get-Item WSMan:\localhost\Client\TrustedHosts).value
      Set-Item WSMan:\localhost\Client\TrustedHosts -Value "$curList, Server01"
      ```
11. On the destination system, if it is on a separate domain without a trust or non-domain joined, add the reverse WSman entries so the destination system trusts either Secret Server or your engines. Run one of the following commands:

    Web server:

    ```
    Set-Item WSMan:\localhost\Client\TrustedHosts -Value <Web Server 1 FQDN>,[<Web Server 2 FQDN>]
    ```

    Engine:

    ```
    Set-Item WSMan:\localhost\Client\TrustedHosts -Value <Distributed Engine 1 FQDN>,
    [<Distributed Engine 2 FQDN>]
    ```
12. Restart either Secret Server or the engine you just trusted.

Enabling CredSSP on Secret Server Agents for PowerShell Script Dependencies

Remote agents were upgraded to distributed engines in Secret Server version 8.9. This section only applies to Secret Server versions 8.8.000020 and earlier.

Remote Agents are only needed for networks that are not directly connected to the network that Secret Server is installed on. If you are not using remote agents, disregard this section.

By default, Secret Server agents inherit the "Enable CredSSP Authentication for WinRM" setting from Secret Server; however, you can override this in the agent configuration file as follows:

1. On the machine running the agent, locate the agent program files. By default, they are at `C:\Program Files (x86)\Thycotic Software Ltd\Secret Server Agent`.
2. Edit the `SecretServerAgentService.exe.Config` file in a text editor.
3. Locate the "UnencryptedSettings" section.
4. Add a new key to that section for EnableCredSSPForWinRM and set it to true. For example:
   `<add key="EnableCredSSPForWinRM" value="true" />`
5. Restart the "Secret Server Agent" service to apply the setting.

Ensure that all configurations are tested in a development environment before applying to production.

Follow the steps in the exact order to avoid configuration errors.

Creating and Using SQL Scripts

You can use SQL scripts in Secret Server to automate specific tasks. You can configure a SQL script as a dependency of a secret and run after the password is successfully changed on the secret.

Creating a SQL Script

1. Search for **Scripts: PowerShell, SQL, SSH**, and on the Scripts page, click **Create Script**.
2. In the New Script page, type the script name in the **Name** text box.
3. Type a description in the **Description** text box.
4. Choose to select the **Enabled** checkbox.
5. In the **Script Type** field select **SQL**.
6. Click the **Category** dropdown list to select the type of script. This will determine where the script resides in Secret Server and more. For instance, the Dependency choice ensures that Remote Password Changing is turned on by enabling it on the Remote Password Changing page.
7. Select the related **Password Changer** from the dropdown.
8. Paste your script into the **Script** text box.
9. When done, click **Save**. The new script appears in the table on the Scripts page.

Using Parameters

Where SQL scripts are used, we provide an arguments text box. It is often beneficial to assign variables to other more meaningful variables.

Examples

SQL

```
UPDATE TABLE cmsuser
SET password = PWDENCRYPT(@Password) WHERE username = @Username;
```

MySQL

```
UPDATE TABLE cmsuser
SET password = PASSWORD(?) WHERE username = ?;
```

PostgreSQL

```
UPDATE TABLE cmsuser
SET passwd = CRYPT(?, GEN_SALT('sha256')) WHERE username = ?;
```

ODBC

```
UPDATE TABLE cmsuser
SET passwd = $Password WHERE username = $Username;
```

Basic Oracle PL/SQL

```
INSERT INTO cmuser values (:username, :password);
```

Advanced Oracle PL/SQL

```
EXECUTE IMMEDIATE 'alter user '|| :username ||' identified by "' || :password || '"';
```

Returning Errors

In situations where the script should fail given specific conditions, the script should explicitly throw an exception. When an exception is thrown, the script stops running and the failure is recorded in the system Log. The script is

considered to have successfully run if no errors or exceptions occur while processing.

Examples

SQL

```
RAISERROR(N'ERROR: %s', 14, 1, N'Failure');
```

MySQL

```
SIGNAL SQLSTATE '45000'
SET MESSAGE_TEXT = 'ERROR: Failure';
```

PostgreSQL

```
DO language plpgsql $$
BEGIN
RAISE EXCEPTION 'ERROR (14)';
END
$$;
```

ODBC

```
RAISERROR(N'ERROR: %s', 14, 1, N'Failure');
```

SQL Example

An issue that occurs in SQL Server database environments is when a linked database is set up with a credential and that credential's password changes. To counter this, you can set up a SQL script to run as a dependency after the password change occurs to drop and recreate the link. Note that you may need to edit the option depending on the desired linked server configuration.

Example

SQL

```
EXEC master.dbo.sp_dropserver @server=@MACHINE, @droplogins='droplogins'
```

```
EXEC master.dbo.sp_addlinkedserver @server = @MACHINE, @srvproduct=N'SQL Server'
EXEC master.dbo.sp_addlinkedsrvlogin
@rmtsrvname=@MACHINE,@useself=N'True',@locallogin=NULL,@rmtuser=NULL,@rmtpassword=NULL
EXEC master.dbo.sp_addlinkedsrvlogin
@rmtsrvname=@MACHINE,@useself=N'False',@locallogin=@LOCALUSERNAME,@rmtuser=@REMOTEUSERNAME
,@rmtpassword=@PASSWORD
```

Parameters

- `@MACHINE` The machine or instance of the server where the linked database exists. For instance, `SERVER\SQL2014`.
- `@LOCALUSERNAME` The local login on the server where the linked database is configured.
- `@REMOTEUSERNAME` The username that is set in the linked database's security info for connecting to the linked database. This should be the username of the secret that the dependency is on.
- `@PASSWORD` This will be the new password after the SQL account's password is changed.

Creating and Using SSH Scripts

SSH scripts can be used in Secret Server to automate specific tasks. An SSH script can be configured as a dependency of a secret and run after the password is successfully changed on the secret.

Creating an SSH Script

1. Search for **Scripts: PowerShell, SQL, SSH**, and on the Scripts page, click **Create Script**.
2. In the New Script page, type the script name in the **Name** text box.
3. Type a description in the **Description** text box.
4. Choose to select the **Enabled** checkbox.
5. In the **Script Type** field select **SSH**.
6. Click the **Category** dropdown list to select the type of script. This will determine where the script resides in Secret Server and more. For instance, the Dependency choice ensures that Remote Password Changing is turned on by enabling it on the Remote Password Changing page.
7. Paste your script into the **Script** text box.
8. When done, click **Save**. The new script appears in the table on the Scripts page.

Scripts return all output results, which allows you to debug your script using the echo command (or any command that will write to standard output).

SSH scripts initiated by Secret Server have a fixed execution timeout of 60 seconds.

The success indicator for an SSH script reflects submission and orchestration success only. It does not reflect the final outcome of the script on the remote endpoint and does not provide endpoint execution progress or feedback.

Rationale: A fixed timeout avoids long-running hangs and provides consistent behavior across deployments.

Guidance:

- Design scripts so each execution completes within 60 seconds.
- Use a short script to initiate longer work on the endpoint and a separate follow-up script to retrieve results later.
- Write progress or results to a known location on the endpoint and have a later step read and return those results.
- Use external orchestration tools to manage long-running operations, with Secret Server initiating only short-lived steps.

For example:

```
echo The users name is $USERNAME
```

An input box for specifying arguments will exist in places where the SSH scripts are used. Argument values are specified next to their associated argument name. Parameters to SSH scripts are referenced through named variables. It is often beneficial to assign parameter variables to other more meaningful variables.

Another example:

```
$GREETING = Welcome back
$NAME = Joe
echo $GREETING $NAME
```

Output: `Welcome back, Joe`

In situations where the script should fail given a specific set of conditions, exit the script with a non-zero status code. When scripts exit with a non-zero status, the failure is logged in the System Log. The script is considered to have successfully run if it does not exit with a non-zero status code.

Example:

```
if [ ! $MEETS_CONDITION -eq 0 ]; then
echo Failure
exit 1;
fi
echo Success
```

Use Case

Update a user's password in the Apache user configuration file when it is changed in Secret Server:

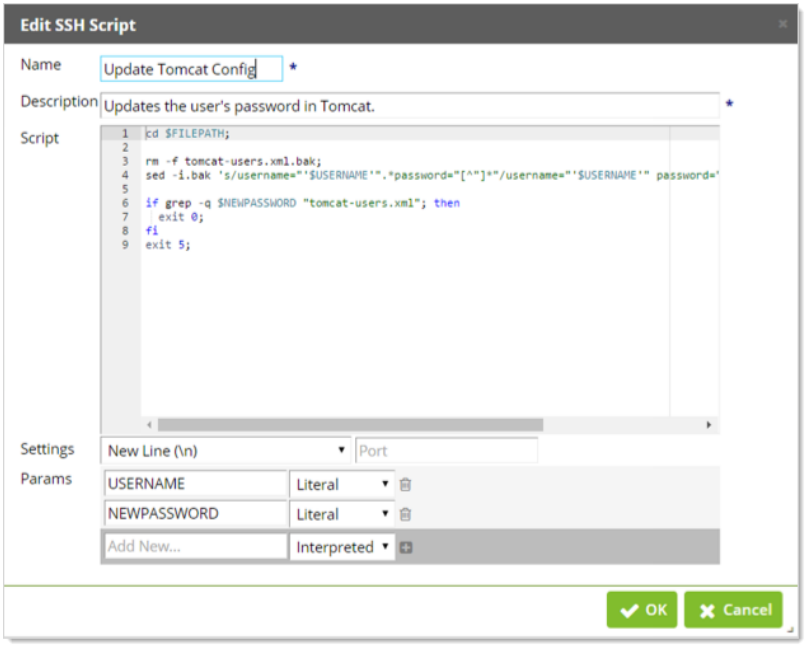
```
cd $FILEPATH;
rm -f tomcat-users.xml.bak;
sed -i.bak 's/username="'$USERNAME'".*password="[^"]*"/username="'$USERNAME'"
password="'$NEWPASSWORD'"/' tomcat-users.xml;
if grep -q $NEWPASSWORD "tomcat-users.xml"; then
exit 0;
fi
exit 5;
```

Adding an SSH Script as a Dependency

1. Search for **Scripts: PowerShell, SQL, SSH**, and on the Scripts page, click **Create Script**.
2. Fill out the required fields **Name**, **Description**, and **Script Type - SSH**.
3. Select **Category** as **Dependency**.
4. Paste your script into the **Script** text box.
5. (Optional) Change the setting for the environmental line ending in case your environment experiences issues with line termination.
6. (Optional) Specify the port that the script will connect to.

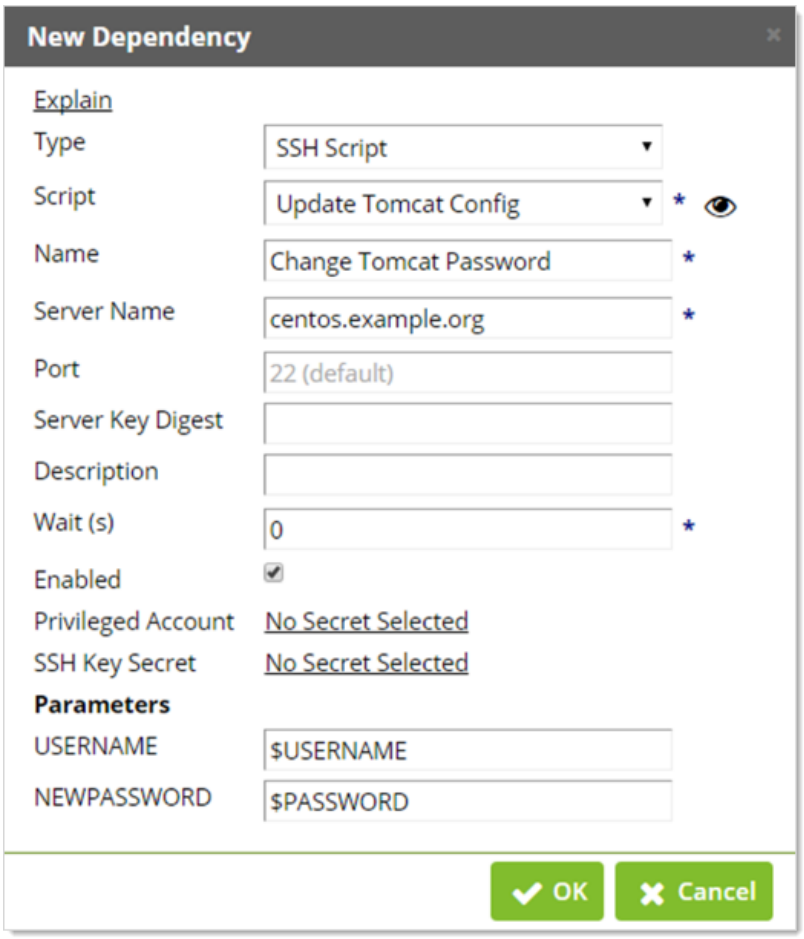
SSH scripts used as dependencies follow the same 60-second execution timeout and orchestration-only success indicator.

When filling out the script there is some important information to remember. If you would like to use one of the Secret Server variables such as $USERNAME, $NEWPASSWORD, or $CURRENTPASSWORD, you need to specify that they are parameters. For example, take the following script from our use case:



Within the script, parameters are specified with the dollar sign prefixed to the name. In the list of parameters, you simply specify their name without the dollar sign. This is so you can fill their values in later when implementing the script as a secret dependency.

When adding the SSH Script as a dependency to a secret, specify the built-in Secret Server variables with the dollar-sign prefix. For example, using our use case:



If a parameter in the script is not specified in the list of parameters, then they will use environmental variables on the remote host.

Dependency Token List

Overview

A list of all valid tokens that can be used in PowerShell, SSH, and SQL dependency script arguments.

PowerShell, SSH, and SQL dependencies can have script arguments that derive their values from values on the dependency, the secret it belongs to, or any other secrets associated for remote password changing. Tokens can also be used in ODBC connection string arguments. Script arguments are defined on dependency changers in Secret Server and on the dependency in earlier versions of Secret Server. The following table lists the tokens available to dependency scripts.

Best Practices

Do not use quotation marks (") in passwords for PowerShell scripts for RPC. Quotation characters are dropped from passwords when passing the $PASSWORD token to a custom password changer PowerShell script, resulting in an authentication failure.

You can add both $PRIOR... or $CURRENT... tags to any of the fields including custom fields.

Wrap Fields in Quotation Marks

When specifying PowerShell arguments, the $fieldname argument is replaced with the information in the field, and *then* the whole string is passed to PowerShell. Thus, if the string returned has spaces, PowerShell parses the spaces as separate arguments, which causes errors.

Therefore, we recommend you wrap your fields in two quotation marks. For example: `"$fieldname"`, which is then parsed by PowerShell as one string.

Avoid Using Spaces in Field Names

We recommend not using spaces within your field names. In many cases, that would not cause a problem, but if the first word in the field name is also a reserved word, it will cause an error because the reserved word is parsed separately from the rest of the field name.

For example, a field named:

`$machine name`

Because `$machine` is a reserved word, the parser would separate the reserved `$machine` value, followed by `name` as a separate argument.

Surrounding the field name in quotation marks would *not* fix this–Secret Server makes the substitution prior to PowerShell parsing the string.

Token List

Table: Dependency Tokens

Token	Available In	Translates To
$[x]${name of any field on secret}	pre-10.0	The value of the field with the same name on the nth secret on the RPC tab for use in custom password changing commands and scripts.
$[x]$PASSWORD	pre-10.0	The password on the nth secret on the RPC tab for use in custom password changing commands and scripts.
$[x]$USERNAME	pre-10.0	The username on the nth secret on the RPC tab for use in custom password changing commands and scripts. Example: $[1]$USERNAME is the username of the first associated secret.

Token	Available In	Translates To
${name of any field on secret}	pre-10.0	The value of the field on the secret with the same name. Examples: $DOMAIN matches the secret's "Domain" field, and $NOTES matches the "Notes" field.
${scan item field name} **Note:** The scan item token is designated for discovery purposes only, whereas other items may function in other capacities.	10.0	The name of any scan item field (defined on the scan item template) that is visible in the dependency edit dialog. If a scan item field is derived from a parent field, you may also use the parent field name as a parameter that translates to this field's value.
$CURRENTPASSWORD	pre-10.0	Deprecated. The password currently on the secret. $CURRENTPASSWORD is not available to the dependency script because when it runs the password has already changed. Use $PRIORPASSWORD instead.
$CURRENTPUBLICKEY	10.2	The public key currently on the secret (context-sensitive to whether script is run before or after key rotation).
$DATABASE	pre-10.0	The value of the Database field from the dependency. Only valid for SQL dependencies unless added as a field by the scan item template (see below).
$DEPENDENCYPRIVILEGEDPASSPHRASE	10.3	The private key passphrase on the privileged account assigned to the dependency.
$DEPENDENCYPRIVILEGEDPASSWORD	10.3	The password on the privileged account assigned to the dependency.
$DEPENDENCYPRIVILEGEDPRIVATEKEY	10.3	The private key on the privileged account assigned to the dependency.
$DEPENDENCYPRIVILEGEDUSERNAME	10.3	The user name on the privileged account assigned to the dependency.
$DEPENDENCYSSHKEY	10.3	The new SSH key to set on the dependency.
$DEPENDENCYSSHKEYPASSPHRASE	10.3	The new passphrase of the SSH key to be set on the dependency.

Token	Available In	Translates To
$MACHINE	10.0	The value of the Machine Name field on the dependency. This is always the second part of the dependency title (<service name> on <machine>).
$NEWPASSWORD	10.2	Deprecated. This is not available to the dependency at the time of the password change. Use $PASSWORD instead.
$NEWPUBLICKEY	10.2	The new public key that is being set on the secret.
$NEWACCESSKEY	10.2	The newly generated Access Key returned from an AWS IAM Key Rotation.
$NEWSECRETKEY	10.2	The newly generated Secret Key returned from an AWS IAM Key Rotation.
$PASSPHRASE	10.2	The passphrase used to encrypt the private key in a public/private key pair on this secret.
$PASSWORD	pre-10.0	The password on the secret.
$PORT	pre-10.0	The value of the Port field from the dependency. Only valid for SQL and SSH dependencies unless added as a field by the scan item template (see below).
$PRIORPASSPHRASE	10.2	The passphrase that was set on the secret before the current passphrase rotation.
$PRIORPASSWORD	10.2	In the context of a password change, this is the password at the beginning of the password change. The password that was set on the secret before the current password change. In the context of run dependency from the Dependency tab, this is the prior value of the password before the last password change.
$PRIORPUBLICKEY	10.2	The public key that was set on the secret before the current key rotation.
$PUBLICKEY	10.2	The public key on the secret.

Token	Available In	Translates To
$SERVICENAME	10.0	The value of the Service Name field on the dependency. Service Name may have a different name based on the dependency type, but it is always the first part of the dependency title (<service name> on <machine>).
$USERNAME	pre-10.0	The username on the secret.

The mappings of these parameters come from the remote password changer, so you can check the mapping by editing the secret template and selecting configure password changing.

Some of these tokens, such as `$PASSWORD`, `$CURRENTPASSWORD`, `$NEWPASSWORD`, and `$PRIORPASSWORD`, may seem to duplicate each other, but they have distinctions based on the context as described above.

In some cases, whether or not the dependency is being changed locally or through a distributed engine may have an impact on what these tokens return. This is due to the asynchronous nature of distributed engines. The newer tokens, such as `$NEWPASSWORD` and `$PRIORPASSWORD`, were created to address this issue. If you are using older tokens, such as `$PASSWORD` and `$CURRENTPASSWORD`, and seeing unexpected results, try using `$PRIORPASSWORD` and `$NEWPASSWORD`.

Using Secret Fields in Scripts

Secret Server supports using PowerShell, SSH, and SQL scripts as dependencies on a secret. These scripts can use information on the secret through the field name prepended with a `$`. For example, `$DOMAIN`, `$PASSWORD`, or `$USERNAME`. Linked secrets are accessible by `$[1]$FIELDNAME` for the first linked secret, `$[2]$FIELDNAME` for the second, and so on.

There are two contexts in which script dependencies run:

- As part of the RPC process. See "Creating RPC Scripts" on page 911.
- When run manually from the Dependencies tab on the secret.

For a complete list of tokens that are available to script dependencies, see "Dependency Token List" on page 1512.

REST API Overview

The REST API for Secret Server provides a robust and flexible way to programmatically interact with the Secret Server platform, enabling seamless integration with other IT systems and automation of critical security processes. The API supports both SOAP and RESTful interfaces, making it accessible to a wide range of programming languages and platforms, including .NET, Java, Python, Ruby, and PowerShell.

SOAP is not supported natively in PowerShell 6+ and only works for Windows PowerShell.

Key Functions

- Authenticating to Secret Server
- Creating and managing secrets
- Configuring folders and Delinea permissions
- Searching for secrets

The REST API uses token-based authentication to ensure secure access and supports various operations to manage secrets and their attributes. This capability is essential for organizations looking to integrate privileged account management into their existing workflows and enhance their DevOps practices.

Key Resources

- REST API Client Generation with Swagger: Learn how to generate clients for different programming languages using Swagger, which can help streamline your API interactions.
- REST API Reference Download: Access comprehensive documentation on REST API endpoints and parameters, essential for developers looking to integrate with Secret Server.
- REST API PowerShell Examples: Explore practical examples of using PowerShell scripts with the REST API, useful for automating tasks and enhancing your DevOps practices.

REST API Client Generation with Swagger

Secret Server contains an OpenAPI Swagger specification file that describes the REST API endpoints. There are several Swagger-based tools available to generate clients. This document describes using some popular ones to generate clients for different languages including C#, Java, and PowerShell. The generated client facilitates calling the Secret Server REST API and indicates API changes with new Secret Server versions.

Please use the article quick links on the right to jump to the section you are interested in.

Generating Clients

C# Client Using NSwagStudio

1. Download and install NSwagStudio (https://github.com/RicoSuter/NSwag/wiki/NSwagStudio)
2. Copy and paste the `swagger.json` file for "Documentation for token authentication." This is located at: `{Your SecretServer Base URL}/Documents/restapi/OAuth/swagger.json`
3. Suggested settings:
   - Namespace: SecretServerAuthentication
   - Inject HttpClient via constructor
   - Generate default values for properties
4. Generate output.
5. Copy output into a C# file in solution.

6. Copy and paste the swagger.json for "Documentation for REST API using bearer token authentication." It is located at `{Your SecretServer Base URL}/Documents/restapi/TokenAuth/swagger.json`.
7. Suggested Settings:
   - Namespace: SecretServerRestClient
   - Inject HttpClient via constructor
   - Generate default values for properties
8. Generate output.
9. Copy output into a C# file in solution

   See "Script Authentication Using Tokens" on page 1489 for creating a token to use in the examples below.

```
// Authenticate:
var httpClient = new HttpClient();
var token = "<TOKEN>";
// Set credentials (token):
httpClient.DefaultRequestHeaders.Authorization = new AuthenticationHeaderValue
("Bearer", token);
// Call REST API:
var client = new SecretServerRestClient.SecretsServiceClient
("https://secretserver.url.local/ss/api/v1", httpClient);
var search = client.SearchAsync(sortBy0_name: "lastHeartBeatStatus", sortBy0_
direction:"asc");
var results = search.Result;
```

C# or .NET Core Client Using OpenAPI Generator

> These client-generation instructions were written with OpenAPI Generator version 5.1.1, which was the latest version at the time. Future versions may fix issues that necessitated some workarounds. If you are using a newer version, you may need to make adjustments.

> These instructions assume that you have Java and .NET Core installed on your machine. They should work on all systems, but the syntax will need to be tweaked for other shells.

1. Follow the steps in Getting OpenAPI Generator.
2. Store the path to the relevant `swagger.json` files as variables. These variables can be either a local file path or a URL.

   ```
   $oauthSwagger = 'OAuth/swagger.json'$tokenAuthSwagger = 'TokenAuth/swagger.json'
   ```

3. Run the following commands to generate the necessary clients. You can run `java -jar openapi-generator-cli.jar help generate` to see advanced options that you may wish to configure. Options specific to the .NET Core generator are described on Config Options for csharp-netcore page.

   ```
   java -jar openapi-generator-cli.jar generate -i $oauthSwagger -g csharp-netcore --skip-
   validate-spec --package-name SecretServerOAuth --remove-operation-id-prefix --additional-
   properties=netCoreProjectFile=true -o oauth-csharpjava -jar openapi-generator-cli.jar
   generate -i $tokenAuthSwagger -g csharp-netcore --skip-validate-spec --package-name
   ```

```
SecretServerTokenAuth --remove-operation-id-prefix --additional-
properties=netCoreProjectFile=true -o tokenauth-csharp
```

4. Build the packages in release mode:

   ```
   dotnet build -c Release oauth-csharp/src/SecretServerOAuthdotnet publish -c Release
   tokenauth-csharp/src/SecretServerTokenAuth
   ```

5. Add the necessary .dll files to your project. The DLLs are located at the paths below:

   ```
   oauth-
   csharp/src/SecretServerOAuth/bin/Release/netstandard2.0/SecretServerOAuth.dlltokenauth-
   csharp/src/SecretServerTokenAuth/bin/Release/netstandard2.0/publish/*.dll
   ```

6. Test the API. For example:

   See "Script Authentication Using Tokens" on page 1489 for creating a token to use in the examples below.

   ```
   var token = "<TOKEN>";
   // Do not use tokenAuthConfig.AccessToken
   // This method can be called repeatedly as the access token expires, old values will be
   overwritten
   tokenAuthConfig.AddApiKey("Authorization", $"{token.TokenType} {token.AccessToken}");
   var foldersApi = new FoldersApi(tokenAuthConfig);
   var folder = await foldersApi.GetAsync(11);
   Console.WriteLine(folder);Console.ReadKey();
   ```

Java Client Using OpenAPI Generator

> These client-generation instructions were written with OpenAPI Generator version 5.1.1, which was the latest version at the time. If you are using a newer version, you may need to make adjustments.

> These instructions assume that you have Java configured on your machine. JDK 8 or greater is required. These instructions should work on all systems, but the syntax will need to be tweaked for other shells.

1. Follow the steps in Getting OpenAPI Generator.
2. Store the path to the relevant `swagger.json` files as variables. These variables can be either a local file path or a URL.

   ```
   $oauthSwagger = 'OAuth/swagger.json'$tokenAuthSwagger = 'TokenAuth/swagger.json'
   ```

3. Run the following commands to generate the necessary clients. You can run `java -jar openapi-generator-cli.jar help generate` to see advanced options that you may wish to configure. Options specific to the Java generator are described on the Config Options for java page.

   ```
   java -jar openapi-generator-cli.jar generate -i $oauthSwagger -g java --skip-validate-spec
   --invoker-package secretserver.oauth.client --api-package secretserver.oauth.api --model-
   package secretserver.oauth.model --group-id secretserver --artifact-id secretserver.oauth
   --remove-operation-id-prefix -o oauth-javajava -jar openapi-generator-cli.jar generate -i
   $tokenAuthSwagger -g java --skip-validate-spec --invoker-package
   secretserver.tokenauth.client --api-package secretserver.tokenauth.api --model-package
   secretserver.tokenauth.model --group-id secretserver --artifact-id secretserver.tokenauth
   --remove-operation-id-prefix -o tokenauth-java
   ```

4. Follow the instructions in `oauth-java/README.md` to include the package in your build process. Alternatively, follow the steps below to generate JAR files and test.

   ```
   cd oauth-java mvn clean install -DskipTestscd ..\tokenauth-java mvn clean install -DskipTests
   ```

5. Include the following JARs in your project (replace version numbers as necessary):

   ```
   oauth-java/target/secretserver.oauth-10.9.9.jartokenauth-java/target/secretserver.tokenauth-10.9.9.jartokenauth-java/target/lib/*.jar
   ```

6. Test the JAR files:

   See "Script Authentication Using Tokens" on page 1489 for creating a token to use in the examples below.

```
// set to the root of the <Secret Server URL /> instance with no trailing slash
String basePath = "https://thycotic.com/SecretServer";
secretserver.oauth.client.ApiClient oauthClient =
secretserver.oauth.client.Configuration.getDefaultApiClient();
secretserver.tokenauth.client.ApiClient tokenAuthClient =
secretserver.tokenauth.client.Configuration.getDefaultApiClient();
String token = "<TOKEN>";tokenAuthClient.setBasePath(basePath
+ "/api");tokenAuthClient.setApiKey(tokenResponse.getTokenType() + " " + token);
FoldersApi foldersApi = new FoldersApi(tokenAuthClient);
FolderModel folderModel = foldersApi.get(11, false, false);
System.out.println(folderModel);
```

PowerShell Using OpenAPI Generator

> These client-generation instructions were written with OpenAPI Generator version 5.1.1, which was the latest version at the time. If you are using a newer version, you may need to make adjustments. The PowerShell generator is in beta.

1. Follow the steps in Getting OpenAPI Generator.
2. Store the path to the relevant `swagger.json` files as variables. These variables can be either a local file path or a URL.

   ```
   $oauthSwagger = 'OAuth/swagger.json'$tokenAuthSwagger = 'TokenAuth/swagger.json\'
   ```

3. Run the following commands to generate the necessary clients. You can run `java -jar openapi-generator-cli.jar help generate` to see advanced options that you may wish to configure. Options specific to the PowerShell generator are described on Config Options for PowerShell page.

   > These commands set disallowAdditionalPropertiesIfNotPresent to false to work around a bug in the generator.

   ```
   java -jar openapi-generator-cli.jar generate -i $oauthSwagger -g PowerShell --skip-validate-spec --package-name SecretServerOAuth --remove-operation-id-prefix -o oauth-psjava -jar openapi-generator-cli.jar generate -i $tokenAuthSwagger -g PowerShell --skip-validate-spec --package-name SecretServerTokenAuth --remove-operation-id-prefix -o tokenauth-ps
   ```

4. Perform a find/replace to work around a bug in the generator:

```
Get-ChildItem ".\tokenauth-ps\src\SecretServerTokenAuth\Model\*.ps1" | Foreach-Object {
(Get-Content $_) | Foreach-Object { $_ -replace "\$AllProperties = \(\)", "$AllProperties
= @()" } | Set-Content $_ }
```

5. Run the following commands to build the PowerShell modules. -Verbose can be specified if desired.

   ```
   .\oauth-ps\Build.ps1.\tokenauth-ps\Build.ps1
   ```

6. Import both modules:

   ```
   Import-Module .\oauth-ps\src\SecretServerOAuthImport-Module .\tokenauth-
   ps\src\SecretServerTokenAuth
   ```

7. Set the base URL of each module. Only edit the first line below. The value must be the full URL to the root of Secret Server **with no trailing slash**, for example `https://thycotic.com/SecretServer`.

   ```
   $baseUrl = "https://thycotic.com/SecretServer"SecretServerOAuth\Set-Configuration -BaseUrl
   $baseUrlSecretServerTokenAuth\Set-Configuration -BaseUrl $baseUrl
   ```

8. Store a token - See "Script Authentication Using Tokens" on page 1489 for creating a token.

9. Set the TokenAuth module to use the token: `SecretServerTokenAuth\Set-Configuration -DefaultHeaders @{ Authorization = $token.token_type + " " + $token.access_token }`

10. Test the folder service Get endpoint (replace the ID as necessary):

    ```
    Get-FolderDetail -id 11
    ```

Postman Workspace

Postman is a REST client with a GUI to easily test API requests. To automatically generate a workspace with Secret Server API calls, click the **Import** button and choose whether to use a local file or a URL. Ensure the **Generate a Postman Collection** check box is selected. The program appears to be doing nothing while importing, but will inform you of success shortly.

Insomnia Workspace

Insomnia is a REST client similar to Postman. To automatically generate a workspace with Secret Server API calls, first click the arrow to open the dropdown, then click **Import/Export**. Click **Import Data**, then **From File** or **From URL** as desired.

Getting OpenAPI Generator

> These client-generation instructions were written with OpenAPI Generator version 4.3.0, which was the latest version at the time. Future versions may fix issues that necessitated some workarounds. If you are using a newer version, you may need to make adjustments.

OpenAPI Generator supports several installation methods, described on their CLI Installation page. You can pick the method most suitable for your environment. The commands in this article use the JAR method for simplicity, but other installation methods use mostly the same command format so only small tweaking should be required.

> All methods require the Java runtime (version 8+).

Self-Signed or Other Invalid Certificates

If you use an SSL certificate that is self-signed or otherwise not technically valid, OpenAPI Generator throws an error if you try to use a URL to `swagger.json` instead of a local file (or when using the Java client). To fix this, you need to import the certificate into Java's certificate store. The following example commands are for Windows, but the same concept applies to Mac and Linux as well.

The default password for the cacerts keystore is `changeit`.

Java 8 stores the cacerts keystore in JAVA_HOME unless it was explicitly changed. `keytool` should also be on your PATH if `java` itself is.

```
keytool -import -keystore "%JAVA_HOME%\jre\lib\security\cacerts" -file "path\to\cert.pem"
```

Java 11 provides a flag on `keytool` to find the cacerts keystore automatically.

```
keytool -import -cacerts -file "path\to\cert.pem"
```

Swagger 2.0 Notes

Some features in our REST API are not currently supported in Swagger 2.0. For example, the sort is an array of a complex objects. The actual API will accept multiple sort levels by passing this query string, `paging.sortBy[0].name=secretname&paging.sortBy[1].name=folderid`. The auto-generated client only allows you to specify the first sort by default. To specify multiple sorts, the serialization needs to be customized. We assumed that multiple sorting levels is probably an advanced feature and or choice will work for most.

REST API Reference Download

Overview

The Secret Server REST API guides are version specific. In fact, they are automatically generated when a Secret Server version is created. Thus, to ensure you have the correct guides *for* your Secret Server version, it is best (but not required) to access the documentation *from* that version of Secret Server; however there are many reasons why this might not be practical, so we provide download links below.

Accessing the Guides

To access the guides:

1. For Secret Server click the question mark icon in the top right of the dashboard and click **REST API Guide**. The Secret Server REST API Guide page appears.
2. Accessing Secret Server through the API and scripts can be powerful mechanism but ensure you are following best practices with the account and access for any script connecting to Secret Server. The Secret Server Software Development Kit for DevOps is recommended for all automated or machine-to-machine scripts. If not

using the SDK, creating an application account for the script access and limiting the permissions both from Role perspective and on Secret themselves is security best practice.

3. On the Secret Server REST API page of your instance, choose one of the three guides:
   - **Bearer token authentication:** Hyperlinked documentation for REST API access using token authentication.
   - **Token authentication:** Instructions for getting an authentication token.
   - **Windows Integrated Authentication:** Hyperlinked documentation for REST API access using Integrated Windows Authentication (IWA).

Downloading the Guides

> Only use the following links if you cannot easily access a guide from a version of Secret Server. There is a possibility the guides below are not the most current versions.

> Only the latest version of each API endpoint is included in this documentation. Previous versions of API endpoints may continue to function if called directly, unless a breaking change has necessitated their removal (for example, if the data returned by the endpoint is no longer available or supported). Older API versions will be deprecated and removed at a future date. We recommend migrating to the latest version of each API method to ensure continued support and compatibility.

Understanding API versioning

While you might still use some older endpoints, it is important to transition to the latest to take advantage of improved functionality and ongoing support. Our changes follow the OpenAPI standard, ensuring that updates do not disrupt your existing scripts by introducing new versions when necessary.

> A transition to a new version is likely a part of an ongoing effort to improve the API's efficiency and functionality. We recognize that maintaining backward compatibility is crucial, and if at all possible we strive to maintain that compatibility, unless there is a compelling reason to not to.

- **Endpoint Changes**: In a new version, some endpoints have equivalents to older ones, but they often differ significantly. For example, an endpoint with a new version might return different data, excluding some fields that were present in older versions. If any of the following changes happen, for any reason, we will publish a new version and leave the old one as is. While we try to avoid it, you may need to adjust your workflows to accommodate those changes.

  The possible changes are:

  - Changing the required input parameters (data type or a new requirement)
  - Changing the output data (data type or removing existing data)
  - Changing the data format of the input or output

  > We strongly recommend transitioning to new endpoints even if the old ones suffice. We cannot guarantee support for old endpoints.

- **Backward Compatibility Concerns**: While the goal is to maintain backward compatibility, there are instances where significant improvements necessitate changes. While it is usual to introduce new endpoints instead of altering the old ones, it is not always possible.
- **Output Optimization**: New endpoints are optimized to provide more relevant data, which might mean less information is returned. This can lead to a more efficient API, but you may need to adjust your workflows to accommodate these changes.
- **Field and Permission Adjustments**: New versions may include changes in field configurations and API permissions, affecting how you access and manipulate data. Even if the old outputs were extensive, the new version might require additional calls to retrieve specific field details.
- **New Functions**: The new version may add functions and endpoints that do not have direct equivalents in the old version. Exploring these new features can enhance your use of the API.

Steps to Transition to New API Versions

- **Review Documentation**: Make sure you have both the previous and the latest API documentation (above) to compare the old and new endpoints. This will help you understand the changes and how to implement them in your systems.
- **Identify Impacted Workflows**: Determine which of your workflows rely on the old endpoints and assess how they will be affected by the transition to to the new ones. You may need to rework some processes to align with the new API structure.
- **Use the New Endpoints**: Explore the new endpoints and functions in the updated version that can enhance your existing workflows or introduce new capabilities.

REST API Examples

The REST API examples for Secret Server provide practical demonstrations of how to interact with the Secret Server platform programmatically using various programming languages. These examples cover essential operations such as authenticating to Secret Server, retrieving secrets, updating secret fields, and managing secret attributes. The examples are designed to be user-friendly and leverage standard HTTP methods and status codes, making them accessible for developers of all skill levels. They include detailed guides for using Python, Perl, and PowerShell, showcasing how to perform common tasks and integrate Secret Server into custom workflows. By following these examples, developers can automate critical security processes, enhance their DevOps practices, and ensure secure and efficient management of privileged accounts.

- REST API PowerShell Scripts
- REST API Python Scripts
- REST API Perl Scripts

REST API PowerShell Scripts

To use the REST API you first must enable Webservices. To do so, go to Admin > Configuration general tab. Enabling Webservices simply makes the ASP.NET REST Webservices built into Secret Server available.

For a full reference of the REST endpoints and parameters, see the "REST API Reference Download" on page 1522.

When using the API to search secrets, the account used must have at least "view" permissions on the full folder path to find the secret.

Secret Server Cloud exclusively supports TLS 1.3. This version includes fixes for known vulnerabilities in older TLS versions and will eventually be required for PCI compliance. The following will need to be added to the top of your scripts because PowerShell defaults to TLS 1.0:

```
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
```

Secret Server Cloud API users: If Delinea One is enabled, *and* an API user logging on has an email address set in Secret Server, the user *must* use the Delinea One password, instead of the local Secret Server password. Using a local account password will fail. Use one of these workarounds:

- Disable Delinea One, if not needed
- Use the Delinea One password instead
- Use a user account that does not have an email address in Secret Server

Please see "Script Authentication Using Tokens" on page 1489 for instructions on acquiring a token for the scripts below.

Authentication

See "Script Authentication Using Tokens" on page 1489 for creating a token to use in the script examples below.

Searching Secrets

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    $filters = "?filter.includeRestricted=true&filter.searchtext=< mySearchText >"
    Write-Host "------------------------------"
    Write-Host "----- Secret Search Values -----"
    Write-Host "------------------------------"

#?filter.searchfield=username&filter.searchfield=displayname&filter.searchfield=filter.sea
rchText=mister&filter.includeinactive=true" -Headers $headers
    $result = Invoke-RestMethod "$api/secrets$filters" -Headers $headers
    Write-Host $result.filter.searchField
    Write-Host $result.total
    foreach($secret1 in $result.records)
    {
       Write-Host $secret1.id" - "$secret1.name" - "$secret1.folderId -
$secret1.lastHeartBeatStatus
    }
    Write-Host "------------------------------"
    Write-Host "----- Secret Lookup Values -----"
    Write-Host "------------------------------"

#?filter.searchfield=username&filter.searchfield=displayname&filter.searchfield=filter.sea
rchText=mister&filter.includeinactive=true" -Headers $headers
    $result = Invoke-RestMethod "$api/secrets/lookup$filters" -Headers $headers
    Write-Host $result.filter.searchField
    Write-Host $result.total
    foreach($secret in $result.records)
    {
```

```
        Write-Host $secret.id" - "$secret.value
    }
    Write-Host "------------------------------"
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd() | ConvertFrom-Json
    Write-Host  $responseBody.errorCode " - " $responseBody.message
    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

Creating a Secret

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    #stub
    $templateId = <Your Secret Template ID>
    $secret = Invoke-RestMethod $api"/secrets/stub?filter.secrettemplateid=$templateId" -
Headers $headers
    #modify
    $secret.name = <Your Secret Name>
    $secret.secretTemplateId = $templateId
    $secret.AutoChangeEnabled = $false
    $secret.autoChangeNextPassword = <Next Password Value>
    $secret.SiteId = <Your Site ID>
    $secret.folderId = <Your Folder ID>
    foreach($item in $secret.items)
    {
      if($item.fieldName -eq "Domain")
      {
        $item.itemValue = <Your Domain>
      }
      if($item.fieldName -eq "Username")
      {
        $item.itemValue = <Username>
      }
```

```
        if($item.fieldName -eq "Password")
        {
          $item.itemValue = <Password>
        }
    }
    $secretArgs = $secret | ConvertTo-Json
    #create
    Write-Host ""
    Write-Host "-----Create secret -----"
    $secret = Invoke-RestMethod $api"/secrets/" -Method Post -Body $secretArgs -Headers
$headers -ContentType "application/json"
    $secret1 = $secret | ConvertTo-Json
    Write-Host $secret1
    Write-Host $secret.id
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd()
    Write-Host $responseBody
}
```

Editing a Secret

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    #get
    $secretId = <Secret ID>
    $secret = Invoke-RestMethod $api"/secrets/$secretId/" -Headers $headers
    #modify
    $secret.RequiresComment = $true #Example only. Available fields to edit can be found
at https://<Your URL>/RestApiDocs.ashx?doc=token-
help#tag/Secrets/operation/SecretsService_UpdateSecret
    $secretArgs = $secret | ConvertTo-Json
    #update
    Write-Host ""
    Write-Host "-----Update secret -----"
    $secret = Invoke-RestMethod $api"/secrets/$secretId" -Method Put -Body $secretArgs -
Headers $headers -ContentType "application/json"
    $secretUpdate = $secret | ConvertTo-Json
```

```
    Write-Host $secretUpdate
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd()
    Write-Host $responseBody
}
```

Checking in a Secret

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    $secretId = <Your Secret ID>
    $secret = Invoke-RestMethod $api"/secrets/$secretId/check-in" -Method Post -Body
$secretArgs -Headers $headers -ContentType "application/json"
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd()
    Write-Host $responseBody
}
```

Deleting a Secret

```
try
{
    $api = "<URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
```

```
    $headers.Add("Authorization", "Bearer $token")
    $secretId = <Your Secret ID>
    Write-Host "----- Delete a Secret -----"
    $deletemodel = Invoke-RestMethod "$api/secrets/$secretId" -Headers $headers -Method
DELETE -ContentType "application/json"
    Write-Host $deletemodel
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd() | ConvertFrom-Json
    Write-Host  $responseBody.errorCode " - " $responseBody.message
    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

Creating a User

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    # create user
    Write-Host ""
    Write-Host "----- Create a User -----"
    $userCreateArgs = @{ #More fields available at https://<Your
URL>/RestApiDocs.ashx?doc=token-help#tag/Users/operation/UsersService_CreateUser
        userName = <Username>
        password = <Password>
        DisplayName = <Display Name>
        enabled = $true #Not required. Default is false.
    } | ConvertTo-Json
    $user = Invoke-RestMethod "$api/users" -Headers $headers -Method Post -ContentType
"application/json" -Body $userCreateArgs
    Write-Host "New User ID : " $user.id
}
catch
{
    Write-Debug "----- Exception -----"
    Write-Host  $_.Exception.Response.StatusCode
```

```
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd() | ConvertFrom-Json
    Write-Host  $responseBody.errorCode " - " $responseBody.message
    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

Update Secret Field

This script requires Secret Server 10.1 or later.

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    #Secret ID and Field to update
    $secretId = <Your Secret ID>
    $fieldToUpdate = <Field to Update>
    $endpoint = "$api/secrets/$secretId/fields/$fieldToUpdate"
    $body = @{
        value = <New Value>
    }| ConvertTo-Json
    echo $endpoint
    echo ------------------------------------------------------------------------------------
------------------
    echo ------------------------------------------------------------------------------------
------------------
    echo "Updating Field $fieldToUpdate"
    $response = Invoke-RestMethod -Method Put -Uri $endpoint -Headers $headers -
ContentType "application/json" -Body $body
    echo $response;
}
catch
{
    Write-Debug "----- Exception -----"
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd() | ConvertFrom-Json
```

```
    Write-Host  $responseBody.errorCode " - " $responseBody.message
    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

Get Secret Field Value

This script requires Secret Server 10.1 or later.

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    #Secret ID and Field to test against
    $secretId = <Your Secret ID>
    $field = <Field name>
    $endpoint ="$api/secrets/$secretId/fields/$field"
    $response = $null
    $response = Invoke-RestMethod -Method Get -Uri $endpoint -Headers $headers
    echo $response;
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd()
    Write-Host  $responseBody.errorCode " - " $responseBody.message
    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

Upload File to Secret

This script requires Secret Server 10.1 or later.

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
    #Secret ID and File to upload
    $fileSecretId = <Your Secret ID>
    $fileFieldToUpdate = <Field Name to Store File>
    echo ----------------------------------------------------------------------------------
------------------
    echo "Uploading file from $fileFieldToUpdate"
    $endpoint ="$api/secrets/$fileSecretId/fields/$fileFieldToUpdate"
    echo $endpoint
    $secretArgs = @{
        fileName = <File Name>
        fileAttachment = [IO.File]::ReadAllBytes(<File Path>)
    } | ConvertTo-Json
    $response = $null
    $response = Invoke-RestMethod -Method Put -Uri $endpoint -Headers $headers -Body
$secretArgs -ContentType "application/json"
    echo $response
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd()
    Write-Host  $responseBody.errorCode " - " $responseBody.message
    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

Download File From Secret

This script requires Secret Server 10.1 or later.

```
try
{
    $api = "<Secret Server URL>/api/v1"
    $token = "<TOKEN>"
    $headers = New-Object "System.Collections.Generic.Dictionary[[String],[String]]"
    $headers.Add("Authorization", "Bearer $token")
```

```
    #Secret ID and File to download
    $fileSecretId = <Your Secret ID>
    $fileFieldToUpdate = <Field Name Storing File>
    $downloadPath = <Your Download path, including file name being downloaded>
    echo "Downloading file from $fileFieldToUpdate"
    $endpoint ="$api/secrets/$fileSecretId/fields/$fileFieldToUpdate"
    echo $endpoint
    $response = $null
    $response = Invoke-RestMethod -Method Get -Uri $endpoint -Headers $headers -OutFile
$downloadPath
    Write-Host $response.Length
    Write-Host $response
}
catch [System.Net.WebException]
{
    Write-Host "----- Exception -----"
    Write-Host  $_.Exception
    Write-Host  $_.Exception.Response.StatusCode
    Write-Host  $_.Exception.Response.StatusDescription
    $result = $_.Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($result)
    $reader.BaseStream.Position = 0
    $reader.DiscardBufferedData()
    $responseBody = $reader.ReadToEnd()
    Write-Host  $responseBody.errorCode " - " $responseBody.message

    foreach($modelState in $responseBody.modelState)
    {
        $modelState
    }
}
```

REST API Python Scripts

This code sample demonstrates how to use Python 3 to authenticate to Secret Server, retrieve a secret, and update secret fields and items.

This code uses the "requests" module, which makes it simple to communicate via REST. You can install the requests module by running: `pip install requests`

An auth token is required to use this script.

```
import http.client
import urllib
import json
import requests
site = '[Secret Server URL" /> Site]' #ex: http://domain.com/SecretServer
authApi = '/oauth2/token'
api = site + '/api/v1'
token = "<TOKEN>"
# REST call to retrieve a secret by ID
def GetSecret(token, secretId):
    headers = {'Authorization':'Bearer ' + token, 'content-type':'application/json'}
    resp = requests.get(api + '/secrets/' + str(secretId), headers=headers)
    if resp.status_code not in (200, 304):
        raise Exception("Error retrieving Secret. %s %s" % (resp.status_code, resp))
    return resp.json()
# REST call method to update the secret on the server
def UpdateSecret(token, secret):
    headers = {'Authorization':'Bearer ' + token, 'content-type':'application/json'}
    secretId = secret['id']
    resp = requests.put(api + '/secrets/' + str(secretId), json=secret, headers=headers)
    if resp.status_code not in (200, 304):
        raise Exception("Error updating Secret. %s %s" % (resp.status_code, resp))
    return resp.json()
# Retrieves the secret item by its "slug" value
def GetItemBySlug(secretItems, slug):
    for x in secret['items']:
        if x['slug'] == slug:
            return x
    raise Exception('Item not found for slug: %s' % slug)
# Updates the secret item on the secret with the updated secret item
def UpdateSecretItem(secret, updatedItem):
```

```
    secretItems = secret['items']
    for x in secretItems:
        if x['itemId'] == updatedItem['itemId']:
            x.update(updatedItem)
            return
    raise Exception('Secret item not found for item id: %s' % str(updatedItem['itemId']))
# Get secret with ID = 1
print("Retrieving Secret with id: 1...")
secret = GetSecret(token, 1)
print("Secret Name: " + secret['name'])
print("Secret ID: " + str(secret['id']))
print("Active: " + str(secret['active']))
# Get the "Notes" secret item
notesItem = GetItemBySlug(secret, 'notes')
print("Notes secret field value: %s" % notesItem['itemValue'])
print()
# Change value of "Notes" secret item
print("Updating secret...")
notesItem.update({'itemValue': 'New Notes Value'})
UpdateSecretItem(secret, notesItem)
print("Secret updated.")
print()
# Change secret values
updateValues = {'name':'Updated Secret Name' }
secret.update(updateValues)
updatedSecret = UpdateSecret(token, secret)
notesItem = GetItemBySlug(updatedSecret, 'notes')
print("Updated Secret Name: " + updatedSecret['name'])
print("Notes secret field value: %s" % notesItem['itemValue'])
```

REST API Perl Scripts

Secret Server web services can be called using scripts. This example demonstrates how to authenticate and retrieve a Secret programmatically in Perl. If connecting to an Installed instance, change the URL to match your site and specify the application name if configured.

This example runs using standard Perl modules and Strawberry Perl v5.24.1.1.

You may need to install REST::Client from CPAN which can be done by running:

```
cpanm REST::Client
```

This module makes interacting with RESTful APIs much easier.

The TSS script below leverages the API created in the TSS with .pm extension file.

The TokenResponse with .pm extension file defines an object that stores the authentication credentials for the session.

The ErrorResponse with .pm extension file defines an object that stores error information should a REST request fail.

The SecretModel with .pm extension file defines an object that stores the Secret information when requesting a particular Secret from the REST API.

TSS.pl:

```
use REST::Client;
use JSON;
use TSS;
# Enter your <Secret Server URL /> web site here.
my $host = 'http://localhost';;
# Enter the application name, should it be defined.
my $applicationPath = '/secretserver';
my $false = 0;
my $true = 1;
my $usingSelfSignedCertificate = $true;
if ($usingSelfSignedCertificate) {
    # Disable hostname validation since this will fail with self-singed certs.
    $ENV{'PERL_LWP_SSL_VERIFY_HOSTNAME'} = $false;
}
# Initialize the TSS Perl API with the connection information provided above.
my $tss = TSS->new(
        secretServerUrl => $host,
        applicationPath => $applicationPath
    );
print "Username: ";
my $input = <STDIN>;
chomp $input;
my $username = $input;
print "Password: ";
$input = <STDIN>;
chomp $input;
my $password = $input;
# Authenticate to <Secret Server URL />
my $response = $tss->getToken($username, $password);
if (ref $response eq 'ErrorResponse') {
    $tss->handleError($response);
    exit();
}
# Persist the API token in our TSS API session.
$tss->tokenResponse($response);
$password = undef;
print "Secret ID to retrieve: ";
$input = <STDIN>;
chomp $input;
my $secretId = $input;
# Retrieve a Secret from <Secret Server URL /> by Secret ID.
$response = $tss->getSecret($secretId);
if (ref $response eq 'ErrorResponse') {
    $tss->handleError($response);
    exit();
}
# Read the SecretModel object
print 'Secret ' . $response->id . ' retrieved successfully. Secret name: ' . $response-
>name . "\r\n";
```

SDK for DevOps Overview

The SDK for DevOps provides a comprehensive set of tools and resources to facilitate secure and efficient management of secrets within development and operational environments. Below is a brief overview of the key components:

- Using the Secret Server SDK for DevOps

The Secret Server SDK offers a robust framework for integrating secret management into your applications. It provides APIs and libraries that allow developers to interact with Secret Server programmatically, ensuring that sensitive information is handled securely.

- Secret Server SDK Integration

SDK Integration focuses on how to seamlessly incorporate the Secret Server SDK into your existing systems. This section provides guidance on setting up the SDK, configuring it for your environment, and leveraging its capabilities to enhance your security posture.

- SDK for DevOps Downloads

This section provides access to the necessary files and resources required to get started with the Secret Server SDK. It includes download links for SDK packages, documentation, and other essential tools.

- SDK CLI

The SDK Command Line Interface (CLI) offers a powerful way to interact with Secret Server from the command line. It enables automation of secret management tasks, making it easier to integrate with CI/CD pipelines and other automated workflows.

Using the Secret Server SDK for DevOps

Overview

The Secret Server Software Development Kit for DevOps tool, was created for securing and streamlining DevOps processes in regard to Secret Server. The SDK for DevOps tool allows you to efficiently engage Secret Server via a Command Line Interface (CLI) without compromising security. It allows for secure retrieval of credentials from, as well as tracking access to a secure vault.

The SDK uses the "REST API Reference Download" on page 1522. The SDK is a .NET library (available via a NuGet package), which you can use in a custom application. The SDK .NET library exposes a limited subset of the REST API.

> You can download the current and legacy versions of the API on the "Downloads for the Secret Server SDK for DevOps" on page 1573 page.

The SDK can run on any version of .NET that supports .NET Standard 2.0 apps including: .NET Core 2.0 plus, .NET Framework 4.6.1 plus, .NET Framework 4.8 plus, .NET 5 plus, .NET 6 plus, and .NET 7 plus.

See the Delinea SDK Integration Doc on GitHub for more information.

The SDK is designed to be used as shown below, not to be run using IWA to retrieve tokens or Secret information. Given this, the SDK is not supported with IWA.

There is also a .NET Core CLI SDK Client that uses the SDK .NET library. The SDK Client was created to allow customers to write automation scripts to access secrets without having to write code to directly access the REST API.

The .NET SDK library and the .NET Core CLI client both:

- Automatically store the credentials and remote server used to acquire an OAUTH token and stores them in a file. For Windows, the file is encrypted file. For Linux, the file needs to be secured by the customer. The token is then used to make subsequent API calls. OAUTH tokens have an expiration time, which is configurable in the UI on the configuration page via **the Session Timeout for Webservices** value..
- Get the contents of a secret.
- Provide client-side caching (SDK client caching).

Secret Server has user and application accounts. Both types of accounts can access Secret Server via the REST API. Application accounts are not counted for licensing purposes. Application accounts can *only* access Secret Server via the REST API. Both account types never expire. Secret Server provides security for automated clients. SDK rules manage permissions. Client IDs are created when `SecretServerClient.Configure()` or `tss init` is called. The client ID is used to reference SDK client instances.

Do NOT give an application account the Administrator Role or all role permissions. It is recommended to only assign the minimum roles needed to complete the task. That means to create a new Role with only the permissions it needs for the application account and only share the secrets needed.

For REST API Client Generation (Advanced), please see "REST API Client Generation with Swagger" on page 1517.

We have a Python SDK that is independent of the SDK .NET library. It allows a Python script to access secrets without requiring REST knowledge. It has access to a small subset of the REST API.

How it Works

The SDK is a console application written in .NET Core that wires up its own credentials based on the machine it is installed on. Those credentials, called **DevOps Users**, do not have any rights in Secret Server but can be assigned to other Secret Server users or application user accounts, mimicking permissions to access secrets.

This removes the widespread DevOps issues with hard coding credentials into scripts and configuration files. Instead, the target system is registered via IP address which is whitelisted, providing REST authentication without entering user credentials. You can use the SDK to retrieve a REST user token for our REST API, or you can use the SDK to perform direct queries on Secret Server.

The SDK establishes secure access points so that PowerShell users can employ the Secret Server API directly from the CLI, without wasting time entering privileged account passwords.

Configuration Overview

Secret Server exposes a REST API interface that is used by the SDK client. When the SDK sends a REST request, Secret Server determines where the request came from (via IP address) and what permissions it should be granted (via a rule set in Secret Server). Once the client is initialized with Secret Server and the rule name, this configuration is stored on the client machine. For Windows, the configuration is encrypted automatically. For Linux, the configuration file needs to be secured by the customer, ready for subsequent calls.

Out of the box, the SDK offers:

- Token retrieval
- Secret retrieval
- Secret field retrieval

We expect to expand the SDK capabilities over time to allow for even greater access to the REST API.

The SDK requires setup in two areas: Secret Server configuration and SDK installation on the DevOps system.

Required Roles and Permissions

- **Administer Configuration**: Allows a user to enable SDK functionality in Secret Server, that is, to enable webservices and the SDK itself.
- **Administer Create Users**: Allows a user to access the **Settings > All settings > Tools and integrations > SDK client** page in Secret Server.
- **Administer scripts**: This permission is required to be able to create an SDK Client Onboarding rule. It allows a user to view and edit PowerShell, SQL, and SSH scripts on the **Scripts Administration** page.
- **Administer Users**: Allows a user to operate the SDK to retrieve account credentials on client machines. Alternatively, you can be the owner of the application account used by the SDK.
- **View Launcher Password**: Allows a user to unmask the password on the view screen of secrets with a launcher. Typically, this includes Web Passwords accounts, Active Directory accounts, Local Windows accounts, and Linux accounts.

Setup Procedure

Task 1: Configuring Secret Server

Configure Secret Server for communication with the SDK

1. Search for **SDK Client**, the SDK Client Management page opens.
2. Under the **Configuration** tab, click **Edit**, and check to select **Enable** SDK Configuration. When done, click **Save**.
3. Search for **Application**.
4. On the Application page click **Edit** and select the **Enable Webservices** check box.
5. Leave the default settings for webservices and click **Save**.

Select or Setup Application Accounts

Select or setup any application accounts that you want for use by SDK clients. Make sure these application accounts have appropriate permissions to access any secrets or execute any operations the client host needs to perform.

To create a new application account with the needed permissions:

1. Search for **Users**, the User Management page appears.
2. Click the **Create user** button. The **Add User** popup appears.
3. Fill in the following fields:
   a. **Username**: the account name.
   b. **Display name**: the searchable name for the account of your choice, can be the same as the username.
   c. **Domain**: leave as is with the default **Local** value.
   d. **New Password** and **Confirm Password**: a password of your choice.
   e. **Email**: type in an email (optional).
   f. Select the **Application Account** checkbox.
   g. **Multifactor authentication**: leave as is with the default **<None>** value.
   h. Make sure the **Enabled** checkbox is selected.
4. Click **Add User**.
5. Create a new role:
   a. Search for **Roles**.
   b. Click **Create Role**. The **Create Role** popup appears.
   c. Type in a **Name** and make sure the **Enabled** checkbox is selected.
   d. Click **Create Role**. The page for the new role appears.
   e. Assign the **View Secret** permission to this role:

i. Select the **Permissions** tab and click **Edit**.

ii. Change the **Scope** selection to **All**, and search for the **View Secret** permission with the search box.

iii. Select it and click **Save**.

6. Assign the role you just created to the application user created above:
   a. Access the role you just created, it has no users assigned.
   b. Under the Assignment tab click **Edit**, the **Scope** option appears. Change its value to **All**.
   c. Search for the user you previously created, toggle the **Domain** option as needed to show all users.
   d. Add the user by selecting the checkbox by its name and clicking **Save**.
7. Assign the **View Launcher Password** role permission to the application user previously created if this account requires access to secrets with launchers associated to them. Use the same steps for assigning this permission as described for View Secret in the previous steps.

Set up an SDK client rule

1. Search for **SDK client**. This will lead you to the SDK Client Management page.
2. Under the **Client Onboarding** tab, click **Create rule**. The **New Rule** page appears.
3. Type in a relevant name in the **Name** field without any spaces. For example: `ProductionWebApp`.
4. Optionally, leave the **Allowed IP Ranges (CIDR)** field blank, or type in an IPV4 address, or use CIDR notation.

   Secret Server will only allow clients to use this rule if they connect from a valid IP address. If not provided, Secret Server will not enforce IP address restrictions on this rule. We strongly recommend using this feature.

   > There is a 250-character limit, so you can only add a few dozen IP addresses unless you use CIDR notation.

   > IPv6 addresses are not supported.

5. For the **User** drop-down list leave the default **All** value selected.
6. In the search box next to the dropdown, look for the application user you just created and select it.

   > Clients are granted the same permissions as this account within Secret Server. If not provided, an account will be automatically created for clients, but will have no default permissions. You must use an application account (the one you created) for the rule. Application accounts are restricted from logging into the system through the normal user interface and do not count towards your license quota.

7. Select the **Require Onboarding Key** checkbox.

   Clients must provide a generated additional key string when authenticating. If not provided, Secret Server allows any client to use the rule if its IP address is within the specified range. We strongly recommend using this feature.

8. When done, click **Save**.

   The page for the new rule you just created will load automatically.

9. Return to the **SDK Client Management** page, and under the **Client Onboarding** tab click on the rule that you have just created, the rule details will expand to the right of the screen.

10. Select **Show Key**, then copy and save the generated onboarding key value, e.g. `U9Ue9PsMYknfoskQvd/0BYMTaTTx2vtWbB/tHI3exDE=`, for future use.

Task 2: Installing the SDK Client

> This requires Secret Server version 10.4+ or Secret Server Cloud.

> IWA is not supported by the SDK.

> The SDK can run on any version of .NET that supports .NET Standard 2.0 apps including: .NET Core 2.0 plus, .NET Framework 4.6.1 plus, .NET 5 plus, and .NET 6 plus.

1. Access "Downloads for the Secret Server SDK for DevOps" on page 1573 and choose the right kit for your platform. We recommend always using the latest version available.
2. Extract/unzip the SDK zip file you downloaded.
   a. Optionally, to get the SDK NuGet packages, see our documentation on GitHub.
3. For Linux systems, you must make the tss program executable by running `chmod u+x tss`.
4. On Linux systems, you must install libunwind:
   - On Red Hat or Centos, run `sudo yum install libunwind libicu`
   - On Ubuntu, run `sudo apt-get install libunwind-dev`
5. For Windows, open a console window by clicking the Start menu and searching for **cmd**.
6. Inside the Command Prompt type `cd [location of the downloaded zip file]/[location of extraction folder]`.

   E.g. `cd downloads/secretserver-sdk-1.5.9-win-x64`
7. To confirm the SDK client tool is installed and working, run help:
   - On Windows, run `tss --help`
   - On non-Windows systems, run `./tss --help`

Task 3: Connecting to Secret Server

Before the client can retrieve data from Secret Server, it must be initialized to connect to the Secret Server instance. This is a one-time operation on the client machine.

> The SDK connection is per user on the machine. If the user who runs the SDK is different than the user who initialized it, the SDK will not work and will need to be re-registered.

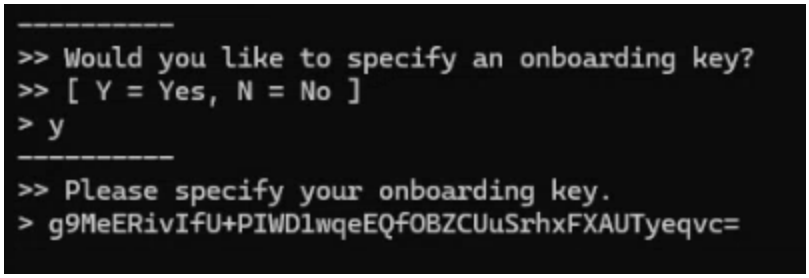
To initialize your connection:

1. Click the Start menu and search for **cmd**.
2. Inside the Command Prompt type `cd [location of the downloaded zip file]\[location of extraction folder]`.

   E.g. `cd downloads\secretserver-sdk-1.5.9-win-x64`
3. Run `tss -i` to use interactive mode:

4. Type `init` and press enter.
5. When prompted for the URL, copy and paste the URL of your Secret Server instance, and press enter.

   E.g. https://[secret server url].
6. You are then prompted to specify the rule you created previously in the SDK Client Management page. Type in the rule name and press enter. E.g `ProductionWebApp`.
7. You are now asked if you wish to specify an onboarding key. Enter **yes**.
8. The prompt to specify the key appears. The key was copied after you created the rule. E.g.: `CNrQwRBscnq4qAZ6v3EIAcE27vQuLlz6KSpfRJHryyA=`. You need to paste it in the Command Prompt window and press enter:



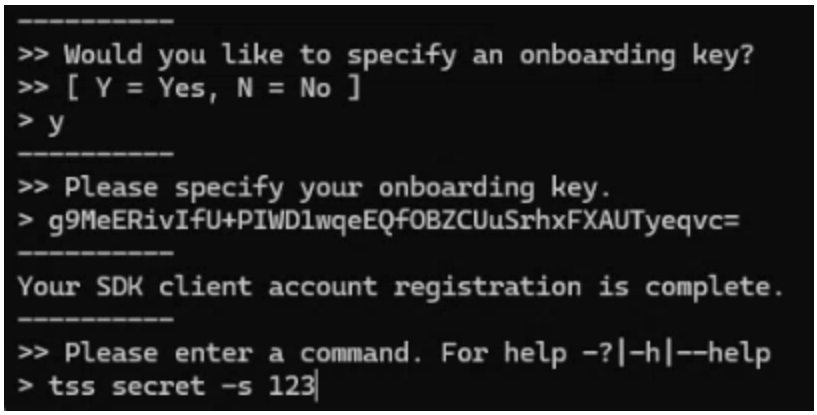
9. The "Your SDK Client account registration is complete" message appears. Keep this window open, do not exit.

10. Return to your Secret Server instance and to the SDK Client Management page.
11. In the **Accounts** tab, click on the account that now appears after performing SDK initialization. The side menu appears with information about the account.
12. Click **View details**.
13. Inside the SDK account page, click **Edit**.
14. Search for the application account/user you previously created in Task 1, e.g:

15. Add the application account username in the box for the **User** search field, it will return a list of users. Pick the one you need and click **Save**.

> If this is not done the SDK Client will return this error: `invalid_client`.

16. Return to the Command Prompt window you kept open. You will now enter the command to view your secret ID `tss secret -s [secret id]`:



17. The prompt to specify a field appears, enter **no**.
18. The Secret will successfully display in the tss application.

Secret Server verifies the client's credentials and IP address restriction (if specified). Once validated, the client and server establish a connection allowing the client to retrieve data from Secret Server.

> **Note:** To perform this operation outside of interactive mode, run `tss init --url [url] -r [rule] -k [key]` using the parameters you recorded earlier for your instance.
>
> Example of operation and parameters to run for connection initialization:
>
> ```
> tss init --url https://myserver/SecretServer/ -r ProductionWebApp -k
> CNrQwRBscnq4qAZ6v3EIAcE27vQuLlz6KSpfRJHryyA=
> ```

Usage Examples

- Retrieving a secret by ID (returns a JSON structure describing the entire secret record): `tss secret -s 4`
- Retrieving all secret field values for a secret by ID: `tss secret -s 4 -ad`
- Retrieving only the value of a particular secret field by secret ID: `tss secret -s 4 -f password`
- Writing a secret field value to a file: `tss secret -s 4 -f password -o passwordfile.txt`
- Retrieving an access token for use in other REST API requests: `tss token`
- Retrieving a secret by ID when that Secret requires a comment: `tss secret -s 4 -c comment`

The SDK client includes an interactive mode (`tss -i`) that allows you to input multiple commands into a series of prompts. To exit interactive mode, run the `exit` command.

SDK Client Management

To view and manage a list of connected SDK clients from within Secret Server:

1. Search for **SDK client**. The SDK Client Management page appears.
2. In the **Accounts** tab a list of connected SDK clients appears for all users if available. You can remove or rename them. You can also filter clients by User.
3. Select the **Client Onboarding** tab to create and manage client onboarding rules.
4. Select the **Configuration** tab to disable or enable all SDK client activity.
5. Select the **Audit** tab to see date and time-stamped SDK client activity concerning onboarding rules and client secrets.
6. To remove the Secret Server connection from a client machine, run the `tss remove` command. This deletes the connection, and the client can no longer retrieve Secret Server data without being re-initialized.

> If you remove a connected SDK client, the user may still be able to reconnect using the client onboarding rule key unless you alter or remove the rule that the client used from Secret Server.

When an SDK client connects to Secret Server, a client ID is generated. These credentials can be revoked, but will remain valid for 15 minutes after revocation, after which their validity expires.

SDK Client Caching

Overview

To increase performance and reliability, you can configure the SDK client to cache values retrieved from Secret Server on the client machine. Cached values are stored on disk. For Windows, the cached values are encrypted automatically. For Linux, the cached values need to be secured by the customer. You can configure client caching in one of four ways:

- **Never** (0): With this default setting, the client never caches Secret Server data. All data requests result in a query directly against the Secret Server instance. If the instance is unavailable, the requests fail.
- **Server Then Cache** (1): With this setting, the client first attempts to retrieve the value from the server. If the server is unavailable, it checks to see if the same value has been previously fetched within a given period, and if so, it will return the cached value. Use this setting to guard against losing connection to Secret Server.
- **Cache Then Server** (2): With this setting, the client first checks to see if the same value has been previously fetched within a given period. If so, it returns the value without consulting the server. If not, it fetches, caches, and returns the value from the server. Use this setting for increased performance by reducing requests sent to Secret Server.
- **Cache Then Server Fallback on Expired Cache** (3): This strategy operates similarly to "Cache Then Server," but if the server is unavailable and an expired value exists in the cache, the client returns that value as a last resort. Use this strategy for increased performance and reliability.

All these cache strategies have a configurable age, in minutes, after which the value is considered expired and not used (except in **Cache Then Server Fallback** mode). Cache settings are set using the client application, see the examples below for more details.

Examples

- Turn off caching: `tss cache --strategy 0`
- Turn on the **Cache Then Server** setting with a cache age of five minutes: `tss cache --strategy 2 --age 5`
- Immediately clear all cached values: `tss cache --bust`
- Show the current cache settings: `tss cache --current`

Anytime you use a cached value, recent changes made to Secret Server may not be applied, including changes to the value itself, permissions, or other access control settings. Examine your organization's security policies and application requirements to determine the best cache settings to use.

Secret Server SDK Integration

SDK Integration in a C# Project

> In this scenario we assume we can recompile the application, and will dynamically retrieve passwords from the vault whenever needed.

Prerequisites

1. Create a rule in Secret Server for client onboarding:
   a. Search for **SDK Client**, the SDK Client Management page opens.
   b. Under the **Client Onboarding** tab, click **Create Rule** to create a new rule.
   c. Name your rule (something that helps identify it, such as the application name).
   d. Assign IPv4 restrictions (optional).
   e. Assign an application user account (create one if you have not already).
   f. Generate a Rule Key (optional).
   g. Click to select the **Require Onboarding Key** check box (optional).
   h. Click the **Save** button.
2. The application account you created needs to have access to the secrets your application needs. Ensure the account permissions are accurate at the folder or secret level.
3. Download the SDK packages from NuGet. You can do this either directly from Visual Studio (recommended) or manually download and install them from Nuget.org. The latest version is almost always preferred.
   On the Nuget site:
   a. Search for "Thycotic" (an older name for one of the companies that became Delinea)
   b. Install the following packages:
      - Thycotic.SecretServer.SDK
      - Thycotic.SecretServer.SDK.Extension.Configuration
      - Thycotic.SecretServer.SDK.Extension.Integration

> The SDK Nuget packages target both .NET Framework v4.5 or higher, or .NET Standard 2.0. Visual Studio will install the appropriate version based on your project type. .NET Standard 2.0 supports either:
>
> - .NET Core 2.0 if building a .NET Core application
> - .NET (Full Framework) 4.6.1

4. In your project, add the following references:

```
using Thycotic.SecretServer.Sdk.Extensions.Integration.Clients;
using Thycotic.SecretServer.Sdk.Extensions.Integration.Models;
using Thycotic.SecretServer.Sdk.Infrastructure.Models;
```

Alternatively, you can instantiate the objects and let Visual Studio add the references for you.

Configuring the SDK

You need to instantiate a new SecretServerClient object to interact with the SDK. Below is sample code:

```
var client = new SecretServerClient();
//configure if not configured
client.Configure(new ConfigSettings
  {
    SecretServerUrl = string,
    RuleName = string,
    RuleKey = string,
    CacheStrategy= CacheStrategy.enum,
    CacheAge= int,
    ResetToken= string
  });
```

The code above registers the integrated client with Secret Server. Below is an explanation of the properties of the client's ConfigSettings:

- `ConfigSettings` is an object
- `SecretServerUrl` is the base URL for your Secret Server (if you have a load balancer then it should be the load balanced URL)
- `RuleName` is the name of the rule we created earlier
- `RuleKey` is the key we generated, can be NULL if no key
- `CacheStrategy` is how the SDK will cache requests. This is an enum with four options:
  - `CacheThenServer`
  - `CacheThenServerAllowExpired` (This allows fallback in case Secret Server is not available and the cache is expired, the SDK will still use the cache until it can contact Secret Server and prime the cache)
  - `Never`
  - `ServerThenCache` (This mode is for redundancy since it will fall back to cache in case Secret Server is not available)
- `CacheAge` is how long the cache is valid before it expires in minutes
- `ResetToken` is a random string to revoke clients and reinitialize them

Once the client is configured for the first time, a series of encrypted configuration files are created. By default they will be saved in the current working directory of your application. This path can be customized with the SecretServerSdkConfigDirectory AppSetting.

If using the .NET Standard version of the SDK, these config files are protected by an encryption key. It is saved in the current user's home directory by default, but this path can also be customized with the SecretServerSdkKeyDirectory AppSetting if necessary.

If you need to change your configuration, change your reset token and the SDK will reinitialize the config files. Otherwise, the SDK will not reconfigure itself as long as it can still access and decrypt the config files. Calls to client.Configure() are ignored if the reset token remains the same and the client has already been configured.

Using the SDK

Now we can use the client to get a secret, token, or a secret field from Secret Server, and pass that to our application:

```
var password = client.GetSecretField(<SECRET ID>,"password"); //replace <SECRET ID>
```

The code above retrieves a password from Secret Server, which we can then pass to a connection string or anywhere a password is needed.

You can call the `GetSecret();` method on the client object to get the full secret object, and then access the items property which holds a collection of the secret fields and their values. How you access these values is up to you, but you can use Linq to query what you are looking for. For instance:

```
var secret = client.GetSecret(<SECRET ID>); //replace <SECRET ID>
var server = secret.Items.First(x => x.Slug == "server").ItemValue;
var username = secret.Items.First(x => x.Slug == "username").ItemValue;
var password = secret.Items.First(x => x.Slug == "password").ItemValue;
var database = secret.Items.First(x => x.Slug == "database").ItemValue;
```

and then use these variables to build a connection string:

```
SqlConnectionStringBuilder builder = new SqlConnectionStringBuilder(GetConnectionString
())
{
    ConnectionString = $"server={server};user id={username};password={password};initial
catalog={database}"
};
```

Here is the complete code sample:

```
using System;
using System.Linq;
using Thycotic.SecretServer.Sdk.Extensions.Integration.Clients;
using Thycotic.SecretServer.Sdk.Extensions.Integration.Models;
using Thycotic.SecretServer.Sdk.Infrastructure.Models;
using System.Data.SqlClient;
namespace SDK.Integration
```

```
{
    class Program
    {
        static void Main(string[] args)
        {
            var url = "";       //replace with Secret Server URL
            var ruleName = "";  //replace with SDK rule name
            var ruleKey = "";   //replace with on boarding key
            var cacheAge = int; //replace with number for cache age
            var secretId = int; //replace with Secret ID
            var client = new SecretServerClient();
            //configure if not configured
            client.Configure(new ConfigSettings
            {
                SecretServerUrl = url,
                RuleName = ruleName,
                RuleKey = ruleKey,
                CacheStrategy= CacheStrategy.CacheThenServerAllowExpired,
                CacheAge= cacheAge, //in minutes
                ResetToken= "Token"
            });
            var secret = client.GetSecret(secretId);
            var server = secret.Items.First(x => x.Slug == "server").ItemValue;
            var username = secret.Items.First(x => x.Slug == "username").ItemValue;
            var password = secret.Items.First(x => x.Slug == "password").ItemValue;
            var database = secret.Items.First(x => x.Slug == "database").ItemValue;
            //connection string example
            SqlConnectionStringBuilder builder = new SqlConnectionStringBuilder
(GetConnectionString())
            {
                ConnectionString = $"server={server};user id={username};password=
{password};initial catalog={database}"
            };
            Console.WriteLine(builder.ConnectionString);
            Console.ReadKey();
        }
        private static string GetConnectionString()
        {
            return "Server=(local);Integrated Security=SSPI;" +
                "Initial Catalog=AdventureWorks";
        }
    }
}
```

SDK Integration in web.config

In this scenario, we assume we cannot recompile the application or prefer not to. The use case is as follows:

ASP.NET web application and is a .NET Standard 2.0 application

- We have a ConnectionString(s) inside of our config file that contains plaintext passwords
- We have appSettings with plaintext passwords that our app uses to connect to external services

The SDK allows us to pull data from Secret Server and inject it in the config file.

The injected data is not available in Application_Start, because this is a HTTP Intercept module it will not have ran yet.

Prerequisites for web.config

1. Create a rule in Secret Server for client onboarding using the same method detailed earlier.
2. Install the Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule Nuget package:
   - This is available in the Nuget package manager from Thycotic. Installing it will also install the necessary dependencies.
   - We recommend this method of installation so dependencies will also be automatically installed, and the Nuget package manager will show when updates are available.
3. It is also possible to manually download the packages from Nuget, but this requires more effort and you won't be notified of updates.
4. The following packages are needed:
   - Thycotic.SecretServer.Sdk
   - Thycotic.SecretServer.Sdk.Extensions.Configuration
   - Thycotic.SecretServer.Sdk.Extensions.Integration
   - Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule
5. After downloading, use 7-Zip or the like to unpack the ngpkg and navigate to the lib directory
6. Make sure you only extract dlls from subdirectories in NetStandard2.0 or net461
7. Copy the extracted dlls to your application's bin folder:
   - Thycotic.SecretServer.Sdk.dll
   - Thycotic.SecretServer.Sdk.Extensions.Configuration.dll
   - Thycotic.SecretServer.Sdk.Extensions.Integration.dll
   - Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule.dll

Configuring the SDK for web.config

1. Open your web.config file in your preferred code editor and add the inside your appSettings tag following:

```
<appSettings>
    <add key="tss:CacheAge" value="<cache-age>" />
    <add key="tss:CacheStrategy" value="<cache-strategy>" />
    <add key="tss:SecretServerUrl" value="<your-secret-server-url>" />
    <add key="tss:RuleName" value="<rule-name>" />
    <add key="tss:RuleKey" value="<rule-key>" />
    <add key="tss:ResetToken" value="<reset-token>" />
</appSettings>
```

   - This will configure the SDK to talk to Secret Server, attach it to a rule, authenticate with the optional pre-shared key, configure caching, and add a reset token for reinitialization. Below is an explanation of these key-value pairs:
     - tss:CacheAge: cache age in minutes, that is how long should the SDK keep the cache before trying to refresh
     - tss:CacheStrategy: should the SDK cache or not? Strategies are numbered 0 - 3
       - 0: Never cache
       - 1: Server then cache
       - 2: Cache then server
       - 3: Cache then server, but allow expired cache if the server is unreachable
     - SecretServerUrl: Your Secret Server URL
     - tss:RuleName: the name of the rule you created in Secret Server
     - tss:RuleKey: the pre-shared key you generated for the rule
     - tss:ResetToken: This is a string value used to reinitialize the SDK. It can be anything, and changing it will cause the client to reinitialize and reregister itself
2. Scroll to:

```
<system.webServer>
    <module>
```

   and add the following:

```
<remove name="ThycoticInterceptModule" />
<add name="ThycoticInterceptModule"
type=
"Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule.Modules.ThycoticInterceptM
odule,Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule" />
```

3. Our section should look like this:

```
<system.webServer>
    <validation validateIntegratedModeConfiguration="false" />
    <modules>
      <remove name="ThycoticInterceptModule" />
      <add name="ThycoticInterceptModule"
          type=
"Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule.Modules.ThycoticInterceptM
odule,Thycotic.SecretServer.Sdk.Extensions.Integration.HttpModule" />
      <remove name="TelemetryCorrelationHttpModule" />
      <add name="TelemetryCorrelationHttpModule"
          type="Microsoft.AspNet.TelemetryCorrelation.TelemetryCorrelationHttpModule,
Microsoft.AspNet.TelemetryCorrelation"
          preCondition="integratedMode,managedHandler" />
      <remove name="ApplicationInsightsWebTracking" />
      <add name="ApplicationInsightsWebTracking"
          type="Microsoft.ApplicationInsights.Web.ApplicationInsightsHttpModule,
Microsoft.AI.Web"
          preCondition="managedHandler" />
    </modules>
  </system.webServer>
```

Important: You may need to add a binding redirect if you run into:

```
Message: System.IO.FileLoadException : Could not load file or assembly
'System.Runtime.InteropServices.RuntimeInformation, Version=0.0.0.0, Culture=neutral,
PublicKeyToken=b03f5f7f11d50a3a' or one of its dependencies. The located assembly's manifest
definition does not match the assembly reference. (Exception from HRESULT: 0x80131040)
```

Simply add the following to your `web.config` file:

```
<dependentAssembly>
    <assemblyIdentity
name="System.Runtime.InteropServices.RuntimeInformation"    publicKeyToken=
"b03f5f7f11d50a3a" culture="neutral" />
    <bindingRedirect oldVersion="0.0.0.0-4.0.2.0" newVersion="4.0.2.0" />
</dependentAssembly>
```

4. Match the version number with what you have installed on your system.

Using web.config

To replace plaintext credentials in your `web.config` file we simply use string interpolation to replace the hard-coded values with Secret Server values as shown below.

Example old ConnectionString:

```
<connectionStrings>
    <clear />
    <add
        name="AdventureWorks2014ConnectionString"
        connectionString="Data Source=sql01.domain.com;Initial
Catalog=AdventureWorks2014;Persist Security Info=True;User ID=sa;Password=SgW#5)zLpo($@d"
```

```
        providerName="System.Data.SqlClient"
    />
  </connectionStrings>
```

Example new ConnectionString with the Secret Server SDK:

```
<connectionStrings>
    <clear />
    <add
        name="AdventureWorks2014ConnectionString"
        connectionString="Data Source=${server};Initial Catalog=${database};Persist
Security Info=True;User ID=${username};Password=${password}?3112"
        providerName="System.Data.SqlClient"
    />
  </connectionStrings>
```

The ?3112 is the secret ID preceded by a question mark.

SDK API: The SecretServerClient() Class

This class has the following methods:

.BustCache()

This method doesn't have an overload. Calling it destroys the SDK's cache of secrets. The SDK configuration is still retained.

.Configure(IConfigSettings settings, [bool force = false])

```
settings
Type: Object
Key value pairs to configure the SDK

force (optional)
Type: boolean
Default: false
Forces the SDK to reconfigure itself
```

```
force (optional)
Type: boolean
Default: false
Forces the SDK to reconfigure itself
```

.GetSecret(int id)

This method returns a secret object based on the REST secret model.

.GetSecretField(int id, string fieldslug)

This method gets a specific field from the secret instead of returning the whole object.

```
id
Type: int32
The secret id needed to retrieve the secret

fieldslug
Type: String
Slug identifier for the secret field password
```

.GetAccessToken()

This method returns a REST API token from Secret Server, after authenticating with the configured SDK account.

.GetAccessTokenAsync()

Just like GetAccessToken but asynchronous.

SDK Client

To get the command-line interface SDK Client tool check out "Downloads for the Secret Server SDK for DevOps" below. This tool is not required to use the SDK NuGet packages.

The SDK Client and SDK NuGet packages are two separate projects with separate versioning. We actively work to maintain feature parity between the two projects, but at times their features may differ.

Downloads for the Secret Server SDK for DevOps

Overview

The Secret Server SDK replaces and improves upon the existing functionality of the .NET/Application API. Users can leverage this SDK to tokenize credentials in scripts and configuration files for .NET web applications. The SDK can also call for a REST Webservices authentication token for added functionality. Finally, the SDK has a local encrypted cache for every location it is installed on to allow for quicker transit times and resiliency in case communication with Secret Server is lost.

To download the SDK command line tool, choose a version and OS platform below. See the "Using the Secret Server SDK for DevOps" on page 1555 topic for how to use the SDK.

> Due to Java's security flaws and the existence of the Secret Server SDK, we will no longer support the Secret Server Java API. If you use the Secret Server Java API, please consider transitioning to the Secret Server SDK.

SDK Client version 1.6.2

Release Notes

- Added .NET 6 target (retains .NET Standard 2.0).
- Dropped support for .NET Framework 4.5.

Downloads

- Windows x64
- MacOS x64

SDK Client version 1.5.5

Release Notes

- Reset the token expiration calculation to use UTC time to avoid unexpected expiration.
- Reworked error handling for secret field-value requests so that the correct error string is extracted from the result if the secret is not accessible.
- Fixed the issue that caused the "tss version" command to return an inaccurate value.
- Updated references to external libraries within the SDK to address reported vulnerabilities.

SDK Client version 1.5.3

Release Notes

Added a "multi" option to the CLI. You can now select one field from multiple secrets in a single call by passing a comma-separated list of multiple Secret IDs and a field name.

SDK Client version 1.4.1

Release Notes

- New option to specify a configuration and cache directory other than the default.
- SDK CLI (`tss`) now has a `--configure-directory` option.
- NuGet SDK packages now check for a `SecretServerSdkKeyDirectory AppSetting`.
- Updated the NuGet SDK packages to support customizing the key storage directory. They now check for a `SecretServerSdkKeyDirectory AppSetting`.
- Updated the NuGet SDK packages to have a `SecretServerClientGetAccessToken()` and `GetAccessTokenAsync()` method, to get a REST or SOAP API token. This is equivalent to the existing SDK CLI command `token`.

- Linux x64 (including RHEL 7 to 8–RHEL 9 uses OpenSSL v3, which the SDK does not support)

SDK Client version 1.3.0

Release Notes

- Upgrade to .NET Core 2.1 Runtime.
- Encrypt configuration with DPAPI on Windows by default.
- New commands to display connection status and version.
- New option to specify a key storage directory other than the default.
- Target multiple OS versions with a single build.

- Red Hat Enterprise Linux 7 x64
- Ubuntu 16.10 x64
- MacOS 10.12 x64

SDK NuGet Packages (Optional)

To get the SDK NuGet packages, check out the documentation on our GitHub page. This package is not required to use the SDK Client.

The SDK Client and SDK NuGet packages are two separate projects with separate versioning. We actively work to maintain feature parity between the two projects, but at times their features may differ.

Secret Server CLI Client Reference

The TSS CLI client is an integration utility that allows you to interact with Secret Server. This guide provides a quick reference for the available commands and options.

> The client is abbreviated as TSS because originally is was the *Thycotic Secret Server* client. Thycotic was one of the companies that became Delinea.

Basic Usage

```
tss [options] [command]
```

Global Options

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--verbose	-v	Output verbose errors

Available Commands

cache

Manage the cache strategy for this instance.

```
tss cache [options]
```

Switch	Abbreviated Switch	Purpose
--age	-a	The cache age defines how long an item can live
--bust	-b	Bust the local cache
--config-directory	-cd	Set the storage directory for the config files
--current	-c	Get the current cache settings

Switch	Abbreviated Switch	Purpose
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--strategy	-s	The cache strategy to use (Never = 0, Server then cache = 1, Cache then server = 2, Cache then server allow fallback on expired cache = 3)
--verbose	-v	Output verbose errors

exit

Exit the Secret Server CLI.

```
tss exit [options]
```

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--verbose	-v	Output verbose errors

init

Initialize this machine to communicate with your Secret Server.

```
tss init [options]
```

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--help	-h, -?	Show help information

Switch	Abbreviated Switch	Purpose
--if-not-exist	-e	Do not generate an error if already initialized
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--onboarding-key	-k	The onboarding key for the rule
--rule-name	-r	The name of the rule that should be matched
--url	-u	The Secret Server URL (https://<name>)
--verbose	-v	Output verbose errors

multi

Get the value of a field from one or more specified secrets.

```
tss multi [options]
```

Switch	Abbreviated Switch	Purpose
--as-dictionary	-ad	Format secret as a dictionary of secret field/value pairs
--config-directory	-cd	Set the storage directory for the config files
--field	-f	The secret field's slug
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--output	-o	The optional output location
--secrets	-s	Comma-separated list of secret IDs (id1,id2,id3,...)
--verbose	-v	Output verbose errors

remove

Remove configuration settings.

```
tss remove [options]
```

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--confirm	-c	Automatically confirm this action without a confirmation prompt
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--verbose	-v	Output verbose errors

secret

Get the value of a field from the specified secret.

```
tss secret [options]
```

Switch	Abbreviated Switch	Purpose
--as-dictionary	-ad	Format secret as a dictionary of secret field/value pairs
--comment	-c	Add a comment
--config-directory	-cd	Set the storage directory for the config files
--field	-f	The secret field's slug
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--output	-o	The optional output location
--secret	-s	The ID of the secret
--verbose	-v	Output verbose errors

status

Display the current connection status of the SDK client.

```
tss status [options]
```

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--verbose	-v	Output verbose errors

token

Retrieve an access token to use in your scripts.

```
tss token [options]
```

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--verbose	-v	Output verbose errors

version

Display the version of the SDK client.

```
tss version [options]
```

Switch	Abbreviated Switch	Purpose
--config-directory	-cd	Set the storage directory for the config files
--full	-f	Display the full diagnostic version of the SDK client
--help	-h, -?	Show help information
--interactive	-i	Enable interactive mode
--key-directory	-kd	Set the storage directory for the config file encryption key
--verbose	-v	Output verbose errors

Syncing with DevOps Secrets Vault

Overview

Secret Server can push its secrets to DevOps Secrets Vault by creating a secret based on the "DevOps Secret Vault Client Credentials" template, which holds the client credentials for a DevOps Secrets Vault tenant. Using the REST API, you can then register a DevOps Secrets Vault tenant in Secret Server. That tenant references that secret to push secrets to DevOps Secrets Vault at a set sync interval.

Behavior Test

You can manually push secrets to the DSV tenant, in addition to Secret Server checking for secrets to push to tenants on a timer. Secret Server will check for if a tenant needs updating every 30 minutes on the cloud or 10 minutes for an on-premises installation. Users are prevented from setting a tenant's sync interval to less than Secret Server's timed iteration because there would be no benefit to doing so. When Secret Server checks for secrets to be pushed to DSV, it only pushes secrets that have been changed since the last time they were updated in DSV. When a secret is pushed to DSV, its sync time is updated.

Fields

All secret fields are copied to DSV except for fields that are marked as "Hide On View." The notes field of a secret maps to the secret description in DSV. Files are Base64 Encoded, then sent to DSV. They are stored as encoded, and need decoding for use.

Setup in Secret Server

To configure pushing secrets to DSV:

1. Create a client in DSV. Save the client ID and secret that are generated when you created it. A DSV client is a container for a password.

> Note that before creating a client, you should create a DSV role - see DSV Role documentation. After that, you should use that role to create a DSV client - see the Client section in DSV documentation. Then, create or edit the specific DSV policy that gives the role access to create DSV secrets on a specified path - see DSV Policies documentation.

2. Create a secret based on the DevOps Secrets Vault Client Credentials template to connect to DSV:
   - Type the name for the new secret in the **Secret Name** text box.
   - Type the DSV client ID in the **Client ID** text box.
   - Type the DSV password for authentication in the **Client Secret** text box. If you do not have one, you can create a new here by clicking the **Generate** button. Then, create or configure a client in DSV using the password.
   - Type the DSV tenant to connect to in the **Tenant** text box. A DSV tenant is your DSV cloud account and the rights to access it. Use the format: `https://<tenantname>.secretsvaultcloud.<region>` with the region being one of the following:
     - U.S. region: `com`
     - E.U. region: `eu`
     - APAC region: `au`
   - Click the **Site** dropdown list to select your Secret Server site.
   - Click the **Create Secret** button.
3. Search for **DevOps Vault**. The DevOps Secrets Vault Tenants page appears.
4. Click **Add New Tenant**. The Add New Tenant popup appears.
5. Type a descriptive name for the tenant in the **Tenant Name** text box. This can be anything you wish.
6. Click the **Client Secret** link to select the secret you created earlier in this instruction.
7. Click the **Sync Interval** list box to select how often you want Secret Server to push secrets to DSV for this tenant.
8. Click the **Save** button.

API Examples

Creating a DevOps Secrets Vault Tenant

Use a POST to `/api/v1/devops-secrets-vault/tenant` using the body below to create a tenant in Secret Server.

```
{
  "Data": {
    "secretId": { "value": 79, "dirty": true },
    "tenantName": { "value": "LJDevTenant", "dirty": true },
    "syncInterval": { "value": 60, "dirty": true },
    "active": { "value": true, "dirty": true }
```

```
    }
  }
```

The secret ID is the client ID for the secret based on the DSV Client Credentials template. The Sync Interval is how often Secret Server checks if secrets needs to be pushed to DSV. Only secrets associated with active tenants are pushed to DSV. You are returned the tenant ID if the POST is successful.

Creating a Sync Map

Use a POST to `/api/v1/devops-secrets-vault/add-sync` using this body to map a secret to a DSV tenant:

```
{
"data": {
  "secretId": {
    "dirty": true,
    "value": 60
  },
  "dsvTenantId": {
    "dirty": true,
    "value": 1
  },
  "active": {
    "dirty": true,
    "value": true
  },
  "fieldNamesPath":{
    "dirty": true,
    "value": [
      "Demo","\$domain","qagreentest"
      ]
    }
  }
}
```

When the secret is mapped to a tenant, an initial sync immediately occurs. Following the initial sync, the secret is checked to determine if updates have been made when the sync Interval expires (making it "dirty") for the mapped tenant. If no changes have been made to the secret, then the secret is not pushed to DSV. You can reference fields from the secret to create the path in DSV. Secret Server will look for a `$`, then search for the following string as the "Field Slug Names" on page 1198 for the secret's template. The path in DSV follows this format: `/secrets/<DSV_secret_name>`.

Manually Syncing a Secret

Use a POST to `/api/v1/devops-secrets-vault/sync` to manually trigger a push to DSV for existing sync maps. The list of integers contains the SyncMapIds of the secret to tenant mapping, so you can control which secret is pushed to which tenant.

```
{
"data": [
  3, 4, 5
  ]
}
```

Listing DevOps Secrets Vault Tenants

List DSV tenants registered to Secret Server by running a GET to `/api/v1/devops-secrets-vault/tenant`. Query parameters accepted:

- `filter.nameSearch=`
- `filter.includeInactive=`

Getting a DevOps Secrets Vault Tenant's Details

View the details of a single tenant by specifying a tenant ID in a GET to `/api/v1/devops-secrets-vault/tenant/{tenantId}`.

Getting the Status of a Secret's Synchronization

View a secret's sync status by running a GET to `/api/v1/devops-secrets-vault/sync/status/{syncMapdId}`.

Getting a List of Secret Synchronization Statuses

View a list of secret sync statuses by running a GET to `/api/v1/devops-secrets-vault/sync/status`. Query parameters accepted:

- `filter.secretId=`
- `filter.includeInactive=`
- `filter.tenantId=`

Secret Server Release Notes

Secret Server release notes provide detailed information about the latest updates, enhancements, and bug fixes for Secret Server. These notes are essential for administrators and users to stay informed about new features, security improvements, and any changes that might affect their usage of the system. Each release note typically includes the release date, version number (for On-Premises versions), a summary of new features, detailed descriptions of enhancements, and a list of resolved issues.

Archived On-Premises versions are those that are no longer supported by Delinea. Archived Cloud versions are those over a year old.

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Secret Server On-Premises Release Notes

These are the release notes for Secret Server On-Premises versions that are still supported by Delinea.

See the Secret Server On-Premises Upgrade Checklist for steps, best practices, tasks, and known issues related to upgrading Secret Server.

Secret Server 11.9.000047 Release Notes

Release Date: On-premises: December 13, 2025

Step Upgrade Required (11.9.6). Versions prior to 11.9.6 need to first upgrade to 11.9.6. The automatic downloads in the product will get the right versions for the step upgrade and then allow upgrades to later versions. But if offline and using the file upload method, versions prior to 11.9.6 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.9.6 and then do the upgrade to 11.9.25 or above.

As of August 31, 2025, Microsoft will retire TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net will require TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.73.0

Protocol Handler: 6.0.3.48

If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Known Issues

Important Technical Change for Secret Server 11.8 and Later

Please carefully review this section prior to upgrading.

Applies to Secret Server On-Premises only.

Overview

Prior to the 11.8 on-premises release, Secret Server On-Premises was delivered in a "dynamically-compiled" state. In this configuration, components of the website, particularly .aspx files, were compiled by IIS upon receiving the

initial request.

Starting with the 11.8 release, the application is pre-compiled, which significantly enhances and accelerates application startup because it eliminates dynamic compilation.

As a result, **some customers may experience startup issues**. Please review the two items below prior to upgrading:

- Pre-compiled applications cannot run in IIS if there is an "App_Code" folder present. Therefore, the version 11.8 upgrade renames this folder automatically on start-up to avoid issues. Please note:
  - In some cases the application pool may not have the permissions to rename the "App_Code" folder, resulting in start-up issues, specifically, the Web page does not load.
  - If the application pool does not have the permissions, you must rename the "App_Code" folder or give the account running the application pool "modify" permissions to the application folder.
  - When finished, perform an iisreset to restart Secret Server.
- If you have manually modified any .aspx files, you will not be able to do so anymore, as those files are compiled already. Do not upgrade until you have verified you do not need the modifications going forward.

Support Articles

Please see the following technical articles for instructions:

- How to prepare for upgrade to Secret Server version 11.8 or higher

New Features

New Remote Password Changers

- Workday: A new password changer to manage credentials for Workday accounts. Workday is an enterprise AI platform.
- Windows (PowerShell): A new, flexible password changer for Windows accounts using PowerShell.

Enhanced Auditing

- Folder Move Auditing: When a Secret is moved, the audit log now records both the previous and new folder names for a clearer audit trail.
- New Auditing Categories: Added auditing for custom dictionaries and new Report Categories.

Bulk Operation Improvements

- Introduced a new "Bulk Operations" on page 195 dashboard for better visibility and management.
- Added auditing for bulk operations to track large-scale changes.

Fixed Issues

ID	Release Notes
427434	Fixed: Incorrect keystroke capture on Italian keyboards. Input capture has been adjusted in protocol handler to account for input language when the host and destination are set to the same input language
608798	Fixed: Front-end and back-end data mismatch. Corrected a varchar type mismatch.
621796	Fixed: Session-connector-recorded sessions using an RDP launcher did not have keystroke data in the file download.
626093	Fixed: Log-level mismatch between Server Nodes page and SS.log file. Changed "All" log level to be "Verbose". Root log level can now be changed in Server Nodes.
629449	Fixed: IBM iSeries RPC character error. Mainframe RCP now supports command <ConditionalTabX> (where X is the command tab size), for example <ConditionalTab10>. This allows for better handling of tabs in scripts.
630794	Fixed: Secret policy error. When global session recording is disabled, validation now prevents updating the secret policy field, which caused an invalid data error.
633276	Fixed: UI error on Secret Access Requests page.
637089	Fixed: Missing audit event. Custom dictionary administration audit added for create and delete.
637092	Fixed: "Report category creation" audit missing.
652076	Fixed: While navigating between the views on the All Secret page, the search box filter would not clear.
654871	Fixed: Ticket system override notifications disappear and reappear.
659707	Fixed: In Platform, the heartbeat status widget would not show heartbeat status. Viewing no longer requires reporting permissions to show the chart.
659765	Fixed: Secret policy launcher setting not appearing on secrets.

ID	Release Notes
660075	Fixed: Secret permissions not showing when exporting the Sharing tab.
660919	Fixed: The saved configuration for a proxied SSH launcher (User Input) appeared empty after save or refresh. "Proxied SSH process" launchers on secret templates with "add mapping" can now save user input to the host field.
662032	Fixed: In the "All Secrets" page, the machine name, and machines columns were not sortable when no records were present.
662056	Fixed: On the security hardening report page, the "force password masking" setting showed even though it no longer exists.
663273	Fixed: When "enable RPC" was disabled on a secret template, secrets based on that template could not be selected for discovery rules.
663978	Fixed: SSH proxy site selection setting was not working for Active Directory secrets.
667266	Fixed: Some fields in HSM configuration were showing up blank.
667821	Fixed: Number of saved reports incorrect on the Reports > Schedule page.
671018	Fixed: Viewing blank passwords incorrectly added an audit entry.
671550	Fixed: Oracle RPC error for SYS account. Added flag indicating that the AS SYS bit on the secret template is in use and passing that into the Oracle credential object.
671705	Fixed: Long keys (SHA512) did not wrap properly in the SSH proxy host fingerprint field.
671707	Fixed: Proxying endpoints UI download dialog is misshaped. Padding added to correct it.
672045	Fixed: The secret and discovery grid did not retain filter state between pages. Fix allows you to filter the grid, go to a secret, click the back button, and retain the applied filters.

ID	Release Notes
673430	Fixed: Unlimited admin mode missing a level-one header. Secret Server configuration title adjusted for accessibility and column added.
673568	Fixed: An issue where the DR replication process would nullify the SecretPolicyId for secrets on a replica if the policy was configured locally on that replica. The replication logic has been corrected to preserve these local policy assignments.
674141	Fixed: Bulk errors returned by the API were not displaying in the active processes dialog.
674212	Fixed: Secret folder permissions issue. The problem occurred when you added users to a folder and set their secret permissions to "None." Before the fix, these users would still appear in the count on the secret's sharing tab. Now, the count only includes users who actually have access to the secrets.
674495	Fixed: Audit results were not displayed when creating a list option in admin categorized List.
674552	Fixed: Session connector launchers could not be viewed/edited by users that did not create the launcher.
675482	Fixed: One time passwords from the home page panel in Platform could throw an error under certain configuration options.
675516	Fixed: Unpinning pinned secrets now did not show in the UI without requiring a refresh.
675833	Fixed: An issue with special characters in search filters. When you typed special characters (like &, %, or #) in a search box, they were not properly encoded in the URL. This applied both when you enter a new search and when you use a saved filter from a URL. Before this fix, special characters could break the filter or cause errors.
676491	Fixed: Business Users could not share secrets when teams were disabled.
677744	Fixed: A playback display issue. A refresh icon was blocking the video during session recording playback. The icon now disappears when you start playing the video, so you can see the full screen without any obstruction.

ID	Release Notes
677808	Fixed: Moving secrets from folders did not indicate target and source folders.
677992	Fixed: Long-running tasks tab was not hidden in cloud. The API only works for on-premises installs.
678002	Fixed: You would see an "Access Denied" error when viewing configuration settings, even if you only lacked access to the certificate secret used in Session Connector settings. Now you can view the configuration without needing access to that specific secret.
678256	Fixed: The system made duplicate network requests when loading the All Secrets view, which slowed down performance. Now it only makes one request, so the page loads faster.
679030	Fixed: Viewing a secret folder did not appear in the Platform recent items list.
679367	Fixed: You received unclear error messages when trying to activate a duplicate secret from the secret home page while duplicates were disabled. Now you will see a clear error message explaining that duplicates are not allowed.
679458	Fixed: You could view a secret that requires a ticket number even when entering an invalid ticket number. This happened with certain ticket system configurations. Now the system properly validates your ticket number before allowing access to the secret.
679624	Fixed: issue in DE 8.4.56.0 that caused Windows SMB heartbeats to fail in certain circumstances.
679646	Fixed: The active tasks panel had several usability issues. You could not toggle between viewing active and completed tasks. The overlay closed too quickly when you moved your mouse away. And error messages weren't easy to spot. Now you can switch between active and completed tasks, the panel stays open longer for easier interaction, and errors are clearly highlighted.

ID	Release Notes
681122	Fixed: You could apply formatting (like bold or italics) to the name when copying a secret. This caused display issues and inconsistencies. Now the system removes any formatting from the secret name during the copy process. The copied secret will have a plain text name only.
682303	Fixed: The Discovery import account dialog displayed text in the wrong language when adding multiple takeover secrets. The "add secret" button and related text were not translated properly. Now all text in the dialog appears in your selected language when you add multiple takeover secrets.
682989	Fixed: A secret with "change password on check in" enabled would automatically check in even when the password change failed after reaching its retry limit. This left the secret in an inconsistent state with the wrong password. Now the secret remains checked out when the password change fails. You can fix the issue and try again without losing track of which secrets need attention.
683754	Fixed: Certain launcher configurations failed to launch when you accessed them from the favorites section on the platform home page. The same launchers worked correctly when accessed from other locations.
683904	Fixed: The PUC failed to match user records correctly for users who had an entry in the tbExternalUserMapping table with IsPlatform set to 0. This caused the system to not recognize their group memberships from the tbUserGroup table. Users affected by this issue may have experienced incorrect permissions or missing access to resources. Now the PUC correctly matches these user records to their group assignments regardless of the IsPlatform setting.
685948	Fixed: Issue with ASRA recordings failing processing when keyboard recording is enabled
686031	Fixed: Performing a bulk "Request Access" operation for multiple secrets that require an approval workflow would fail. The "Duration" field was not loading correctly, preventing users from completing the request. This has been resolved, and bulk requests for secrets with workflows now function as expected.

ID	Release Notes
687294	Fixed: Resolved an issue introduced in a recent update where approvers in a workflow could not view or manage a secret access request unless they also had "View" permission on the secret itself. This prevented users in roles like auditing from completing their approval tasks. This change restores the intended behavior, allowing approvers to process requests without requiring direct permissions on the secret.
687453	Fixed: Localization errors. Localization strings added for extended mappings: WebSphere Privileged Account, Windows Account (PowerShell) takeover, Workday Service Account (11.9.6), and Certificate with Private Key (added in 11.8.9).

Improvements

ID	Release Notes
590528	Improved: Added warning when disabling an ASRA collection.
597072	Improved: Workday RPC integration added.
637212	Improved: Now able to save client-override IP address ranges with the allow list client type after editing.
642214	Improved: New "Windows Account (PowerShell)" secret template.
664028	Improved: In Platform, Secret Server configuration now includes setting descriptions, two column layout as appropriate, and some settings are now hidden (they are controlled by other Platform settings). These include UI inactivity timeout and custom logos.
665213	Improved: Efficiency of database calls for RPC selection.
665401	Improved: Converted AdminChallengeView.aspx to an Angular page. The new page can be accessed as a tab on the PBA configuration page.
665567	Improved: Added the ability to stop any in-progress bulk operation. Added Bulk Operations Dashboard page to view current and past bulk operations. Replaced the modal bulk progress dialog with non-modal toast-like bulk ops component.
666003	Improved: Added Bulk Operations dashboard page. See features.

ID	Release Notes
668309	Improved: When a data sync occurs in the Platform Upgrade Center (PUC), a message appears in the data sync section of the PUC showing the count of the successes and errors of the last sync along with a link to View the Log.
668334	Improved: When a user is going through an upgrade in the Platform Upgrade Center, if SS has logos and logos do not exist in Platform, the logos are automatically copied to Platform, and the step is completed.
668335	Improved: Automated the secure access step in the Platform Upgrade Center.
670297	Improved: Added a throttle: "Max Number of Passwords That Can be Changed at One Time" setting for Entra ID RPC.
674228	Improved: Added Delinea desktop widget for folders, showing a context-aware secret grid.
675940	Improved: Updated precheck messages for Active Directory groups. When you set up AD Groups in the PUC, you now see clearer messages about the group type. The system was showing these warnings too often before. Now the messages only appear when they're actually needed based on your environment's settings.
675983	Improved: AjaxControlToolkit dependencies were removed.
678116	Improved: Added a slider in the bulk operations, which allows selection of how many records you wish to download.
678532	Improved: Added safeguards for external vaults to require linked secret transforms in order to push the values.
679328	Improved: Folder pinning does not evaluate folder access. Changed to improve security when using pinned folders.
679363	Improved: Removed the legacy secret import pages (import.aspx, advancedimport.aspx).
679524	Improved: Added the ability to map individual Secret Serverand Platform users.
679677	Improved: The "Send legacy emails" setting has been removed. All secret access request emails and event subscription emails now go through your inbox. The system no longer supports the old email format.

ID	Release Notes
680903	Improved: The customized branding step in the PUC now runs automatically in the background before the secure access step begins. When you start the secure access step, you will see a single progress bar that tracks both processes. This streamlines the setup process so you do not need to manually run the branding step separately.
680904	Improved: Removed unhelpful prechecks, and added completion indicator messaging.
681158	Improved: Several API endpoints and one internal advanced configuration audit page were missing proper permission checks. Users could potentially access data they should not see. Now the system verifies your permissions before allowing access to these endpoints and the audit page.
682292	Improved: Platform users can now apply "Administer Bulk Operations" when in unified mode.
682425	Improved: Modified logic in DataProviderEncryptionHandler.Transform so that key is not generated and saved when decrypting a default configuration with no prior system key.
682948	Improved: Moving folder note is now very specific for audit notes
682952	Improved: The IBM i-series heartbeat and password changer now support the feature. This gives you more flexibility when configuring how the system interacts with IBM i-series screens during automated password changes and connection tests.
683576	Improved: You can now enable a decal pattern for charts in your user profile. This feature adds visual patterns to chart elements This is a preview feature, so not all charts support decal patterns yet.
684304	Improved: Secret RPC no longer happens every 10 minutes in some configurations, restoring the original behavior.

Secret Server 11.9.000025 Release Notes

Release Date: On-premises: October 9, 2025

The Secret Server 11.9.000025 release is nearly identical to the withdrawn 11.9.000024. There are two additional fixes at the end of the table. One of those, 679118, is the issue that caused us to withdraw the previous version. For convenience, all of the previous fixes and enhancements were copied to here.

Step Upgrade Required (11.9.6). Versions prior to 11.9.6 need to first upgrade to 11.9.6. The automatic downloads in the product will get the right versions for the step upgrade and then allow upgrades to later versions. But if offline and using the file upload method, versions prior to 11.9.6 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.9.6 and then do the upgrade to 11.9.25 or above.

As of August 31, 2025, Microsoft will retire TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net will require TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

11.9.000024 Patch

This patch restores upgrade functionality. You will still need to perform the upgrade to 11.9.25 after applying the patch.

If you cannot upgrade from 11.9.000024 to 11.9.000025 or later, it is likely you are affected by the bug that caused the withdrawal of 11.9.000024. To apply the patch:

1. Stop Secret Server:
   a. Stop the distributed engine service or services.
   b. Stop Secret Server web node application pool or pools.
   c. If applicable, stop RabbitMQ through the `rabbitmqctl stop_app` command:
      i. Open Command Prompt as an admin.

         Change directories to `C:\Program Files\RabbitMQ Server\rabbitmq_server*\sbin`
      ii. Run `rabbitmqctl stop_app` command in the command prompt window.
2. Download the patched DLL and replace the original in the `bin` subdirectory of the IIS application directory, for example:

   `C:\inetpub\wwwroot\SecretServer\bin\Thycotic.ihawu.Business.dll`.

   The download hashes are:
   - Calculated on 2025-10-10 17:30:43Z
   - SHA1(11.9.24_UpgradePatch.zip)= 29adba35fe30b6cd8439459e2b840685a209b6c7
   - SHA256(11.9.24_UpgradePatch.zip)= e1413474aac98e0108ddcf83f02316540a236b508adfb1c46c278c64b3d6979b
3. Restart Secret Server:

a. If applicable, start RabbitMQ through the rabbitmqctl start_app command. This is the same process as above except the command would be `rabbitmqctl start_app`.

b. Start the Secret Server web node application pool or pools.

c. Start the distributed engine service or services.

4. Upgrade to 11.9.000025 or later.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.64.0

Protocol Handler: 6.0.3.42

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Known Issues

When viewing Session Recordings in Secret Server 11.9.000025, there is a known UI issue that shows an overlay over the video until clicked. This will not occur on the first session viewed but will on subsequent session recordings viewed within the end user's application session. This looks like sessions are not loading, but clicking on the video player will remove the overlay and allow viewing as usual.

Important Technical Change for Secret Server 11.8 and Later

> Please carefully review this section prior to upgrading.

> Applies to Secret Server On-Premises only.

Overview

Prior to the 11.8 on-premises release, Secret Server On-Premises was delivered in a "dynamically-compiled" state. In this configuration, components of the website, particularly .aspx files, were compiled by IIS upon receiving the initial request.

Starting with the 11.8 release, the application is pre-compiled, which significantly enhances and accelerates application startup because it eliminates dynamic compilation.

As a result, **some customers may experience startup issues**. Please review the two items below prior to upgrading:

- Pre-compiled applications cannot run in IIS if there is an "App_Code" folder present. Therefore, the version 11.8 upgrade renames this folder automatically on start-up to avoid issues. Please note:
  - In some cases the application pool may not have the permissions to rename the "App_Code" folder, resulting in start-up issues, specifically, the Web page does not load.

  - If the application pool does not have the permissions, you must rename the "App_Code" folder or give the account running the application pool "modify" permissions to the application folder.
  - When finished, perform an iisreset to restart Secret Server.
- If you have manually modified any .aspx files, you will not be able to do so anymore, as those files are compiled already. Do not upgrade until you have verified you do not need the modifications going forward.

Support Articles

Please see the following technical articles for instructions:

- How to prepare for upgrade to Secret Server version 11.8 or higher

New Features

Role Permission for API Key Generation

We added a new role permission called "Generate API token from user interface." This role permission grants access to the interface for generating API tokens within the user's profile area. It has been granted to all roles as it was previously a feature available to all users.

Unlimited Administrator Renamed to Unlimited Vault Access

To better represent the functionality that Unlimited Administrator provides, it has been renamed to Unlimited Vault access. The Unlimited Administrator and Enable Unlimited Administrator role permissions, Unlimited Administrator Configuration page, and page header notification have all been updated to use the new terminology.

Proxy Bypass for Privileged Remote Access

Privileged Remote Access is a feature available in the Delinea Platform and provides much of the same functionality as the SSH and RDP proxies. In most scenarios, both are not required to be used concurrently. There is now a secret setting on the security tab which dictates whether or not a PRA launch (Open with Remote Access) uses SSH/RDP.

Customer-Managed Encryption Keys

With Customer-Managed Encryption Keys (CMEK), you can now own and manage your encryption keys, ensuring exclusive control and compliance with industry standards. CMEK enables cloud adoption for customers with strict compliance needs. CMEK uses the Azure Managed HSM service.

Key Benefits

- Exclusive Control: Maintain exclusive control over the encryption and decryption of your sensitive cloud data. Even in the unlikely event of a compromise or legal action against Delinea, your data remains secure and accessible only to you.
- Seamless Integration: Our solution integrates seamlessly with Azure Managed HSM, Amazon EKS, and Fortanix, allowing you to use your own managed key stores for all encryption operations.

- Compliance Assurance: Meet strict security and compliance requirements with ease. This feature is designed to support regulatory frameworks such as GDPR and HIPAA, making it ideal for security-conscious enterprises.
- Centralized Key Management: Security architects and cloud administrators can centralize and control key management, ensuring that all encryption/decryption operations use customer-owned keys. Audit logs provide transparency and traceability of key access and usage.

> This feature does not cover on-premises key management or key management solutions outside Azure, Amazon, or Fortanix.

Improvements

ID	Release Notes
590845	Improved: Added a new option in data retention to only remove data directly related to secret sessions.
635436	Improved: Clarified error message around Service Now credential secrets so users will know they need a secret with a username and password or the appropriate extended mapping.
638054	Improved: The permissions report now filters inactive users.
642215	Improved: Added support for WebSphere Integration password changer.
643148	Improved: Video segments can now be appended to an already processed session recording when they arrive later because the session was resumed.
643365	Improved: Import Secrets page enhancements: Localized all error messages. Errors are summarized in the header with counts for each type of error, for instance "Duplicate secret name (42)". Added an Errors column that displays all the errors for each row. The grid is sortable by error or secret name.
644180	Improved: Increased performance of teams-related queries.
649041	Improved: All secret pickers have been updated to use the latest design.
650468	Improved: Updated grids to allow for full-screen mode while in modals and large panels.
652544	Improved: Added login auditing to authentication.
652955	Improved: Grid component now supports grouping and has updated header cells with options.

ID	Release Notes
653785	Improved: Added new folder search tab for selecting folders in the "Move to Folder" bulk operation. This enables users to choose subfolders where they don't have access to the parent folder.
654386	Improved: Default discovery report name changed to clearly describe the report results.
655154	Improved: Simplified the on-premises database upgrade message and added a link to the Delinea docs "Upgrading Secret Server" section.
663529	Improved: Deep linking when Privilege Manager is installed now skips the application picker.
663690	Improved: Updated to angular 20.1.6.
663852	Improved: Application/service accounts no longer require email address to be migrated.
663988	Improved: Cloud maintenance pages styling updated.
664296	Improved: Updated AVBlocks library to support TLS/HTTPS.
664626	Improved: Updated NuGet packages and dependencies.
664727	Improved: User principal name added to the user detail page.
664835	Improved: Added new secret templates for Open API Key, IBM Watson API Key, and Hugging Face API Token.
664852	Improved: Added a new secret template for Google Vertex AI Service Account.
664860	Improved: Added the Azure AI Compute Credentials secret template.
664866	Improved: Added the AWS SageMaker Access template.
664872	Improved: Added the "AI Compute Node SSH Key" secret template.
664873	Improved: Added new AI Endpoint Certificates secret template.
665041	Improved: Unlimited Administrator feature renamed to Unlimited Vault Access.
665400	Improved: Dual control has been converted to use the new UI interface and the previous ASPX interface has been removed.

ID	Release Notes
666012	Improved: Added ticket details including: Reason for ticket override approve or deny in secret audit Inbox ticket override approval with approve/deny reason Inbox ticket override approval with approver/denier details
666061	Improved: V1 for GroupMembership Patch has new filter to allow for updating inactive users. V1 return IDs are not processed as they will not be found. Partial patch will succeed but unfound IDs will be returned.
666244	Improved: Grid component header style updates.
666477	Improved: Domain was added to the group and user selection modals for the PIC.
666562	Improved: Added preview panel to discovery computer scan log.
666718	Improved: Add display name and descending sort.
666752	Improved: Updated Oracle MDAC version to 23.9 for Oracle dependency scripts, heartbeats and password changers.
666947	Improved: V1 Patch Group/Users now has options to add more debugging in response. V1 now also has options to take inactive/active users. Will do partial success, but indicate in body if there are failed users that have not processed in the PATCH.
667026	Improved: Added PRA bypass security option on Secrets. When checked, if proxy is enabled and a secret is launched via remote access, proxy is bypassed.
667054	Improved: If defined, Session Connector launchers are now displayed in secrets.
667498	Improved: Updates for smaller screens where search opens in a modal.
667628	Improved: Salesforce heartbeat and RPC now use v.64 API.
668328	Improved: Update Platform Integration Center to be named Platform Upgrade Center along with various other wording changes within the Platform Upgrade Center.
669355	Improved: Updated chips across Secret Server to use updated colors and move towards "success" for most cases where state is some form of success.

ID	Release Notes
669471	Improved: Updated wizards to display their steps in tab-like styles, and updated wizards in dialogs to more closely match wizards in full pages.
669571	Improved: Removed link to secret legacy import and redirected old secret import pages to updated import pages.
671235	Improved: Thycotic.Video now uses TLS/HTTPS for the default license validation.
671843	Improved: Okta heartbeat now supports Global MFA under Global Security Policy.

Fixed Issues

ID	Release Notes
466453	Fixed: DE prematurely closes proxied sessions which use session recording. For those using the Distributed Engine app.config to modify DataDeliveryToleranceSeconds for SSH Proxy sessions, that setting is now contained in the ConfigurationAdvanced.aspx page and can be set there. When set there, re-configuring the app.config every upgrade of the Distributed Engine will no longer be necessary. This is supported with Distributed Engine versions newer than 8.4.59.0
555124	Fixed: Platform displayed "DoubleLock" instead of "QuantumLock" on the "Delinea Command Relay" page secret selection area. In Platform > Sites and Engines > Any Site > Settings >Delinea Command Relay > Select secret with Quantum Lock enabled. String resource has been changed from DoubleLock to Quantumlock where appropriate.
562738	Fixed: Discovery manual host range limit. Changed to populate network discovery list with large batch sizes.
580687	Fixed: Site options "Enable CredSSP Authentication" and "WinRm Endpoint" now sync properly with database when auto filled.
581201	Fixed: Inapplicable, On-Prem-related links and text on the Session Recording page have been removed from Secret Server Cloud and Platform.
584688	Fixed: Teradata heartbeat and remote password changing now work.
596685	Fixed: Internet connectivity not on the new diagnostics page. On premises "Check connectivity" button added to diagnostics page.

ID	Release Notes
622351	Fixed: The number of secrets for policy application appeared as a negative number.
630945	Fixed: Secret Server Cloud stats for session monitoring storage were not pulling from database tables.
632826	Fixed: Report subscribers did not display all the users and groups from user management.
633090	Fixed: An issue with audit message for changing the checkout time of a secret not displaying correctly.
633790	Fixed: Distributed engine would fail changing a local account password on the same server it is hosted on, but a different distributed engine would succeed.
633915	Fixed: The error "KeyNotFoundException" appeared on an API call for an individual secret summary when using the parameter autoCheckout as false had been resolved.
634054	Fixed: Password field validation logic prevented assignment of privileged accounts to policies when password fields aren't mapped.
637889	Fixed: The All Secrets Heartbeat column sometimes disappeared on initial load.
638065	Fixed: When switching between the general and matches tab, the template fields did not maintain their values properly.
640532	Fixed: SessionConnector/RDS Launchers (RDP child launcher) keystrokes were not reliably recorded when keystroke recording was enabled.
641379	Fixed: Email notification inbox template mapped incorrect URL for ItemName.Folder. Email templates now honor folder link interpolation.
642172	Fixed: SSC group search only searches the 1st page of results. When searching for members in a Secret Server group, the search now looks at both the username and the display name fields, where before it only was searching against the display name.
643365	Import Secrets page enhancements: Localized all error messages. Errors are summarized in the header with counts for each type of error, i.e. "Duplicate secret name (42)". Added an Errors column that displays all the errors for each row. The grid is sortable by error or secret name.

ID	Release Notes
643500	Fixed: Secret policies were automatically applied to secrets within folders generated through the import process.
643683	Fixed: Secret name was not displayed in response sample in the secret dependencies endpoint.
643816	Fixed: When a script was run with "test script," the UI would not inform the user of completion.
644133	Fixed: Precompiled application exceptions were thrown on startup. Created startup task to rename App_Code directory if it exists.
645792	Fixed: Adding more than 35 users in "managed by specific users" provided no information.
648671	Fixed: Distributed Engine offline status was not adhering to the "Engine Callback Interval." The engine callback interval for an engine's site now takes precedence over the global callback interval when determining the engine's offline status.
651392	Fixed: In the discovery account import dialog wizard final step, clicking import would not show any API errors without closing the dialog. Now, to complete the wizard the errors either need to be resolved and resubmitted or the user can click cancel.
654232	Fixed: Secret list views did not sort in the correct order when navigating to the view.
654867	Fixed: Inbox notifications created column is now a date and not a date time since format.
654872	Fixed: Ticket override requests are no longer sent to the requestor when they are an approver in multiple groups.
655760	Fixed: Override requestor received approval and denial reason on email.
659868	Fixed: Target will no longer appear on Platform audits if the audit does not have a secret ID.
660026	Fixed: When a ticket override request that had been approved was later denied, the secret comment needed to be entered again, if required, upon the next secret request from the user.

ID	Release Notes
660064	Fixed: An issue on the password changers list, where the Active Secret Count column was not populated.
660127	Fixed: The favorite button in the secret grid no longer has a true/false tooltip.
660328	Fixed issue where Reset Password button was showing twice.
660439	Fixed: ProductName variable would show up instead of actual name.
660724	Fixed: Broken Entrust HTTP POST SAML. Adjusted referrer policy to strict-origin-when-cross-origin for better compatibility and standards consistency.
663706	Fixed: No global search results or direct menu option for session connector settings in DP, SSC settings, or configuration search. Added navigation links to session connector settings page.
663979	Fixed: Security fixes for manual rolling upgrade process.
664523	Fixed: Ticket override section hidden on new ticket creation. To update these settings, edit the ticket system after it is created.
664540	Fixed: Ticket override option not displaying for secret access request. Ticket override flow is now triggered in secret access requests as well as request comments.
665388	Fixed: Removed legacy AdminDiagnostics.aspx and AdminClustering.aspx pages.
665454	Fixed: Editing template permissions with search filters applied no longer removes users that did not match the previously applied search results.
665997	Fixed: Day logs were not displayed if you selected the last 5 days option.
666228	Fixed an issue where grid item totals could get stuck infinitely loading.
666577	Fixed: Ticket override disable-ticket system did not deny pending. If a ticket system with pending ticket overrides is disabled or the override option removed, all pending ticket override requests will be denied.

ID	Release Notes
666829	Fixed: Redirected from Secret Server PIC when already opted in. When you have previously opted-in to Platform without going through the PIC and visit the PIC in Secret Server, a new Launch platform button has been added to the Opt-in step card.
667282	Fixed: HSM Audit log popup was misaligned,
667601	Fixed: Breadcrumb was missing on some item-details pages.
668379	Fixed: The import export settings in the configuration search now show up when launchers are disabled.
668731	Fixed: Updated tooltips for user membership types to accurately reflect license usage.
668853	Fixed: Federation step in the PIC got into an incorrect state when the Federation step is In Progress but has no SS providers.
669165	Fixed: Discovery import account dialog is now localized.
669194	Fixed: Passwords containing semicolon (;) broke regular expression logic.
669220	Fixed: Loading favorites threw an error in some scenarios.
670350	Fixed: Wrong chip background color when progressing through PIC steps.
670351	Fixed: Test button was showing instead of delete button on dependencies that do not have test buttons.
670694	Fixed: Manually changing root personal folder permissions via Unlimited Admin could throw error.
670898	Fixed: In secret import an incorrect button would appear while trying to import from XML.
671312	Fixed: Some downloaded records were inconsistent.
671357	Fixed: Removed unused legacy UI components.

ID	Release Notes
679118	Fixed: A critical issue where upgrading from Secret Server 11.9.24 to subsequent versions would fail when session recording video processing files (AVBlocks DLL) were locked. The upgrade mechanism now properly handles locked DLL files, ensuring successful upgrades even when session recording is active with on-demand video processing disabled.
679458	Fixed: An invalid ticket number could be ignored on a secret that requires view comment on some ticket-system configurations.

Secret Server 11.9.000024 Release Notes

> The Secret Server 11.9.000024 release has been withdrawn due to an issue that prevents automatic updates to subsequent versions. We will provide more information as we investigate this issue.

Release Date: On-premises: September 24, 2025

> As of August 31, 2025, Microsoft will retire TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net will require TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.64.0

Protocol Handler: 6.0.3.42

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Known Issues

When viewing Session Recordings in Secret Server 11.9.000024, there is a known UI issue that shows an overlay over the video until clicked. This will not occur on the first session viewed but will on subsequent session recordings viewed within the end user's application session. This looks like sessions are not loading, but clicking on the video player will remove the overlay and allow viewing as usual.

Important Technical Change for Secret Server 11.8 and Later

> Please carefully review this section prior to upgrading.

Applies to Secret Server On-Premises only.

Overview

Prior to the 11.8 on-premises release, Secret Server On-Premises was delivered in a "dynamically-compiled" state. In this configuration, components of the website, particularly .aspx files, were compiled by IIS upon receiving the initial request.

Starting with the 11.8 release, the application is pre-compiled, which significantly enhances and accelerates application startup because it eliminates dynamic compilation.

As a result, **some customers may experience startup issues**. Please review the two items below prior to upgrading:

- Pre-compiled applications cannot run in IIS if there is an "App_Code" folder present. Therefore, the version 11.8 upgrade renames this folder automatically on start-up to avoid issues. Please note:
  - In some cases the application pool may not have the permissions to rename the "App_Code" folder, resulting in start-up issues, specifically, the Web page does not load.
  - If the application pool does not have the permissions, you must rename the "App_Code" folder or give the account running the application pool "modify" permissions to the application folder.
  - When finished, perform an iisreset to restart Secret Server.
- If you have manually modified any .aspx files, you will not be able to do so anymore, as those files are compiled already. Do not upgrade until you have verified you do not need the modifications going forward.

Support Articles

Please see the following technical articles for instructions:

- How to prepare for upgrade to Secret Server version 11.8 or higher

New Features

Role Permission for API Key Generation

We added a new role permission called "Generate API token from user interface." This role permission grants access to the interface for generating API tokens within the user's profile area. It has been granted to all roles as it was previously a feature available to all users.

Unlimited Administrator Renamed to Unlimited Vault Access

To better represent the functionality that Unlimited Administrator provides, it has been renamed to Unlimited Vault access. The Unlimited Administrator and Enable Unlimited Administrator role permissions, Unlimited Administrator Configuration page, and page header notification have all been updated to use the new terminology.

Proxy Bypass for Privileged Remote Access

Privileged Remote Access is a feature available in the Delinea Platform and provides much of the same functionality as the SSH and RDP proxies. In most scenarios, both are not required to be used concurrently. There

is now a secret setting on the security tab which dictates whether or not a PRA launch (Open with Remote Access) uses SSH/RDP.

Improvements

ID	Release Notes
590845	Improved: Added a new option in data retention to only remove data directly related to secret sessions.
635436	Improved: Clarified error message around Service Now credential secrets so users will know they need a secret with a username and password or the appropriate extended mapping.
638054	Improved: The permissions report now filters inactive users.
642215	Improved: Added support for WebSphere Integration password changer.
643148	Improved: Video segments can now be appended to an already processed session recording when they arrive later because the session was resumed.
643365	Improved: Import Secrets page enhancements: Localized all error messages. Errors are summarized in the header with counts for each type of error, for instance "Duplicate secret name (42)". Added an Errors column that displays all the errors for each row. The grid is sortable by error or secret name.
644180	Improved: Increased performance of teams-related queries.
649041	Improved: All secret pickers have been updated to use the latest design.
650468	Improved: Updated grids to allow for full-screen mode while in modals and large panels.
652544	Improved: Added login auditing to authentication.
652955	Improved: Grid component now supports grouping and has updated header cells with options.
653785	Improved: Added new folder search tab for selecting folders in the "Move to Folder" bulk operation. This enables users to choose subfolders where they don't have access to the parent folder.
654386	Improved: Default discovery report name changed to clearly describe the report results.

ID	Release Notes
655154	Improved: Simplified the on-premises database upgrade message and added a link to the Delinea docs "Upgrading Secret Server" section.
663529	Improved: Deep linking when Privilege Manager is installed now skips the application picker.
663690	Improved: Updated to angular 20.1.6.
663852	Improved: Application/service accounts no longer require email address to be migrated.
663988	Improved: Cloud maintenance pages styling updated.
664296	Improved: Updated AVBlocks library to support TLS/HTTPS.
664626	Improved: Updated NuGet packages and dependencies.
664727	Improved: User principal name added to the user detail page.
664835	Improved: Added new secret templates for Open API Key, IBM Watson API Key, and Hugging Face API Token.
664852	Improved: Added a new secret template for Google Vertex AI Service Account.
664860	Improved: Added the Azure AI Compute Credentials secret template.
664866	Improved: Added the AWS SageMaker Access template.
664872	Improved: Added the "AI Compute Node SSH Key" secret template.
664873	Improved: Added new AI Endpoint Certificates secret template.
665041	Improved: Unlimited Administrator feature renamed to Unlimited Vault Access.
665400	Improved: Dual control has been converted to use the new UI interface and the previous ASPX interface has been removed.
666012	Improved: Added ticket details including: Reason for ticket override approve or deny in secret audit Inbox ticket override approval with approve/deny reason Inbox ticket override approval with approver/denier details

ID	Release Notes
666061	Improved: V1 for GroupMembership Patch has new filter to allow for updating inactive users. V1 return IDs are not processed as they will not be found. Partial patch will succeed but unfound IDs will be returned.
666244	Improved: Grid component header style updates.
666477	Improved: Domain was added to the group and user selection modals for the PIC.
666562	Improved: Added preview panel to discovery computer scan log.
666718	Improved: Add display name and descending sort.
666752	Improved: Updated Oracle MDAC version to 23.9 for Oracle dependency scripts, heartbeats and password changers.
666947	Improved: V1 Patch Group/Users now has options to add more debugging in response. V1 now also has options to take inactive/active users. Will do partial success, but indicate in body if there are failed users that have not processed in the PATCH.
667026	Improved: Added PRA bypass security option on Secrets. When checked, if proxy is enabled and a secret is launched via remote access, proxy is bypassed.
667054	Improved: If defined, Session Connector launchers are now displayed in secrets.
667498	Improved: Updates for smaller screens where search opens in a modal.
667628	Improved: Salesforce heartbeat and RPC now use v.64 API.
668328	Improved: Update Platform Integration Center to be named Platform Upgrade Center along with various other wording changes within the Platform Upgrade Center.
669355	Improved: Updated chips across Secret Server to use updated colors and move towards "success" for most cases where state is some form of success.
669471	Improved: Updated wizards to display their steps in tab-like styles, and updated wizards in dialogs to more closely match wizards in full pages.

ID	Release Notes
669571	Improved: Removed link to secret legacy import and redirected old secret import pages to updated import pages.
671235	Improved: Thycotic.Video now uses TLS/HTTPS for the default license validation.
671843	Improved: Okta heartbeat now supports Global MFA under Global Security Policy.

Fixed Issues

ID	Release Notes
466453	Fixed: DE prematurely closes proxied sessions which use session recording. For those using the Distributed Engine app.config to modify DataDeliveryToleranceSeconds for SSH Proxy sessions, that setting is now contained in the ConfigurationAdvanced.aspx page and can be set there. When set there, re-configuring the app.config every upgrade of the Distributed Engine will no longer be necessary. This is supported with Distributed Engine versions newer than 8.4.59.0
555124	Fixed: Platform displayed "DoubleLock" instead of "QuantumLock" on the "Delinea Command Relay" page secret selection area. In Platform > Sites and Engines > Any Site > Settings >Delinea Command Relay > Select secret with Quantum Lock enabled. String resource has been changed from DoubleLock to Quantumlock where appropriate.
562738	Fixed: Discovery manual host range limit. Changed to populate network discovery list with large batch sizes.
580687	Fixed: Site options "Enable CredSSP Authentication" and "WinRm Endpoint" now sync properly with database when auto filled.
581201	Fixed: Inapplicable, On-Prem-related links and text on the Session Recording page have been removed from Secret Server Cloud and Platform.
584688	Fixed: Teradata heartbeat and remote password changing now work.
596685	Fixed: Internet connectivity not on the new diagnostics page. On premises "Check connectivity" button added to diagnostics page.
622351	Fixed: The number of secrets for policy application appeared as a negative number.

ID	Release Notes
630945	Fixed: Secret Server Cloud stats for session monitoring storage were not pulling from database tables.
632826	Fixed: Report subscribers did not display all the users and groups from user management.
633090	Fixed: An issue with audit message for changing the checkout time of a secret not displaying correctly.
633790	Fixed: Distributed engine would fail changing a local account password on the same server it is hosted on, but a different distributed engine would succeed.
633915	Fixed: The error "KeyNotFoundException" appeared on an API call for an individual secret summary when using the parameter autoCheckout as false had been resolved.
634054	Fixed: Password field validation logic prevented assignment of privileged accounts to policies when password fields aren't mapped.
637889	Fixed: The All Secrets Heartbeat column sometimes disappeared on initial load.
638065	Fixed: When switching between the general and matches tab, the template fields did not maintain their values properly.
640532	Fixed: SessionConnector/RDS Launchers (RDP child launcher) keystrokes were not reliably recorded when keystroke recording was enabled.
641379	Fixed: Email notification inbox template mapped incorrect URL for ItemName.Folder. Email templates now honor folder link interpolation.
642172	Fixed: SSC group search only searches the 1st page of results. When searching for members in a Secret Server group, the search now looks at both the username and the display name fields, where before it only was searching against the display name.
643365	Import Secrets page enhancements: Localized all error messages. Errors are summarized in the header with counts for each type of error, i.e. "Duplicate secret name (42)". Added an Errors column that displays all the errors for each row. The grid is sortable by error or secret name.
643500	Fixed: Secret policies were automatically applied to secrets within folders generated through the import process.

ID	Release Notes
643683	Fixed: Secret name was not displayed in response sample in the secret dependencies endpoint.
643816	Fixed: When a script was run with "test script," the UI would not inform the user of completion.
644133	Fixed: Precompiled application exceptions were thrown on startup. Created startup task to rename App_Code directory if it exists.
645792	Fixed: Adding more than 35 users in "managed by specific users" provided no information.
648671	Fixed: Distributed Engine offline status was not adhering to the "Engine Callback Interval." The engine callback interval for an engine's site now takes precedence over the global callback interval when determining the engine's offline status.
651392	Fixed: In the discovery account import dialog wizard final step, clicking import would not show any API errors without closing the dialog. Now, to complete the wizard the errors either need to be resolved and resubmitted or the user can click cancel.
654232	Fixed: Secret list views did not sort in the correct order when navigating to the view.
654867	Fixed: Inbox notifications created column is now a date and not a date time since format.
654872	Fixed: Ticket override requests are no longer sent to the requestor when they are an approver in multiple groups.
655760	Fixed: Override requestor received approval and denial reason on email.
659868	Fixed: Target will no longer appear on Platform audits if the audit does not have a secret ID.
660026	Fixed: When a ticket override request that had been approved was later denied, the secret comment needed to be entered again, if required, upon the next secret request from the user.
660064	Fixed: An issue on the password changers list, where the Active Secret Count column was not populated.

ID	Release Notes
660127	Fixed: The favorite button in the secret grid no longer has a true/false tooltip.
660328	Fixed issue where Reset Password button was showing twice.
660439	Fixed: ProductName variable would show up instead of actual name.
660724	Fixed: Broken Entrust HTTP POST SAML. Adjusted referrer policy to strict-origin-when-cross-origin for better compatibility and standards consistency.
663706	Fixed: No global search results or direct menu option for session connector settings in DP, SSC settings, or configuration search. Added navigation links to session connector settings page.
663979	Fixed: Security fixes for manual rolling upgrade process.
664523	Fixed: Ticket override section hidden on new ticket creation. To update these settings, edit the ticket system after it is created.
664540	Fixed: Ticket override option not displaying for secret access request. Ticket override flow is now triggered in secret access requests as well as request comments.
665388	Fixed: Removed legacy AdminDiagnostics.aspx and AdminClustering.aspx pages.
665454	Fixed: Editing template permissions with search filters applied no longer removes users that did not match the previously applied search results.
665997	Fixed: Day logs were not displayed if you selected the last 5 days option.
666228	Fixed an issue where grid item totals could get stuck infinitely loading.
666577	Fixed: Ticket override disable-ticket system did not deny pending. If a ticket system with pending ticket overrides is disabled or the override option removed, all pending ticket override requests will be denied.
666829	Fixed: Redirected from Secret Server PIC when already opted in. When you have previously opted-in to Platform without going through the PIC and visit the PIC in Secret Server, a new Launch platform button has been added to the Opt-in step card.

ID	Release Notes
667282	Fixed: HSM Audit log popup was misaligned,
667601	Fixed: Breadcrumb was missing on some item-details pages.
668379	Fixed: The import export settings in the configuration search now show up when launchers are disabled.
668731	Fixed: Updated tooltips for user membership types to accurately reflect license usage.
668853	Fixed: Federation step in the PIC got into an incorrect state when the Federation step is In Progress but has no SS providers.
669165	Fixed: Discovery import account dialog is now localized.
669194	Fixed: Passwords containing semicolon (;) broke regular expression logic.
669220	Fixed: Loading favorites threw an error in some scenarios.
670350	Fixed: Wrong chip background color when progressing through PIC steps.
670351	Fixed: Test button was showing instead of delete button on dependencies that do not have test buttons.
670694	Fixed: Manually changing root personal folder permissions via Unlimited Admin could throw error.
670898	Fixed: In secret import an incorrect button would appear while trying to import from XML.
671312	Fixed: Some downloaded records were inconsistent.
671357	Fixed: Removed unused legacy UI components.

Secret Server 11.9.000006 Release Notes

Release Date: On-premises: August 4, 2025

As of August 31, 2025, Microsoft will retire TLS 1.0 protocol support for Azure Application Gateways. Thus, updates.thycotic.net will require TLS 1.2 for all connections. Secret Server On-Premises instances released prior to 2018 may not support TLS 1.2 and will no longer receive update notifications after this change. All other product functionality will remain unaffected. Customers running older versions should upgrade to a supported version to continue receiving update notifications.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.59.0

Protocol Handler: 6.0.3.39

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Important Technical Change for Secret Server 11.8 and Later

> Please carefully review this section prior to upgrading.

> Applies to Secret Server On-Premises only.

Overview

Prior to the 11.8 on-premises release, Secret Server On-Premises was delivered in a "dynamically-compiled" state. In this configuration, components of the website, particularly .aspx files, were compiled by IIS upon receiving the initial request.

Starting with the 11.8 release, the application is pre-compiled, which significantly enhances and accelerates application startup because it eliminates dynamic compilation.

As a result, **some customers may experience startup issues**. Please review the two items below prior to upgrading:

- Pre-compiled applications cannot run in IIS if there is an "App_Code" folder present. Therefore, the version 11.8 upgrade renames this folder automatically on start-up to avoid issues. Please note:
  - Rename this folder after the upgrade.
  - In some cases the application pool may not have the permissions to rename the "App_Code" folder, resulting in start-up issues, specifically, the Web page does not load.
  - If the application pool does not have the permissions, you must rename the "App_Code" folder or give the account running the application pool "modify" permissions to the application folder.
  - When finished, perform an iisreset to restart Secret Server.
- If you have manually modified any .aspx files, you will not be able to do so anymore, as those files are compiled already. Do not upgrade until you have verified you do not need the modifications going forward.

Support Articles

Please see the following technical articles for instructions:

- How to prepare for upgrade to Secret Server version 11.8 or higher

New Features

Multi-Cloud Security and Integration

- **AWS Secrets Manager Integration** extends our distributed vaulting initiative beyond Azure, providing seamless integration with Amazon's AWS Secrets Manager. Administrators can centrally vault, manage, update, and rotate credentials in AWS Secrets Manager, further addressing secret sprawl challenges across multi-cloud environments. It enables centralized, seamless management of all secrets without sacrificing latency or developer or business agility while managing Non-Human Identities (NHIs) and Artificial Identities (AIs) with maintained security and governance.
- **External vault automatic lists for Azure Key Vault and AWS Secrets Manager** simplifies the vault linking process by automatically presenting available vaults, reducing configuration complexity and potential errors during setup.

Performance and Scalability

- **API performance optimization** addresses excessive launcher session polling that was generating over 120 million monthly API calls, significantly reducing server load and infrastructure costs while maintaining functionality.
- **Secret search performance improvements** deliver a 66% improvement in secret search speed compared to previous versions.
- **Bulk operations performance enhancement** significantly improves reliability and performance for large-scale secret operations. Enhanced secret imports and bulk operations now split large requests into smaller chunks, preventing failures due to message-size limits and boosting performance by up to 20% for operations involving tens of thousands of secrets.

Security and Compliance

- **Security enhancements for auditing** creates separate controls for password view, secret view, and comment-required auditing. This allows customers in higher security environments to audit password view events in real-time while managing business productivity by less aggressively requiring comments.
- **Session management improvements** include better RDP proxy session tracking, automatic session closure when checkout expires, and enhanced keystroke recording capabilities for SSH-tunneled connections. These improvements provide better visibility and control over privileged sessions.

User Experience and Management

- **Personal folder duplicate secret management provides granular control over duplicate secret names** by allowing duplicates in separate personal folders while maintaining restrictions elsewhere. This enhancement uses an improved enumeration-based configuration system that eliminates conflicting Boolean settings.
- **Request forced checkout enhancement** builds upon the 11.8 feature with improved UI display and better handling of secrets in pending status, providing administrators with more control over secret access during incident response scenarios.
- **Increased Windows password changer flexibility** offers increased configurability for authentication methods and their order, with enhanced server message block (SMB) fallback options that provide more granular control over heartbeat and password change operations.

Licensing and Availability

Extended resilient secrets availability to Secret Server Professional resolves licensing issues that previously blocked this feature. Customers with a Secret Server Professional license can now access the resilient secrets pages without encountering license-required error messages.

Improvements

ID	Release Notes
524382	Improved: Updated UI for configuration export to highlight that only CSV and XML formats are supported.
527531	Improved: Users can now use regular expression to identify Sudo password prompts from UNIX in languages other than English.
550918	Improved: Updated the GCP service account to HB with a privilege account, when provided.
551474	Improved: The Referrer-Policy has been added as "no-referrer." The Permissions-Policy has been updated with a more restrictive set of permissions.
557027	Improved: A user with only "list" permissions for a given secret will no longer see a launcher button in the secret grid/list. A user with only "list" permissions on a secret will now be able to favorite that secret.
561827	Improved: Changed the handling of the domain field in RDP proxy credentials to avoid unnecessary Kerberos TGT DNS lookups.
604531	Improved: Added advanced setting to pause RPC and heartbeat to help enable multi-day migrations.
604871	Improved: Plugin created to allow changing and resetting of QuantumLock passwords from Platform.
608421	Improved: Group names now show their domain names when viewed on the Platform Group Synchronization page.
609118	Improved: Optimized the Inbox - Secret Access Requests query for better performance. Added clearer error messages for failures when approving or denying secret access requests.
612530	Improved: SSH-tunneled connections that are not encrypted, such as Telnet, can have keystrokes recorded based on a new setting on the custom launcher.

ID	Release Notes
615870	Improved: Increased reliability when specifying the Platform Redirect URL.
617040	Improved: Secret search performance by merging two operations into one.
619399	Improved: Added an option on the Windows service discovery scanner to use the pre-Windows 2000 user logon name for discovered Windows services.
619452	Improved: Secret Server user audit logs from Platform are now more verbose.
620268	Improved: The api/v1/secret-extensions/web-secret-templates endpoint now returns templates that contain URL list fields as well as URL fields.
620615	Improved: Added a field to Active Directory account secrets that shows expiration date for that account's password in Active Directory, if available.
621245	Improved: Extended the OpenLDAP configuration to allow for optional exclusion of the paging control.
621586	Improved: Updated pipeline behavior for viewing secrets. Pipelines will always run no matter how frequently a secret is viewed.
624262	Improved: A validation error is now provided when a user attempts to orphan a quantumlock group by removing the only user assigned to the group.
626043	Improved: When an RDS session connector session is begun, the RDP file that is downloaded by the user can now be signed using a password-protected pkcs#12 certificate with a private key. This prevents the negative user experience of yellow security warning when opening an RDP file coming from Delinea.
626246	Improved: Support for keystroke-only recording in session connector.
628761	Improved: Added "request force checkout" feature.
631811	Improved: When clicking the All Secret Templates option inside of a user's secrets tab, you are now redirected to the Secret Templates settings page that lists all of the secret templates.

ID	Release Notes
632693	Improved: A user with only the "List" permission on a secret no longer gets an "access denied" redirect upon clicking the launcher icon. They now see a descriptive error message instead.
632768	Improved: Added a banner to Azure AD secrets warns of Microsoft's pending retirement of a PowerShell module underpinnings the password changer for those secrets.
633084	Improved: Updated some Japanese translations.
634668	Improved: Updated Secret Server to use the new shared clipboard service. Updated shared clipboard service to use fallback when in non-secure contexts. Removed clipboard plugin use from clipboard service.
637109	Improved: Text for event pipelines secret email updated to indicate you can send the email to any role, not just owners.
637403	Improved: Directory services now enforces a maximum number of results for Active Directory group searches, reducing query times for customers with large group structures.
638247	Improved: Users with view-only permissions on a folder can now see which policy is applied on a folder.
638771	Improved: The Group Member grid now properly takes up the full height available instead of leaving a gap on large screens.
638911	Improved: Removed legacy CustomLauncherEdit/View.aspx pages.
638915	Improved: Legacy SimpleHome.aspx page was removed.
638928	Improved: Removed legacy secret access-request .aspx pages.
639164	Improved: The legacy license .aspx pages have been removed.
639773	Improved: Added a new report for active users and all users for secrets.
640087	Improved: Added option to allow duplicate secret names in separate personal folders.
640202	Improved: Performance when there are a great number of folders for the following : modifying folders. modifying user display names, or changing the personal folder root name (if personal folders are enabled).

ID	Release Notes
640487	Improved: Added more configurability to the Windows password changer for the method and method order.
640554	Improved: LimitedMode no longer limits AD sync, creating and editing secrets, importing secrets, and web service use.
640556	Improved: UI banner now notifies admins of systems exceeding license limits.
640688	Improved: Scan Template Detail page: an unused scan template can now be deleted. Required Fields now change according to scan type selection.
640783	Improved: $SECRETID and $[x]$SECRETID are now available for scripting
641022	Improved: Folder-detail performance.
641879	Improved: The DR replica now handles events where the DR feature deletes folder(s) assigned to "automatic export" by disabling automatic export.
642213	Improved: Check out, check out extended, and check in Syslog events now contain the UTC times of check out and check in.
642250	Improved: Platform Integration can no longer be disabled when unified mode is enabled and all users are sourced from Platform. This prevents users from locking themselves out of their instance. In the event that Platform Integration can be disabled, a dialog warns the user of the consequences.
643200	Improved: Added a data link between the SDK client account and onboarding rule so when an SDK onboarding rule is deleted all SDK client accounts created from that rule get their access revoked.
643381	Improved: Added a configuration setting under user experience to set the duration for the password mask to begin hiding input again.
643721	Improved: Secret access requests can now be published to the Delinea Platform for other services such as the intelligent authorization agent.
643866	Improved: Added a tab on the User Management page titled OAuth Expiration that lets users delete previously issued OAuth tokens.

ID	Release Notes
644419	Improved: Added Automatic listing when adding an external vault link to Azure Key Vault added.
644548	Improved: DR button order swapped and grid fixed to have more uniform styling on the status chips.
644589	Improved: Now, during provisioning, we retry validation of Secret Server credentials. If upon retry validation still fails, it notifies the orchestrator that provisioning has failed.
644596	Improved: Performance of session monitor search when HasKeystrokes is enabled.
644755	Improved: Converted the update status endpoint to use a PATCH to prevent unnecessary value changes.
644847	Improved: A banner now reminds admins when their usage license is exceeded.
644887	Improved: Added QuantumLock actions to the user profile.
645147	Improved: When a user lacks access to a session recording, they see a more informative error page.
646302	Improved: The legacy bookmark pages are now disabled by default. They can be re-enabled from settings > user experience > Disable legacy bookmark pages. These pages will be completely removed in an upcoming release.
646932	Improved: Updated design for adding widgets to the desktop.
647178	Improved: Attempting to create an Active Directory discovery source when discovery is disabled now informs you that discovery is disabled and needs to be enabled.
647190	Improved: Admins now receive a reminder in the UI when license usage has exceeded licensing limits.

ID	Release Notes
647689	Improved: HSM process: When enabling and disabling the HSM or rotating the HSM key a backup of the encryption.config is created. To prevent a bad state where the database has updated and the encryption.config was not, the database changes are rolled back to the prior state. Also, when rotating the HSM key with PKCS11, if selecting the current DLL, the system will prevent changing the token label and user pin. Since the PKCS11 library already has an open session and cannot close, this prevents potentially saving the wrong information.
647936	Improved: Added capability to select from multiple settings with distinct behaviors to set how duplicate secret names are handled in the Permission Options section.
648752	Improved: Performance of resilient secrets excluding all data related to QuantumLocked secrets.
649210	Improved: Protocol handler parameter checking when using install options was extended to address CVE-2024-12908.
649708	Improved: Resilient Secrets now falls under "Professional" licensing without need of an add on.
649863	Improved: Updated workflow and secret approvals to use the template arguments for the ticket system.
649955	Improved: Reduced the likelihood of an incorrect query returning too many results.
650476	Improved: Increased flexibility for the Windows Password Heartbeat. The Enable SMB Fallback option, previously on the remote heartbeat configuration options, has been replaced with options directly under the advanced settings under Windows Password Changer. This allows you to toggle RPC and SMB heartbeat attempts and determine the order. Previous Enable SMB Heartbeat configuration has been translated to the new settings. The new options for flexibility do require DE version 8.4.56.0.
650658	Improved: Legacy bookmarklet pages were removed.
650720	Improved: The legacy session recording search and viewing pages were removed.
650755	Improved: Several legacy message pages, such as a read only mode description, have been removed and replaced with newer versions.

ID	Release Notes
650853	Improved: Reduced CPU use within the website and background worker.
651315	Improved: Removed the HSM legacy .aspx pages.
651333	Improved: Password type audit grid updated to angular.
653208	Improved: Drop down options added for email configuration.
653299	Improved: The secret view that opens in the right panel has been cleaned up to make the copy icons more visible and keyboard access has been enhanced.
653422	Improved: Added a throttle: "Max Number of Passwords That Can be Changed at One Time setting for Entra ID password changer."
653719	Improved: Adjusted MDI partner API URLs to match the new URL.
655545	Improved: Platform is now running on angular 20.
659980	Improved: Legacy discovery .aspx pages were removed.
661443	Improved: Manage Directory Groups button was removed from the Groups page. It just linked to directory services, which is easily accessed in the left navigation panel.
661831	Improved: The legacy discovery .aspx pages have been removed.

Fixed Issues

ID	Release Notes
527950	Fixed: Cloud customers using PBA would see an erroneous error message indicating that the PBA site was not ready.
556437	Fixed: A user without "force check in" permissions is no longer be offered a check out button in the inline view or checkout page. This was for a secret that was in a failed RPC state and not currently checked out to any other user. Instead, the user sees an error making them aware of the RPC failure. An admin or user that does have those permissions is still shown a check out button as they need to be able to see the secret even in a failed state to fix it.
557815	Fixed: The Test Slack configuration button on the Slack Integration page did not work correctly when the form was not in edit mode.

ID	Release Notes
562377	Fixed: Accounts that did not have local logon privileges could not be used to run application pool dependencies.
563476	Fixed: Sessions were not automatically closed when the secret checkout expires.
569459	Fixed: On the SAML Identity Providers page, we display the date and expiration status of the identity-provider-configured certificate. We can also log if an expired certificate is used for a login in the SAML log. We added an explanation of why expired certificates continue to work to the Identity Providers page.
572558	Fixed: The "api/v1/one-time-password-code" call throwing a 500 error.
578291	Fixed: Session recording search times out.
578885	Fixed: Enhanced secret imports and bulk operations, enabling large requests to be split into smaller chunks, to prevent failures due to message-size limits. This change improves reliability for bulk operations with tens of thousands of secrets and boosts performance by up to 20%.
588963	Fixed: The "IsDeleted" field for Active Directory groups was not processed when syncing through a distributed engine.
596179	Fixed: Known issues around adding fields. Cancel button now works correctly.
612930	Fixed: Issue where users could select HSM settings without the Administer HSM permission.
616850	Fixed: Resolved issues where debug log messages could be read as errors when displaying group members in directory services.
618947	Fixed: The password type for a secret template is no longer removed when both RPC and heartbeat are turned off.
619161	Fixed: Email PIN code loop with federated login. Resolved issue where browsers using SAML authentication with email-based MFA would send a new PIN email every 5 minutes due to automatic page refresh. Added audit logging for PIN requests to improve troubleshooting capabilities.
624185	Fixed: Automatic user management would not reenable users on login.

ID	Release Notes
627425	Fixed: Maximum file size allowed decimal values in Security File Restriction page.
627910	Fixed: Missing Add Member button on the Teams page.
628730	Fixed: If using Integrated Windows Authentication with web services, there could be a failure from an unrelated SSH Proxy Terminal SSH key Unix authentication method if set to "Password or Public Key."
630656	Fixed: Legacy password changers were disabled in new installs and could not be modified
634234	Fixed: Event pipeline "increment/decrement variable" task had issues accepting string values in an event pipeline.
635932	Fixed: When adding associated secrets in a bulk operation, the remove link would not always show for a secret you just added.
638045	Fixed: Approval settings for non-secret policies.
638256	Fixed: An inaccurate error message for session recordings when launch is not detected.
638964	Fixed: RDP proxy session tracking. Resolved an issue where RDP proxy sessions that were opened using proxy credentials (not protocol handler) were not being marked as launched, causing them to be missing from session search results.
639151	Fixed: Resolved issue with PostgreSQL password-change functionality.
640392	Fixed: DR replication data loss when the replica encounters save errors. Resolved issue where running "new data since last replication" could result in permanent data loss if the replica encountered errors during save, causing subsequent replications to skip the failed data entirely. Fixed replication state tracking to ensure failed items are retried in future partial replications.
640808	Fixed: Request Force Checkout button is now displayed while the secret is in a pending status and the "request force checkout" feature is enabled
640978	Fixed: The bulk secret field update now works when MFA is enabled on any secret that is selected.

ID	Release Notes
641375	Fixed: Adding and removing fields did not work correctly if none of the new or existing fields were edited.
641376	Fixed: Export CSV on reports and the auto export storage download now work in Platform.
641566	Fixed: The dates of tbPlatformIntegrationStep were either not being set or being reset in certain scenarios. This has been fixed for all of the steps except the Unification step that will be fixed in a separate card.
641630	Fixed: Secret audits did not correctly link to the new session recording UI.
642223	Fixed: A total count issue when searching subfolders and secrets and then checking and unchecking items.
643226	Fixed: Password changes now trigger an external key-vault push for the linked secret.
643492	Fixed: Discovery but where EntraID users or roles would not display properly in "Network TreeView" under the root EntraID tenant node.
643677	Fixed: AFT token validation errors now return an error code instead of a 500 status code with no body.
643715	Fixed: An issue with the "maximum login failures" shortcut leading to the wrong configuration area.
643815	Fixed: TOTP codes from the favorite dashboard in Platform now work.
643869	Fixed: Save button was enabled when modifying file attachments before any change was made.
644593	Fixed: Corrected workflow email links for Platform to point to Platform URLs not SSC URLs.
644921	Fixed: Discovery source ID was not being read correctly for Entra ID Members, which led to problems viewing and importing accounts.
645106	Fixed: Issue that could sometimes prevent validation of the Platform URL from the Secret Server configuration page.
645923	Fixed: The "ThycoticSystem" internal user now has the display name "Delinea System."

ID	Release Notes
646732	Fixed: Issue where Entra ID discovery would cause errors when field names in the Privileged Secret template were changed.
646957	Fixed: Periodic error when retrieving favicons.
647271	Fixed: Active Directory invites did not get created in Secret Server
647291	Fixed: A new version install could cache old en.json localization files. Language files now include cache-busting tags.
647351	Fixed: Locked users in Platform were not disabled in Secret Server.
647639	Fixed: An issue that could block OIDC authentication.
647691	Fixed: Account scan template was not display after saving on the Scan Template Detail page.
647852	Fixed: A localization issue on the Discovery Rules List page.
648239	Fixed: Template selection issue on discovery rules.
648534	Fixed: Long secret names did not wrap properly when shown as credentials for a discovery scanner.
648665	Fixed: The Validate Connectivity button was not visible when configured to use processing location as the website.
648769	Fixed: 404 error when loading the application load. To prevent this, custom language resources are only loaded if the files exist.
648844	Fixed: The CSV report download button did not work in Platform.
648998	Fixed: The Preview panel, once closed, would not reappear until opened again.
649098	Fixed: Anti-forgery token logic caused pages to refresh in some circumstances.
649167	Fixed: Secrets did not show inherit permissions properly when searching in the grid. Folders now show the inherits permissions column when shown in the grid.
649273	Fixed. The date range filter could be removed from the discovery computer scan results tab.

ID	Release Notes
651907	Fixed: Resolved an upgrade failure to 11.7.25-11.8.1 for on-premises Windows customers using a non-en-us locale.
651955	Fixed: A fresh on-prem install got stuck at the Create Initial User page.
652482	Fixed: Scan template names were not populated in a dropdown on the PasswordChangerEditScanItemTemplateEdit.aspx page.
652648	Fixed: The Edit button is now visible but disabled on non-editable scan templates.
652855	Fix: Tunneled RDP proxy data could be stored in the database erroneously under certain conditions. This data is encrypted by the RDP protocol and therefore is not useable as keystroke data and should not be stored.
653644	Fixed: Secret policy launcher tab clipped the far right side of the form selects.
654670	Fixed: Secret share no longer adds groups to the Platform Allowed group list when adding from external groups.
655397	Fixed: On-premises edge case where if the web role had a cached valid license the disaster recovery process was allowed to begin but the background worker could not see a valid license and would do nothing. Now a log is generated.
655439	Fixed: Bug where the SAML Metadata Download XML button did not work.
659912	Fixed: The script editor (report, scripts) would sometimes show an error with the text "canceled."
660018	Fixed: A WRONGTYPE issue caused by calling redis.GetList on a "List<string>" type object. Caching once again applies for this value.

Known Issues

- After upgrading to version 11.8, users might see "Language Resource Not Found (admin.external-secrets)" on the Secrets tab. This was caused by old language files that were cached and not updated for the new menu item. The solution to this issue is to:
  - Clear their cache for the Secret Server URL or for their entire browser.
  - Incognito can also be used if the cache can't be cleared.

- A "hard refresh" (CTRL + Shift + R) that bypasses the cache does not fix this issue

Refer to the following support article for more information.

Secret Server 11.8.000001 Release Notes

Release Date: On-premises: May 7, 2025

> Secret Server 11.8.0 was rolled back while we investigated potential issues with Azure AD logins. This version is the result of that investigation and is essentially the same as 11.8.0.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.51.0

Protocol Handler: 6.0.3.35

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Important Technical Change for Secret Server 11.8

> Please carefully review this section prior to upgrading.

> Applies to Secret Server On-Premises only.

Overview

Prior to the 11.8 on-premises release, Secret Server On-Premises was delivered in a "dynamically-compiled" state. In this configuration, components of the website, particularly .aspx files, were compiled by IIS upon receiving the initial request.

Starting with the 11.8 release, the application is pre-compiled, which significantly enhances and accelerates application startup because it eliminates dynamic compilation.

As a result, **some customers may experience startup issues**. Please review the two items below prior to upgrading:

- Pre-compiled applications cannot run in IIS if there is an "App_Code" folder present. Therefore, the version 11.8 upgrade renames this folder automatically on start-up to avoid issues. Please note:
  - In some cases the application pool may not have the permissions to rename the "App_Code" folder, resulting in start-up issues, specifically, the Web page does not load.
  - If the application pool does not have the permissions, you must rename the "App_Code" folder or give the account running the application pool "modify" permissions to the application folder.
  - When finished, perform an iisreset to restart Secret Server.

- If you have manually modified any .aspx files, you will not be able to do so anymore, as those files are compiled already. Do not upgrade until you have verified you do not need the modifications going forward.

Support Articles

Please see the following technical articles for instructions:

- How to prepare for upgrade to Secret Server version 11.8 or higher
- After Upgrading to Secret Server 11.8, the Web Page is No Longer Loading

New Features

Azure Key Vault Integration

Azure Key Vault Integration (AKVI) simplifies management and governance of NHI's and secrets from the CSP's native vaults. With AKVI you can centrally manage and update secrets to one or more Azure Key Vaults and rotate passwords or values more frequently. With fine grained roles and permissions, audit and logging, AKVI provides increased governance, visibility, and awareness of secrets managed in Azure Key Vault without affecting development velocity or processes. AKVI is available on Secret Server Cloud, the Delinea Platform, and Secret Server On Premises.

Additional Approval Workflow Type

A new approval workflow type is available, allowing owners to bypass approval while ensuring approvers still require it. The "Standard Including Editors and Approvers (Owners do not need approval)" option offers more flexibility in approval processes to meet organizational needs.

Bulk RPC on Secrets with Checkout Enabled

Bulk RPC actions are available to secrets with checkout enabled. This feature uses random passwords during bulk operations, ensuring that passwords remain secure and hidden, even during bulk updates, without compromising secret integrity.

Bulk Update Secret Fields

Bulk updates for secret fields are now available, enabling users to edit and update multiple fields across secrets in the folder view. This simplifies importing and formatting secrets, streamlining secret management for large datasets.

Request Force Checkout

It is now possible to globally enable the Request Force Checkout functionality in the Settings > Configuration > User Experience menu. This feature allows a user that does not hold the Force Check Out privilege to request access to a secret that is in a checked out state. This will send an approval request to the Owner of the Secret to approve them access, at which point the checkout session will be transferred to the requesting user.

This is primarily designed to allow a user access to a secret that is unable to change password, though it has the "Change Password on Checkin" setting configured. This allows an administrator to permit an appropriate user access to the secret without taking direct action or checking the secret out to their user.

Global Manual Approver Workflow for Ticketing Systems

A manual approval workflow is now available for scenarios where the primary ticketing system, like ServiceNow, is unavailable. This fallback option ensures that users can still gain access to secrets through a manual approval process, maintaining workflow continuity even during system outages.

Keystroke-Only Recording for Session Connector

A new "Keystroke Only" recording mode has been added to the Session Connector, allowing keystrokes to be recorded without screen recording. This option meets legal requirements in regions where screen recording is restricted while still capturing important session data for security purposes.

PowerShell 7 Support for Scripts

Secret Server now supports PowerShell 7 scripts, allowing users to run both legacy PowerShell scripts and PowerShell 7 scripts. This update ensures compatibility with the latest thycotic.secretserver module and helps avoid disruptions from version conflicts.

PowerShell Ticket Integration—User Information Passed as Arguments

PowerShell ticket integration has been enhanced to pass user information (userID, username, and email) as arguments in scripts. This update provides greater flexibility for ticket validation, enabling more customized and user-specific logic in ticket-related actions.

Pre-Compiled Version of Secret Server On-Premises

All Secret Server On-Premises releases from 11.8 onwards are pre-compiled. This change significantly enhances and accelerates application startup by eliminating the time required for dynamic compilation.

Secret Icons

Secret Icons allows you to display icons for secrets in the secret list, and secret details page. Icons can be set at both the secret and secret template levels.

> Secret website favicons are now pulled by Secret Server by default, even if secret icons are not enabled. This can cause unexpected traffic to hit the public internet as Secret Server gathers those flavicons. To change the behavior or disable it entirely, you can set the icons at the application, template, or secret level or you can toggle the "Enable icon gathering" setting to stop the process. That setting is enabled by default. See "Secret Icons" on page 1160 for details.

Fixed Issues

Ticket	Description
405016	Fixed: The RPC by Day report is now formatted to user's time zone.

Ticket	Description
527950	Fixed: Addressed an issue where cloud customers using PBA would see an erroneous error message indicating that the PBA site was not ready.
530294	Fixed: Key rotation failure. We now allow a particular password type to be set for account take-over when importing an account into Secret Server.
537916	Fixed: The folder-permission API now requires view or administer folder permissions to query by a folder ID. Previously, you could also do this with the personal folders role permission.
539187	Fixed: Secret access request viewing very slow. Bug fixed with loading large numbers of secret access requests.
546108	Fixed: Add a "Matches" tab on discovery account rules to show computer accounts that match the defined rule condition. This replaces the account rule filter on the network view that has been removed.
549816	Fixed: Fixed an issue where when using the Advanced Session Recording Agent, in certain situations the recording process would not be stopped.
556742	Fixed: An issue that prevented empty dependency groups from being deleted.
557774	Fixed: Errant heartbeat every five minutes. When creating a new secret template with heartbeat enabled, if you do not change the interval value it will now correctly assign heartbeat interval of 60 minutes.
559102	Fixed: An issue where large-item-count folder searching was broken.
560138	Fixed: The secret template fields grid would not always load all records properly if there were more than 60 fields on a template.
564689	Fixed: User appearing locked out after the lockout period. On the User General page (admin page), added an Unlock User button and chips and messages to reflect lockout interval for user locked out by failed logins.
566423	Fixed: Resolved an issue where downloaded report names appeared garbled when the language was set to Japanese or Simplified Chinese. Fixed: An issue in the Platform where downloaded reports were incorrectly named "null." Reports now display the correct filenames based on the selected language.
567596	Fixed: Resolved an intermittent issue during DR replication where foreign-key constraint errors occurred with categorized lists, ensuring successful replication across supported versions.
571212	Fixed: Test Script page not working. SQL parameters now work in the new UI.

Ticket	Description
571231	Fixed: Role audit log error. The Action field of role audit logs now display correctly when the log is created in a language that uses Unicode characters
572558	Fixed: api/v1/one-time-password-code call getting a 500 error.
575503	Fixed: A dependent library used in SAML in has been updated to close potential security vulnerabilities. It uses a different version of a saml.config when using the legacy SAML configuration, and a conversion process to update saml.config has been added to the upgrade system. Please see documentation "Troubleshooting SAML Configuration Errors After Upgrading" if using a saml.config file and having issues.
578291	Fixed: Session recording search times out.
578890	Fixed: Removing a launcher having multiple secrets linked will no longer fail.
580156	Fixed: Handled a case where cached Secure TPC connections to a Syslog server connected via domain name were not removed when no longer active.
580299	Fixed: An issue with /api/v1/launchers/secret endpoint throwing errors with complex URLs.
581180	Fixed: An error when checkout had expired, switching to the settings tab on a secret would throw a red banner error instead of redirecting the user to the checkout page.
582171	Fixed: Double email notifications for access approval request. Access request emails will now indicate a status of the workflow. Viewing a workflow online will also render a visualization of the workflow status.
582538	Fixed: An issue where session messages sent from would not show during RDP Proxy sessions.
582728	Fixed: An issue where users who had permission to edit secrets could not toggle auto-change using the bulk action on secrets that should have allowed it, based on the permission set in the secret's template.
583939	Fixed: Incorrect active session display. Secret active launcher sessions now updates list when a session is launched from the page.
585609	Fixed: error when removing scanners from a discovery source. Added a custom exception for "scanner X already added" and UI refresh to stay in synch with back end.
591272	Fixed: An issue with the Launcher template when modifying the field "Use SSH Tunneling with SSH Proxy."
591708	Fixed: Issue with scan template parent field where it showed a number instead of name.

Ticket	Description
593801	Fixed: An issue with SSH key integration expiration configuration.
595169	Fixed: An issue where there was no option to add a step in a workflow. It is no longer possible to delete the last step from a workflow. Existing workflows with no steps will now display a default starting step when opened to edit.
595565	Fixed: An issue where dependency changers in SSC were not passing arguments to scripts, resulting in empty output files. Dependency changers now correctly pass arguments, and the status no longer incorrectly shows as disabled.
596179	Fixed: Known issues around adding fields. Cancel button now works correctly.
597088	Fixed: Working as designed—no code changes.
598102	Fixed Keystrokes for the RDS version of the Secret Server protocol handler. Fixed version is 6.0.3.32.
599173	Fixed: In active sessions inside a launched secret, when the username that launched the secret contains Unicode characters, they displayed incorrectly.
599511	Fixed: When submitting a secret access request with a custom duration, start values that are in the past are no longer permitted.
601706	Fixed: Intermittent Azure message loss. Implemented retry logic for publishing to Azure service bus queues.
602389	Addressed performance issues by optimizing database handling to resolve high deadlock rates (over 8,000 per hour) affecting the tbSecret and tbUser tables under heavy load.
603681	Fixed: Resolved a password display Issue (with "comment required" enabled) where, after waiting on the Overview tab for 5+ minutes, the password was displayed as [object Object] instead of prompting for a comment again. Users are now correctly required to re-enter a comment when accessing the password.
603721	Fixed: Enhanced Resilient secrets log text information and added operation progress percentage estimation Fixed issue where Resilient secrets operation was not interrupting on operation timeout
603779	Fixed: An issue with category and report permissions showing 0 items when permissions are assigned to users.

Ticket	Description
605053	Fixed: Heartbeat and password reset failures. Added more support for expired AD account password changers. Secrets that use an AD privileged password changer to rotate the password for an expired AD account will successfully complete the rotation process. Previous behavior involved rotating successfully and then failing the verify step, resulting in the new password not being saved on the side. Subsequent heartbeats may fail for the secret since the account is expired. Password Changes using a secrets own credentials may fail as well.
607434	Fixed: Discovery analysis SQL timeouts. The query that populates the discovered account metrics has been made more efficient. It should no longer have timeout issues.
608342	Fixed: PRA launcher shows on favorite and recent panel.
608395	Fixed: Columns that should have been hidden were selectable in the column selector. If selected, they would (incorrectly) display until page reload. The conditionally available columns are now correctly set visible or hidden in the column selector.
612930	Fixed: Fixed issue where users could select HSM settings without the “Administer HSM” permission
614002	Fixed: Turkish not displaying correctly in email. Turkish characters should publish correctly in email HTML.
614465	Fixed: Tooltip location on the Launcher Configuration page.
616185	Fixed: Resolved an issue where users could add members to a migrated group in SSC via individual user modifications. Now, all membership changes must be managed in the Platform, ensuring proper access control.
616221	Fixed: In SSC the from email address field in email configuration settings is restricted to the secretservercloud domain and the TLD excludes .co.uk as a valid option. On premises instances will only validate that it is a valid email address format but will allow any domain to be input.
617344	Fixed: An issue with password that contains username and added a new item to the local-user password configuration area that optionally prevents the password containing the username.
617429	Fixed: Issue where an invalid version number could cause Secret Server to become unresponsive.
617445	Fixed: Updated command sets to no longer add extra spacing between lines, and added validation around comments in command sets, instead of auto-removing extra comments, to reduce confusion on save.
617607	Fixed: Discovery services grid did not sort. Added computer Services API endpoint so the computer services component now has paging and sorting.

Ticket	Description
618528	Fixed: Resolved an issue where secret policy settings were not properly inherited by secrets, causing discrepancies in the Approval page. Additionally, the "Language Resource Not Found: OnlyOptionViaPolicy" message has been fixed. Secret policy settings now correctly apply as expected.
618869	Fixed: An error with "Default Only" on RPC schedule on an active secret policy.
619554	Fixed: On-Premises instances with PRA will now get emails to Secret Server instead of the Platform instance.
620165	Fixed: Display to show .delinea.app when opting into a prod instance.
620268	Fixed: The api/v1/secret-extensions/web-secret-templates endpoint now returns templates that contain URL list fields as well as URL fields.
620338	Fixed: An issue with "minimum required character count" rules options containing an invalid choice.
621226	Fixed: Resolved an issue where repeated execution of Entra ID secret heartbeats would cause a "Headers too long" error.
621573	Fixed: When running in Platform, the breadcrumb link on the platform group and configuration page is now correct.
621935	Fixed: Resolved an issue where viewing a secret with MFA enabled incorrectly logged "Password Displayed" in audit entries. Now, the audit log correctly records the action as "View" when no other interactions occur.
622254	Fixed: Resolved a bug where—when Platform is integrated with Cloud and Open ID Connect Platform login is used—in some situations, the redirected Platform login page would be incorrect.
622479	Fixed: Error during opt-in in PIC for Europe region.
626465	Fixed: Audit with no notes. Secret policies should no longer create an empty audit log when modifying launcher settings but reverting changes before saving.
626702	Fixed: An issue with users not being re-enabled when logging in through Platform after being disabled by automatic user management.
627109	Fixed: Launchers filter was incorrectly labeled was "Template."
627246	Fixed: The field header example on secret import now wraps correctly.
627291	Fixed: The "All launchers" option of the launcher filter now returns all results as expected.

Ticket	Description
627619	Fixed: Changed database cleanup logic which was causing some heartbeat/RPC audit records for inactive secrets to be removed before the "Max Secret Log Length" was reached.
627650	Fixed: Addressed issue where an error would be thrown when editing a command set with an empty command field.
627731	Fixed: If an Entra discovery source is created in Secret Server, and Platform integration is configured with Inventory Forward enabled, there was a bug if deleting any roles from the Discovery Network View in Secret Server. It would cause Entra roles to show up in Platform inventory.
628439	Fixed: Corrected a typo on Launcher Mapping page.
629517	Fixed: Resolved an issue from the previous update where toggling an Active Directory account's expiration status could prevent verification after a password change.
629584	Fixed: An issue with the password compliance check notification on a secret.
630728	Fixed: A bug where saving an approval method for a secret does not persist correctly.
631133	Fixed: An issue introduced in engine version 8.4.47 where AD privileged password changing would erroneously report failure for accounts that had null values for the "accountExpires" attribute.
632269	Fixed: Secret Server API endpoint /v1/secrets/{ID}/settings now responds with TOTP values if conditions are correct.
632693	Fixed: A User who has only the List permission on a secret will no longer get an access denied redirect upon clicking the launcher icon. They will now see a descriptive error message instead.
634286	Fixed: Issues with dropdown options causing enum values to be displayed for the Secret Security Approval Type so that correct localized strings are displayed.
634484	Fixed: Excessive CPU usage by correcting the SessionKey parameter to varchar, eliminating implicit conversion.
635135	Fixed: The "Ignore permission errors" checkbox is now available without a page refresh.
635550	Fixed: Addressed erroneous exception in the background worker when updating valid redirect URIs.
637136	Fixed: Do not include azure domains or inactive AD domains in group-type precheck.

Ticket	Description
637139	Fixed: Users missing their ExtendedUserMapping will register as a warning in the precheck instead of an error.
637373	Fixed: Corrected regression where secrets were counted twice in some scenarios. Secrets grid count functionality restored. Count ("# Items") is the sum of the number of first-child subfolders and the number of secrets in the current folder.
637690	Fixed: Incorrect GUI label. Updated Log Level filter label from "Site" to "Log Level."
638073	Fixed: A bug that prevented the secure-Platform-access step in the PIC from auto-skipping.
638238	Fixed: Fixed NG0203 error preventing folder selection dialog from popping up .
638317	Fixed: In the Data Sync step of the PIC, a new column (pre-check) was added to the 'Add exclusions' and 'Select data' dialogs. In the 'Select data' dialog, you may no longer select and synch a group with a pre-check error.
639151	Fixed: Resolved issue with PostgresSQL password change functionality.
640235	Fixed: Corrected a regression which caused the secrets grid to show "999,999,999 Items".
640554	Fixed: LimitedMode no longer blocks functionality related to AD sync, creating and editing secrets, importing secrets, use of web services.
640601	Fixed: Grid now adds the file extension when it does not exist, so files are properly downloaded as .csv
640808	Fixed: Request force checkout button is now displayed while the secret is in a pending status and the request force checkout feature is enabled
641566	Fixed: The dates of tbPlatformIntegrationStep were either not being set or being reset in certain scenarios. This has been fixed for all of the steps except the Unification step which will be fixed in a separate card.
641879	Fixed: Replica now handles event where Disaster Recovery feature deletes folder(s) assigned to Automatic Export by disabling Automatic Export.
642042	Fixed: A PIC precheck error was added when a username in Secret Server does not follow the regular expression rules defined in Platform.
642286	Fixed: Addressed issue that could cause errors forwarding computers to inventory.
643304	Fixed: The status of the customize branding step in the PIC no longer resets from Skipped to Ready to start when the page is refreshed.

Ticket	Description
643677	Fixed: AFT token validation errors will now return an error code instead of just a 500 status code with no body.
643841	Fixed: A fix was made for the opt-in step of the PIC if the user refreshes the page once the opt-in process has begun.

Improvements

Ticket	Description
460275	Improved: Updated session recording logic to allow already running processes to be recorded from after the point of the session launch if said process was listed in the "Additional Processes" list for the launcher.
546156	Improved: Logging in when MFA setup is required now immediately redirects the user to configure MFA.
561827	Improved: Changed methodology for handling the domain field in RDP Proxy credentials to avoid unnecessary Kerberos TGT DNS lookups.
566484	Improved: Reports page size minimum has increased to 60.
569459	Improved: On the SAML Identity Providers page, we display the date and expiration status of the Identity Provider configured certificate. We also log if an expired certificate is used for a login in the SAML log. An explanation of why expired certificates will continue to work has been added to the Identity Providers page.
575905	Improved: Updated scanner template creation UI to combine both OU Input templates and non-OU Input templates into the same dropdown in categories.
580253	Improved: No dynamic update for active sessions. Active launchers section on secrets now updates every 30 seconds to show an updated list of active launchers.
582378	Improved: Updated grids using timestamps to use datetime in order to properly respect user preferences.
586608	Improved: Password validation failures for dictionary now indicate, "Dictionary words including common number substitutions."
593543	Improved: Removed time zone tooltips from reports to reduce confusion when time zones are set by the report.
594323	Improved: Empty pinned folders now inform users of the empty sections.

Ticket	Description
595169	Improved: It is no longer possible to delete the last step from a workflow. Existing workflows with no steps will now display a default starting step when opened to edit.
603721	Improved: Resilient secrets log text information and added operation progress percentage estimation. Fixed: An issue where resilient secrets operation was not interrupted on operation timeout.
605210	Improved: Performance of discovery scanner delete. Increased timeout to 24 hours, lowered isolation level where possible, and added logging for each delete operation.
609101	Improved: Added a non-configurable 30-second secret password timeout to improve security and reduce stale password issues. The timeout applies to: Show password—hides after 30 seconds (previously visible forever). Copy password—password value cached for 30 seconds only. Copy password icon clicks after that will trigger a fresh API call (to reduce stale password conflicts). Note that this does not affect the value that was already copied to the clipboard, only what will be copied when the user clicks the copy password icon.
610739	Improved: Performance improvements were made to the "Shared with me" Secret View, and the "Browse All Folders" view for customers with many folders in a highly nested structure.
611190	Improved: In the secret template list field, list and URL list now have their "dispose for display" boxes checked by default to denote the data's plaintext status. The expose for display control is also disabled so that it can not be unchecked by accident.
611573	Improved: Updates to Discovery Scan Status Report Query.
612177	Improved: Error handling for Platform credentials that become invalid.
612739	Improved: A new setting, "Disable Legacy Bookmark Pages," has been added the admin/user experience section. This setting is false by default. When true, the legacy bookmark pages used by legacy WPF will be disabled. This allows administrators to disable the setting and ensure they do not have any of these legacy clients that require it. This setting will default to disabled in a future release.
614508	Improved: Added the ability to view the Active Directory group type. This is displayed under the General tab of a group. If a group does not have a type, it will display as a hyphen. Otherwise, it will show one of the following: Global, Universal, or DomainLocal.
615870	Improved: Improve reliability when specifying the Platform Redirect URL.
616620	Improved: Secret export will now audit the current "Export" action and a new "Export retrieved" action to indicate that the user retrieved the file. Previously, you could close the browser window before retrieving the export file.

Ticket	Description
618004	Improved: Through the user experience settings, a user can use a new "COMMENT" audit action to separate the VIEW action of a checkout (or ITMS) protected secret from the required comment.
619399	Improved: Added an option on the Windows Service Discovery Scanner to use the Pre-Windows-2000 user logon name for discovered Windows services.
619512	Improved: Event pipeline set-custom-value tasks can now increment or decrement pipeline variables by custom values.
619515	Improved: Added additional group type validation (empty group types and DomainLocal group types) for the Data Sync step in the PIC. If empty group types are detected, users are prompted that there are empty group types and are instructed to run the directory services sync. For any DomainLocal groups found, an error message appears in the pre-check table within the Data Sync step stating that DomainLocal groups are not supported.
620202	Improved: Added additional response information when autofilling values.
621513	Improved: Grid columns are now all set to a fixed width at their current width when a user resizes any column. This makes resizing columns easier.
626041	Improved: Modifications to build pipeline to precompile, copy and overwrite precompiled assets to webroot folder. Packaging and installer remain as they were prior to PR.
626668	Improved: With Platform Integration, support for the setting "Create Groups during synchronization" is completely deprecated. Now, all Platform native groups will be created automatically and any directory groups through Platform need manual linking.
626881	Improved: Updated discovery import rules to prevent duplicate account creation and unintended unlinking of service and Active Directory accounts. Added broader test coverage, including integration tests, to ensure correct matching, unmatching, and unchanged behavior when re-running imports.
627169	Improved: Updated discovery analysis layout to emulate dashboard styles and to better accommodate large datasets.
627297	Improved: Added a new date and time range filter to Session Monitoring.
627303	Improved: Added a new state flag to indicate whether the Delinea enablement code has been entered.
627304	Improved: Added a new state flag to indicate the customer has completed the Platform integration.

Ticket	Description
627344	Improved: The inbox template editor now includes options to select message properties by selecting which message. This helps clarify that only message properties on the targeted message are available to merge into the template.
627607	Improved: Added Computer Services API endpoint; Computer Services component now has paging and sorting.
628034	Improved: Removed Transloco dependency.
628761	Improved: Added request force checkout feature
628801	Improved: Delinea's new code signing certificate is now trusted when validating upgrade versions for the future. Protocol handler releases before 6.0.3.34 will upgrade to 6.0.3.34 before newer versions to ensure the auto upgrade process will work.
631776	Improved: The application picker that appears when both Secret Server and Privilege Manager are installed has an updated design. This slightly increases the speed of the login process.
631811	Improved: When clicking the option inside of a user's secrets tab you will be redirected to the Secret Templates settings page that lists all of the secret templates.
633054	Improved: Optimized memory management to reduce latency buildup in the US BGW, preventing performance degradation over time. Restored ASP.NET metrics for better visibility into garbage collection and CPU usage.
633244	Improved: Additional logging added during the enabling of unified mode in the PIC .
633996	Improved: PowerShell Core (6+) support added to the scripts page.
634022	Improved: A new bulk secret action was added to allow for updating a field across multiple secrets. The value can be prepended, appended, or replace the existing value.
634158	Improved: Improved memory utilization of the background worker in Cloud.
634668	Improved: Updated Secret Server to use the new shared clipboard service. Updated shared clipboard service to use fallback when on non-secure contexts. Removed clipboard plugin use from clipboard service.
635475	Improved: Enhancements to ticket system configuration, allowing for more nuanced interactions between ticket validation and require approval flows.
635732	Improved: Added PasswordTypeIds as a filter on the api/v1/secret-templates-list endpoint.
635803	Improved: Only the users that are migrated are validated.

Ticket	Description
635963	Improved: Added an Advanced Configuration setting that will restrict the amount of secret Item History that will be replicated due to the sheer size of that table with relation to the value of replicating a history beyond a certain point. The default number of item histories to be replicated is set to 3.
635970	Improved: Updated libraries to achieve more control when inter-operating with Platform users.
636130	Improved: When enabled, "Show secret icons" in User Experience will display icons for secrets in grid, card, and detail view.
638653	Improved: Secret components on Dashboard (Favorites, Recent etc.) will now only cache Secret passwords for 30 seconds on copy to clipboard, as in other Secret views.
638678	Improved: Administrators can configure the DCM experience for non-business users
638730	Improved: Updated Platform Upgrade Center TOTP message to clarify which users TOTP information will be migrated.
638911	Improved: Removed legacy CustomLauncherEdit/View.aspx pages
638915	Improved: Legacy SimpleHome.aspx page removed
638928	Improved: Removed legacy secret access request aspx pages.
639164	Improved: The legacy license aspx pages have been removed.
639851	Improved: Added caching to improve container configuration, API performance and reliability.
640213	Improved: legacy discovery, secret import, and script pages now have a note indicating they will be removed in a future release.
640556	Improved: Admins of systems exceeding licenses limits will be notified via UI banner.
640783	Improved: $SECRETID / $[x]$SECRETID are now available for scripting
642250	Improved: Platform Integration can no longer be disabled when unified mode is enabled and all users are sourced from Platform. This prevents users from locking themselves out of their instance. If Platform Integration can be disabled, a dialog warns the user of the consequences.

Known Issues

- After upgrading to version 11.8, users might see "Language Resource Not Found (admin.external-secrets)" on the Secrets tab. This was caused by old language files that were cached and not updated for the new menu item. The solution to this issue is to:

- Clear their cache for the Secret Server URL or for their entire browser.
- Incognito can also be used if the cache can't be cleared.
- A "hard refresh" (CTRL + Shift + R) that bypasses the cache does not fix this issue

Refer to the following support article for more information.

Secret Server 11.8.000000 Release Notes

Release Date: On-premises: Rolled Back

> Secret Server 11.8 has was rolled back while we investigated potential issues with Azure AD logins. Please see "Secret Server 11.8.000001 Release Notes" on page 1634 for 11.8.1.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.51.0

Protocol Handler: 6.0.3.35

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Important Technical Change for Secret Server 11.8

> Please carefully review this section prior to upgrading.

> Applies to Secret Server On-Premises only.

Overview

Prior to the 11.8 on-premises release, Secret Server On-Premises was delivered in a "dynamically-compiled" state. In this configuration, components of the website, particularly .aspx files, were compiled by IIS upon receiving the initial request.

Starting with the 11.8 release, the application is pre-compiled, which significantly enhances and accelerates application startup because it eliminates dynamic compilation.

As a result, **some customers may experience startup issues**. Please review the two items below prior to upgrading:

- Pre-compiled applications cannot run in IIS if there is an "App_Code" folder present. Therefore, the version 11.8 upgrade renames this folder automatically on start-up to avoid issues. Please note:
  - In some cases the application pool may not have the permissions to rename the "App_Code" folder, resulting in start-up issues, specifically, the Web page does not load.

  - If the application pool does not have the permissions, you must rename the "App_Code" folder or give the account running the application pool "modify" permissions to the application folder.
  - When finished, perform an iisreset to restart Secret Server.
- If you have manually modified any .aspx files, you will not be able to do so anymore, as those files are compiled already. Do not upgrade until you have verified you do not need the modifications going forward.

Support Articles

Please see the following technical articles for instructions:

- How to prepare for upgrade to Secret Server version 11.8 or higher
- After Upgrading to Secret Server 11.8, the Web Page is No Longer Loading

New Features

Azure Key Vault Integration

Azure Key Vault Integration (AKVI) simplifies management and governance of NHI's and secrets from the CSP's native vaults. With AKVI you can centrally manage and update secrets to one or more Azure Key Vaults and rotate passwords or values more frequently. With fine grained roles and permissions, audit and logging, AKVI provides increased governance, visibility, and awareness of secrets managed in Azure Key Vault without affecting development velocity or processes. AKVI is available on Secret Server Cloud, the Delinea Platform, and Secret Server On Premises.

Additional Approval Workflow Type

A new approval workflow type is available, allowing owners to bypass approval while ensuring approvers still require it. The "Standard Including Editors and Approvers (Owners do not need approval)" option offers more flexibility in approval processes to meet organizational needs.

Bulk RPC on Secrets with Checkout Enabled

Bulk RPC actions are available to secrets with checkout enabled. This feature uses random passwords during bulk operations, ensuring that passwords remain secure and hidden, even during bulk updates, without compromising secret integrity.

Bulk Update Secret Fields

Bulk updates for secret fields are now available, enabling users to edit and update multiple fields across secrets in the folder view. This simplifies importing and formatting secrets, streamlining secret management for large datasets.

Global Manual Approver Workflow for Ticketing Systems

A manual approval workflow is now available for scenarios where the primary ticketing system, like ServiceNow, is unavailable. This fallback option ensures that users can still gain access to secrets through a manual approval process, maintaining workflow continuity even during system outages.

PowerShell 7 Support for Scripts

Secret Server now supports PowerShell 7 scripts, allowing users to run both legacy PowerShell scripts and PowerShell 7 scripts. This update ensures compatibility with the latest thycotic.secretserver module and helps avoid disruptions from version conflicts.

PowerShell Ticket Integration—User Information Passed as Arguments

PowerShell ticket integration has been enhanced to pass user information (userID, username, and email) as arguments in scripts. This update provides greater flexibility for ticket validation, enabling more customized and user-specific logic in ticket-related actions.

Pre-Compiled Version of Secret Server On-Premises

All Secret Server On-Premises releases from 11.8 onwards are pre-compiled. This change significantly enhances and accelerates application startup by eliminating the time required for dynamic compilation.

Secret Icons

Secret Icons allows you to display icons for secrets in the secret list, and secret details page. Icons can be set at both the secret and secret template levels.

> Secret website favicons are now pulled by Secret Server by default, even if secret icons are not enabled. This can cause unexpected traffic to hit the public internet as Secret Server gathers those flavicons. To change the behavior or disable it entirely, you can set the icons at the application, template, or secret level or you can toggle the "Enable icon gathering" setting to stop the process. That setting is enabled by default. See "Secret Icons" on page 1160 for details.

Fixed Issues

Ticket	Description
405016	Fixed: The RPC by Day report is now formatted to user's time zone.
527950	Fixed: Addressed an issue where cloud customers using PBA would see an erroneous error message indicating that the PBA site was not ready.
530294	Fixed: Key rotation failure. We now allow a particular password type to be set for account take-over when importing an account into Secret Server.
537916	Fixed: The folder-permission API now requires view or administer folder permissions to query by a folder ID. Previously, you could also do this with the personal folders role permission.
539187	Fixed: Secret access request viewing very slow. Bug fixed with loading large numbers of secret access requests.

Ticket	Description
546108	Fixed: Add a "Matches" tab on discovery account rules to show computer accounts that match the defined rule condition. This replaces the account rule filter on the network view that has been removed.
549816	Fixed: Fixed an issue where when using the Advanced Session Recording Agent, in certain situations the recording process would not be stopped.
556742	Fixed: An issue that prevented empty dependency groups from being deleted.
557774	Fixed: Errant heartbeat every five minutes. When creating a new secret template with heartbeat enabled, if you do not change the interval value it will now correctly assign heartbeat interval of 60 minutes.
559102	Fixed: An issue where large-item-count folder searching was broken.
560138	Fixed: The secret template fields grid would not always load all records properly if there were more than 60 fields on a template.
564689	Fixed: User appearing locked out after the lockout period. On the User General page (admin page), added an Unlock User button and chips and messages to reflect lockout interval for user locked out by failed logins.
566423	Fixed: Resolved an issue where downloaded report names appeared garbled when the language was set to Japanese or Simplified Chinese. Fixed: An issue in the Platform where downloaded reports were incorrectly named "null." Reports now display the correct filenames based on the selected language.
567596	Fixed: Resolved an intermittent issue during DR replication where foreign-key constraint errors occurred with categorized lists, ensuring successful replication across supported versions.
571212	Fixed: Test Script page not working. SQL parameters now work in the new UI.
571231	Fixed: Role audit log error. The Action field of role audit logs now display correctly when the log is created in a language that uses Unicode characters
572558	Fixed: api/v1/one-time-password-code call getting a 500 error.
575503	Fixed: A dependent library used in SAML in has been updated to close potential security vulnerabilities. It uses a different version of a saml.config when using the legacy SAML configuration, and a conversion process to update saml.config has been added to the upgrade system. Please see documentation "Troubleshooting SAML Configuration Errors After Upgrading" if using a saml.config file and having issues.
578291	Fixed: Session recording search times out.

Ticket	Description
578890	Fixed: Removing a launcher having multiple secrets linked will no longer fail.
580156	Fixed: Handled a case where cached Secure TPC connections to a Syslog server connected via domain name were not removed when no longer active.
580299	Fixed: An issue with /api/v1/launchers/secret endpoint throwing errors with complex URLs.
581180	Fixed: An error when checkout had expired, switching to the settings tab on a secret would throw a red banner error instead of redirecting the user to the checkout page.
582171	Fixed: Double email notifications for access approval request. Access request emails will now indicate a status of the workflow. Viewing a workflow online will also render a visualization of the workflow status.
582538	Fixed: An issue where session messages sent from would not show during RDP Proxy sessions.
582728	Fixed: An issue where users who had permission to edit secrets could not toggle auto-change using the bulk action on secrets that should have allowed it, based on the permission set in the secret's template.
583939	Fixed: Incorrect active session display. Secret active launcher sessions now updates list when a session is launched from the page.
585609	Fixed: error when removing scanners from a discovery source. Added a custom exception for "scanner X already added" and UI refresh to stay in synch with back end.
591272	Fixed: An issue with the Launcher template when modifying the field "Use SSH Tunneling with SSH Proxy."
591708	Fixed: Issue with scan template parent field where it showed a number instead of name.
593801	Fixed: An issue with SSH key integration expiration configuration.
595169	Fixed: An issue where there was no option to add a step in a workflow. It is no longer possible to delete the last step from a workflow. Existing workflows with no steps will now display a default starting step when opened to edit.
595565	Fixed: An issue where dependency changers in SSC were not passing arguments to scripts, resulting in empty output files. Dependency changers now correctly pass arguments, and the status no longer incorrectly shows as disabled.
596179	Fixed: Known issues around adding fields. Cancel button now works correctly.
597088	Fixed: Working as designed—no code changes.

Ticket	Description
598102	Fixed Keystrokes for the RDS version of the Secret Server protocol handler. Fixed version is 6.0.3.32.
599173	Fixed: In active sessions inside a launched secret, when the username that launched the secret contains Unicode characters, they displayed incorrectly.
599511	Fixed: When submitting a secret access request with a custom duration, start values that are in the past are no longer permitted.
601706	Fixed: Intermittent Azure message loss. Implemented retry logic for publishing to Azure service bus queues.
602389	Addressed performance issues by optimizing database handling to resolve high deadlock rates (over 8,000 per hour) affecting the tbSecret and tbUser tables under heavy load.
603681	Fixed: Resolved a password display Issue (with "comment required" enabled) where, after waiting on the Overview tab for 5+ minutes, the password was displayed as [object Object] instead of prompting for a comment again. Users are now correctly required to re-enter a comment when accessing the password.
603721	Fixed: Enhanced Resilient secrets log text information and added operation progress percentage estimation Fixed issue where Resilient secrets operation was not interrupting on operation timeout
603779	Fixed: An issue with category and report permissions showing 0 items when permissions are assigned to users.
605053	Fixed: Heartbeat and password reset failures. Added more support for expired AD account password changers. Secrets that use an AD privileged password changer to rotate the password for an expired AD account will successfully complete the rotation process. Previous behavior involved rotating successfully and then failing the verify step, resulting in the new password not being saved on the side. Subsequent heartbeats may fail for the secret since the account is expired. Password Changes using a secrets own credentials may fail as well.
607434	Fixed: Discovery analysis SQL timeouts. The query that populates the discovered account metrics has been made more efficient. It should no longer have timeout issues.
608342	Fixed: PRA launcher shows on favorite and recent panel.
608395	Fixed: Columns that should have been hidden were selectable in the column selector. If selected, they would (incorrectly) display until page reload. The conditionally available columns are now correctly set visible or hidden in the column selector.
612930	Fixed: Fixed issue where users could select HSM settings without the “Administer HSM” permission

Ticket	Description
614002	Fixed: Turkish not displaying correctly in email. Turkish characters should publish correctly in email HTML.
614465	Fixed: Tooltip location on the Launcher Configuration page.
616185	Fixed: Resolved an issue where users could add members to a migrated group in SSC via individual user modifications. Now, all membership changes must be managed in the Platform, ensuring proper access control.
616221	Fixed: In SSC the from email address field in email configuration settings is restricted to the secretservercloud domain and the TLD excludes .co.uk as a valid option. On premises instances will only validate that it is a valid email address format but will allow any domain to be input.
617344	Fixed: An issue with password that contains username and added a new item to the local-user password configuration area that optionally prevents the password containing the username.
617429	Fixed: Issue where an invalid version number could cause Secret Server to become unresponsive.
617445	Fixed: Updated command sets to no longer add extra spacing between lines, and added validation around comments in command sets, instead of auto-removing extra comments, to reduce confusion on save.
617607	Fixed: Discovery services grid did not sort. Added computer Services API endpoint so the computer services component now has paging and sorting.
618528	Fixed: Resolved an issue where secret policy settings were not properly inherited by secrets, causing discrepancies in the Approval page. Additionally, the "Language Resource Not Found: OnlyOptionViaPolicy" message has been fixed. Secret policy settings now correctly apply as expected.
618869	Fixed: An error with "Default Only" on RPC schedule on an active secret policy.
619554	Fixed: On-Premises instances with PRA will now get emails to Secret Server instead of the Platform instance.
620165	Fixed: Display to show .delinea.app when opting into a prod instance.
620268	Fixed: The api/v1/secret-extensions/web-secret-templates endpoint now returns templates that contain URL list fields as well as URL fields.
620338	Fixed: An issue with "minimum required character count" rules options containing an invalid choice.
621226	Fixed: Resolved an issue where repeated execution of Entra ID secret heartbeats would cause a "Headers too long" error.

Ticket	Description
621573	Fixed: When running in Platform, the breadcrumb link on the platform group and configuration page is now correct.
621935	Fixed: Resolved an issue where viewing a secret with MFA enabled incorrectly logged "Password Displayed" in audit entries. Now, the audit log correctly records the action as "View" when no other interactions occur.
622254	Fixed: Resolved a bug where—when Platform is integrated with Cloud and Open ID Connect Platform login is used—in some situations, the redirected Platform login page would be incorrect.
622479	Fixed: Error during opt-in in PIC for Europe region.
626465	Fixed: Audit with no notes. Secret policies should no longer create an empty audit log when modifying launcher settings but reverting changes before saving.
626702	Fixed: An issue with users not being re-enabled when logging in through Platform after being disabled by automatic user management.
627109	Fixed: Launchers filter was incorrectly labeled was "Template."
627246	Fixed: The field header example on secret import now wraps correctly.
627291	Fixed: The "All launchers" option of the launcher filter now returns all results as expected.
627619	Fixed: Changed database cleanup logic which was causing some heartbeat/RPC audit records for inactive secrets to be removed before the "Max Secret Log Length" was reached.
627650	Fixed: Addressed issue where an error would be thrown when editing a command set with an empty command field.
627731	Fixed: If an Entra discovery source is created in Secret Server, and Platform integration is configured with Inventory Forward enabled, there was a bug if deleting any roles from the Discovery Network View in Secret Server. It would cause Entra roles to show up in Platform inventory.
628439	Fixed: Corrected a typo on Launcher Mapping page.
629517	Fixed: Resolved an issue from the previous update where toggling an Active Directory account's expiration status could prevent verification after a password change.
629584	Fixed: An issue with the password compliance check notification on a secret.
630728	Fixed: A bug where saving an approval method for a secret does not persist correctly.
631133	Fixed: An issue introduced in engine version 8.4.47 where AD privileged password changing would erroneously report failure for accounts that had null values for the "accountExpires" attribute.

Ticket	Description
632269	Fixed: Secret Server API endpoint /v1/secrets/{ID}/settings now responds with TOTP values if conditions are correct.
632693	Fixed: A User who has only the List permission on a secret will no longer get an access denied redirect upon clicking the launcher icon. They will now see a descriptive error message instead.
634286	Fixed: Issues with dropdown options causing enum values to be displayed for the Secret Security Approval Type so that correct localized strings are displayed.
634484	Fixed: Excessive CPU usage by correcting the SessionKey parameter to varchar, eliminating implicit conversion.
635135	Fixed: The "Ignore permission errors" checkbox is now available without a page refresh.
635550	Fixed: Addressed erroneous exception in the background worker when updating valid redirect URIs.
637136	Fixed: Do not include azure domains or inactive AD domains in group-type precheck.
637139	Fixed: Users missing their ExtendedUserMapping will register as a warning in the precheck instead of an error.
637373	Fixed: Corrected regression where secrets were counted twice in some scenarios. Secrets grid count functionality restored. Count ("# Items") is the sum of the number of first-child subfolders and the number of secrets in the current folder.
637690	Fixed: Incorrect GUI label. Updated Log Level filter label from "Site" to "Log Level."
638073	Fixed: A bug that prevented the secure-Platform-access step in the PIC from auto-skipping.
638238	Fixed: Fixed NG0203 error preventing folder selection dialog from popping up .
638317	Fixed: In the Data Sync step of the PIC, a new column (pre-check) was added to the 'Add exclusions' and 'Select data' dialogs. In the 'Select data' dialog, you may no longer select and synch a group with a pre-check error.
639151	Fixed: Resolved issue with PostgresSQL password change functionality.
640235	Fixed: Corrected a regression which caused the secrets grid to show "999,999,999 Items".
640554	Fixed: LimitedMode no longer blocks functionality related to AD sync, creating and editing secrets, importing secrets, use of web services.
640601	Fixed: Grid now adds the file extension when it does not exist, so files are properly downloaded as .csv

Ticket	Description
640808	Fixed: Request force checkout button is now displayed while the secret is in a pending status and the request force checkout feature is enabled
641566	Fixed: The dates of tbPlatformIntegrationStep were either not being set or being reset in certain scenarios. This has been fixed for all of the steps except the Unification step which will be fixed in a separate card.
641879	Fixed: Replica now handles event where Disaster Recovery feature deletes folder(s) assigned to Automatic Export by disabling Automatic Export.
642042	Fixed: A PIC precheck error was added when a username in Secret Server does not follow the regular expression rules defined in Platform.
642286	Fixed: Addressed issue that could cause errors forwarding computers to inventory.
643304	Fixed: The status of the customize branding step in the PIC no longer resets from Skipped to Ready to start when the page is refreshed.
643677	Fixed: AFT token validation errors will now return an error code instead of just a 500 status code with no body.
643841	Fixed: A fix was made for the opt-in step of the PIC if the user refreshes the page once the opt-in process has begun.

Improvements

460275	Improved: Updated session recording logic to allow already running processes to be recorded from after the point of the session launch if said process was listed in the "Additional Processes" list for the launcher.
546156	Improved: Logging in when MFA setup is required now immediately redirects the user to configure MFA.
561827	Improved: Changed methodology for handling the domain field in RDP Proxy credentials to avoid unnecessary Kerberos TGT DNS lookups.
566484	Improved: Reports page size minimum has increased to 60.
569459	Improved: On the SAML Identity Providers page, we display the date and expiration status of the Identity Provider configured certificate. We also log if an expired certificate is used for a login in the SAML log. An explanation of why expired certificates will continue to work has been added to the Identity Providers page.

575905	Improved: Updated scanner template creation UI to combine both OU Input templates and non-OU Input templates into the same dropdown in categories.
580253	Improved: No dynamic update for active sessions. Active launchers section on secrets now updates every 30 seconds to show an updated list of active launchers.
582378	Improved: Updated grids using timestamps to use datetime in order to properly respect user preferences.
586608	Improved: Password validation failures for dictionary now indicate, "Dictionary words including common number substitutions."
593543	Improved: Removed time zone tooltips from reports to reduce confusion when time zones are set by the report.
594323	Improved: Empty pinned folders now inform users of the empty sections.
595169	Improved: It is no longer possible to delete the last step from a workflow. Existing workflows with no steps will now display a default starting step when opened to edit.
603721	Improved: Resilient secrets log text information and added operation progress percentage estimation. Fixed: An issue where resilient secrets operation was not interrupted on operation timeout.
605210	Improved: Performance of discovery scanner delete. Increased timeout to 24 hours, lowered isolation level where possible, and added logging for each delete operation.
609101	Improved: Added a non-configurable 30-second secret password timeout to improve security and reduce stale password issues. The timeout applies to: Show password—hides after 30 seconds (previously visible forever). Copy password—password value cached for 30 seconds only. Copy password icon clicks after that will trigger a fresh API call (to reduce stale password conflicts). Note that this does not affect the value that was already copied to the clipboard, only what will be copied when the user clicks the copy password icon.
610739	Improved: Performance improvements were made to the "Shared with me" Secret View, and the "Browse All Folders" view for customers with many folders in a highly nested structure.
611190	Improved: In the secret template list field, list and URL list now have their "dispose for display" boxes checked by default to denote the data's plaintext status. The expose for display control is also disabled so that it can not be unchecked by accident.
611573	Improved: Updates to Discovery Scan Status Report Query.
612177	Improved: Error handling for Platform credentials that become invalid.

612739	Improved: A new setting, "Disable Legacy Bookmark Pages," has been added the admin/user experience section. This setting is false by default. When true, the legacy bookmark pages used by legacy WPF will be disabled. This allows administrators to disable the setting and ensure they do not have any of these legacy clients that require it. This setting will default to disabled in a future release.
614508	Improved: Added the ability to view the Active Directory group type. This is displayed under the General tab of a group. If a group does not have a type, it will display as a hyphen. Otherwise, it will show one of the following: Global, Universal, or DomainLocal.
615870	Improved: Improve reliability when specifying the Platform Redirect URL.
616620	Improved: Secret export will now audit the current "Export" action and a new "Export retrieved" action to indicate that the user retrieved the file. Previously, you could close the browser window before retrieving the export file.
618004	Improved: Through the user experience settings, a user can use a new "COMMENT" audit action to separate the VIEW action of a checkout (or ITMS) protected secret from the required comment.
619399	Improved: Added an option on the Windows Service Discovery Scanner to use the Pre-Windows-2000 user logon name for discovered Windows services.
619512	Improved: Event pipeline set-custom-value tasks can now increment or decrement pipeline variables by custom values.
619515	Improved: Added additional group type validation (empty group types and DomainLocal group types) for the Data Sync step in the PIC. If empty group types are detected, users are prompted that there are empty group types and are instructed to run the directory services sync. For any DomainLocal groups found, an error message appears in the pre-check table within the Data Sync step stating that DomainLocal groups are not supported.
620202	Improved: Added additional response information when autofilling values.
621513	Improved: Grid columns are now all set to a fixed width at their current width when a user resizes any column. This makes resizing columns easier.
626041	Improved: Modifications to build pipeline to precompile, copy and overwrite precompiled assets to webroot folder. Packaging and installer remain as they were prior to PR.
626668	Improved: With Platform Integration, support for the setting "Create Groups during synchronization" is completely deprecated. Now, all Platform native groups will be created automatically and any directory groups through Platform need manual linking.
626881	Improved: Updated discovery import rules to prevent duplicate account creation and unintended unlinking of service and Active Directory accounts. Added broader test coverage, including integration tests, to ensure correct matching, unmatching, and unchanged behavior when re-running imports.

627169	Improved: Updated discovery analysis layout to emulate dashboard styles and to better accommodate large datasets.
627297	Improved: Added a new date and time range filter to Session Monitoring.
627303	Improved: Added a new state flag to indicate whether the Delinea enablement code has been entered.
627304	Improved: Added a new state flag to indicate the customer has completed the Platform integration.
627344	Improved: The inbox template editor now includes options to select message properties by selecting which message. This helps clarify that only message properties on the targeted message are available to merge into the template.
627607	Improved: Added Computer Services API endpoint; Computer Services component now has paging and sorting.
628034	Improved: Removed Transloco dependency.
628761	Improved: Added request force checkout feature
628801	Improved: Delinea's new code signing certificate is now trusted when validating upgrade versions for the future. Protocol handler releases before 6.0.3.34 will upgrade to 6.0.3.34 before newer versions to ensure the auto upgrade process will work.
631776	Improved: The application picker that appears when both Secret Server and Privilege Manager are installed has an updated design. This slightly increases the speed of the login process.
631811	Improved: When clicking the option inside of a user's secrets tab you will be redirected to the Secret Templates settings page that lists all of the secret templates.
633054	Improved: Optimized memory management to reduce latency buildup in the US BGW, preventing performance degradation over time. Restored ASP.NET metrics for better visibility into garbage collection and CPU usage.
633244	Improved: Additional logging added during the enabling of unified mode in the PIC .
633996	Improved: PowerShell Core (6+) support added to the scripts page.
634022	Improved: A new bulk secret action was added to allow for updating a field across multiple secrets. The value can be prepended, appended, or replace the existing value.
634158	Improved: Improved memory utilization of the background worker in Cloud.

634668	Improved: Updated Secret Server to use the new shared clipboard service. Updated shared clipboard service to use fallback when on non-secure contexts. Removed clipboard plugin use from clipboard service.
635475	Improved: Enhancements to ticket system configuration, allowing for more nuanced interactions between ticket validation and require approval flows.
635732	Improved: Added PasswordTypeIds as a filter on the api/v1/secret-templates-list endpoint.
635803	Improved: Only the users that are migrated are validated.
635963	Improved: Added an Advanced Configuration setting that will restrict the amount of secret Item History that will be replicated due to the sheer size of that table with relation to the value of replicating a history beyond a certain point. The default number of item histories to be replicated is set to 3.
635970	Improved: Updated libraries to achieve more control when inter-operating with Platform users.
636130	Improved: When enabled, "Show secret icons" in User Experience will display icons for secrets in grid, card, and detail view.
638653	Improved: Secret components on Dashboard (Favorites, Recent etc.) will now only cache Secret passwords for 30 seconds on copy to clipboard, as in other Secret views.
638678	Improved: Administrators can configure the DCM experience for non-business users
638730	Improved: Updated Platform Upgrade Center TOTP message to clarify which users TOTP information will be migrated.
638911	Improved: Removed legacy CustomLauncherEdit/View.aspx pages
638915	Improved: Legacy SimpleHome.aspx page removed
638928	Improved: Removed legacy secret access request aspx pages.
639164	Improved: The legacy license aspx pages have been removed.
639851	Improved: Added caching to improve container configuration, API performance and reliability.
640213	Improved: legacy discovery, secret import, and script pages now have a note indicating they will be removed in a future release.
640556	Improved: Admins of systems exceeding licenses limits will be notified via UI banner.
640783	Improved: $SECRETID / $[x]$SECRETID are now available for scripting

642250	Improved: Platform Integration can no longer be disabled when unified mode is enabled and all users are sourced from Platform. This prevents users from locking themselves out of their instance. If Platform Integration can be disabled, a dialog warns the user of the consequences.

Known Issues

- After upgrading to version 11.8, users might see "Language Resource Not Found (admin.external-secrets)" on the Secrets tab. This was caused by old language files that were cached and not updated for the new menu item. The solution to this issue is to:
  - Clear their cache for the Secret Server URL or for their entire browser
  - Incognito can also be used if the cache can't be cleared
  - A "hard refresh" (CTRL + Shift + R) that bypasses the cache does not fix this issue

  Refer to the following support article for more information.

Secret Server 11.7.000061 Release Notes

Release Date: On-premises: February 10, 2025

Version Information

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.43.0

Protocol Handler: 6.0.3.33

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Improvements

548904	Improved: Performance updates for SSH Proxy when using an SFTP subsystem connection.
558857	Improved: New UI for selecting restricted lists on teams. Allows user to select and manage more than 60 lists.
560728	Improved: The activity items in the session recording list have been simplified and extended details now appear below the video when a user clicks.
585624	Improved: TOTP history icons on the secret settings tab are now always visible and do not require hovering to see.

595555	Improved: Downloading event subscriptions now includes the target column in the .csv file.
601841	Improved: The API call to create a group now has a flag to control behavior for pre-existing group names. The flag specifies whether the call should fail creating groups or if the API should generate a unique name by appending a suffix as it did before.
602146	Improved: UI of Platform Migration Center has been localized.
602588	Improved: Added additional logging to clarify the reasons why a secret was skipped for RPC.
603971	Improved: Report editor SQL runner now updates columns when the SQL columns are updated.
607689	Improved: Accounts with a heartbeat failure status on an associated secret, displaying an error chip in the network view, now display a "heartbeat failed" chip and message on the details tab.
609150	Improved: Added support for French (Canadian), Italian, Dutch, and Polish.
609271	Improved: Updated the API to handle the "Quote Tokens" setting for PowerShell script secret dependencies.
609274	Improved: Changed default for timeout to Platform from 100 seconds to 5 minutes. Made this into an advanced configuration option in case it needs to be adjusted in the future.
610216	Improved: Details pages for secret-associated discovery accounts now include localized detailed messages below the "heartbeat failed error" chip for all heartbeat failure statuses.
610768	Improved: Added sorting to the directory account grid under the discovery network view.
613946	Improved: Added a user preference to underline links.
614507	Improved: Added a text instruction for Step 2 of the Platform Upgrade Center.
615583	Improved: Favorite and recent added as login home options.
615589	Improved: Stub secret API endpoint will now include which fields map to the password changer.

615939	Improved: Secret Server now contains support for PostgreSQL account secrets. PostgreSQL account secrets can participate in heartbeat and RPC operations.
615740	Improved: Selecting a filter will now announce the filter description after reading the label (accessibility).
616742	Improved: Upon selecting a single select filter the selected option is now associated and announced (accessibility).
616744	Improved: Remove filter button now uniquely announces which filter will be removed instead of just "remove filter" (accessibility).

Fixed Issues

521501	Fixed: Old sessions still showed in "Active Session" dashboard. Session recording report now shows real-time active session result when navigating.
545095	Fixed: In a secret's card view, under the shared users section, the initials allowed into the small colored Icon for each user was reduced from three to two, as some combinations of three letters were long enough to overflow the icon.
548022	Fixed: Updating roles on a group will no longer impact secret template permissions. Prior to this change, the TemplateCreateSecret role would show on the roles tab and get removed upon update of roles.
548815	Fixed: REST API doc for getting token now indicates that the user name can include the domain.
548967	Fixed: Discovery take over created secrets with the same name even when "Allow duplicate secret names" is set to false.
584024	Fixed: Multi-line text will now formats correctly when exported to a .csv file.
592485	Fixed: A check was added to verify that at least one permission from Secret Server is available in Platform to ensure users are not locked out during migration.

594281	Fixed: There was an issue where the ITSM integration script failed to run, resulting in an 'Object reference not set to an instance of an object' error when the 'Ticket System Publicly Available' option was disabled and a specific site was selected. The script now executes properly regardless of this setting, ensuring ITSM integration works as expected.
595576	Fixed: Bulk reactivation of disabled secrets that have deactivated templates now works, consistent with activating them one by one with a disabled template.
603969	Fixed: Report editor layout clipping issues.
604097	Fixed: Increased the timeout period for discovery scans to two days, allowing longer-running scans to complete without being canceled.
605349	Fixed: Resolved error that prevented a restricted user from updating lists on a secret.
605427	Fixed: Addressed an issue where customers without outbound internet access might be unable to generate session recordings.
606973	Fixed: Updated SafeReportSqlChecker to prevent queries using "sysdatabases" and bypassing table exclusions by prepending "dbo."
607694	Fixed: Addressed an issue where some computer accounts showed a "computer scan error" chip in details but not in the network view grid.
607730	Fixed: Resolved a resilient secret issue where in-progress replication log summaries were truncated mid-sentence during large dataset replication causing the replication state to remain stuck as "partially successful" even when the process completed successfully. This fix ensures smoother replication workflows, even for environments with large datasets.
608089	Fixed: Corrected the column label in the Discovery Network View. Previously mislabeled as "Full Name," the column now correctly displays as "Account Total" for improved clarity and accuracy.
610542	Fixed: Addressed a timing issue that could cause localization keys to show instead of the actual text in Platform.
610595	Fixed: Addressed an edge case where computers from a disabled discovery source would still appear in the Platform inventory.
610621	Fixed: UserId update (instead of name) for internal vault accounts.

611124	Fixed: User's enabled status is no longer determined by licensing and permission during sync from Platform to Secret Server.
611863	Fixed: Azure Active Directory renamed to Microsoft Entra domain on the directory services grid following Microsoft's renaming guidelines.
612788	Fixed: Addressed issue with being able to correct expired Azure AD domain credentials for clients that are not yet using "sync secrets."
613129	Fixed: Corrected a typo on add scanners filter localization that showed a duplicate option instead of "Show all scanners."
613755	Fixed: Directory services log now indicates Microsoft Entra instead of Azure AD.
614044	Fixed: Force check-in now allows the user to get into a secret when the password change is failing, canceled, and retried.
614742	Fixed: Updated filter for secret favorites is now applied properly.
615582	Fixed: When using Platform with Secret Server, an Active Directory user using a connector that is removed from Platform could be re-enabled in Secret Server.
616739	Fixed: The "Add item" button on top of grids is now labeled "Add filter."
616745	Fixed: The multi-select filter is now properly defined as role=menuitemcheckbox and the search announces how many are selected (accessibility).
626850	Fixed: An issue where secret policies configured with the "Standard" approval setting (where editors and approvers do not need approval) were not applying correctly. Instead, the Require Approval Type field incorrectly displayed as No Approval Required, overriding the expected policy behavior. The policy now correctly applies to secrets, ensuring that approval requirements reflect the assigned policy settings.

Known Issues

None at this time.

Secret Server 11.7.000060 Release Notes

Release Date: On-premises: January 24, 2025

Version Information

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.43.0

Protocol Handler: 6.0.3.32

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

614742	Fixed: Updated filter for secret favorites is now applied properly.
615582	Fixed: When using Platform with Secret Server, an Active Directory user using a connector that is removed from Platform could be re-enabled in Secret Server.
616739	Fixed: The "Add item" button on top of grids is now labeled "Add filter."
616745	Fixed: The multi-select filter is now properly defined as role=menuitemcheckbox and the search announces how many are selected (accessibility).

Known Issues

None at this time.

Secret Server 11.7.000049 Release Notes

Release Date: On-premises: November 26, 2024

Version Information

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.39.0

Protocol Handler: 6.0.3.31

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Improvements

537407	Improved: Sorting by a secret field for which there are no secrets now indicates such instead of just displaying an unknown column.
541150	Improved: When the Radius two-factor authentication login page loads for Secret Server, focus is now set to the password box, so you do not have to click it before typing.
545215	Improved: Unix discovery sources are now enabled by default when created successfully.
551651	Improved: Secret template fields can now be passed-in as arguments to ticket system scripts.
554428	Improved: Notification messages now disappear from the unread screen once marked read.
554463	Improved: Audit logging for user and group changes.
569648	Improved: Updated secret export to make it more resilient for larger environments.
572584	Improved: Added security hardening report and warnings to discourage or prevent password type changers that rely on JScape libraries due to security vulnerability.
575586	Improved: Upgraded audit notes for secret RPC settings changes. Added RPC_SCHEDULE_UPDATED and RPC_AUTOCHANGE_UPDATED secret audit actions.
575589	Improved: Disaster Recovery feature now replicates Open LDAP domain sync settings.
578673	Improved: Localization updates on the scripting pages.
578682	Improved: Inbox templates, rules, and resource grids converted to latest component grid.
580088	Improved: Azure Active Directory domains now use sync secrets yet remain backwards compatible for existing Azure Active Directory domains that still directly store the domain's client id, client secret, and tenant ID.

580662	Improved: Expanding the folder row in a secret grid informs the user inline if they lack access to see the folder owners instead of redirecting to a full access denied error page.
582196	Improved: Added a setting to redirect all users to log in through Platform integration settings.
584486	Improved: Removed case sensitivity from scriptable discovery lookup calls to find OUs for a computer.
584579	Improved: Site sorting is now in alphabetical order in dropdowns, lists, and more.
584837	Improved: Secret audits now have the ability to filter by audit action type via a multiselect filter.
586768	Improved: SQL editor dialog is now the full viewport height and width.
586770	Improved: Discovery accounts bulk action checkboxes removed on some pages where they were not necessary
587667	Improved: Secret Server custom URL is now being sent to Platform as an accepted redirect URL.
588435	Improved: Converted grids on three Automatic Export pages (Audit, Log and Storage) to thy-data-view for consistent look, feel, and functionality, such as allowing Notes field to be fully viewed in right panel on row click rather than via a tooltip.
590053	Improved: We now only show synchronized directory service groups in the list if active.
590073	Improved: OU column is now available on Discovery Network view.
590111	Improved: Discovery log and computer scan logs filter updated to latest component for accessibility.
590933	Improved: Discovery now has full detail pages for Entra entities, and they also appear in the new larger panel.
591264	Improved: Discovery network view now opens a larger panel with more information including the last error message. The large panel supports wider screen sizes as well to give side-by-side viewing of the grid and panel.
591933	Improved: Search performance improved for typical users.
592094	Improved: Bulk sync now does one insert SQL for a list of users and not one per user.
592264	Improved: Added a precheck to ensure we don't try to migrate native/hybrid users that are missing their extended mapping, which likely would have resulted in strange duplication behavior
592499	Improved: Groups created in Platform now default to being set as "Migrated" for their migration state.
592713	Improved: Category list converted to latest grid component.

592715	Improved: Azure AD Domains now use sync secrets. As part of this, searching for a suitable secret template to serve as the sync secret must have Client Id, Client secret, and Tenant Id fields mapped for its secret type. This applies to the Azure App registration secret template out of the box.
593909	Improved: Attempting to log into an application account through the UI will no longer add a successful login audit event for that user. Successful and failed login attempts are still logged.
595158	Improved: Secret Server reports can now be saved as a shortcut on the Platform desktop.
595573	Improved: The opt-in step allows a user to add a new Platform tenant. It is the first step to integrate from Secret Server to Platform. This step is a part of the redesign of the Easy Move integration tool.
595730	Improved: The team-members list page has been updated for easier adding and removing of members. The entire domain inclusion option has been moved to the team general tab.
595732	Improved: Roles mapped to the "All Vault Users" group in Secret Server are now be mapped to the "Everybody" group in Platform after migration runs if the "All Vault Users" group is selected for that migration.
595945	Improved: Report list page heading is now semantically correct.
595948	Improved: Secret quick-access page heading is now semantically correct.
596411	Improved: Updated Platform migration prechecks by adding new information precheck type.
596413	Improved: QuantumLock audit grid updated to latest component.
596695	Improved: Updated BouncyCastle.Cryptography package to a non-vulnerable version.
596927	Improvement. Added the ability to prompt for site selection when launching an SSH session through a DE proxy.
597484	Improved: You can now pick values less than four hours in the minimum Platform sync configuration.
597621	Improved: When on prem has a cluster issue, the license pages are now accessible from any web node.
599089	Improved: A new user experience setting has been added called, "Separate Secret Audit for Comment." When this is true, a secret that requires comment will have an additional audit entry with an action of "Comment." This allows a secret to be commented on and checked out but not viewed. Without this setting the secret audit will show a "View" action with the comment text and then the checkout. Now you will see "Comment," "Checkout," and then "View" only once they have actually viewed the secret.
599421	Improved: Creating a new Active Directory discovery source is now full page instead of in a modal.

599481	Improved: ITDR Service Accounts are now handled via messaging in Secret Server.
599717	Improved: Session monitoring routes were updated to no longer include /admin.
599937	Improved: Converted the disaster recovery audit to the new grid component.
600029	Improved: Converted the disaster recovery Log to the new grid component.
600137	Improved: Platform users metadata replicates fully to a disaster recovery replica instance.
600425	Improved: Converted directory services domain audit to the new grid component.
600639	Improved: Converted the export-import settings audit page to thy-data-view.
600664	Improved: For Secret Server Cloud customers integrated with Platform, disabled the underlying "Create Groups During Synchronization" setting, which was previously able to be enabled, and already disabled for the vast majority of customers. This setting would automatically create domain groups during synchronization, which we now require to be specifically created. Platform Cloud groups are already automatically created and this behavior is unaffected.
600797	Improved: Converted the secret-erase list grids to the new grid component.
601395	Improved: Discovery pages are now accessible at /discovery instead of /admin/discovery. This change also decreases the pack size of the admin and discovery modules.
601455	Improved: The toggle expand and favorite star in the global right panel widget now properly have aria-labels, aria-controls, and aria-expanded tags.
601456	Improved: Service users created in Platform are now mapped to application accounts in Secret Server.
601459	Improved: ITDR account created via OAuth token or messaging from identity.
602245	Improved: Updates to the opt-in flow: Platform region field is now read only by default, and regionEditable=true|false query parameter is available to override the default.
602371	Improved: Added security hardening report and warnings to discourage or prevent password type changers that rely on JScape libraries due to security vulnerability.
602443	Improved: Users can now navigate to and from licenses page to clustering pages.
602663	Improved: Resilient secrets now handle additional conflict scenarios between the source and replica.
602778	Improved: Updated IBM dark mode left navigation for better accessibility experience.
603115	Improved: Reduced Redis calls for many operations for performance purposes.

603328	Improved: Added logging to capture specific failure codes from Entra ID when performing heartbeat.
603363	Improved: Refresh button was added to the migration audit tab of Platform Upgrade Center.Improved: Filters implemented on migration audit tab of Platform Upgrade Center.
603364	Improved: A filter of object type was added to the log tab of the Platform Upgrade Center.
603978	Improved: Password changers grid now includes columns for can edit and Secret usage count. Some additional filters were also added.
603980	Improved: VaultBroker updating a URL requires a valid connection with the Secret Server instance before allowing updates.
604471	Improved: Added security hardening report and warnings to discourage/prevent password type changers that rely on JScape libraries due to security vulnerability.
604568	Improved: Updated UI to only make one call to the "enable unified mode" endpoint.
609745	Improved: Performance of launcher session cleanup
609923	Improved: Added a check to Platform configuration in Secret Server that prevents synchronization of Platform data (users, groups, roles, etc.) to Secret Server while migration from Secret Server to Platform is running.

Fixed Issues

451250	Fixed: Addressed an issue where, when editing a user, the Duo multifactor authentication option would be missing when Radius and Duo had already been configured and the user had the Administer Users permission. Fixed: Addressed an issue where saving a User with the Duo Multifactor authentication option would throw an error when Radius and Duo had already been configured and the user had the Administer Users permission.
477012	Fixed: "What Secrets have failed heartbeat?" no longer shows secret with a failed heartbeat when their template has heartbeats turned off.
513832	Fixed: Sorting issue on the Groups tab in user management
514188	Fixed: Issue with MobaXterm launches and multiple credential-save prompts.
517513	Fixed: Not being able to add XML files where the key file folder is located because DPAPI read all XML files in that folder and did not find the correct and expected format, which caused an error and disconnected from the Secret Server instance.
541011	Fixed: Guide dialogs now properly focus the guide and trap tab.
543702	Fixed: Session recording processing no longer causes a false session recording view event

544916	Fixed: Corrected Cipher Suite connection issue to AWS EC2 instances with public keys only.
544998	Fixed: SSH key expiration in label description is displayed correctly now.
547577	Fixed: Event subscription language resource corrected for "Engine" and "Export Secrets" events.
561895	Fixed: Workflow Approval email "View this item" contained incorrect link, not directing users to a page where they could approve the request
563019	Fixed: "Minimum Required Character Count Rules" on password requirements reverts when updating other things on password requirements.
563367	Fixed: Addressed an issue where the video recording tab would display for session recordings that were keystroke only.
563529	Fixed: UI issue on report schedule page where unchecking "send email" for report distribution blocked saving.
567824	Fixed: SAML Log no longer opens a dialog and a preview panel.
569536	Fixed: Issue were using Secret Server SDK 1.5.7 or earlier after upgrading to 11.7 gave an "Object reference not set to an instance of an object." error when trying to retrieve a secret. The fix appears in version 1.5.9.
570798	Fixed: In the SDK Client Management > Client Onboarding Page, when viewing a user with an onboarding key required, if the key is visible in the side panel and you select another user with a key required, the key that is shown now updates to be the key associated with the most recently selected user.
571356	Fixed: Event queue not clearing. Adjusted the location of and query of the EventQueue cleanup process.
572635	Fixed: RPC errors for SAP template secrets, which were occurring with SAP "systemuser" user types, even when using a privileged account.
575347	Fixed: IBM code editor resources properly shared to allow editor to load.
575767	Fixed: Removed Thycotic.Ihawu.UnitTests.Web and Thycotic.Ihawu.UnitTests.Web.Rest from repository, which have not been active since 2018.
575896	Fixed: Enabled Entra ID Password Changer to appropriately handle heartbeat on accounts where MFA is applied through a Conditional Access Policy.
576164	Fixed: Added DelayBackgroundStartupMilliseconds to fix a race condition during the PKCS #11 login after integrating with the Entrust HSM. This will delay the background workers so the web node can log in to the PKCS #11 library first.

580552	Fixed: Group sharing with Secret Server secrets for groups would not trigger a sync for all existing users in Secret Server.
581752	Fixed: Custom report names with double quotations in them no longer throw an error when downloading a report to a .csv and will download successfully. The .csv will not contain the quotations, but they will remain in the name on Secret Server.
581802	Fixed: Some edge cases related to Platform Federation could result in a group losing its members in Secret Server.
585612	Fixed: A duplicate role assignment during migration was fixed so that the migration matches what was in Secret Server .
586300	Fixed: When a date is downloaded from a grid, it now properly formats according to the selected download date format.
586526	Fixed: Card and grid mode "last connected" field now shows the correct time and match.
586528	Fixed: Resolved an issue where attempting to use a Session Connector launcher with "Open with Remote Access" would throw an error when attempting to launch
587596	Fixed: NVDA now displays the correct labels for the tree component.
587768	Fixed: A bug where the password changing field of discovery rules would not update. The password changing settings now persists for all discovery rules.
588849	Fixed: Addressed Null Ref errors in SyncSessionToPlatformMessage.
588873	Fixed: Corrected impacts on user access by enabling or disabling DTC.
589002	Fixed: Token name-wrapping issue fixed on secret dependency dialog.
589194	Fixed: A bug where the source field of discovery rules would not update. Source settings now persist on all discovery rules.
589245	Fixed: When Secret Server was integrated with Platform and a federated user logs and connects to an AD user in Secret Server, the Platform sync could remove AD groups (from Secret Server AD Synchronization) because that was not a supported configuration. Now, we prevent the removal of AD groups from a Secret Server user during Platform synchronization if the connected Platform user source is Federation. Platform synchronization of groups when a Platform user source is Active Directory/connector and the Secret Server user is an Active Directory user will work as before. We are doing this as harm reduction until the configuration in Platform is set up to be compatible with supported scenarios.
589332	Fixed: Creating an access request with custom dates or times displayed an incorrect warning or had incorrect dates or times when approved.

589821	Fixed: Addressed a very rare edge case where a synchronized AD or Azure AD group flagged as "SynchronizeNow" that is also inactive could block synchronization from running indefinitely.
589824	Fixed: Issue where Entra ID accounts could be mistakenly identified as directory accounts in the discovery network view.
589974	Fixed: Issue that prevented creating empty discovery sources.
589977	Fixed: Addressed red banner issue on session monitoring page when using v2 grid filters.
590058	Fixed: Azure AD synchronization did not handle groups with null ADGuid fields. Added filter criteria in Thycotic.ActiveDirectory to filter out cases causing errors.
590449	Fixed: An issue where active users in inactive domains (an exceedingly rare edge case that we do not natively support) caused groups to fail importing valid users.
591870	Fixed: Migration work now considers users that have come from Platform (either Platform Native or Hybrid users) when migrating. It was indirectly ignoring them before under certain circumstances
591954	Fixed: Issue with connections remaining open with Windows local account RPC.
592169	Fixed: A duplicate group was created when Platform syncs back to Secret Server after a group is migrated.
592877	Fixed: The product link for installing browser extensions led to the documentation home rather than the proper page. Clicking OK now takes you to the correct page, "Installing Browser Extensions" on page 707.
592981	Fixed: Password dictionary uploads no longer fail due to Unix line endings.
593023	Fixed: Saving ticket system as publicly available now saves properly.
593302	Fixed: Changed Entra ID discovery scanner so it returns UPN for account name instead of display name.
593348	Fixed: Entra ID discovery can now identify members of a role who are assigned to that role through a group.
593359	Fixed: Issue that prevented Entra ID Roles from being automatically scanned by discovery.
593531	Fixed: In Platform, the browse all link in the folder tree that appeared after 1000 folders were shown was missing /vault in the URL.
593702	Fixed: An issue where the Entra ID discovery scanner flow could not be applied from the dialog that appears when creating an Entra ID discovery source.

593947	Fixed: When you launch a secret that requires checkout, you are no longer redirected to the secret detail page.
594073	Fixed: Discovery scanner text had a typo in the scanner CID notation example text.
594094	Fixed: An issue that prevented a resilient secrets (DR) replica from updating Secret Server after the source has been updated with 11.7.31.
594680	Fixed: Typo in Secret Erase Request.
594732	Fixed: DE Vulnerabilities cleaned up and verified removed.
595541	Fixed: Typo in bulk record selection dialog.
595553	Fixed: Some single-edit dialog fields were not properly linked to their label.
595556	Fixed: Inbox breadcrumb was going to a 404 error and has been removed.
595758	Fixed: Secrets with checkout and require comment will now have a combined option in the secret grid options menu for a secret. You can configure these to be separate as prior to this release in admin/user experience.
596124	Fixed: In the SDK Client Management > Client Onboarding Page, when viewing a user with an onboarding key required, if the key is visible in the side panel and you select another user with a key required, the key that is shown now updates to be the key associated with the most recently selected user.
596363	Fixed: Directory services will no longer appear in search when running in Platform.
596370	Fixed: Discovery computer scan results now properly defaults to showing the last hour.
596663	Fixed: An issue where certain usernames were unable to automatically sudo with SSH Proxy.
596721	Fixed: Resolved a case where event pipeline activity records were not being cleaned up according to the retention settings.
596851	Fixed: Secret template fields grid in reorder mode had an empty column heading.
597021	Fixed: Resolved an edge case of unmigrated users from Secret Server to Platform and ability to change usernames.
597482	Fixed: Addressed issue where a secret policy with an inactive user in an approver group could cause downstream issues when modifying related secrets.

598013	Fixed: Addressed a case where URI's were compared before normalization and canonicalization potentially leading to over matching against the approved list. Added additional validation that the downloaded installer's batch file was in the expected format.
598083	Fixed: An issue where failed video conversions would not clean up temp files.
599034	Fixed: Resolved accessibility issues on workflow and custom SSH cipher suites.
599078	Fixed: Corrected validation on tenant customization page.
599386	Fixed: Issue with updating workflow step names.
599798	Fixed: Folder searches now work when search text is in uppercase.
599966	Fixed: Platform/SSC to Onprem SS DR was unable to login as a Platform user. Added code to copy the custom URL from Secret Server every five minutes and send it over to platform as a valid redirect URL
600132	Fixed: An issue where users were unable to create secret policy via API with jumpbox site ID not set.
600415	Fixed: Entra ID heartbeat can now handle accounts that are pending MFA Enrollment. Added enhanced error handling to Entra ID account heartbeat.
602238	Fixed: IBM code editor resources properly shared to allow editor to load.
602673	Fixed: Two logic errors (one in the Easy Move path and one in the External User Mapping path) that were causing a null ref when trying to create a new user incorrectly. Domain users that are disabled by AutomaticUserManagement will no longer incorrectly cause a duplicate local user to be generated during migration and no null ref audit will be generated.
603148	Fixed: Addressed an issue where an exceptionally large foreign key in tbStatusMessage could cause errors when inserting records.
605472	Fixed: Addressed an issue that could prevent user creation and mapping of users from Platform when pre-existing users had been disabled by automatic user disabling.
610193	Fixed: Issue for creating vendor users when instance is already at maximum user licensed count.

Known Issues

None at this time.

Secret Server 11.7.000031 Release Notes

On-premises: August 20, 2024

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.33.0

Protocol Handler: 6.0.3.29

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

New Features

Entra ID Discovery

We are excited to introduce Entra ID discovery in Delinea's Secret Server! This enhancement expands our current discovery feature by adding support for Microsoft's Entra ID, alongside our existing AWS and GCP discovery types.

With Entra ID discovery, Secret Server can now scan Microsoft Entra ID for roles and users, importing users as secrets based on the Entra ID User Account template. This completes the suite of features necessary for Secret Server to discover and manage accounts from Microsoft's Entra ID.

Bug Fixes, Changes, and Enhancements

Bug Fixes

Fixed “Secret Erase” translation in some non-English languages.

Fixed a bug where distributed engines ignored WinRM quota limits.

Fixed a bug with running disaster recovery data replication from an older source to a newer replica.

Fixed a UI issue with discovery Import where the button would not respond due to validation against hidden fields.

Fixed an issue during Platform group synchronization where groups with long names would cause an error.

Fixed an issue so users and roles now always show in SSC, even if in unified mode, but still are hidden when using Platform.

Fixed an issue that prevented resilient secrets (DR) replica from updating Secret Server after the source has been updated with 11.7.31.

Fixed an issue to restore configurability of secrets associated with custom launchers.

Fixed an issue where enabling QuantumLock on a secret threw the error “The partner transaction manager has disabled its support for remote/network transactions.”

Fixed an issue where stored data growth impacted proxy sessions. The secret session table is now managed and part of the supported tables of the data retention feature. Secret session records are now truncated in accordance with the existing data retention configuration. Please make sure to review your organization's Data Retention “Max Record Age” settings.

Fixed an issue where the “All time” filter on the inbox might not show all results.

Fixed an issue where users with MFA enabled would be incorrectly sent to the home page on login, instead of the page they were attempting to access.

Fixed an issue where video conversion failed due to SQL deadlock

Fixed content security policy fields for frame-ancestors.

Fixed incorrect access checks concerning reports.

Fixed incorrect Secret search totals when filtering by multiple templates.

Fixed issue where the “su -id” command was failing when the user did not have access to view the password for the secret they were elevating to.

Fixed issue where the maximum log Length was not used to truncate the tbSystemLog.

Fixed issue with “What folder permissions exist” report. Groups with no active users now properly included on the report

Fixed main navigation alignment issues.

Fixed ServiceNow allowed status validation over distributed engine.

Fixed the “view detail” link on the user detail panel.

Fixed The folder tree is now updated when Unlimited Vault Access mode is toggled.

Fixed timeouts for large amounts of data—paging for user audits is now done in the database.

Fixed: “Minimum Required Character Count Rules” on password requirements reverts when updating other things on password requirements.

Fixed: A user that did not have the “view launcher password” role permission was unable to create a secret that had a required password because the password field was hidden.

Fixed: About page links not working.

Fixed: Added null checks for username.

Fixed: Added support for Cisco devices when using a question mark after the command or partial command. This allows Cisco to work as normal, while not allowing the blocked commands.

Fixed: Addressed an issue where a launcher type field that was replicated via resilient secrets would not function with all prompt-able field names.

Fixed: Addressed one scenario where a backend process that publishes session information would error.

Fixed: Adjusted secret overview tab to not use a banner for heartbeat failed.

Fixed: Adjusted Secret tab pending password change status to be a chip instead of a banner.

Fixed: Audit handler was missing the “View Configuration Unlimited Admin” permission as an option.

Fixed: Authentication errors are now 401s for API requests and in Platform.

Fixed: Broken “view detail” link on the user detail panel.

Fixed: Creating an access request with custom dates/times displayed an incorrect warning or had incorrect dates/times when approved.

Fixed: Customers who had Easy Move to Platform had duplicate groups created in Secret Server and the existing permissions from the original Secret Server group were not honored. It now disables this new duplicate group and connects the original group to the Platform group as originally expected.

Fixed: Discovery runtime summary information is now correctly accessible for screen readers.

Fixed: Distributed engine now respects the MaxShellsPerUser setting for PowerShell tasks. If the setting is set, engine will throttle tasks that leverage PowerShell and requeue messages that are over quota.

Fixed: During forwarding of inventory data from discovery in Secret Server to Platform inventory, with large amounts of computers, the processes could time out. Made the database calls more efficient and the process no longer times out.

Fixed: Extended the Migration Center to migrate all active roles.

Fixed: Folder path now shows when specified in secret import preview.

Fixed: Heartbeat listed as “pending” when the heartbeat is actually disabled. This occurred when the pending status did not resolve before the secret was disabled.

Fixed: Improved “Regenerate Platform Credentials” to attempt to forward credentials to connected Secret Server Cloud automatically (behind feature flag).

Fixed: Improved compatibility with Windows high contrast mode.

Fixed: In some scenarios only the first 30 subfolders were loaded on initial load for a single folder.

Fixed: In some scenarios the folder tree would not auto-expand when linking directly to a folder.

Fixed: Left navigation expand/collapse toggle incorrectly labeled for screen readers.

Fixed: Login SSH key menu showing properly in cloud when configured.

Fixed: Mobile logo now displaying properly.

Fixed: Most KB links now point to docs.delinea.com instead of delinea.center for redirects to the documentation article.

Fixed: Newer versions of Safari can now play session recordings in Platform.

Fixed: Pinned folders now re-root the tree to the selected pinned folder.

Fixed: Reduced situations where a check-in error could occur when already checked-in.

Fixed: Removed links to legacy create discovery wizard pages.

Fixed: Resolved an issue that caused SAML logins to fail, resulting in a rollback of the previous update.

Fixed: Resolved an issue where approvals that cross a day threshold from UTC could not be requested.

Fixed: Resolved secret permission issue when many user and groups had been selected and only the 60 were saved when edited again. Resolved for teams selection as well.

Fixed: RPC errors for SAP template secrets, which were occurring with SAP “system user” user types, even when using a privileged account during the RPC.

Fixed: Searching in all secrets now shows the full folder path for folder search results.

Fixed: Secret Key rotation failed with the error “Thycotic.AppCore.Cryptography.MacMismatchException: Exception of type 'Thycotic.AppCore.Cryptography.MacMismatchException' was thrown.”

Fixed: Secret password compliance is now calculated when a password is updated to empty and the password is not required. Prior to this, the secret would maintain the compliance flag that was calculated when the password had a value. A password with some characters might fail compliance, but if there is no password and it is not required, then it is compliant.

Fixed: ServiceNow integration could fail with a misleading error due to a space in the domain name.

Fixed: Site name now wraps instead of truncating on the “sites and engines” page so you can read the whole site name.

Fixed: SQL report editor is now properly announced for accessibility.

Fixed: SSH keep-alives sent to the proxy are now relayed to the endpoint server.

Fixed: Suggested secret template toggle, when creating an inline secret from new discovery source, is now more closely positioned to the template list to be more clear.

Fixed: Teams group membership removed when more than 60 items in Team.

Fixed: The SSH key-expiration configuration value now displays correctly.

Fixed: Thycotic One Login Link.

Fixed: Unlimited Vault Access mode audit dialog box is now correctly aligned.

Fixed: Updated all the logs to be warnings and information and to state whether they retried or not.

Fixed: Updated Discovery Network view to better handle extremely large record numbers.

Fixed: Updated the distributed engine service to persist the current the web-proxy.config file upon update. When upgrading to version from version 8.4.29.0 or lower, the web-proxy.config will be overwritten, but any upgrades afterwards will preserve it.

Fixed: User username link was sometimes unusable. It is is no longer a link. View details link is in menu and preview panel.

Fixed: When viewing folder targets for event pipeline policies the full path is now shown.

Fixed: when viewing the access-request inbox, the request start date and requested date were transposed.

Changes

Change: Admin breadcrumb renamed to Settings.

Change: Corrected license expiration banner link.

Change: Platform now specifies Secret Server configuration.

Change: Removed the color mode toggle from the top navigation as it is available under user preferences.

Change: RequirePlatformMfa field is now deprecated.

Change: The delinea.vault/secretserver/access permission has been removed. This no longer controls Secret Server access for Platform users.

Change: The SSL menu item is removed as it is not an option that can be modified in cloud.

Change: User list detail link added back based on user feedback.

Enhancements

Enhancement: Added “RPC PRIVILEGED SECRET UPDATED” and “RPC PRIVILEGED SECRET REMOVED” events to audits.

Enhancement: Added a “Clear cached AD credentials” button in cloud.

Enhancement: Added a “test syslog” button to syslog pages in configuration.

Enhancement: Added a direct link for launching connection manager.

Enhancement: Added a setting to redirect all users to log in through Platform integration settings.

Enhancement: Added AIX support for SSH Proxy su automatic password entry.

Enhancement: Added an OOB RPC template for Okta. Okta requires an “Generic API” secret as the RPC privileged account.

Enhancement: Added an OOB RPC template for ServiceNow. ServiceNow requires an account to have Admin or write permissions to the password field, or an account with those permissions as its RPC privileged account to change the password.

Enhancement: Added DSV links to the Platform settings page.

Enhancement: Added landing page for when the user is unable to access Secret Server instead of showing banners.

Enhancement: Aria label added to inline secret-preview copy buttons. Main search category toggles now keyboard accessible.

Enhancement: Associated secrets will now show “No Access” in the secret name if you do not have access to it.

Enhancement: Converted grids on 3 Automatic Export pages (Audit, Log and Storage) to thy-data-view for consistent look/feel and functionality, such as allowing Notes field to be fully viewed in right panel on row click rather than via tooltip.

Enhancement: Converted key management to the latest design and added a verification checkbox confirmation step.

Enhancement: Creating secrets in REST API now accepts optional parameters for privileged secret ID and associated secrets.

Enhancement: Heartbeat and password-compliance notices now use chips instead of banners.

Enhancement: Improved startup logging for distributed engines.

Enhancement: New import secret page allows you to import when global setting requires that secrets are in folders.

Enhancement: On premises now shows a diagnostics section under settings in the left navigation panel.

Enhancement: The left navigation folder tree now expands on focus to show longer folder names.

Enhancement: Updated password compliance label to a chip.

Enhancement: Updated Putty to version 0.81. Updated version addresses several Putty vulnerabilities, including the Terrapin vulnerability.

Enhancement: Updated Redis library for improved Redis operations.

Enhancement: Updated the server nodes page.

Enhancement: Updated the user profile menu to have more consistent styling and include links to the account details page.

Enhancement: Updated user experience for adding custom logos to Platform instances.

Enhancement: Updated user sorting to cover 2FA.

Enhancement: When a Secret Server is integrated with a Platform tenant, any Platform cloud groups are now automatically and quickly be created in Secret Server to be available for permission delegation.

Secret Server 11.7.000016 Release Notes

On-premises: June 12, 2024

11.7.000016 resolves a problem with older versions of Rabbit MQ (before 3.10) impacting DE version 8.4.31 that shipped with 11.7.000015. We pulled 11.7.000015 to resolve this issue. All other features, enhancements and bug fixes from 11.7.000015 are now in 11.7.000016

For convenience, we repeated the Features, Enhancements, and Bugs sections from the 11.7.000015 release notes here.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.32.0

Protocol Handler: 6.0.3.28

If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Features

Entra ID Secret Template for RPC

Secret Server has supported Azure AD remote password changing for several years, this overhaul creates a new password changer and template, Entra ID, that uses Oauth application credentials as a privileged account to change a user password. Entra ID is Microsoft's comprehensive cloud-based identity and access management solution that helps organizations securely manage identities and access across their Microsoft services and applications. Our password changer and template support MFA and conditional-access policies and does not require PowerShell.

Enhancements

- Enhancement: Updated PuTTY to version 0.81. The new version addresses several PuTTY vulnerabilities, including the Terrapin vulnerability.
- Enhancement: Added AIX support for SSH Proxy su automatic password entry.
- Enhancement: Added the same-site attribute to browser cookies, which is a security feature that helps prevent cross-site request forgery (CSRF) attacks. Same Site attribute value was set to lax to create a balance between security and usability.
- Enhancement: Increased back-end performance of event queue processing when there are a lot of inbox rules.
- Enhancement: Security issue contact instructions are now available at ./well-known/Security as specified in RFC9116.
- Enhancement: Significantly improved the performance of secret searches when using displayed secret fields.
- Enhancement: Updated Secure Blackbox to latest version. Secure Blackbox FIPS support was updated in documentation.
- Enhancement: Updated SSH functionality through Secure Blackbox to address Terrapin.

Bug Fixes

- Fixed "Secret Erase" translation in some non-English languages.
- Fixed a critical security vulnerability in the SOAP webservice.
- Fixed a policy validation issue that occurred when using a $itemvariable.variablename in schedule pipeline minutes.
- Fixed a UI issue where some site connectors were incorrectly showing as disabled.
- Fixed a visual bug when checking out a secret.
- Fixed an issue were a command would fail to enter vi or vim mode and would allow blocked commands. Also fixed an issue where using su before vi or vim would fail and would allow blocked commands.
- Fixed an issue where a ticket number was not present in SIEM logging.
- Fixed an issue where an error dialog appeared when adding a dependency with associated secrets.
- Fixed an issue where deleting computers from the discovery network view failed to show a confirmation dialog box before continuing.
- Fixed an issue where Handling secrets that fail heartbeat/password changes when using a PowerShell script threw a MaxShellsPerUser exception. For heartbeat: Added a new heartbeat status called "NeedsImmediateRetry" to bypass the secret-template retry interval. For Password Change: Ensured the retry attempts are not increased after failure.
- Fixed an issue where launching a secret from the new search would launch the first secret from the results returned, not the selected secret.
- Fixed an issue where OAuth parameters were not validated. The OpenIdConnect flow has been adjusted to validate the redirection URI.
- Fixed an issue where removing fields from discovery scan templates threw a disableField error.
- Fixed an issue where searching for a quotation mark could cause an error.
- Fixed an issue where secret export/import links in the All Settings Category view were missing.
- Fixed an issue where users other than owners could view TOTP backup codes.
- Fixed an issue where users with MFA enabled would be incorrectly sent to the home page on login, instead of the page they were attempting to access.
- Fixed an issue where IWA prevented DR sync calls from being processed correctly.
- Fixed an issue with adding discovery sources that match the domain of a current secret.
- Fixed an issue with key utilization within SOAP and REST API token generation.
- Fixed and issue where toggling a favorite secret triggered a grid refresh.
- Fixed issue where the "su -id" command was failing when the user did not have access to view the password for the secret they were elevating to.
- Fixed issues that could cause incorrect group or user interactions between Secret Server and Platform. We corrected an issue with Platform group synchronization that would not correctly add all group memberships when synching over 1000 groups.

- Fixed some issues with easy-move edge cases and system display.
- Fixed timeouts for large amounts of data—paging for user audits is now done in the database.
- Fixed unclear RPC logging. Updated the log message to clearly indicate when a password sets the next run time and is not doing a change attempt.
- Improved the placement of Secret Server user admin and role links. They are now on the top level in All Settings under the category header.
- Improved the UI for SSH cipher pages.

Secret Server 11.7.000015 Release Notes

On-premises: May 22, 2024

> Out of an abundance of caution, we are temporarily pulling down SS version 11.7.15 (on-premises) to resolve a problem with older versions of RabbitMQ (before 3.10) impacting DE version 8.4.31, which is shipped with SS 11.7.15. If you still require version 11.7.15, please contact Delinea Support to assist you further. You may install it as long as you do not upgrade the DE to version 8.4.31. We are working on resolving this issue and releasing an update within the next two weeks. This issue does not impact Secret Server Cloud.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.31.0

Protocol Handler: 6.0.3.28

> If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

Features

Entra ID Secret Template for RPC

Secret Server has supported Azure AD remote password changing for several years, this overhaul creates a new password changer and template, Entra ID, that uses Oauth application credentials as a privileged account to change a user password. Entra ID is Microsoft's comprehensive cloud-based identity and access management solution that helps organizations securely manage identities and access across their Microsoft services and applications. Our password changer and template support MFA and conditional-access policies and does not require PowerShell.

Enhancements

- Enhancement: Updated PuTTY to version 0.81. The new version addresses several PuTTY vulnerabilities, including the Terrapin vulnerability.
- Enhancement: Added AIX support for SSH Proxy su automatic password entry.

- Enhancement: Added the same-site attribute to browser cookies, which is a security feature that helps prevent cross-site request forgery (CSRF) attacks. Same Site attribute value was set to lax to create a balance between security and usability.
- Enhancement: Increased back-end performance of event queue processing when there are a lot of inbox rules.
- Enhancement: Security issue contact instructions are now available at ./well-known/Security as specified in RFC9116.
- Enhancement: Significantly improved the performance of secret searches when using displayed secret fields.
- Enhancement: Updated Secure Blackbox to latest version. Secure Blackbox FIPS support was updated in documentation.
- Enhancement: Updated SSH functionality through Secure Blackbox to address Terrapin.
- Enhancement: Added new permission Migrate Data to Platform. This permission will be automatically applied to roles that contain both the Administer Users and Administer Platform Integration role permissions.

Bug Fixes

- Fixed "Secret Erase" translation in some non-English languages.
- Fixed a critical security vulnerability in the SOAP webservice.
- Fixed a policy validation issue that occurred when using a $itemvariable.variablename in schedule pipeline minutes.
- Fixed a UI issue where some site connectors were incorrectly showing as disabled.
- Fixed a visual bug when checking out a secret.
- Fixed an issue were a command would fail to enter vi or vim mode and would allow blocked commands. Also fixed an issue where using su before vi or vim would fail and would allow blocked commands.
- Fixed an issue where a ticket number was not present in SIEM logging.
- Fixed an issue where an error dialog appeared when adding a dependency with associated secrets.
- Fixed an issue where deleting computers from the discovery network view failed to show a confirmation dialog box before continuing.
- Fixed an issue where Handling secrets that fail heartbeat/password changes when using a PowerShell script threw a MaxShellsPerUser exception. For heartbeat: Added a new heartbeat status called "NeedsImmediateRetry" to bypass the secret-template retry interval. For Password Change: Ensured the retry attempts are not increased after failure.
- Fixed an issue where launching a secret from the new search would launch the first secret from the results returned, not the selected secret.
- Fixed an issue where OAuth parameters were not validated. The OpenIdConnect flow has been adjusted to validate the redirection URI.
- Fixed an issue where removing fields from discovery scan templates threw a disableField error.
- Fixed an issue where searching for a quotation mark could cause an error.
- Fixed an issue where secret export/import links in the All Settings Category view were missing.

- Fixed an issue where users other than owners could view TOTP backup codes.
- Fixed an issue where users with MFA enabled would be incorrectly sent to the home page on login, instead of the page they were attempting to access.
- Fixed an issue where IWA prevented DR sync calls from being processed correctly.
- Fixed an issue with adding discovery sources that match the domain of a current secret.
- Fixed an issue with key utilization within SOAP and REST API token generation.
- Fixed and issue where toggling a favorite secret triggered a grid refresh.
- Fixed issue where the "su -id" command was failing when the user did not have access to view the password for the secret they were elevating to.
- Fixed issues that could cause incorrect group or user interactions between Secret Server and Platform. We corrected an issue with Platform group synchronization that would not correctly add all group memberships when synching over 1000 groups.
- Fixed some issues with easy-move edge cases and system display.
- Fixed timeouts for large amounts of data—paging for user audits is now done in the database.
- Fixed unclear RPC logging. Updated the log message to clearly indicate when a password sets the next run time and is not doing a change attempt.
- Improved the placement of Secret Server user admin and role links. They are now on the top level in All Settings under the category header.
- Improved the UI for SSH cipher pages.

Secret Server 11.7.000002 Release Notes

Release Date (On-premises): May 15, 2024

> **Critical security release**—We recommend all Secret Server installations to be updated to this release immediately or at your earliest convenience.

This Security Release corrects the encryption key used in identity token generation to prevent third party decryption and modification of the authentication token, with a CVSS score of 7.5, with vector AV:N/AC:H/PR:H/UI:R/S:C/C:H/I:H/A:L.

This vulnerability was identified internally during our investigation of any earlier vulnerability that was resolved in version 11.7.000001.

> This release invalidates currently issues authentication tokens, and will result in all logon sessions being invalidated. Users may need to reauthenticate to Secret Server after applying this update.

Delinea Platform and Secret Server Cloud

Delinea Platform and Secret Server Cloud have been patched and are no longer vulnerable.

Step Upgrade Process

- A Step Upgrade is required from versions prior to 11.5.2 (11.5.000002) before you can upgrade to 11.7.2 (11.7.000002).
- The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.7.000002 upgrade.
- If offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.000002 (or 11.5.000003) and then upgrade to 11.7.000002.

For instructions on upgrading in general, go to "Upgrading Secret Server" on page 143

Secret Server 11.7.000001 Release Notes

Critical security release–We require all Secret Server installations to be updated to this release immediately or at your earliest convenience.

Release Date (On-premises): April 13, 2024

Security Update

We became aware of a critical vulnerability in the SOAP API which could allow an attacker to bypass authentication. The REST API was not impacted.

This update addresses the above security vulnerability and impacts all versions of Secret Server. Hashes the for upgrade have been updated for this change.

Details are available on the Delinea Trust Center. Please register and subscribe to get future updates directly to your inbox.

The direct link to the topic is Secret Server Vulnerability.

Remediation

The direct link to the topic is Secret Server Vulnerability.

Remediation

If your Secret Server instance is exposed to the public internet, you are at significant risk and you should perform these steps immediately.

1. Use the Remediation Guide to modify the Secret Server implementation to mitigate the vulnerability
2. As a precautionary measure rotate your passwords often until mitigation is in place.
3. Use the Remediation Guide to examine audit histories for any evidence of exploitation
4. As soon as the patch is available, patch all systems.

The support team is available to guide your team through these steps and answer any questions from you or your team.

Delinea Platform and Secret Server Cloud

Delinea Platform and Secret Server Cloud have been patched and are no longer vulnerable.

Step Upgrade Process

- A Step Upgrade is required from versions prior to 11.5.2 (11.5.000002) before you can upgrade to 11.7.1 (11.7.000001).
- The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.7.000001 upgrade.
- If offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.000002 (or 11.5.000003) and then do the upgrade to 11.7.000001.

For instructions on upgrading in general, go to "Upgrading" on page 142

If You Cannot Upgrade to 11.7.1

If you are on an older version of Secret Server and you cannot upgrade to the latest version, please contact our support team for assistance and guidance.

- Prevented Thycotic One sync from syncg Platform native users. This allows Platform native users to log in the rare situation they synced with Thycotic One. Then the administrator clears the system Platform User mappings.

Secret Server 11.7.000000 GA Release Notes

On-premises: March 27, 2024

For convenience, this release note also contains items from the 11.7 EA release (11.6.000043), which constitutes most of the changes.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.24.0

Protocol Handler: 6.0.3.27

With this version, protocol handler has received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

Step Upgrade Required (11.5.2). Versions prior to 11.5.2 need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6.x upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.x.

For instructions on upgrading in general, go to "Upgrading" on page 142.

New Features

QuantumLock

Secret Server's *QuantumLock* is a feature that provides an additional security layer by protecting secret data using asymmetric encryption (a public/private key pair) where the private key is a human-generated password. This feature is independent of regular permissions, Secret Server login access, or physical access to the machine running Secret Server.

A shortcut way of thinking about QuantumLocks is as an extra password for secrets that is held by a set group of users. In addition, both the password and the group of users are reusable for other secrets. In addition, QuatumLocks future-proof our digital security infrastructure against the advancing capabilities of quantum computing.

QuantumLock is an upgrade of the earlier doublelock feature. Besides the name change, the difference is QuantumLock offers the option to use a quantum-safe algorithm for encapsulation to protect the private key, specifically CRYSTALS Kyber-1024, which is designed to counter the potential threat from quantum computers to current encryption methods.

Usability Improvements

Left Navigation Panel

With this release, we have made several improvements to the left navigation sub-menu to provide a better user experience. Some of the most common configuration settings have been moved to the top of the menu. For more information about the latest changes, please see "Main Navigation Drawers" on page 184.

Improved Search

The main search is greatly improved. It now includes content search results as well as users. A status bar shows the full folder path for long secret-folder paths. Highlighted search categories include:

- Content
- Favorites
- Folders
- Secrets
- Users

Form Usability Improvements

Overall form information density is improved—forms have less white space between rows.

Configuration Redesign

Our configuration redesign has been available as a preview feature for several versions, and is now fully released.

More content from standalone configuration pages is available directly within the configuration page, as well as section, setting and value search, and is available in Settings > Search configuration

Enhancements

New for GA:

- Enhancement: Improved performance of Secret Search when searching within a folder.
- Enhancement: Custom proxied launchers can now be mapped to a secret's list fields which behaves as an allow-list restriction. This is only allowed without the launcher's "Additional Field" enabled. Only one list field can be used in the mapping.
- Enhancement: Applied several SSH Proxy optimizations to increase performance and throughput.
- Enhancement: Added a warning because WPF allows launching to a freeform <user input> url, which is not recommended.
- Enhancement: Users with "Force Check-in" Permission can now always force secret check in, including the secrets that failed a password change on check-in. Previously, that required "Force check-in" and owner permissions on the secret.
- Enhancement: Password fields on a secret view now indicate if the secret has a password that is non-compliant.
- Enhancement: Added two new password requirement rules that enforce the amount of character repetition allowed in passwords.

Carried over from EA:

- Enhancement: Numerous grids were updated to used the enabled/disabled chip pattern.
- Enhancement: The secret dependencies page was updated. In addition to improved usability, you can filter by groups and run bulk operations across those groups.
- Enhancement: The Dependency Changers page was updated
- Enhancement: The user management user-list grid was updated. It now allows you to perform a bulk action on all users, not just the visibly loaded ones.
- Enhancement: The group list grid was updated.
- Enhancement: Discovery analysis now includes scan results since last run, which is useful for seeing what has succeeded or had an error since the last run.
- Enhancement: A discovery computer-scan results tab was added that allows for searching local computer-scan successes and failures.
- Enhancement: Session recording agent pages were updated.

- Enhancement: ticket system pages were updated.
- Enhancement: Launching a secret now users a dialog flow. This allows launching without having to leave the grid. For example, you can launch and checkout a secret in the launcher flow.
- Enhancement: Diagnostics pages were updated.
- Enhancement: Bulk actions in grids now shows bulk actions at the top of the grid.
- Enhancement: Added search text filter to launcher grid.
- Enhancement: Simplified legacy pages' left navigation design. Removed obsolete setup left navigation menu.
- Enhancement: Secret Server's disaster recovery can now replicate teams, sites, metadata, and secret history.
- Enhancement: Platform users can now use step-up MFA to validate their identity when resetting QuantumLock passwords.
- Enhancement: Added a new setting to the ticket system configuration to optionally avoid prompting for a comment when "Comment not required" is configured.
- Enhancement: Added support for near-real-time processing of Platform user and group updates in Secret Server.
- Enhancement: Added a link to configuration audits on the Remote Password Changing page.
- Enhancement: Added a running log to disaster recovery so progress and duration per table can be tracked during replication.
- Enhancement: Added an event subscription called "Disaster Recovery Replication Success."
- Enhancement: Added auditing of password change schedules.
- Enhancement: Folders in favorites quick access are now filtered when searching.
- Enhancement: Improved HSM cryptography by adding support for AES 256 encryption. This ensures that all keys protecting the secret key will be at the same strength for organizations requiring this level of encryption.
- Enhancement: If an Azure Active Directory configuration in directory services becomes corrupt, you can now view and update the credentials to fix it.
- Enhancement: improved internal security checking around launchers.
- Enhancement: Improved SSH proxy block-command handling in VIM.
- Enhancement: Launching a secret now opens in a dialog allowing launch to occur without leaving the grid or current page. Restricted actions like checkout can be performed in the dialog.
- Enhancement: On the Proxying Configuration page, you can now automatically generate new SSH proxy host keys.
- Enhancement: Platform configuration settings were added to disaster recovery.
- Enhancement: Secret search performance improvements. The secret grid now only requests extended fields that are showing. When column selections are updated, a new request is made only if the extended field choices have changes.
- Enhancement: Secrets grid modal on the Secret Erase Requests search page now auto-scrolls.
- Enhancement: The login policy now supports line breaks.

- Enhancement: The secret search API now has a comma-delimited filter parameter for template IDs, which allows searching beyond IIS URL limits compared to the existing array version. Both are still available.
- Enhancement: The user profile allows for date and time format setting.
- Enhancement: Updated the toast message displayed when saving user preferences to accommodate screen readers.
- Enhancement: Users are no longer redirected from the licensing page.
- Enhancement: When Secret Server Cloud is Platform integrated, there is now an "Add from External Directory" option in secret sharing that allows searching directory sources from Platform to add users or groups.
- Enhancement: Added new optional parameter "nobus=true" to the healthcheck endpoint. This allows a faster response in situations where no lookup of the bus status is required.
- Enhancement: Adjusted the password compliance validation job to process more secrets on each run.
- Enhancement: Discovery port scanner now aborts if elapsed time expires prior to windows TCP handshake. Discovery port scanner will now also log a helpful message if the windows TCP stack aborts due to reaching the windows internal max syn retry count.
- Enhancement: The schedule pipeline task in event pipeline policies now supports using a variable for the schedule delay input.
- Enhancement: Unlimited Vault Access can now check in checked out secrets by other users.
- Enhancement: Added a Computer Scan Results tab to discovery.
- Enhancement: Added a new option to the Distributed Engine page for configuring "pending engines" that allows a pending engine to be assigned to a site without activation.
- Enhancement: Added a note to audits when the system disables a Secret Server user.
- Enhancement: Added an SDK link.
- Enhancement: Added the table tbTerminalConnectionHistory to the list of tables that is handled by the database cleanup consumer. It will periodically delete any records over a certain age, which can be customized by the user.
- Enhancement: Custom proxied launchers can now be mapped to a secret's list fields which behaves as an allow list restriction. This is only allowed without the launcher's "Additional Field" enabled. Only one list field can be used in the mapping.

Bug Fixes

New for GA:

- Fixed an issue when a syslog server is configured to use a DE and is having connection issues, it can trigger a restart of the DE, interrupting proxy sessions. Now, the syslog circuit breaker does not trigger a restart of the DE.
- Fixed issue with SecureCRT failing to connect to terminal with public key and 2FA on.
- Adjusted the endpoint `/api/v1/secret-access-requests` for better performance.

- Fixed an issue where going to Platform groups and removing (disabling) a group and then searching Platform and re-adding that group made a duplicate instead of enabling the existing group. Additionally, Platform group synchronization now ignores all disabled groups when making membership changes.
- Fixed an issue where a DE unhandled exception disconnected all SSH Proxy users.
- Fixed an issue where if a group has been imported from Platform from an AD source and was then added into directory synchronization as an AD group, it re-used that Platform group rather than creating a new group.
- Fixed an issue where the launcher icon could show when launchers were not allowed.
- Fixed Start Date and Queue Date on "pipeline activity" when viewing an individual run.
- Reduced the frequency of pre-audit validation errors.
- Improved the handling of duplicate platform permissions and added a delta to clean up existing duplicates.
- Fixed an issue where in some configurations secrets could not be created.
- Fixed back-end errors when publishing audits to the audit service.
- Fixed an issue where sorting did not work in card view.
- Explicitly mentioned the Integrated windows authentication requirement on the Database page.
- Fixed an issue where there was no option to select "none" as a default role in Platform/Configuration preview.
- Fixed an issue where encryption-related fields, which are not replicated, were not being populated on replicated sites. These fields were not populated when sites are first saved to the replica.
- Made UI adjustments to ensure that extended fields should be properly requested when column preferences is setup or when using the defaults with extended fields.
- Fixed an issue where the expanded state of the left navigation pane was not preserved correctly.

Carried over from EA:

- Fixed an issue where a distributed engine would not start when proxying was enabled.
- Fixed an issue where the "Add Scanner" Button was not displayed on the Discovery Scanner page.
- Updated installer EULA.
- Fixed an issue where terminating all sessions except the current one would log the user out and report an error.
- Fixed the secret permissions API to handle an edge case that could incorrectly return null when the userid filter parameter was specified.
- Fixed UI to only call secret-detail RPC API when RPC is enabled.
- Fixed the secret-key re-encryptor with a multithreaded lock to prevent an IndexOutOfRangeException while using an HSM.
- Fixed an issue where users checking out a secret with a failed remote password change would potentially see a loading icon indefinitely.
- Fixed an issue where users were redirected to the Secret Server start page instead of the activation center page when using the offline method for license activation.
- Fixed an issue where pre-checkout created an extra pipeline policy activity entry that stayed in a pending state.

- Fixed an issue where "Administer Secret Templates" permission was erroneously required to add a dependency to a secret. "View Secret Templates" is now sufficient.
- Fixed a DR issue where deleting items connected to MetadataItemData orphans it.
- Fixed a session recording issue where a launch would show two records.
- Fixed an issue where Secret Server On Premise launchers list duplicates some items and other launchers do not show up.
- Fixed an issue so the SSH Proxy's processing delay is now respected and defaults to 0, no delay.
- Fixed permission issues with the "View Session Recording" and "View Session Monitoring" roles.
- Fixed an issue where maximum consecutive character rules for passwords did not work and were enforced as expected in the password field.
- Fixed an issue where the group members page was incorrectly showing a maximum of 59 users.
- Fixed a duplicate personal group name when a user got deleted and re-added during disaster recovery replication.
- Fixed when roles were assigned, sometimes no audit record was made.
- Added a warning added because WPF allows launching to a free-form <user input> url, which is not recommended.
- Added "view all folders" link that appears when folders are filtered in a pin view.
- Added a download button for session recording to Secret Server. The change does not appear for vault sessions in Platform.
- Added aria labels to the notification bell to support screen readers.
- Added new REST API patch method to controller which calls pre-existing latestversion.txt processing code.
- Added protocol handler step-up upgrade. Protocol handler will not try to upgrade versions 6.0.3.26 to newer versions as they must be updated manually. Released new 6.0.3.27 version which will be able to upgrade to future versions.
- Adjusted license tracking for session-recording-enabled secrets so that secrets that have no launchers are excluded.
- Adjusted organization of some administrative menu items in the configuration preview.
- Adjusted permissions on Session Monitoring page so that users with "View Own Session Recordings" permission will only see their own recordings.
- Adjusted the display of administrative items from Platform to avoid perceived duplication.
- Adjusted the log level downward for certain engine messages for syslog to avoid overloading the engine log table.
- Applied a more reasonable default SQL timeout.
- Clarified explanatory information on the Secret Import page to highlight that file fields are ignored.
- Converted dependency template management section to new UI.
- Converted Initial User page to the new UI.

- Corrected an issue where the Distributed Engine page did not respect the "Deleted" filter.
- Disabled the legacy bookmarklet pages.
- Disaster recovery now migrates teams.
- Fixed a client-side error on the Secret Settings page when viewed from Platform.
- Fixed a display issue on the IP Address restrictions page.
- Fixed a missing localization-key issue.
- Fixed a visual bug on secret templates so the password type dropdown no longer appears as "None" if a password type has been set.
- Fixed an edge case that could result in duplicate disabled usernames, possibly causing DR conflicts.
- Fixed an error that could occur on the Advanced Session Recording page.
- Fixed an HTML-encoded document link in discovery scanner.
- Fixed an issue an erroneous warning popup appeared saying a distributed engine is required for Active Directory when the SSC cloud instance has "Azure AD Domain" as the only domain.
- Fixed an issue on the Admin Roles page where the edit button for role permissions was mistakenly requiring "Administer Role Assignment" instead of "Administer Role Permission."
- Fixed an issue that could cause an incorrect error message to display when using the SQL report editor.
- Fixed an issue that could cause the secret picker to display with a horizontal scroll bar.
- Fixed an issue when searching in Secret Share with the "Add from External Directory" option with results of more than 2100 groups would throw an error.
- Fixed an issue where a proper validation message may not display when trying to give a duplicate name to a group.
- Fixed an issue where a secret erase request could no longer be canceled.
- Fixed an issue where banner text referenced only "engine," which was potentially confusing. It now mentions "distributed engine" explicitly.
- Fixed an issue where created hooks would not display on the secret.
- Fixed an issue where enabling RPC on a template through the API could impair the template's functionality.
- Fixed an issue where existing linked groups under the Platform Integration area on the Groups tab would not load.
- Fixed an issue where if a non-local site was used to send syslog to the syslog server any failure was queued back into the database (tbsyslogfailedmessage) and resent indefinitely. This has been resolved. Additionally, we implemented a syslog circuit-breaker system if a non-local site is used to prevent flooding the message queues with syslog messages when failure is expected.
- Fixed an issue where localization load requests would wait indefinitely in some cases.
- Fixed an issue where pinned folders would not be removed when the corresponding folder was deleted.
- Fixed an issue where Platform synchronization was running too frequently in some cases.

- Fixed an issue where renaming or copying the "Oracle Account (Template Ver 2)" secret template caused password changes to fail.
- Fixed an issue where Resilient Secrets (DR) sent secret field launchers across the wire for every replication.
- Fixed an issue where selecting Generate New SSH Key on a secret would not generate a new SSH key.
- Fixed an issue where sorting the launchers list by name could display duplicates.
- Fixed an issue where the checkout screen could briefly show while a secret is loading.
- Fixed an issue where the child launcher type was not always visible on the new custom launcher page.
- Fixed an issue where the Everybody group from Platform would not match up properly with the Everybody group from Platform User sync. Corrected the display name of the Platform "Everybody" group.
- Fixed an issue where the light mode collapsed toolbar showed the dark mode logo.
- Fixed an issue where the notification bell could show when there were no notifications.
- Fixed an issue where the Preserve SSH Client Process setting did not correctly display as checked.
- Fixed an issue where the SSH custom cipher was not applied when missing a value from the section.
- Fixed an issue where the synchronized groups displayed could sometimes return all the groups from the domain.
- Fixed an issue where the web launcher would not respect the mapped URL field when multiple URL fields existed on the secret.
- Fixed an issue where unnecessary audits could be written. Fixed an issue where DR Secret Server instances were ignoring licensing updates from Cloud Manager.
- Fixed an issue where upgrade banner was always showing when auto-update was off. Now shows only if at least one engine is lower version than latest.
- Fixed an issue where users could click New Secret multiple times when also uploading files.
- Fixed and incorrect launcher edit field description.
- Fixed buttons that should be grayed out. Run RPC Now can no longer be run when RPC is disabled. Run heartbeat Now can no longer be run when heartbeat is disabled.
- Fixed dark mode IBM password tooltips and banner color-contrast issues.
- Fixed edge case bug if SSH Block Listing causes duplicate sessions that break SSH Proxy.
- Fixed error that could occur when creating a new folder with the folder panel minimized.
- Fixed inconsistent logs between source and replica on partial success. Fatal error is now persisted across the wire so the replica is aware that the source had a fatal error
- Fixed incorrect logging error in AuthenticateWithAdConsumer.
- Fixed issue in directory sync where a search result with an attribute containing an empty list could cause an error.
- Fixed issue where the upper right search bar would not always switch to the selected secret when a selected secret was on a tab other than the General tab.

- Fixed issue with a test script modal where reopening the modal would show the selected secret's ID instead of its name.
- Fixed issue with folder permission editing when updating a path directly.
- Fixed link to dependency templates on the Secret Dependency tab.
- Fixed logic error where the RAS flag was not being referenced before deciding to delete the database entry that reflected additional users.
- Fixed long secret-template names to wrap better in folder edit.
- Fixed missing option. System group in Secret Server Cloud can now have metadata deleted.
- Fixed Platform permissions cached on Secret Server to replicate so they will be respected on a replica instance.
- Fixed query for obtaining services for a directory account in discovery. Fixed check on discovery source name when creating an empty discovery source.
- Fixed secret policies not showing as deleted after deleting a secret. Secret names on the RPC tab of a secret policy will now include "Inactive" if a secret is not active.
- Fixed text alignment. Left aligned the comment text on the MFA security view. The icon and button remain centered.
- Fixed the link to the subscription page from the banner.
- Fixed the REST API token endpoint path. The documentation generator, in removing the "api" string from the beginning of all routes, was also removing embedded occurrences. It now removes it only from the start of the route strings.
- Fixed the secrets grid on the Secret Erase Request Approval page (in a modal opened via a link button) that was obscured in dark mode and nearly indistinguishable in light mode. This is now an inline grid with auto-scroll.
- Fixed visual bug when removing current user's folder owner permissions.
- Folders in "Shared with Me" Quick Access menu are now filtered when searching.
- If a user's encrypted TOTP reset Guid gets corrupted, an administrator is now able to reset their TOTP.
- Improved error handling on the OpenId Configuration page.
- Improved the UI on the Collections Management page for advanced session recording agents.
- In the prior upgrade file set for 11.6.3, fixed an issue with SQL Delta 11.5.000006. Removed a SQL hint on the SQL index that was incompatible with non-Enterprise editions prior to SQL Server 2016 SP1 due to a compatibility issue with data compression. The incompatible hint was not necessary, so the delta was updated. Hashes for upgrade were updated for this change.
- Legacy RPC admin page removed.
- Legacy user and group management aspx pages removed.
- Limited Mode now goes to the correct link in SSC.
- Made performance improvements for the "What Secret Permissions Exist?" report.
- Prevented Thycotic One sync from syncg Platform native users. This allows Platform native users to log in in the rare situation they synced with Thycotic One. Then the administrator clears the system Platform User mappings.

- Queries executed in the chart and SQL editor for custom reports will now take the Use Database Paging setting into account so that the result is the same as if the query was being saved as a report.
- Removed legacy ASPX pages for secret templates.
- Removed link for managing licenses from the Cloud Subscriptions page.
- Secret Server was updated to use the same player for session recordings as platform.
- Set the GET SDK Client Account, SDK Client Audit, and SDK Client Rule API calls to set the operator parameter to 1 if it is not supplied by the caller when a User ID filter is specified.
- Switching pinned folders now resets the text search.
- Updated auditing for users modifying allowed cipher suite algorithms.
- Updated diagnostics page and licensing expiration checks to correctly handle non-US date patterns.
- Updated event subscription and workflow grids.
- Updated password requirement audits to correctly audit missed fields.
- Updated the action-handler secret-launch dialog layout to reflect design changes.
- Updated the Cloud Subscription page to the new UI.
- Updated the Dependency Changes List page to the new UI.
- Updated the Diagnostics page to the new UI.
- Updated the display for secret locked pages to address a wrapping issue with DoubleLock.
- Updated the distributed engine log UI updated. It now remembers your last selected site, system log grid UI updated, and the last selected log level.
- Updated the EventDetails token within Event Subscriptions to correctly capture secret comments.
- Updated the logout.aspx page to avoid errors being generated in rare cases when executing the SAML SLO flow.
- Updated the ticket system list page to the new UI.
- Updated user preferences page for better accessibility.
- web.config now allows explicit definition of allowed HTTP verbs.
- Addressed an issue where discovery rules would not correctly display the selected secret template or password type.
- Adjusted discovery scanning to minimize potential SQL deadlocks during the scanning process.
- Adjusted Secret Server and distributed engine to support 3.x versions of SAP .NET Connector.
- Converted HSM to a new UI page with a new PKCS11 API type. This new option enables you to protect your MEK and secret keys with an AES 256 key, bringing the strength of all keys to AES 256. After setting up PKCS#11 with your HSM vendor, you use the vendor cryptoki library (dll), token label and user pin to integrate with Secret Server. NOTE: You will need to disable the HSM first, to switch to the new PKCS11 API type. See the Hardware Security Module for more details.
- Enable Audit Integration on the Platform Configuration page can now be turned on.

- Extended timeout for some indexing steps for customers with over one million secrets.
- Fixed an issue that caused folder permissions to not update under specific circumstances.
- Fixed an issue where long column names did not wrap in the column selector.
- Fixed an issue where searching for a secret name using a substring within a single word would not always return results.
- Fixed an issue where the Dashboard Overview tab was not selected by default.
- Fixed an issue where the main search did not return content and updated the search design.
- Fixed an issue where the New Folder button would be incorrectly hidden in certain situations when displayed from Platform.
- Fixed an issue where the system log filter preference had an error when all was selected as the last used filter.
- Fixed an issue where the folder tree disappeared when there were more than 1,000 folders accessed and UAM was enabled.
- Fixed an issue with the discovery splash image margin.
- Fixed bug where changing the client ID did not update unless the client secret was updated as well.
- Fixed display issue for Secret edit modal on Discovery scope page.
- Fixed issue with QuantumLock Assign Users grid not displaying correctly after editing then canceling.
- Fixed the folder audit download to show the correct title.
- Improved exception logging for certain scenarios related to launching.
- License requirement message for secret policies updated to Pro Edition or higher.
- Removed no-longer-used bookmarklet login pages.
- Updated API documentation for updating team membership.
- Updated the Secret Import to handle a trailing whitespace in the folder path to prevent bug where created the child folder at the root level.
- Updated the ticket system detail page to the modern UI framework.

Secret Server 11.7.000000 EA Release Notes

On-premises: February 28, 2024

> The 11.7.000000 EA (Early Access) release number is officially 11.6.000043. The official release number will become 11.7.x when the GA (General Availability) release becomes available.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.23.0

Protocol Handler: 6.0.3.27

With this version, protocol handler has received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

Step Upgrade Required (11.5.2). Versions prior to 11.5.2 need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6.x upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.x.

For instructions on upgrading in general, go to "Upgrading" on page 142.

New Features

QuantumLock

Secret Server's *QuantumLock* is a feature that provides an additional security layer by protecting secret data using asymmetric encryption (a public/private key pair) where the private key is a human-generated password. This feature is independent of regular permissions, Secret Server login access, or physical access to the machine running Secret Server.

A shortcut way of thinking about QuantumLocks is as an extra password for secrets that is held by a set group of users. In addition, both the password and the group of users are reusable for other secrets. In addition, QuatumLocks future-proof our digital security infrastructure against the advancing capabilities of quantum computing.

QuantumLock is an upgrade of the earlier doublelock feature. Besides the name change, the difference is QuantumLock offers the option to use a quantum-safe algorithm for encapsulation to protect the private key, specifically CRYSTALS Kyber-1024, which is designed to counter the potential threat from quantum computers to current encryption methods.

Usability Improvements

Left Navigation Panel

With this release, we have made several improvements to the left navigation sub-menu to provide a better user experience. Some of the most common configuration settings have been moved to the top of the menu. For more information about the latest changes, please see "Main Navigation Drawers" on page 184.

Improved Search

The main search is greatly improved. It now includes content search results as well as users. A status bar shows the full folder path for long secret-folder paths. Highlighted search categories include:

- Content
- Favorites
- Folders
- Secrets
- Users

Form Usability Improvements

Overall form information density is improved–forms have less white space between rows.

Configuration Redesign

Our configuration redesign has been available as a preview feature for several versions, and is now fully released.

More content from standalone configuration pages is available directly within the configuration page, as well as section, setting and value search, and is available in Settings > Search configuration

Enhancements

- Enhancement: Numerous grids were updated to used the enabled/disabled chip pattern.
- Enhancement: The secret dependencies page was updated. In addition to improved usability, you can filter by groups and run bulk operations across those groups.
- Enhancement: The Dependency Changers page was updated
- Enhancement: The user management user-list grid was updated. It now allows you to perform a bulk action on all users, not just the visibly loaded ones.
- Enhancement: The group list grid was updated.
- Enhancement: Discovery analysis now includes scan results since last run, which is useful for seeing what has succeeded or had an error since the last run.
- Enhancement: A discovery computer-scan results tab was added that allows for searching local computer-scan successes and failures.
- Enhancement: Session recording agent pages were updated.
- Enhancement: ticket system pages were updated.
- Enhancement: Launching a secret now users a dialog flow. This allows launching without having to leave the grid. For example, you can launch and checkout a secret in the launcher flow.
- Enhancement: Diagnostics pages were updated.
- Enhancement: Bulk actions in grids now shows bulk actions at the top of the grid.
- Enhancement: Added search text filter to launcher grid.
- Enhancement: Simplified legacy pages' left navigation design. Removed obsolete setup left navigation menu.
- Enhancement: Secret Server's disaster recovery can now replicate teams, sites, metadata, and secret history.

- Enhancement: Platform users can now use step-up MFA to validate their identity when resetting QuantumLock passwords.
- Enhancement: Added a new setting to the ticket system configuration to optionally avoid prompting for a comment when "Comment not required" is configured.
- Enhancement: Added support for near-real-time processing of Platform user and group updates in Secret Server.
- Enhancement: Added a link to configuration audits on the Remote Password Changing page.
- Enhancement: Added a running log to disaster recovery so progress and duration per table can be tracked during replication.
- Enhancement: Added an event subscription called "Disaster Recovery Replication Success."
- Enhancement: Added auditing of password change schedules.
- Enhancement: Folders in favorites quick access are now filtered when searching.
- Enhancement: Improved HSM cryptography by adding support for AES 256 encryption. This ensures that all keys protecting the secret key will be at the same strength for organizations requiring this level of encryption.
- Enhancement: If an Azure Active Directory configuration in directory services becomes corrupt, you can now view and update the credentials to fix it.
- Enhancement: improved internal security checking around launchers.
- Enhancement: Improved SSH proxy block-command handling in VIM.
- Enhancement: Launching a secret now opens in a dialog allowing launch to occur without leaving the grid or current page. Restricted actions like checkout can be performed in the dialog.
- Enhancement: On the Proxying Configuration page, you can now automatically generate new SSH proxy host keys.
- Enhancement: Platform configuration settings were added to disaster recovery.
- Enhancement: Secret search performance improvements. The secret grid now only requests extended fields that are showing. When column selections are updated, a new request is made only if the extended field choices have changes.
- Enhancement: Secrets grid modal on the Secret Erase Requests search page now auto-scrolls.
- Enhancement: The login policy now supports line breaks.
- Enhancement: The secret search API now has a comma-delimited filter parameter for template IDs, which allows searching beyond IIS URL limits compared to the existing array version. Both are still available.
- Enhancement: The user profile allows for date and time format setting.
- Enhancement: Updated the toast message displayed when saving user preferences to accommodate screen readers.
- Enhancement: Users are no longer redirected from the licensing page.
- Enhancement: When Secret Server Cloud is Platform integrated, there is now an "Add from External Directory" option in secret sharing that allows searching directory sources from Platform to add users or groups.

- Enhancement: Added new optional parameter "nobus=true" to the healthcheck endpoint. This allows a faster response in situations where no lookup of the bus status is required.
- Enhancement: Adjusted the password compliance validation job to process more secrets on each run.
- Enhancement: Discovery port scanner now aborts if elapsed time expires prior to windows TCP handshake. Discovery port scanner will now also log a helpful message if the windows TCP stack aborts due to reaching the windows internal max syn retry count.
- Enhancement: The schedule pipeline task in event pipeline policies now supports using a variable for the schedule delay input.
- Enhancement: Unlimited Vault Access can now check in checked out secrets by other users.
- Enhancement: Added a Computer Scan Results tab to discovery.
- Enhancement: Added a new option to the Distributed Engine page for configuring "pending engines" that allows a pending engine to be assigned to a site without activation.
- Enhancement: Added a note to audits when the system disables a Secret Server user.
- Enhancement: Added an SDK link.
- Enhancement: Added the table tbTerminalConnectionHistory to the list of tables that is handled by the database cleanup consumer. It will periodically delete any records over a certain age, which can be customized by the user.
- Enhancement: Custom proxied launchers can now be mapped to a secret's list fields which behaves as an allow list restriction. This is only allowed without the launcher's "Additional Field" enabled. Only one list field can be used in the mapping.

Bug Fixes

- Fixed an issue where a distributed engine would not start when proxying was enabled.
- Fixed an issue where the "Add Scanner" Button was not displayed on the Discovery Scanner page.
- Updated installer EULA.
- Fixed an issue where terminating all sessions except the current one would log the user out and report an error.
- Fixed the secret permissions API to handle an edge case that could incorrectly return null when the userid filter parameter was specified.
- Fixed UI to only call secret-detail RPC API when RPC is enabled.
- Fixed the secret-key re-encryptor with a multithreaded lock to prevent an IndexOutOfRangeException while using an HSM.
- Fixed an issue where users checking out a secret with a failed remote password change would potentially see a loading icon indefinitely.
- Fixed an issue where users were redirected to the Secret Server start page instead of the activation center page when using the offline method for license activation.
- Fixed an issue where pre-checkout created an extra pipeline policy activity entry that stayed in a pending state.

- Fixed an issue where "Administer Secret Templates" permission was erroneously required to add a dependency to a secret. "View Secret Templates" is now sufficient.
- Fixed a DR issue where deleting items connected to MetadataItemData orphans it.
- Fixed a session recording issue where a launch would show two records.
- Fixed an issue where Secret Server On Premise launchers list duplicates some items and other launchers do not show up.
- Fixed an issue so the SSH Proxy's processing delay is now respected and defaults to 0, no delay.
- Fixed permission issues with the "View Session Recording" and "View Session Monitoring" roles.
- Fixed an issue where maximum consecutive character rules for passwords did not work and were enforced as expected in the password field.
- Fixed an issue where the group members page was incorrectly showing a maximum of 59 users.
- Fixed a duplicate personal group name when a user got deleted and re-added during disaster recovery replication.
- Fixed when roles were assigned, sometimes no audit record was made.
- Added a warning added because WPF allows launching to a free-form <user input> url, which is not recommended.
- Added "view all folders" link that appears when folders are filtered in a pin view.
- Added a download button for session recording to Secret Server. The change does not appear for vault sessions in Platform.
- Added aria labels to the notification bell to support screen readers.
- Added new REST API patch method to controller which calls pre-existing latestversion.txt processing code.
- Added protocol handler step-up upgrade. Protocol handler will not try to upgrade versions 6.0.3.26 to newer versions as they must be updated manually. Released new 6.0.3.27 version which will be able to upgrade to future versions.
- Adjusted license tracking for session-recording-enabled secrets so that secrets that have no launchers are excluded.
- Adjusted organization of some administrative menu items in the configuration preview.
- Adjusted permissions on Session Monitoring page so that users with "View Own Session Recordings" permission will only see their own recordings.
- Adjusted the display of administrative items from Platform to avoid perceived duplication.
- Adjusted the log level downward for certain engine messages for syslog to avoid overloading the engine log table.
- Applied a more reasonable default SQL timeout.
- Clarified explanatory information on the Secret Import page to highlight that file fields are ignored.
- Converted dependency template management section to new UI.
- Converted Initial User page to the new UI.

- Corrected an issue where the Distributed Engine page did not respect the "Deleted" filter.
- Disabled the legacy bookmarklet pages.
- Disaster recovery now migrates teams.
- Fixed a client-side error on the Secret Settings page when viewed from Platform.
- Fixed a display issue on the IP Address restrictions page.
- Fixed a missing localization-key issue.
- Fixed a visual bug on secret templates so the password type dropdown no longer appears as "None" if a password type has been set.
- Fixed an edge case that could result in duplicate disabled usernames, possibly causing DR conflicts.
- Fixed an error that could occur on the Advanced Session Recording page.
- Fixed an HTML-encoded document link in discovery scanner.
- Fixed an issue an erroneous warning popup appeared saying a distributed engine is required for Active Directory when the SSC cloud instance has "Azure AD Domain" as the only domain.
- Fixed an issue on the Admin Roles page where the edit button for role permissions was mistakenly requiring "Administer Role Assignment" instead of "Administer Role Permission."
- Fixed an issue that could cause an incorrect error message to display when using the SQL report editor.
- Fixed an issue that could cause the secret picker to display with a horizontal scroll bar.
- Fixed an issue when searching in Secret Share with the "Add from External Directory" option with results of more than 2100 groups would throw an error.
- Fixed an issue where a proper validation message may not display when trying to give a duplicate name to a group.
- Fixed an issue where a secret erase request could no longer be canceled.
- Fixed an issue where banner text referenced only "engine," which was potentially confusing. It now mentions "distributed engine" explicitly.
- Fixed an issue where created hooks would not display on the secret.
- Fixed an issue where enabling RPC on a template through the API could impair the template's functionality.
- Fixed an issue where existing linked groups under the Platform Integration area on the Groups tab would not load.
- Fixed an issue where if a non-local site was used to send syslog to the syslog server any failure was queued back into the database (tbsyslogfailedmessage) and resent indefinitely. This has been resolved. Additionally, we implemented a syslog circuit-breaker system if a non-local site is used to prevent flooding the message queues with syslog messages when failure is expected.
- Fixed an issue where localization load requests would await indefinitely in some cases.
- Fixed an issue where pinned folders would not be removed when the corresponding folder was deleted.
- Fixed an issue where Platform synchronization was running too frequently in some cases.

- Fixed an issue where renaming or copying the "Oracle Account (Template Ver 2)" secret template caused password changes to fail.
- Fixed an issue where Resilient Secrets (DR) sent secret field launchers across the wire for every replication.
- Fixed an issue where selecting Generate New SSH Key on a secret would not generate a new SSH key.
- Fixed an issue where sorting the launchers list by name could display duplicates.
- Fixed an issue where the checkout screen could briefly show while a secret is loading.
- Fixed an issue where the child launcher type was not always visible on the new custom launcher page.
- Fixed an issue where the Everybody group from Platform would not match up properly with the Everybody group from Platform User sync. Corrected the display name of the Platform "Everybody" group.
- Fixed an issue where the light mode collapsed toolbar showed the dark mode logo.
- Fixed an issue where the notification bell could show when there were no notifications.
- Fixed an issue where the Preserve SSH Client Process setting did not correctly display as checked.
- Fixed an issue where the SSH custom cipher was not applied when missing a value from the section.
- Fixed an issue where the synchronized groups displayed could sometimes return all the groups from the domain.
- Fixed an issue where the web launcher would not respect the mapped URL field when multiple URL fields existed on the secret.
- Fixed an issue where unnecessary audits could be written. Fixed an issue where DR Secret Server instances were ignoring licensing updates from Cloud Manager.
- Fixed an issue where upgrade banner was always showing when auto-update was off. Now shows only if at least one engine is lower version than latest.
- Fixed an issue where users could click New Secret multiple times when also uploading files.
- Fixed and incorrect launcher edit field description.
- Fixed buttons that should be grayed out. Run RPC Now can no longer be run when RPC is disabled. Run heartbeat Now can no longer be run when heartbeat is disabled.
- Fixed dark mode IBM password tooltips and banner color-contrast issues.
- Fixed edge case bug if SSH Block Listing causes duplicate sessions that break SSH Proxy.
- Fixed error that could occur when creating a new folder with the folder panel minimized.
- Fixed inconsistent logs between source and replica on partial success. Fatal error is now persisted across the wire so the replica is aware that the source had a fatal error
- Fixed incorrect logging error in AuthenticateWithAdConsumer.
- Fixed issue in directory sync where a search result with an attribute containing an empty list could cause an error.
- Fixed issue where the upper right search bar would not always switch to the selected secret when a selected secret was on a tab other than the General tab.

- Fixed issue with a test script modal where reopening the modal would show the selected secret's ID instead of its name.
- Fixed issue with folder permission editing when updating a path directly.
- Fixed link to dependency templates on the Secret Dependency tab.
- Fixed logic error where the RAS flag was not being referenced before deciding to delete the database entry that reflected additional users.
- Fixed long secret-template names to wrap better in folder edit.
- Fixed missing option. System group in Secret Server Cloud can now have metadata deleted.
- Fixed Platform permissions cached on Secret Server to replicate so they will be respected on a replica instance.
- Fixed query for obtaining services for a directory account in discovery. Fixed check on discovery source name when creating an empty discovery source.
- Fixed secret policies not showing as deleted after deleting a secret. Secret names on the RPC tab of a secret policy will now include "Inactive" if a secret is not active.
- Fixed text alignment. Left aligned the comment text on the MFA security view. The icon and button remain centered.
- Fixed the link to the subscription page from the banner.
- Fixed the REST API token endpoint path. The documentation generator, in removing the "api" string from the beginning of all routes, was also removing embedded occurrences. It now removes it only from the start of the route strings.
- Fixed the secrets grid on the Secret Erase Request Approval page (in a modal opened via a link button) that was obscured in dark mode and nearly indistinguishable in light mode. This is now an inline grid with auto-scroll.
- Fixed visual bug when removing current user's folder owner permissions.
- Folders in "Shared with Me" Quick Access menu are now filtered when searching.
- If a user's encrypted TOTP reset Guid gets corrupted, an administrator is now able to reset their TOTP.
- Improved error handling on the OpenId Configuration page.
- Improved the UI on the Collections Management page for advanced session recording agents.
- In the prior upgrade file set for 11.6.3, fixed an issue with SQL Delta 11.5.000006. Removed a SQL hint on the SQL index that was incompatible with non-Enterprise editions prior to SQL Server 2016 SP1 due to a compatibility issue with data compression. The incompatible hint was not necessary, so the delta was updated. Hashes for upgrade were updated for this change.
- Legacy RPC admin page removed.
- Legacy user and group management aspx pages removed.
- Limited Mode now goes to the correct link in SSC.
- Made performance improvements for the "What Secret Permissions Exist?" report.
- Prevented Thycotic One sync from syncg Platform Native users. This allows Platform native users to log in in the rare situation they synced with Thycotic One. Then the administrator clears the system Platform User

mappings.

- Queries executed in the chart and SQL editor for custom reports will now take the Use Database Paging setting into account so that the result is the same as if the query was being saved as a report.
- Removed legacy ASPX pages for secret templates.
- Removed link for managing licenses from the Cloud Subscriptions page.
- Secret Server was updated to use the same player for session recordings as platform.
- Set the GET SDK Client Account, SDK Client Audit, and SDK Client Rule API calls to set the operator parameter to 1 if it is not supplied by the caller when a User ID filter is specified.
- Switching pinned folders now resets the text search.
- Updated auditing for users modifying allowed cipher suite algorithms.
- Updated diagnostics page and licensing expiration checks to correctly handle non-US date patterns.
- Updated event subscription and workflow grids.
- Updated password requirement audits to correctly audit missed fields.
- Updated the action-handler secret-launch dialog layout to reflect design changes.
- Updated the Cloud Subscription page to the new UI.
- Updated the Dependency Changes List page to the new UI.
- Updated the Diagnostics page to the new UI.
- Updated the display for secret locked pages to address a wrapping issue with DoubleLock.
- Updated the distributed engine log UI updated. It now remembers your last selected site, system log grid UI updated, and the last selected log level.
- Updated the EventDetails token within Event Subscriptions to correctly capture secret comments.
- Updated the logout.aspx page to avoid errors being generated in rare cases when executing the SAML SLO flow.
- Updated the ticket system list page to the new UI.
- Updated user preferences page for better accessibility.
- web.config now allows explicit definition of allowed HTTP verbs.
- Addressed an issue where discovery rules would not correctly display the selected secret template or password type.
- Adjusted discovery scanning to minimize potential SQL deadlocks during the scanning process.
- Adjusted Secret Server and distributed engine to support 3.x versions of SAP .NET Connector.
- Converted HSM to a new UI page with a new PKCS11 API type. This new option enables you to protect your MEK and secret keys with an AES 256 key, bringing the strength of all keys to AES 256. After setting up PKCS#11 with your HSM vendor, you use the vendor cryptoki library (dll), token label and user pin to integrate with Secret Server. NOTE: You will need to disable the HSM first, to switch to the new PKCS11 API type. See the Hardware Security Module for more details.

- Enable Audit Integration on the Platform Configuration page can now be turned on.
- Extended timeout for some indexing steps for customers with over one million secrets.
- Fixed an issue that caused folder permissions to not update under specific circumstances.
- Fixed an issue where long column names did not wrap in the column selector.
- Fixed an issue where searching for a secret name using a substring within a single word would not always return results.
- Fixed an issue where the Dashboard Overview tab was not selected by default.
- Fixed an issue where the main search did not return content and updated the search design.
- Fixed an issue where the New Folder button would be incorrectly hidden in certain situations when displayed from Platform.
- Fixed an issue where the system log filter preference had an error when all was selected as the last used filter.
- Fixed an issue where the folder tree disappeared when there were more than 1,000 folders accessed and UAM was enabled.
- Fixed an issue with the discovery splash image margin.
- Fixed bug where changing the client ID did not update unless the client secret was updated as well.
- Fixed display issue for Secret edit modal on Discovery scope page.
- Fixed issue with QuantumLock Assign Users grid not displaying correctly after editing then canceling.
- Fixed the folder audit download to show the correct title.
- Improved exception logging for certain scenarios related to launching.
- License requirement message for secret policies updated to Pro Edition or higher.
- Removed no-longer-used bookmarklet login pages.
- Updated API documentation for updating team membership.
- Updated the Secret Import to handle a trailing whitespace in the folder path to prevent bug where created the child folder at the root level.
- Updated the ticket system detail page to the modern UI framework.

Secret Server 11.6.000025 GA Release Notes

On-premises: January 24, 2024

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.21.0

Protocol Handler: 6.0.3.27

With this version, protocol handler has received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

Step Upgrade Required (11.5.2). Versions prior to 11.5.2 need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6.x upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.x.

For instructions on upgrading in general, go to "Upgrading" on page 142.

New Features

HSM PKCS #11 API Support and AES256 Key Integration

We are pleased to announce a significant enhancement in the Hardware Security Module (HSM) functionality. This enhancement marks the integration of support for the PKCS #11 APIs, achieved through the use of vendor-provided DLLs. This development not only extends our compatibility with a broader range of cryptographic tokens and HSMs that comply with the PKCS #11 standard but also ensures optimized performance across HSM models and manufacturers.

Moreover, this update provides the capability to leverage Advanced Encryption Standard (AES) 256-bit keys within the HSM, affording security and performance benefits, bringing our HSM integration in line with the majority of cryptographic functions used elsewhere in our products. This underscores our commitment to providing top-tier security features, crucial for safeguarding sensitive data in high-security environments.

The integration of PKCS #11 API support and AES256 not only enhances our security landscape but also offers increased flexibility and compatibility. This update enables users to more effectively use their existing HSM more effectively and provides an expanded array of cryptographic operations options, meeting diverse security needs.

Detailed information on configuring and utilizing the new HSM functions can be found in our updated documentation See "Using Hardware Security Modules" on page 1461 for details.

You will need to disable the HSM first to switch to the new PKCS11 API type. See "Using Hardware Security Modules" on page 1461 for details.

Enhancements

- Enhancement: Added a link to configuration audits on the Remote Password Changing page.
- Enhancement: Added a running log to disaster recovery so progress and duration per table can be tracked during replication.
- Enhancement: Added an event subscription called "Disaster Recovery Replication Success."

- Enhancement: Added auditing of password change schedules.
- Enhancement: Folders in favorites quick access are now filtered when searching.
- Enhancement: Improved HSM cryptography by adding support for AES 256 encryption. This ensures that all keys protecting the secret key will be at the same strength for organizations requiring this level of encryption.
- Enhancement: If an Azure Active Directory configuration in directory services becomes corrupt, you can now view and update the credentials to fix it.
- Enhancement: improved internal security checking around launchers.
- Enhancement: Improved SSH proxy block-command handling in VIM.
- Enhancement: Launching a secret now opens in a dialog allowing launch to occur without leaving the grid or current page. Restricted actions like checkout can be performed in the dialog.
- Enhancement: On the Proxying Configuration page, you can now automatically generate new SSH proxy host keys.
- Enhancement: Platform configuration settings were added to disaster recovery.
- Enhancement: Secret search performance improvements. The secret grid now only requests extended fields that are showing. When column selections are updated, a new request is made only if the extended field choices have changes.
- Enhancement: Secrets grid modal on the Secret Erase Requests search page now auto-scrolls.
- Enhancement: The login policy now supports line breaks.
- Enhancement: The secret search API now has a comma-delimited filter parameter for template IDs, which allows searching beyond IIS URL limits compared to the existing array version. Both are still available.
- Enhancement: The user profile allows for date and time format setting.
- Enhancement: Updated the toast message displayed when saving user preferences to accommodate screen readers.
- Enhancement: Users are no longer redirected from the licensing page.
- Enhancement: When Secret Server Cloud is Platform integrated, there is now an "Add from External Directory" option in secret sharing that allows searching directory sources from Platform to add users or groups.

Bug Fixes

- Added "view all folders" link that appears when folders are filtered in a pin view.
- Added a download button for session recording to Secret Server. The change does not appear for vault sessions in Platform.
- Added aria labels to the notification bell to support screen readers.
- Added new REST API patch method to controller which calls pre-existing latestversion.txt processing code.
- Added protocol handler step-up upgrade. Protocol handler will not try to upgrade versions 6.0.3.26 to newer versions as they must be updated manually. Released new 6.0.3.27 version which will be able to upgrade to future versions.

- Adjusted license tracking for session-recording-enabled secrets so that secrets that have no launchers are excluded.
- Adjusted organization of some administrative menu items in the configuration preview.
- Adjusted permissions on Session Monitoring page so that users with "View Own Session Recordings" permission will only see their own recordings.
- Adjusted the display of administrative items from Platform to avoid perceived duplication.
- Adjusted the log level downward for certain engine messages for syslog to avoid overloading the engine log table.
- Applied a more reasonable default SQL timeout.
- Clarified explanatory information on the Secret Import page to highlight that file fields are ignored.
- Converted dependency template management section to new UI.
- Converted Initial User page to the new UI.
- Corrected an issue where the Distributed Engine page did not respect the "Deleted" filter.
- Disabled the legacy bookmarklet pages.
- Disaster recovery now migrates teams.
- Fixed a client-side error on the Secret Settings page when viewed from Platform.
- Fixed a display issue on the IP Address restrictions page.
- Fixed a missing localization-key issue.
- Fixed a visual bug on secret templates so the password type dropdown no longer appears as "None" if a password type has been set.
- Fixed an edge case that could result in duplicate disabled usernames, possibly causing DR conflicts.
- Fixed an error that could occur on the Advanced Session Recording page.
- Fixed an HTML-encoded document link in discovery scanner.
- Fixed an issue an erroneous warning popup appeared saying a distributed engine is required for Active Directory when the SSC cloud instance has "Azure AD Domain" as the only domain.
- Fixed an issue on the Admin Roles page where the edit button for role permissions was mistakenly requiring "Administer Role Assignment" instead of "Administer Role Permission."
- Fixed an issue that could cause an incorrect error message to display when using the SQL report editor.
- Fixed an issue that could cause the secret picker to display with a horizontal scroll bar.
- Fixed an issue when searching in Secret Share with the "Add from External Directory" option with results of more than 2100 groups would throw an error.
- Fixed an issue where a proper validation message may not display when trying to give a duplicate name to a group.
- Fixed an issue where a secret erase request could no longer be canceled.

- Fixed an issue where banner text referenced only "engine," which was potentially confusing. It now mentions "distributed engine" explicitly.
- Fixed an issue where created hooks would not display on the secret.
- Fixed an issue where enabling RPC on a template through the API could impair the template's functionality.
- Fixed an issue where existing linked groups under the Platform Integration area on the Groups tab would not load.
- Fixed an issue where if a non-local site was used to send syslog to the syslog server any failure was queued back into the database (tbsyslogfailedmessage) and resent indefinitely. This has been resolved. Additionally, we implemented a syslog circuit-breaker system if a non-local site is used to prevent flooding the message queues with syslog messages when failure is expected.
- Fixed an issue where localization load requests would await indefinitely in some cases.
- Fixed an issue where pinned folders would not be removed when the corresponding folder was deleted.
- Fixed an issue where Platform synchronization was running too frequently in some cases.
- Fixed an issue where renaming or copying the "Oracle Account (Template Ver 2)" secret template caused password changes to fail.
- Fixed an issue where Resilient Secrets (DR) sent secret field launchers across the wire for every replication.
- Fixed an issue where selecting Generate New SSH Key on a secret would not generate a new SSH key.
- Fixed an issue where sorting the launchers list by name could display duplicates.
- Fixed an issue where the checkout screen could briefly show while a secret is loading.
- Fixed an issue where the child launcher type was not always visible on the new custom launcher page.
- Fixed an issue where the Everybody group from Platform would not match up properly with the Everybody group from Platform User sync. Corrected the display name of the Platform "Everybody" group.
- Fixed an issue where the light mode collapsed toolbar showed the dark mode logo.
- Fixed an issue where the notification bell could show when there were no notifications.
- Fixed an issue where the Preserve SSH Client Process setting did not correctly display as checked.
- Fixed an issue where the SSH custom cipher was not applied when missing a value from the section.
- Fixed an issue where the synchronized groups displayed could sometimes return all the groups from the domain.
- Fixed an issue where the web launcher would not respect the mapped URL field when multiple URL fields existed on the secret.
- Fixed an issue where unnecessary audits could be written. Fixed an issue where DR Secret Server instances were ignoring licensing updates from Cloud Manager.
- Fixed an issue where upgrade banner was always showing when auto-update was off. Now shows only if at least one engine is lower version than latest.
- Fixed an issue where users could click New Secret multiple times when also uploading files.
- Fixed and incorrect launcher edit field description.

- Fixed buttons that should be grayed out. Run RPC Now can no longer be run when RPC is disabled. Run heartbeat Now can no longer be run when heartbeat is disabled.
- Fixed dark mode IBM password tooltips and banner color-contrast issues.
- Fixed edge case bug if SSH Block Listing causes duplicate sessions that break SSH Proxy.
- Fixed error that could occur when creating a new folder with the folder panel minimized.
- Fixed inconsistent logs between source and replica on partial success. Fatal error is now persisted across the wire so the replica is aware that the source had a fatal error
- Fixed incorrect logging error in AuthenticateWithAdConsumer.
- Fixed issue in directory sync where a search result with an attribute containing an empty list could cause an error.
- Fixed issue where the upper right search bar would not always switch to the selected secret when a selected secret was on a tab other than the General tab.
- Fixed issue with a test script modal where reopening the modal would show the selected secret's ID instead of its name.
- Fixed issue with folder permission editing when updating a path directly.
- Fixed link to dependency templates on the Secret Dependency tab.
- Fixed logic error where the RAS flag was not being referenced before deciding to delete the database entry that reflected additional users.
- Fixed long secret-template names to wrap better in folder edit.
- Fixed missing option. System group in Secret Server Cloud can now have metadata deleted.
- Fixed Platform permissions cached on Secret Server to replicate so they will be respected on a replica instance.
- Fixed query for obtaining services for a directory account in discovery. Fixed check on discovery source name when creating an empty discovery source.
- Fixed secret policies not showing as deleted after deleting a secret. Secret names on the RPC tab of a secret policy will now include "Inactive" if a secret is not active.
- Fixed text alignment. Left aligned the comment text on the MFA security view. The icon and button remain centered.
- Fixed the link to the subscription page from the banner.
- Fixed the REST API token endpoint path. The documentation generator, in removing the "api" string from the beginning of all routes, was also removing embedded occurrences. It now removes it only from the start of the route strings.
- Fixed the secrets grid on the Secret Erase Request Approval page (in a modal opened via a link button) that was obscured in dark mode and nearly indistinguishable in light mode. This is now an inline grid with auto-scroll.
- Fixed visual bug when removing current user's folder owner permissions.
- Folders in "Shared with Me" Quick Access menu are now filtered when searching.
- If a user's encrypted TOTP reset Guid gets corrupted, an administrator is now able to reset their TOTP.

- Improved error handling on the OpenId Configuration page.
- Improved the UI on the Collections Management page for advanced session recording agents.
- In the prior upgrade file set for 11.6.3, fixed an issue with SQL Delta 11.5.000006. Removed a SQL hint on the SQL index that was incompatible with non-Enterprise editions prior to SQL Server 2016 SP1 due to a compatibility issue with data compression. The incompatible hint was not necessary, so the delta was updated. Hashes for upgrade were updated for this change.
- Legacy RPC admin page removed.
- Legacy user and group management aspx pages removed.
- Limited Mode now goes to the correct link in SSC.
- Made performance improvements for the "What Secret Permissions Exist?" report.
- Prevented Thycotic One sync from syncg Platform Native users. This allows Platform native users to log in in the rare situation they synced with Thycotic One. Then the administrator clears the system Platform User mappings.
- Queries executed in the chart and SQL editor for custom reports will now take the Use Database Paging setting into account so that the result is the same as if the query was being saved as a report.
- Removed legacy ASPX pages for secret templates.
- Removed link for managing licenses from the Cloud Subscriptions page.
- Secret Server was updated to use the same player for session recordings as platform.
- Set the GET SDK Client Account, SDK Client Audit, and SDK Client Rule API calls to set the operator parameter to 1 if it is not supplied by the caller when a User ID filter is specified.
- Switching pinned folders now resets the text search.
- Updated auditing for users modifying allowed cipher suite algorithms.
- Updated diagnostics page and licensing expiration checks to correctly handle non-US date patterns.
- Updated event subscription and workflow grids.
- Updated password requirement audits to correctly audit missed fields.
- Updated the action-handler secret-launch dialog layout to reflect design changes.
- Updated the Cloud Subscription page to the new UI.
- Updated the Dependency Changes List page to the new UI.
- Updated the Diagnostics page to the new UI.
- Updated the display for secret locked pages to address a wrapping issue with DoubleLock.
- Updated the distributed engine log UI updated. It now remembers your last selected site, system log grid UI updated, and the last selected log level.
- Updated the EventDetails token within Event Subscriptions to correctly capture secret comments.
- Updated the logout.aspx page to avoid errors being generated in rare cases when executing the SAML SLO flow.

- Updated the ticket system list page to the new UI.
- Updated user preferences page for better accessibility.
- web.config now allows explicit definition of allowed HTTP verbs.

Secret Server 11.6.000004 Release Notes

On-premises: December 6, 2023

Important security release–we recommend all affected Secret Server On-Premise customers upgrade as soon as possible. This update addresses a security vulnerability recently discovered during internal testing and impacts all versions of Secret Server. A SQL Injection vulnerability was found in the REST API. Hashes for upgrade have been updated for this change. This issue is rated HIGH with a score of 7.2 on the Common Vulnerability Scoring System (CVSS): CVSS:3.1/AV:N/AC:L/PR:H/UI:N/S:U/C:H/I:H/A:H

This vulnerability has been patched in Secret Server Cloud, so there is no additional update to address it.

The minimum required engine version is 8.3.0.0.

Step Upgrade Required (11.5.2). Versions prior to 11.5.2 need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6 upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.4.

For instructions on upgrading in general, go to "Upgrading" on page 142.

Secret Server 11.6.000003 GA Release Notes

For convenience, this document contains the release notes from the 11.6.000000 EA and 11.6.000002 GA releases.

Release Date and Notes

A new Delinea certificate signature has been applied to our binary files so if you are using the old Thycotic Certificate signature, you need to update to the new or you may experience an interruption of service.

We identified and resolved an issue with the latest Secret Server 11.6.000002 for some On-Premise users. Although the issue was intermittent and inconsistent, out of an abundance of caution and a commitment to quality, we deployed Secret Server 11.6.3. Please download Secret Server 11.6.3 at your earliest convenience.

On-premises: September 28, 2023 (September 26, 2023 GA)

This release contains a silent update that fixed an issue with SQL Delta 11.5.000006. We removed a SQL hint on the SQL index that was incompatible with non-Enterprise editions prior to SQL Server 2016 SP1 due to a compatibility issue with data compression. The incompatible hint was not necessary so the delta was updated. Hashes for upgrade have been updated for this change.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.16.0

Protocol Handler: 6.0.3.26

Note: Step Upgrade Required (11.5.2). Versions prior to 11.5.2 will need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6 upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.

Feature Enhancements

View Own Session Recordings Permission

A new permission has been added "View Own Session Recordings". With this permission, a user can be restricted to only viewing the recordings that they initiated. If the user with this permission clicks on a recording initiated and owned by another user, they will get an Access Denied window. In addition, the "View Session Recordings" permission has been renamed to "View All Session Recordings".

Session Monitoring Playback Page UI Conversion

The Session Recording playback page has been updated to the new UI, including a new video player with additional controls. The SSH keystroke-only playback page and the video playback page have been merged, and the available elements will be shown. The legacy player is still available as a link from the new video playback page.

Note: The activity graph and download button have not yet been implemented for the new page, although they are available on the legacy page if needed.

Manual Password Change for Checked Out Secrets

Secrets with Change Password on Checkin configured now have the "Change Password Now" functionality available. This will enable the standard functionality of a password change, and the secret will also complete the automatic password change on checking in. This is to allow maintenance and testing of secrets protected in this

manner, and a pending password change must be completed before the check-in process is allowed to begin in order to maintain a secure order of operations.

Updated User Selection Interface

Various locations around the product provide a user selection interface to provide the ability to select a user as the target of a particular configuration, such as the permissions, groups, and roles pages. These have been updated throughout the product to provide more data about the users in the list. You may now view, filter, and search for users by their Username, Display Name, or Email.

Automated Password Change on Import

An option has been added to the Import Secret function to mark each secret's password to immediately change after import. With this option enabled, a user who has had access to view the list of secrets will no longer know the password of the secrets once they have completed the import. The option is available for CSV and XML and can be flagged via the UI and API.

Enhancements

11.6.000002 GA

- Improvement: We made Web HTML elements IDs unique to prevent conflicts and keep buttons accessible.
- Improvement: Enhanced the user experience when navigating Secret Server with no permissions
- Improvement: Added filtering of the Description field of the Discovery Network View when entering search text.
- Improvement: Increased the specificity of an exception when accessing the REST API without permission—it now returns AccessDeniedException instead of API_AccessDenied.

11.6.000000 EA

- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: (Disaster Recovery/Resilient Secrets):Data replication will now create personal folders for replicated users in cases where the replica blocks or does not allow personal folders to be replicated. This is only if personal folders are enabled on the replica.
- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: Fixed issues with user and group syncing between Secret Server Cloud and the Delinea Platform.
- Improvement: Added a "Managed" field to the Discovery Network view to show when a discovery item is managed.
- Improvement: The Password Requirement Audit has been converted to the new UI.
- Improvement: The Secret Dependency Changers editor has been converted to the new UI.
- Improvement: Dependency Templates are now available in the new UI.

- Improvement: Session playback player UI has been updated.
- Improvement: The Launcher Audits page has been migrated to the new UI.
- Improvement: Discovery Service Accounts Detail Page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Added a Quick Access link to see all secrets you currently have checked out.
- Improvement: Updated Createuser.aspx to redirect to the new user creation page.
- Improvement: Updated the group role assignment UI.
- Improvement: Group membership assignment UI updated.
- Improvement: Group role assignment UI updated.
- Improvement: Updated process for populating a forthcoming computer-centric view.
- Improvement: Session recording search now uses updated filter pattern.
- Improvement: The built-in "Everyone" group was renamed "All Vault Users."
- Improvement: Enhanced new Discovery Area to include some additional fields and added logic for the error chip being displayed
- Improvement: Added a Copy button for Data Source URL on Disaster Recovery - Outgoing Setup Steps modal.
- Improvement: New Vault User Details in the Platform overview for Users tab. It requires a Vault to be successfully connected and configured for the details to appear, otherwise the section does not appear.
- Improvement: Added banners to various Roles/Permissions pages in Secret Server Cloud and Platform with links to help navigate between the two.
- Improvement: Secret Share tab UI has been updated to match the permission setting experience for setting folder permissions. Domain name is now displayed for users on the secret share tab.
- Improvement: Fixed an issue where the folder permissions tab would load slowly with large numbers of users.
- Improvement: Updated group membership management pages to use new design patterns.
- Improvement: The display name of the secret Vault is now set via the Platform. The Vault subcategories for Reporting, Inbox, and administration have been updated to reflect Secret Server.
- Improvement: Analysis tab of Discovery no longer includes disabled Discovery Sources in managed/unmanaged counts.
- Improvement: Administration Configuration Launcher Settings now displays the Enable Protocol Handler Auto-Update setting in cloud.
- Improvement: View Log was hidden for Directory Accounts since there's no computer associated to show the log of.
- Improvement: Added Application from tbAuditSecret to session search results model and session model.
- Improvement: When discovery is running the network view performance would timeout depending on SQL locks. This should no longer happen.

- Improvement: Discovery scanners added an option to "Add child scanner" which filters available scanners to show only applicable child scanners.
- Improvement: Disaster Recovery Add-On Licensing handling added.
- Improvement: Secret template fields table has been updated and has an improved drag and drop experience.
- Improvement: Secret panel is more mobile friendly.
- Improvement: Syslog/CEF logging enhanced to capture more detailed metadata for secrets that contain fields/data that map to the following SIEM fields: Account Name, Account Domain, Target Server, Request ID (that is from Ticketing System). Additionally, failed attempts to access secrets due to Ticket Validation errors are now also logged to Secret Audits.
- Improvement: New inbox notification bell with panel, allows for viewing and approving inbox items without having to navigate through the site.
- Improvement: The Security Audit Log page has been converted to the latest UI.
- Improvement: A donut chart showing different Operating Systems in discovery has been added to the Analysis tab of discovery.
- Improvement: Live viewing has been added to the new session monitoring.
- Improvement: The new UI Discovery Rules page now shows the correct Secret Template name.
- Improvement: Secret policy now links to the policy on the secret general tab.
- Improvement: A loading indicator now shows when opening the discovery add scanner dialog.
- Improvement: The main top left logo will link to the users preferred login home if it is the dashboard or all secrets.
- Improvement: The COM+ scanner will be able to be added, but there will be a note in the preview panel letting the user know that the scanner will not work for a site that is set to UseWebsite.
- Improvement: A preview chip has been added to Multifactor Authentication on Secrets and its supporting configuration pages.
- Improvement: A new field "Full Name" has been added to the discovery network view to give a more detailed version of the item's name.
- Improvement: Default columns have been added per Item Type in the discovery network view.
- Improvement: Dependency Tokens are now available on the dependency edit screen.
- Improvement: Enhanced loading times of Secret Server elements in Delinea Platform.
- Improvement: REST API documentation has links to individual services that load quickly.
- Improvement: Added filter on recorded-sessions endpoint to filter out applications, particularly 'RemoteAccessService' when in platform
- Improvement: Implemented a message shim in the Vault Broker to inform Secret Server that a user's platform permissions have changed.
- Improvement: Updated the Vault Settings and Vault User Detail Tabs with some UI changes.

- Improvement: Converted the creation of a Password Changer when Create Password Changer is selected from the Password Changers list in Remote Password Changing.
- Improvement: Added a filter of secretIDs to the Secret Search endpoint to that Secrets can be filtered by SecretID.
- Improvement: Terminate, limit to 5 minutes, and message only have been added to live viewing in the new session monitoring
- Improvement: The heading for Vault within Platform User Management details has been updated to read its value from within Platform.
- Improvement: The text for page title, breadcrumbs, and navigation for Secret Server Reporting have been updated in Platform to match.
- Improvement: Added Search Groups column to Discovery Network View.
- Improvement: Added more instructions regarding Disaster Recovery's data storage path configuration setting.
- Improvement: Added configuration setting to determine which secret permission is required to change Remote Password Changing settings on a Secret. Owner or Edit.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Added a WMI Service Timeout setting to the cloud advanced configuration page to help with dependency changes that take more time than the allotted 60 seconds.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: Improved performance of Secret Search for customers with large numbers of Secrets.
- Improvement: Updated data type to support frequent users of session recording that was crashing the encoding process.
- Improvement: Secrets with text field based URL lists are now searchable.
- Improvement: Platform users can login to Terminal using SSH Key Integration.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: When Platform integration is active the integration page will now have a button to reset mappings from Delinea Platform.
- Improvement: AD Privilege Password changer now has Remote Password Change timeout minutes Advanced Setting.
- Improvement: Better handling of unexpected heartbeat behavior to mitigate reported Distributed Engine stalling.
- Improvement: Connect As Credentials on Secret works better with SSH Keys for su user switching.
- Improvement: Updated links on the Security Hardening Report to new UI pages
- Improvement: When creating a new send to syslog task you no longer get a default schedule. Most of the templates didn't create a schedule, now they're all consistent.
- Improvement: Session monitoring search now supports searching by a single secret.

- Improvement: When a Secret is assigned to a site the user does not have access to due to Teams restriction, they will see the word "Restricted" instead of "Site Name (Inactive)".
- Improvement: Mitigated issue in large bulk secret actions.
- Improvements: The "Synchronization Running" message for DR will now only appear if there is a recorded start time for DR in the past and a finish time that is in the future.
- Improvement: Added Secret Field validation on the Template level to ensure users cannot create a "Secret Name" field on a template.
- Improvement: Default values for Secret Fields such as port will now be replicated for Disaster Recovery.
- Improvement: A user with only direct access to a report and the "browse reports" role permission can add that report to the dashboard.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Report column preferences will be saved and applied when viewing a report.
- Improvement: The Secrets grid now updates displayed data and selected columns simultaneously.
- Improvement: Improved error logging and efficiency for calls coming from Delinea Platform.
- Improvement: Quick access filters now both apply when updated.
- Improvement: Knowledge base links within Platform Vault now link to their intended location.
- Improvement: Corrected edge case that could result in a session view audit being placed on the incorrect Secret.
- Improvement: The Parent Scan Template will be filtered to the type and will default to the first item in the list on create. The proper fields will be shown based on the type.
- Improvement: If a secret is inactivated after initially viewing the secret, a user that cannot view inactive secrets will no longer get an error from secret heartbeat.
- Improvement: Clicking cancel when editing folder permissions will clear any active filters.
- Improvement: Editing folder permissions now has a split button that allows for directly entering edit or add group/user mode.
- Improvement: The Secrets Quick Access link when collapsed, now targets the correct destination.
- Improvement: The Platform Opt In modal styling has been adjusted to no longer display with scroll bars.
- Improvement: Secret Share and Folder Permissions: Show disabled edit button until filters are loaded since split button does not yet support disabled.
- Improvement: API calls to /v[1/2]/secrets/{id} now update the Recents secrets data source.
- Improvement: When viewing Event Pipeline Activity details, selecting an Activity Detail record from the grid now displays the selected Activity's details.
- Improvement: Added query parameter for PipelineId to pass back when viewing specific pipeline activity
- Improvement: Discovery Scanner will not allow deletion until Secret selection is changed.
- Improvement: Remote Password Changing: Check for DNS Mismatch now visible and functional in Cloud.

- Improvement: EventTime token is available in pipeline scripts. $EventTime - event date and time of the event ("yyyy'-'MM'-'dd'T'HH':'mm':'ss").
- Improvement: The preview chips for Multifactor on Secrets have been removed.
- Improvement: Creating a User SSH Key in Platform downloads the private key with a proper filename.
- Improvement: Cipher Suite Configuration now allows configuration of allowed Host Key Algorithms.

Bug Fixes

11.6.000002 GA

- Placed part of the "secret save" process into a transaction so that changes would be rolled back if a timeout occurred.
- Fixed a bug that prevented expanding a secret created using a custom template on All Secrets View.
- Added a bulk operation to set password requirements on multiple secrets.
- Added a "password displayed" audit when viewing a secret transition history.
- Allowed AutoChangeSchedule to be usable when CheckoutChangePassword is enabled.
- Fixed the Inbox link in the left navigation panel.
- Extended the "secret hook" timeout from 30 seconds to 2 minutes. Hooks now use the "Event Pipelines Maximum Script Run Time (Minutes)" advanced setting to extend beyond 2 minutes.
- Fixed a localization issue when a discovery item has a scan item template that is not out of the box.
- Fixed issue with secret permissions displaying incorrectly on the Secret Share page.

11.6.000000 EA

- On-premise only: Fixed logic issue for on-premise instance that was using the wrong minimum heartbeat interval. Minimum heartbeat interval set back to 5 minutes.

  Fixed an issue where Viewing Session Connector Custom Launchers without access to the RDS Credentials secret would show an error.
- Fixed an issue where unplayable session recording videos would display an infinite load instead of the appropriate error.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where Pause times for ODBC Remote Password Changers were not adhered to. If you feel your RPC's are running slowly, check the pause times and remove them if they are not needed for the RPC action.
- Fixed an issue where Web Password Filler didn't work in certain instances due to an ambiguity in interpreting the Secret Server URL.
- Fixed an issue where setting custom expiration dates in all time zones did not work correctly.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where the secret name would incorrectly display on the New Discovery Import Rules page.
- Fixed an issue with negative numbers exporting incorrectly when exporting to a CSV file.

- Fixed an issue where a large number of SSH terminal connection history records causing timeouts.
- Fixed an issue with hidden days until deletion field when enabling deletion in the retention schedule. Added localization to error when trying to submit days less than or equal to the archive retention value.
- Fixed an issue with passwords being uneditable if RPC is set to use a Privileged Secret to which the user has no access to. Restored explanatory banner.
- Fixed an issue where secrets aren't synced with DevOps in cloud with when triggered by pipelines.
- Fixed issue in discovery where computer scans were sometimes throwing string truncation exceptions.
- Fixed an issue where TOTP Secret Settings edit button was available to users who could not edit the settings.
- Fix an issue with editing Session Connector Custom Launcher Port.
- Fixed a UI issue with the launcher popup window showing an option the user didn't have permission for.
- Fixed an issue where configuring a new session connector launcher might not show all available launcher types.
- Fixed an issue where configuring "Use Additional Prompt" on launchers might prevent save.
- Fixed an issue with the TemplateCreateSecret role link.
- Fixed an issue with View Launcher Password.
- Fixed an issue where users with only 'View' access on a Secret would be unable to view the Password if there was a custom launcher with arguments configured for that Secret Template.
- Fixed an issue with DSV sync for secret with file type fields and no file set.
- Fixed an issue with localization on folder Metadata page.
- Fixed an issue with sorting for Checkout User Id and Checkout User.
- Fixed an issue with ODBC password changing that broke postgres and mySQL changing.
- Fixed a logging issue with Dependency changes ran through Distributed Engine being skipped due to conditions.
- Fixed an issue where the generate SSH key returns a 500 exception.
- Fixed an issue where the SSHCipherSuiteModel GetAsync returned a 500 exception.
- Fixed an issue where the CreatePublicSSHKey returned a 500 Exception.
- Fixed an issue where Discovery Scanners could not be removed until the associated secrets had been edited.

Secret Server 11.6.000002 GA Release Notes

For convenience, this document also contains the release notes from the 11.6.000000 EA release.

Release Date and Notes

On-premises: September 26, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.16.0

Protocol Handler: 6.0.3.26

Note: Step Upgrade Required (11.5.2). Versions prior to 11.5.2 will need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6 upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.

Feature Enhancements

View Own Session Recordings Permission

A new permission has been added "View Own Session Recordings". With this permission, a user can be restricted to only viewing the recordings that they initiated. If the user with this permission clicks on a recording initiated and owned by another user, they will get an Access Denied window. In addition, the "View Session Recordings" permission has been renamed to "View All Session Recordings".

Session Monitoring Playback Page UI Conversion

The Session Recording playback page has been updated to the new UI, including a new video player with additional controls. The SSH keystroke-only playback page and the video playback page have been merged, and the available elements will be shown. The legacy player is still available as a link from the new video playback page.

Note: The activity graph and download button have not yet been implemented for the new page, although they are available on the legacy page if needed.

Manual Password Change for Checked Out Secrets

Secrets with Change Password on Checkin configured now have the "Change Password Now" functionality available. This will enable the standard functionality of a password change, and the secret will also complete the automatic password change on checking in. This is to allow maintenance and testing of secrets protected in this

manner, and a pending password change must be completed before the check-in process is allowed to begin in order to maintain a secure order of operations.

Updated User Selection Interface

Various locations around the product provide a user selection interface to provide the ability to select a user as the target of a particular configuration, such as the permissions, groups, and roles pages. These have been updated throughout the product to provide more data about the users in the list. You may now view, filter, and search for users by their Username, Display Name, or Email.

Automated Password Change on Import

An option has been added to the Import Secret function to mark each secret's password to immediately change after import. With this option enabled, a user who has had access to view the list of secrets will no longer know the password of the secrets once they have completed the import. The option is available for CSV and XML and can be flagged via the UI and API.

Enhancements

11.6.000002 GA

- Improvement: We made Web HTML elements IDs unique to prevent conflicts and keep buttons accessible.
- Improvement: Enhanced the user experience when navigating Secret Server with no permissions
- Improvement: Added filtering of the Description field of the Discovery Network View when entering search text.
- Improvement: Increased the specificity of an exception when accessing the REST API without permission—it now returns AccessDeniedException instead of API_AccessDenied.

11.6.000000 EA

- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: (Disaster Recovery/Resilient Secrets):Data replication will now create personal folders for replicated users in cases where the replica blocks or does not allow personal folders to be replicated. This is only if personal folders are enabled on the replica.
- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: Fixed issues with user and group syncing between Secret Server Cloud and the Delinea Platform.
- Improvement: Added a "Managed" field to the Discovery Network view to show when a discovery item is managed.
- Improvement: The Password Requirement Audit has been converted to the new UI.
- Improvement: The Secret Dependency Changers editor has been converted to the new UI.
- Improvement: Dependency Templates are now available in the new UI.

- Improvement: Session playback player UI has been updated.
- Improvement: The Launcher Audits page has been migrated to the new UI.
- Improvement: Discovery Service Accounts Detail Page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Added a Quick Access link to see all secrets you currently have checked out.
- Improvement: Updated Createuser.aspx to redirect to the new user creation page.
- Improvement: Updated the group role assignment UI.
- Improvement: Group membership assignment UI updated.
- Improvement: Group role assignment UI updated.
- Improvement: Updated process for populating a forthcoming computer-centric view.
- Improvement: Session recording search now uses updated filter pattern.
- Improvement: The built-in "Everyone" group was renamed "All Vault Users."
- Improvement: Enhanced new Discovery Area to include some additional fields and added logic for the error chip being displayed
- Improvement: Added a Copy button for Data Source URL on Disaster Recovery - Outgoing Setup Steps modal.
- Improvement: New Vault User Details in the Platform overview for Users tab. It requires a Vault to be successfully connected and configured for the details to appear, otherwise the section does not appear.
- Improvement: Added banners to various Roles/Permissions pages in Secret Server Cloud and Platform with links to help navigate between the two.
- Improvement: Secret Share tab UI has been updated to match the permission setting experience for setting folder permissions. Domain name is now displayed for users on the secret share tab.
- Improvement: Fixed an issue where the folder permissions tab would load slowly with large numbers of users.
- Improvement: Updated group membership management pages to use new design patterns.
- Improvement: The display name of the secret Vault is now set via the Platform. The Vault subcategories for Reporting, Inbox, and administration have been updated to reflect Secret Server.
- Improvement: Analysis tab of Discovery no longer includes disabled Discovery Sources in managed/unmanaged counts.
- Improvement: Administration Configuration Launcher Settings now displays the Enable Protocol Handler Auto-Update setting in cloud.
- Improvement: View Log was hidden for Directory Accounts since there's no computer associated to show the log of.
- Improvement: Added Application from tbAuditSecret to session search results model and session model.
- Improvement: When discovery is running the network view performance would timeout depending on SQL locks. This should no longer happen.

- Improvement: Discovery scanners added an option to "Add child scanner" which filters available scanners to show only applicable child scanners.
- Improvement: Disaster Recovery Add-On Licensing handling added.
- Improvement: Secret template fields table has been updated and has an improved drag and drop experience.
- Improvement: Secret panel is more mobile friendly.
- Improvement: Syslog/CEF logging enhanced to capture more detailed metadata for secrets that contain fields/data that map to the following SIEM fields: Account Name, Account Domain, Target Server, Request ID (that is from Ticketing System). Additionally, failed attempts to access secrets due to Ticket Validation errors are now also logged to Secret Audits.
- Improvement: New inbox notification bell with panel, allows for viewing and approving inbox items without having to navigate through the site.
- Improvement: The Security Audit Log page has been converted to the latest UI.
- Improvement: A donut chart showing different Operating Systems in discovery has been added to the Analysis tab of discovery.
- Improvement: Live viewing has been added to the new session monitoring.
- Improvement: The new UI Discovery Rules page now shows the correct Secret Template name.
- Improvement: Secret policy now links to the policy on the secret general tab.
- Improvement: A loading indicator now shows when opening the discovery add scanner dialog.
- Improvement: The main top left logo will link to the users preferred login home if it is the dashboard or all secrets.
- Improvement: The COM+ scanner will be able to be added, but there will be a note in the preview panel letting the user know that the scanner will not work for a site that is set to UseWebsite.
- Improvement: A preview chip has been added to Multifactor Authentication on Secrets and its supporting configuration pages.
- Improvement: A new field "Full Name" has been added to the discovery network view to give a more detailed version of the item's name.
- Improvement: Default columns have been added per Item Type in the discovery network view.
- Improvement: Dependency Tokens are now available on the dependency edit screen.
- Improvement: Enhanced loading times of Secret Server elements in Delinea Platform.
- Improvement: REST API documentation has links to individual services that load quickly.
- Improvement: Added filter on recorded-sessions endpoint to filter out applications, particularly 'RemoteAccessService' when in platform
- Improvement: Implemented a message shim in the Vault Broker to inform Secret Server that a user's platform permissions have changed.
- Improvement: Updated the Vault Settings and Vault User Detail Tabs with some UI changes.

- Improvement: Converted the creation of a Password Changer when Create Password Changer is selected from the Password Changers list in Remote Password Changing.
- Improvement: Added a filter of secretIDs to the Secret Search endpoint to that Secrets can be filtered by SecretID.
- Improvement: Terminate, limit to 5 minutes, and message only have been added to live viewing in the new session monitoring
- Improvement: The heading for Vault within Platform User Management details has been updated to read its value from within Platform.
- Improvement: The text for page title, breadcrumbs, and navigation for Secret Server Reporting have been updated in Platform to match.
- Improvement: Added Search Groups column to Discovery Network View.
- Improvement: Added more instructions regarding Disaster Recovery's data storage path configuration setting.
- Improvement: Added configuration setting to determine which secret permission is required to change Remote Password Changing settings on a Secret. Owner or Edit.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Added a WMI Service Timeout setting to the cloud advanced configuration page to help with dependency changes that take more time than the allotted 60 seconds.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: Improved performance of Secret Search for customers with large numbers of Secrets.
- Improvement: Updated data type to support frequent users of session recording that was crashing the encoding process.
- Improvement: Secrets with text field based URL lists are now searchable.
- Improvement: Platform users can login to Terminal using SSH Key Integration.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: When Platform integration is active the integration page will now have a button to reset mappings from Delinea Platform.
- Improvement: AD Privilege Password changer now has Remote Password Change timeout minutes Advanced Setting.
- Improvement: Better handling of unexpected heartbeat behavior to mitigate reported Distributed Engine stalling.
- Improvement: Connect As Credentials on Secret works better with SSH Keys for su user switching.
- Improvement: Updated links on the Security Hardening Report to new UI pages
- Improvement: When creating a new send to syslog task you no longer get a default schedule. Most of the templates didn't create a schedule, now they're all consistent.
- Improvement: Session monitoring search now supports searching by a single secret.

- Improvement: When a Secret is assigned to a site the user does not have access to due to Teams restriction, they will see the word "Restricted" instead of "Site Name (Inactive)".
- Improvement: Mitigated issue in large bulk secret actions.
- Improvements: The "Synchronization Running" message for DR will now only appear if there is a recorded start time for DR in the past and a finish time that is in the future.
- Improvement: Added Secret Field validation on the Template level to ensure users cannot create a "Secret Name" field on a template.
- Improvement: Default values for Secret Fields such as port will now be replicated for Disaster Recovery.
- Improvement: A user with only direct access to a report and the "browse reports" role permission can add that report to the dashboard.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Report column preferences will be saved and applied when viewing a report.
- Improvement: The Secrets grid now updates displayed data and selected columns simultaneously.
- Improvement: Improved error logging and efficiency for calls coming from Delinea Platform.
- Improvement: Quick access filters now both apply when updated.
- Improvement: Knowledge base links within Platform Vault now link to their intended location.
- Improvement: Corrected edge case that could result in a session view audit being placed on the incorrect Secret.
- Improvement: The Parent Scan Template will be filtered to the type and will default to the first item in the list on create. The proper fields will be shown based on the type.
- Improvement: If a secret is inactivated after initially viewing the secret, a user that cannot view inactive secrets will no longer get an error from secret heartbeat.
- Improvement: Clicking cancel when editing folder permissions will clear any active filters.
- Improvement: Editing folder permissions now has a split button that allows for directly entering edit or add group/user mode.
- Improvement: The Secrets Quick Access link when collapsed, now targets the correct destination.
- Improvement: The Platform Opt In modal styling has been adjusted to no longer display with scroll bars.
- Improvement: Secret Share and Folder Permissions: Show disabled edit button until filters are loaded since split button does not yet support disabled.
- Improvement: API calls to /v[1/2]/secrets/{id} now update the Recents secrets data source.
- Improvement: When viewing Event Pipeline Activity details, selecting an Activity Detail record from the grid now displays the selected Activity's details.
- Improvement: Added query parameter for PipelineId to pass back when viewing specific pipeline activity
- Improvement: Minimum Heartbeat interval reduced from 15 to 5 minutes.
- Improvement: Discovery Scanner will not allow deletion until Secret selection is changed.

- Improvement: Remote Password Changing: Check for DNS Mismatch now visible and functional in Cloud.
- Improvement: EventTime token is available in pipeline scripts. $EventTime - event date and time of the event ("yyyy'-'MM'-'dd'T'HH':'mm':'ss").
- Improvement: The preview chips for Multifactor on Secrets have been removed.
- Improvement: Creating a User SSH Key in Platform downloads the private key with a proper filename.
- Improvement: Cipher Suite Configuration now allows configuration of allowed Host Key Algorithms.

Bug Fixes

11.000002 GA

- Placed part of the "secret save" process into a transaction so that changes would be rolled back if a timeout occurred.
- Fixed a bug that prevented expanding a secret created using a custom template on All Secrets View.
- Added a bulk operation to set password requirements on multiple secrets.
- Added a "password displayed" audit when viewing a secret transition history.
- Allowed AutoChangeSchedule to be usable when CheckoutChangePassword is enabled.
- Fixed the Inbox link in the left navigation panel.
- Extended the "secret hook" timeout from 30 seconds to 2 minutes. Hooks now use the "Event Pipelines Maximum Script Run Time (Minutes)" advanced setting to extend beyond 2 minutes.
- Fixed a localization issue when a discovery item has a scan item template that is not out of the box.
- Fixed issue with secret permissions displaying incorrectly on the Secret Share page.

11.000000 EA

- Fixed an issue where Viewing Session Connector Custom Launchers without access to the RDS Credentials secret would show an error.
- Fixed an issue where unplayable session recording videos would display an infinite load instead of the appropriate error.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where Pause times for ODBC Remote Password Changers were not adhered to. If you feel your RPC's are running slowly, check the pause times and remove them if they are not needed for the RPC action.
- Fixed an issue where Web Password Filler didn't work in certain instances due to an ambiguity in interpreting the Secret Server URL.
- Fixed an issue where setting custom expiration dates in all time zones did not work correctly.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where the secret name would incorrectly display on the New Discovery Import Rules page.
- Fixed an issue with negative numbers exporting incorrectly when exporting to a CSV file.
- Fixed an issue where a large number of SSH terminal connection history records causing timeouts.

- Fixed an issue with hidden days until deletion field when enabling deletion in the retention schedule. Added localization to error when trying to submit days less than or equal to the archive retention value.
- Fixed an issue with passwords being uneditable if RPC is set to use a Privileged Secret to which the user has no access to. Restored explanatory banner.
- Fixed an issue where secrets aren't synced with DevOps in cloud with when triggered by pipelines.
- Fixed issue in discovery where computer scans were sometimes throwing string truncation exceptions.
- Fixed an issue where TOTP Secret Settings edit button was available to users who could not edit the settings.
- Fix an issue with editing Session Connector Custom Launcher Port.
- Fixed a UI issue with the launcher popup window showing an option the user didn't have permission for.
- Fixed an issue where configuring a new session connector launcher might not show all available launcher types.
- Fixed an issue where configuring "Use Additional Prompt" on launchers might prevent save.
- Fixed an issue with the TemplateCreateSecret role link.
- Fixed an issue with View Launcher Password.
- Fixed an issue where users with only 'View' access on a Secret would be unable to view the Password if there was a custom launcher with arguments configured for that Secret Template.
- Fixed an issue with DSV sync for secret with file type fields and no file set.
- Fixed an issue with localization on folder Metadata page.
- Fixed an issue with sorting for Checkout User Id and Checkout User.
- Fixed an issue with ODBC password changing that broke postgres and mySQL changing.
- Fixed a logging issue with Dependency changes ran through Distributed Engine being skipped due to conditions.
- Fixed an issue where the generate SSH key returns a 500 exception.
- Fixed an issue where the SSHCipherSuiteModel GetAsync returned a 500 exception.
- Fixed an issue where the CreatePublicSSHKey returned a 500 Exception.
- Fixed an issue where Discovery Scanners could not be removed until the associated secrets had been edited.

Secret Server 11.6.000000 EA Release Notes

Release Date and Notes

On-premises: September 12, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.16.0

Protocol Handler: 6.0.3.26

> Step Upgrade Required (11.5.2). Versions prior to 11.5.2 will need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6 upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6. For instructions on upgrading in general, go to "Upgrading" on page 142.

Feature Enhancements

View Own Session Recordings Permission

A new permission has been added "View Own Session Recordings". With this permission, a user can be restricted to only viewing the recordings that they initiated. If the user with this permission clicks on a recording initiated and owned by another user, they will get an Access Denied window. In addition, the "View Session Recordings" permission has been renamed to "View All Session Recordings".

Session Monitoring Playback Page UI Conversion

The Session Recording playback page has been updated to the new UI, including a new video player with additional controls. The SSH keystroke-only playback page and the video playback page have been merged, and the available elements will be shown. The legacy player is still available as a link from the new video playback page.

> **Note:** The activity graph and download button have not yet been implemented for the new page, although they are available on the legacy page if needed.

Manual Password Change for Checked Out Secrets

Secrets with Change Password on Checkin configured now have the "Change Password Now" functionality available. This will enable the standard functionality of a password change, and the secret will also complete the automatic password change on checking in. This is to allow maintenance and testing of secrets protected in this manner, and a pending password change must be completed before the check-in process is allowed to begin in order to maintain a secure order of operations.

Updated User Selection Interface

Various locations around the product provide a user selection interface to provide the ability to select a user as the target of a particular configuration, such as the permissions, groups, and roles pages. These have been updated throughout the product to provide more data about the users in the list. You may now view, filter, and search for users by their Username, Display Name, or Email.

Automated Password Change on Import

An option has been added to the Import Secret function to mark each secret's password to immediately change after import. With this option enabled, a user who has had access to view the list of secrets will no longer know the password of the secrets once they have completed the import. The option is available for CSV and XML and can be flagged via the UI and API.

Enhancements

- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: (Disaster Recovery/Resilient Secrets):Data replication will now create personal folders for replicated users in cases where the replica blocks or does not allow personal folders to be replicated. This is only if personal folders are enabled on the replica.
- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: Fixed issues with user and group syncing between Secret Server Cloud and the Delinea Platform.
- Improvement: Added a "Managed" field to the Discovery Network view to show when a discovery item is managed.
- Improvement: The Password Requirement Audit has been converted to the new UI.
- Improvement: The Secret Dependency Changers editor has been converted to the new UI.
- Improvement: Dependency Templates are now available in the new UI.
- Improvement: Session playback player UI has been updated.
- Improvement: The Launcher Audits page has been migrated to the new UI.
- Improvement: Discovery Service Accounts Detail Page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Added a Quick Access link to see all secrets you currently have checked out.
- Improvement: Updated Createuser.aspx to redirect to the new user creation page.
- Improvement: Updated the group role assignment UI.
- Improvement: Group membership assignment UI updated.
- Improvement: Group role assignment UI updated.
- Improvement: Updated process for populating a forthcoming computer-centric view.

- Improvement: Session recording search now uses updated filter pattern.
- Improvement: The built-in "Everyone" group was renamed "All Vault Users."
- Improvement: Enhanced new Discovery Area to include some additional fields and added logic for the error chip being displayed
- Improvement: Added a Copy button for Data Source URL on Disaster Recovery - Outgoing Setup Steps modal.
- Improvement: New Vault User Details in the Platform overview for Users tab. It requires a Vault to be successfully connected and configured for the details to appear, otherwise the section does not appear.
- Improvement: Added banners to various Roles/Permissions pages in Secret Server Cloud and Platform with links to help navigate between the two.
- Improvement: Secret Share tab UI has been updated to match the permission setting experience for setting folder permissions. Domain name is now displayed for users on the secret share tab.
- Improvement: Fixed an issue where the folder permissions tab would load slowly with large numbers of users.
- Improvement: Updated group membership management pages to use new design patterns.
- Improvement: The display name of the secret Vault is now set via the Platform. The Vault subcategories for Reporting, Inbox, and administration have been updated to reflect Secret Server.
- Improvement: Analysis tab of Discovery no longer includes disabled Discovery Sources in managed/unmanaged counts.
- Improvement: Administration Configuration Launcher Settings now displays the Enable Protocol Handler Auto-Update setting in cloud.
- Improvement: View Log was hidden for Directory Accounts since there's no computer associated to show the log of.
- Improvement: Added Application from tbAuditSecret to session search results model and session model.
- Improvement: When discovery is running the network view performance would timeout depending on SQL locks. This should no longer happen.
- Improvement: Discovery scanners added an option to "Add child scanner" which filters available scanners to show only applicable child scanners.
- Improvement: Disaster Recovery Add-On Licensing handling added.
- Improvement: Secret template fields table has been updated and has an improved drag and drop experience.
- Improvement: Secret panel is more mobile friendly.
- Improvement: Syslog/CEF logging enhanced to capture more detailed metadata for secrets that contain fields/data that map to the following SIEM fields: Account Name, Account Domain, Target Server, Request ID (that is from Ticketing System). Additionally, failed attempts to access secrets due to Ticket Validation errors are now also logged to Secret Audits.
- Improvement: New inbox notification bell with panel, allows for viewing and approving inbox items without having to navigate through the site.
- Improvement: The Security Audit Log page has been converted to the latest UI.

- Improvement: A donut chart showing different Operating Systems in discovery has been added to the Analysis tab of discovery.
- Improvement: Live viewing has been added to the new session monitoring.
- Improvement: The new UI Discovery Rules page now shows the correct Secret Template name.
- Improvement: Secret policy now links to the policy on the secret general tab.
- Improvement: A loading indicator now shows when opening the discovery add scanner dialog.
- Improvement: The main top left logo will link to the users preferred login home if it is the dashboard or all secrets.
- Improvement: The COM+ scanner will be able to be added, but there will be a note in the preview panel letting the user know that the scanner will not work for a site that is set to UseWebsite.
- Improvement: A preview chip has been added to Multifactor Authentication on Secrets and its supporting configuration pages.
- Improvement: A new field "Full Name" has been added to the discovery network view to give a more detailed version of the item's name.
- Improvement: Default columns have been added per Item Type in the discovery network view.
- Improvement: Dependency Tokens are now available on the dependency edit screen.
- Improvement: Enhanced loading times of Secret Server elements in Delinea Platform.
- Improvement: REST API documentation has links to individual services that load quickly.
- Improvement: Added filter on recorded-sessions endpoint to filter out applications, particularly 'RemoteAccessService' when in platform
- Improvement: Implemented a message shim in the Vault Broker to inform Secret Server that a user's platform permissions have changed.
- Improvement: Updated the Vault Settings and Vault User Detail Tabs with some UI changes.
- Improvement: Converted the creation of a Password Changer when Create Password Changer is selected from the Password Changers list in Remote Password Changing.
- Improvement: Added a filter of secretIDs to the Secret Search endpoint to that Secrets can be filtered by SecretID.
- Improvement: Terminate, limit to 5 minutes, and message only have been added to live viewing in the new session monitoring
- Improvement: The heading for Vault within Platform User Management details has been updated to read its value from within Platform.
- Improvement: The text for page title, breadcrumbs, and navigation for Secret Server Reporting have been updated in Platform to match.
- Improvement: Added Search Groups column to Discovery Network View.
- Improvement: Added more instructions regarding Disaster Recovery's data storage path configuration setting.

- Improvement: Added configuration setting to determine which secret permission is required to change Remote Password Changing settings on a Secret. Owner or Edit.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Added a WMI Service Timeout setting to the cloud advanced configuration page to help with dependency changes that take more time than the allotted 60 seconds.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: Improved performance of Secret Search for customers with large numbers of Secrets.
- Improvement: Updated data type to support frequent users of session recording that was crashing the encoding process.
- Improvement: Secrets with text field based URL lists are now searchable.
- Improvement: Platform users can login to Terminal using SSH Key Integration.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: When Platform integration is active the integration page will now have a button to reset mappings from Delinea Platform.
- Improvement: AD Privilege Password changer now has Remote Password Change timeout minutes Advanced Setting.
- Improvement: Better handling of unexpected heartbeat behavior to mitigate reported Distributed Engine stalling.
- Improvement: Connect As Credentials on Secret works better with SSH Keys for su user switching.
- Improvement: Updated links on the Security Hardening Report to new UI pages
- Improvement: When creating a new send to syslog task you no longer get a default schedule. Most of the templates didn't create a schedule, now they're all consistent.
- Improvement: Session monitoring search now supports searching by a single secret.
- Improvement: When a Secret is assigned to a site the user does not have access to due to Teams restriction, they will see the word "Restricted" instead of "Site Name (Inactive)".
- Improvement: Mitigated issue in large bulk secret actions.
- Improvements: The "Synchronization Running" message for DR will now only appear if there is a recorded start time for DR in the past and a finish time that is in the future.
- Improvement: Added Secret Field validation on the Template level to ensure users cannot create a "Secret Name" field on a template.
- Improvement: Default values for Secret Fields such as port will now be replicated for Disaster Recovery.
- Improvement: A user with only direct access to a report and the "browse reports" role permission can add that report to the dashboard.

- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Report column preferences will be saved and applied when viewing a report.
- Improvement: The Secrets grid now updates displayed data and selected columns simultaneously.
- Improvement: Improved error logging and efficiency for calls coming from Delinea Platform.
- Improvement: Quick access filters now both apply when updated.
- Improvement: Knowledge base links within Platform Vault now link to their intended location.
- Improvement: Corrected edge case that could result in a session view audit being placed on the incorrect Secret.
- Improvement: The Parent Scan Template will be filtered to the type and will default to the first item in the list on create. The proper fields will be shown based on the type.
- Improvement: If a secret is inactivated after initially viewing the secret, a user that cannot view inactive secrets will no longer get an error from secret heartbeat.
- Improvement: Clicking cancel when editing folder permissions will clear any active filters.
- Improvement: Editing folder permissions now has a split button that allows for directly entering edit or add group/user mode.
- Improvement: The Secrets Quick Access link when collapsed, now targets the correct destination.
- Improvement: The Platform Opt In modal styling has been adjusted to no longer display with scroll bars.
- Improvement: Secret Share and Folder Permissions: Show disabled edit button until filters are loaded since split button does not yet support disabled.
- Improvement: API calls to /v[1/2]/secrets/{id} now update the Recents secrets data source.
- Improvement: When viewing Event Pipeline Activity details, selecting an Activity Detail record from the grid now displays the selected Activity's details.
- Improvement: Added query parameter for PipelineId to pass back when viewing specific pipeline activity
- Improvement: Minimum Heartbeat interval reduced from 15 to 5 minutes.
- Improvement: Discovery Scanner will not allow deletion until Secret selection is changed.
- Improvement: Remote Password Changing: Check for DNS Mismatch now visible and functional in Cloud.
- Improvement: EventTime token is available in pipeline scripts. $EventTime - event date and time of the event ("yyyy'-'MM'-'dd'T'HH':'mm':'ss").
- Improvement: The preview chips for Multifactor on Secrets have been removed.
- Improvement: Creating a User SSH Key in Platform downloads the private key with a proper filename.
- Improvement: Cipher Suite Configuration now allows configuration of allowed Host Key Algorithms.

Bug Fixes

- Fixed an issue where Viewing Session Connector Custom Launchers without access to the RDS Credentials secret would show an error.
- Fixed an issue where unplayable session recording videos would display an infinite load instead of the appropriate error.
- Fixed an issue where a secret template could be saved without RPC mappings configured.

Secret Server: 11.5.000002 Release Notes

> This release resolves an issue that was discovered shortly after we published the 11.5.000001 General Availability release. The 11.5.000001 release was rolled back, and this release supersedes it.

> For convenience, this note also contains changes and features from the "Secret Server: 11.5.000000 EA Release Notes" on page 1754 and "Secret Server: 11.5.000001 GA Release Notes" on page 1751 release notes, not just the changes from 11.5.000002.

Release Dates and Notes

On-Premises: July 19, 2023.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.8.0

> The minimum required engine version is 8.3.0.0.

Protocol Handler: 6.0.3.26

New Features

Checked Out Secret View

We added checked out secret view to Quick Access in the Secrets Folder panel. This is a quick view, showing users all of the secrets that are currently checked out to them.

RADIUS Silent Answer

Silent answer is a new configuration option for RADIUS that allows setting the RADIUS response to a defined string value. This is to support push notification and other interactive variations in advanced RADIUS authentication configuration. The new setting replaces "Attempt User Password" and allows for sending the user password or another predefined string.

Check Out Recovery

We adjusted the behavior of "Force Check In" to allow secret owners with the "Force Check In" role permission to force check in secrets that are set to "Change Password on Check in." The secret is automatically checkout to the owner who initiate the force check in. This helps in situations where a checked out secret with a failing RPC configuration will not check in and remains with a user who cannot remediate the issue. With this change, an owner can take ownership of the checkout session, remediate the secret configuration, and then complete a normal secret check in.

Syslog Metadata for Launched Sessions

For built in launchers on a launch event, the launch target host is included within the details of the Syslog message as an additional "Host" field. Previously, this was only sent for launchers requiring host selection but now includes launchers with a static host-target mapping.

Launcher Administration Page Conversion

We updated the Launcher Administration pages under Secret Templates to use our new UI patterns with a modern design. No functionality is affected, but the page is more responsive and intuitive.

SSH Key Authentication Passphrase Requirement

We added a new configuration setting to the login configuration page that allows administrators to enable a mandatory requirement for passphrases when users generate SSH keys for SSH Terminal key authentication.

Enhancements

- Improvement: Upgraded error logging and efficiency for calls coming from Delinea Platform.
- Improvement: A user with only direct access to a report and the "browse reports" role permission can add that report to the dashboard.
- Improvement: Added a "Managed" field to the Discovery Network view to show when a discovery item is managed.
- Improvement: Added a Quick Access link to see all secrets you currently have checked out.

- Improvement: Added a refresh button to the Discovery Network view to refresh the data without having to refresh the entire page, losing the selected filtering.
- Improvement: Added a WMI Service Timeout setting to the cloud advanced configuration page to help with dependency changes that take more time than the allotted 60 seconds.
- Improvement: Added new tab to Discovery with overall metrics of discovered items and their statuses.
- Improvement: Added two columns to the Secret Grid—Checked Out User Id and Checked Out User. These show who has the secret checked out if the secret has check out enabled.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: Clicking on graph elements in discovery analysis now links to a filtered network view.
- Improvement: Disaster recovery date replication now syncs all SecretFieldLauncher items each time instead of just the updated ones.
- Improvement: Discovery Service Accounts Detail Page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Enhanced the User Audit report to also exclude manually changed passwords.
- Improvement: Group membership assignment UI updated.
- Improvement: Group role assignment UI updated.
- Improvement: Implemented "select all" for the Discovery Network View.
- Improvement: Recently viewed secrets are now tracked within Platform. Configuration settings are now refreshed via navigation within Vault in Platform.
- Improvement: RPC heartbeat logs are now combined into a tabbed view with run buttons.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: The built-in "Everyone" group was renamed "All Vault Users."
- Improvement: The Delete folders function in disaster recovery can now delete more than 2100 folders or subfolders on the replica.
- Improvement: The Delinea Platform integration configuration now has additional validations for Login URL.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: Updated Createuser.aspx to redirect to the new user creation page.
- Improvement: Updated group membership management pages to use new design patterns.
- Improvement: Updated the folder permission assignment UI.
- Improvement: Updated the group role assignment UI.
- Improvement: Updated the text and product descriptions used during the Platform opt-In experience.
- Improvement: Added a Managed field to the Discovery Network view to show when a discovery item is managed.

- Improvement: Added a Password Age column for display on the reworked Discovery Network View
- Improvement: Added a Quick Access link to see all Secrets you currently have checked out.
- Improvement: Added filters to the secret search API endpoint to filter the results by checked out status: paging.filter.showSecretsCheckedOutByUser and paging.filter.showCheckedOutSecrets
- Improvement: Added info to logs to indicate why users cannot match or create users in SSC. Find this at Secrets > Admin > Platform Integration > Logs tab. Common notifications include DuplicateUserMappedToDifferentProviderName: The user was initially setup to a different Platform source, the URL or userid (provider key) changed, indicating the original use was deleted. MaxLicensedUsersException: All licenses are taken so additional users cannot be added.
- Improvement: Added integration support for Platform users matching local SS users that do not have an @ in their name. If platform user is username@local or username@tenantname then the username portion will be used to match local users on the SS side.
- Improvement: Added support for LDAP RFC2307 group membership, used in OpenLDAP.
- Improvement: Added the option to require a passphrase for user public SSH keys.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: Discovery service accounts detail page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Distributed engines no longer need directory services enabled to perform discovery.
- Improvement: Introduced a new Launch Secret role permission, which is needed to use launchers. This permission is automatically granted to roles with the View Secret permission, which previously controlled this behavior.
- Improvement: Removed the secretitemvaluetransitionhistory.aspx page and replaced it with an API endpoint, removing the possibility of bypassing the Hide Launcher Password control.
- Improvement: RPC heartbeat and password change logs are now full screen instead of a dialog box.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: The new folder icon in the secret panel no longer shows if the user does not have the Administer Folders role permission.
- Improvement: The user audit report now has a filter panel and a description for how rotated secrets are calculated for this report.
- Improvement: There is now a pending RPC screen and a timer that checks you back in, blocking seeing secret info indefinitely.
- Improvement: Users can no longer access secrets that have failed processing a password change. Instead, they are shown a message stating the change failed.
- Improvement: We now initially load 60 secrets when viewing a grid to support 4k monitors. This was previously 30.

- Improvement: Within the details of the syslog message, there is now a username field that contains the mapped username for the launcher on a launch event. It appears as Username: [<username>] for the built in launchers.
- Improvement: Within the details of the syslog message, there is now a Host field with the value of the mapped host for the launcher on a launch event. It appears as Host: [<host>] for the built in launchers.

Bug Fixes

- Addressed an issue where users with only "view" access on a secret were unable to view the password if there was a custom launcher with arguments configured for that secret template.
- Fixed an issue where "Close launcher on check in" on the replication source would prevent sessions from being launched on the replica.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where discovery import would incorrectly assign a secret as an associated account, as opposed to a privileged account.
- Fixed an issue where existence of secrets set to expire over a hundred years in the future would cause expiration reports and event subscriptions to stop triggering.
- Fixed an issue where heartbeat and RPC log downloads would save without an extension. Now correctly saves with a .csv extension.
- Fixed an issue where launching secrets with URL List and session recording enabled displayed a "Bad Request" message.
- Fixed an issue where OpenID Connect or SAML accounts could not export secrets as they did not have a password and were not licensed for doublelock. DoubleLock is now available in professional licenses.
- Fixed an issue where the API endpoint api/v1/secrets/{id}/fields/{slug}/ logged an audit that the password was displayed when the actual password was not returned to the user due to "hide launcher password" being enabled. This could happen from some UI actions.
- Fixed an issue where the Edit button for User Management => Groups appeared when you did not have "Administer Role Assignment" permission. The action was denied in the API, so this was a cosmetic change.
- Fixed an issue where the folder audit page would unexpectedly show an access denied message.
- Fixed an issue where the folder permissions tab would load slowly with large numbers of users.
- Fixed an issue where the German localization for "Password Should Exclude" was incorrect.
- Fixed an issue where the new Discovery Network View UI would display a license error in the Professional Edition.
- Fixed an issue where secret name would incorrectly display on the New Discovery Import Rules page.
- Fixed an issue where the SubscriptionName condition for a notification rule would display the event subscription ID instead. It now correctly uses the name when the user has the appropriate roles to list the subscriptions.
- Fixed an issue where TOTP Secret Settings edit button was available to users who could not edit the settings.
- Fixed an issue where unplayable session recording videos would display an infinite load instead of the appropriate error.

- Fixed an issue with negative numbers exporting incorrectly when exporting to a CSV file.
- Fixed an issue with pinning a folder returned a "Folder not Found" error.
- Fixed an issue with secret search producing SQL errors for customers with a lot of secret templates.
- Fixed an issue where the SSH Proxy would stop processing new incoming connections.
- Fixed conditions that prevented users from being removed from a group due to the system incorrectly identifying that they would be unable to complete the same operation.
- Fixed issues with user and group syncing between Secret Server Cloud and the Delinea Platform.
- Fixed the TemplateCreateSecret role link.
- Updated links on the Security Hardening Report to new UI pages.
- Fixed an issue to improve Platform integration user sync if duplicate usernames were already in Secret Server.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where DR email alerts were not sent out.
- Fixed an issue where extended fields were not properly exported to CSV files.
- Fixed an issue where keystroke data from the advanced session recording agent did not appear in the keystroke activity details area of the playback page.
- Fixed an issue where large messages from distributed engines to engine workers would not process. Engine workers may have crashed especially frequently in environments having four or more workers, including Secret Server Cloud.
- Fixed an issue where LDAP sync via distributed engines would not work when the base DN was different from DC.
- Fixed an issue where links on the Session Monitoring page while in grid mode would not correctly link to Secret Server Cloud with authentication.
- Fixed an issue where the API endpoint api/v1/secrets/{id}/fields/{slug}/ logged an audit that the password was displayed when the actual password was not returned to the user due to hide launcher password being enabled.
- Fixed an issue where the Confirm Action button in the bulk operation dialog box would remain active while the operation is processing. This is now correctly disabled to prevent initiating the action multiple times.
- Fixed an issue where the SubscriptionName condition for a notification rule would display the event subscription ID instead. It now correctly uses the name when the user has the appropriate roles to list the subscriptions.
- Fixed an issue where the terminate session mouseover tooltip displayed incorrect text.
- Fixed an issue with a secret template name validation message not showing.
- Fixed an issue with negative numbers exporting incorrectly when exporting a CSV.
- Fixed an issue with new Platform trials not creating personal folders in Secret Server.
- Fixed an issue with stacked dialog boxes. The CSS styles for the Platform Opt In dialog box have been adjusted to align with Angular15.

- Fixed conditions that prevented users from being removed from a group due to the system incorrectly identifying that they would be unable to complete the same operation.
- Fixed issues with user and group syncing between Secret Server Cloud and Platform.
- Fixed usability on specific UI areas for a better user experience.
- Updated Createuser.aspx to redirect to the new user management.

Future and Recent Deprecations

This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.5.000001 GA Release Notes

This release has been temporarily delayed while we while we investigate a newly reported issue.

This note only contains changes between the EA and GA releases. Earlier changes and all the features are in the "Secret Server: 11.5.000000 EA Release Notes" on page 1754).

Release Dates and Notes

On-Premises: July 6, 2023.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.8.0

The minimum required engine version is 8.3.0.0.

Protocol Handler: 6.0.3.26

New Features

See the "Secret Server: 11.5.000000 EA Release Notes" on page 1754) for features.

Enhancements

- Improvement: A user with only direct access to a report and the "browse reports" role permission can add that report to the dashboard.
- Improvement: Added a "Managed" field to the Discovery Network view to show when a discovery item is managed.
- Improvement: Added a Quick Access link to see all secrets you currently have checked out.
- Improvement: Added a refresh button to the Discovery Network view to refresh the data without having to refresh the entire page, losing the selected filtering.

- Improvement: Added a WMI Service Timeout setting to the cloud advanced configuration page to help with dependency changes that take more time than the allotted 60 seconds.
- Improvement: Added new tab to Discovery with overall metrics of discovered items and their statuses.
- Improvement: Added two columns to the Secret Grid—Checked Out User Id and Checked Out User. These show who has the secret checked out if the secret has check out enabled.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: Clicking on graph elements in discovery analysis now links to a filtered network view.
- Improvement: Disaster recovery date replication now syncs all SecretFieldLauncher items each time instead of just the updated ones.
- Improvement: Discovery Service Accounts Detail Page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Enhanced the User Audit report to also exclude manually changed passwords.
- Improvement: Group membership assignment UI updated.
- Improvement: Group role assignment UI updated.
- Improvement: Implemented "select all" for the Discovery Network View.
- Improvement: Recently viewed secrets are now tracked within Platform. Configuration settings are now refreshed via navigation within Vault in Platform.
- Improvement: RPC heartbeat logs are now combined into a tabbed view with run buttons.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: The built-in "Everyone" group was renamed "All Vault Users."
- Improvement: The Delete folders function in disaster recovery can now delete more than 2100 folders or subfolders on the replica.
- Improvement: The Delinea Platform integration configuration now has additional validations for Login URL.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: Updated Createuser.aspx to redirect to the new user creation page.
- Improvement: Updated group membership management pages to use new design patterns.
- Improvement: Updated the folder permission assignment UI.
- Improvement: Updated the group role assignment UI.
- Improvement: Updated the text and product descriptions used during the Platform opt-In experience.

Bug Fixes

- Fixed an issue where "Close launcher on check in" on the replication source would prevent sessions from being launched on the replica.
- Fixed an issue where a secret template could be saved without RPC mappings configured.

- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where discovery import would incorrectly assign a secret as an associated account, as opposed to a privileged account.
- Fixed an issue where existence of secrets set to expire over a hundred years in the future would cause expiration reports and event subscriptions to stop triggering.
- Fixed an issue where heartbeat and RPC log downloads would save without an extension. Now correctly saves with a .csv extension.
- Fixed an issue where launching secrets with URL List and session recording enabled displayed a "Bad Request" message.
- Fixed an issue where OpenID Connect or SAML accounts could not export secrets as they did not have a password and were not licensed for doublelock. DoubleLock is now available in professional licenses.
- Fixed an issue where the API endpoint api/v1/secrets/{id}/fields/{slug}/ logged an audit that the password was displayed when the actual password was not returned to the user due to "hide launcher password" being enabled. This could happen from some UI actions.
- Fixed an issue where the Edit button for User Management => Groups appeared when you did not have "Administer Role Assignment" permission. The action was denied in the API, so this was a cosmetic change.
- Fixed an issue where the folder audit page would unexpectedly show an access denied message.
- Fixed an issue where the folder permissions tab would load slowly with large numbers of users.
- Fixed an issue where the German localization for "Password Should Exclude" was incorrect.
- Fixed an issue where the new Discovery Network View UI would display a license error in the Professional Edition.
- Fixed an issue where secret name would incorrectly display on the New Discovery Import Rules page.
- Fixed an issue where the SubscriptionName condition for a notification rule would display the event subscription ID instead. It now correctly uses the name when the user has the appropriate roles to list the subscriptions.
- Fixed an issue where TOTP Secret Settings edit button was available to users who could not edit the settings.
- Fixed an issue where unplayable session recording videos would display an infinite load instead of the appropriate error.
- Fixed an issue with negative numbers exporting incorrectly when exporting to a CSV file.
- Fixed an issue with pinning a folder returned a "Folder not Found" error.
- Fixed an issue with secret search producing SQL errors for customers with a lot of secret templates.
- Fixed an issue where the SSH Proxy would stop processing new incoming connections.
- Fixed conditions that prevented users from being removed from a group due to the system incorrectly identifying that they would be unable to complete the same operation.
- Fixed issues with user and group syncing between Secret Server Cloud and the Delinea Platform.
- Fixed the TemplateCreateSecret role link.
- Updated links on the Security Hardening Report to new UI pages.

Future and Recent Deprecations

This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.5.000000 EA Release Notes

Release Dates and Notes

On-Premises: June 9, 2023.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.8.0

Protocol Handler: 6.0.3.26

New Features

Checked Out Secret View

We added checked out secret view to Quick Access in the Secrets Folder panel. This is a quick view, showing users all of the secrets that are currently checked out to them.

RADIUS Silent Answer

Silent answer is a new configuration option for RADIUS that allows setting the RADIUS response to a defined string value. This is to support push notification and other interactive variations in advanced RADIUS authentication configuration. The new setting replaces "Attempt User Password" and allows for sending the user password or another predefined string.

Check Out Recovery

We adjusted the behavior of "Force Check In" to allow secret owners with the "Force Check In" role permission to force check in secrets that are set to "Change Password on Check in." The secret is automatically checkout to the owner who initiate the force check in. This helps in situations where a checked out secret with a failing RPC configuration will not check in and remains with a user who cannot remediate the issue. With this change, an owner can take ownership of the checkout session, remediate the secret configuration, and then complete a normal secret check in.

Syslog Metadata for Launched Sessions

For built in launchers on a launch event, the launch target host is included within the details of the Syslog message as an additional "Host" field. Previously, this was only sent for launchers requiring host selection but now includes launchers with a static host-target mapping.

Launcher Administration Page Conversion

We updated the Launcher Administration pages under Secret Templates to use our new UI patterns with a modern design. No functionality is affected, but the page is more responsive and intuitive.

SSH Key Authentication Passphrase Requirement

We added a new configuration setting to the login configuration page that allows administrators to enable a mandatory requirement for passphrases when users generate SSH keys for SSH Terminal key authentication.

Enhancements

- Improvement: Added a Managed field to the Discovery Network view to show when a discovery item is managed.
- Improvement: Added a Password Age column for display on the reworked Discovery Network View
- Improvement: Added a Quick Access link to see all Secrets you currently have checked out.
- Improvement: Added filters to the secret search API endpoint to filter the results by checked out status: paging.filter.showSecretsCheckedOutByUser and paging.filter.showCheckedOutSecrets
- Improvement: Added info to logs to indicate why users cannot match or create users in SSC. Find this at Secrets > Admin > Platform Integration > Logs tab. Common notifications include DuplicateUserMappedToDifferentProviderName: The user was initially setup to a different Platform source, the URL or userid (provider key) changed, indicating the original use was deleted. MaxLicensedUsersException: All licenses are taken so additional users cannot be added.
- Improvement: Added integration support for Platform users matching local SS users that do not have an @ in their name. If platform user is username@local or username@tenantname then the username portion will be used to match local users on the SS side.
- Improvement: Added support for LDAP RFC2307 group membership, used in OpenLDAP.
- Improvement: Added the option to require a passphrase for user public SSH keys.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: Discovery service accounts detail page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Distributed engines no longer need directory services enabled to perform discovery.
- Improvement: Introduced a new Launch Secret role permission, which is needed to use launchers. This permission is automatically granted to roles with the View Secret permission, which previously controlled this behavior.
- Improvement: Removed the secretitemvaluetransitionhistory.aspx page and replaced it with an API endpoint, removing the possibility of bypassing the Hide Launcher Password control.
- Improvement: RPC heartbeat and password change logs are now full screen instead of a dialog box.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: The new folder icon in the secret panel no longer shows if the user does not have the Administer Folders role permission.
- Improvement: The user audit report now has a filter panel and a description for how rotated secrets are calculated for this report.

- Improvement: There is now a pending RPC screen and a timer that checks you back in, blocking seeing secret info indefinitely.
- Improvement: Users can no longer access secrets that have failed processing a password change. Instead, they are shown a message stating the change failed.
- Improvement: We now initially load 60 secrets when viewing a grid to support 4k monitors. This was previously 30.
- Improvement: Within the details of the syslog message, there is now a username field that contains the mapped username for the launcher on a launch event. It appears as Username: [<username>] for the built in launchers.
- Improvement: Within the details of the syslog message, there is now a Host field with the value of the mapped host for the launcher on a launch event. It appears as Host: [<host>] for the built in launchers.

Bug Fixes

- Fixed an issue to improve Platform integration user sync if duplicate usernames were already in Secret Server.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where DR email alerts were not sent out.
- Fixed an issue where extended fields were not properly exported to CSV files.
- Fixed an issue where keystroke data from the advanced session recording agent did not appear in the keystroke activity details area of the playback page.
- Fixed an issue where large messages from distributed engines to engine workers would not process. Engine workers may have crashed especially frequently in environments having four or more workers, including Secret Server Cloud.
- Fixed an issue where LDAP sync via distributed engines would not work when the base DN was different from DC.
- Fixed an issue where links on the Session Monitoring page while in grid mode would not correctly link to Secret Server Cloud with authentication.
- Fixed an issue where the API endpoint api/v1/secrets/{id}/fields/{slug}/ logged an audit that the password was displayed when the actual password was not returned to the user due to hide launcher password being enabled.
- Fixed an issue where the Confirm Action button in the bulk operation dialog box would remain active while the operation is processing. This is now correctly disabled to prevent initiating the action multiple times.
- Fixed an issue where the SubscriptionName condition for a notification rule would display the event subscription ID instead. It now correctly uses the name when the user has the appropriate roles to list the subscriptions.
- Fixed an issue where the terminate session mouseover tooltip displayed incorrect text.
- Fixed an issue with a secret template name validation message not showing.
- Fixed an issue with negative numbers exporting incorrectly when exporting a CSV.
- Fixed an issue with new Platform trials not creating personal folders in Secret Server.
- Fixed an issue with secret search producing SQL errors for customers with a lot of secret templates.

- Fixed an issue with stacked dialog boxes. The CSS styles for the Platform Opt In dialog box have been adjusted to align with Angular15.
- Fixed conditions that prevented users from being removed from a group due to the system incorrectly identifying that they would be unable to complete the same operation.
- Fixed issues with user and group syncing between Secret Server Cloud and Platform.
- Fixed usability on specific UI areas for a better user experience.
- Updated Createuser.aspx to redirect to the new user management.

Future and Recent Deprecations

This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.4.000031 Release Notes

11.4.000032 is a retroactive patch for this release. Please see "Secret Server 11.7.000001 Release Notes" on page 1692 for details.

Release Dates and Notes

On-Premises: May 17, 2023.

This maintenance release fixes the issues that caused us to roll back release 11.4.000030 to 11.4.000002 after discovering some bugs that could significantly affect a minority of customers.

Please see "Secret Server: 11.4.000030 Release Notes" on the next page for complete release notes.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.7.0

Protocol Handler: 6.0.3.26

Bug Fixes

- Fixed an issue where the engine worker process would fail to receive and process large messages.
- Fixed an issue where the engine worker process would crash when proxy session recording was enabled in multi-node environments.

Future and Recent Deprecations

This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.4.000030 Release Notes

Release Dates and Notes

On-Premises: May 2, 2023.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.7.0

Protocol Handler: 6.0.3.26

Important: We rolled back release 11.4.000030 to 11.4.000002 after discovering some bugs that can significantly affect a minority of customers. See the first two Known Issues for details. We apologize for any inconvenience, especially for the delay in releasing the new, resilient secrets and other enhancements. It is a top priority for engineering to fix this. An updated release should be available by May 20th, 2023.

Known Issues

- Very large messages sent from distributed engines back to Secret Server are not processed due to a bug in the message processing code. This can include messages related to Active Directory synchronization, discovery, and keystroke recording. See the note at the top of this topic.
- In installations with multiple nodes, launched sessions that are RDP or SSH proxied and recorded may cause the engine worker on a node to crash. The probability of a crash increases with each additional node running, becoming nearly certain at eight or more nodes. See the note at the top of this topic.
- The distributed engine (DE) package that came with Secret Server (Cloud and On-Premise) 11.3.x prevents Secret Server from performing a DE auto-upgrade—making a manual upgrade necessary. See the Distributed Engine Auto-Upgrade Does Not Work bulletin for details.

  Note: This is not required for admins who already completed a manual upgrade for any version of 11.4.

Enhancements

Secret Folder Panel Redesign

We reworked the secret folder panel for additional functionality and a more streamlined user experience. Direct access to the folder panel from outside of the secrets view was found to unnecessarily clutter the navigation menu, and the panel is now visible on the Secrets page. In addition, we enhanced the following:

- We added a "Quick Access" section to the folder panel, which offers a single page combining the following sections:
  - Search
  - Favorite Secrets
  - Most Used Secrets
  - Session Secrets—Secrets accessed this session, allowing the user to return to a secret they have accessed in this browser session

  - Recent Secrets—Most recently accessed secrets, within this session or others
  - Shared With Me—Secrets that are shared with you but not in folders that you may view
- Added a "New Folder" button to the top of the folder tree.
- Pinned folders are now placed at the top of the tree instead of listed in a dropdown. Pinned folders give easier access to your favorite folders. When a pinned folder is selected, the displayed folder tree is based on the that pinned folder rather than the entire tree. The same applies to the content of "Quick Access," which displays secrets in the selected, pinned folder.
- A guide now displays for new users the first time they view the secrets page, introducing components and changes.

Other Enhancements

- DR: Created more robust data ambiguity handling when data replication processes a table where there is a multi-field unique key. These included giving precedence to source data when applicable or throwing an error when an ambiguity cannot be resolved.
- DR: Added an advanced configuration setting (defaulting to 3 hours) so that a long-running DR process will detect the configured amount of elapsed time and end the DR process, forcing the business user to manually run it again.
- DR: Read-only mode can now be enabled in Secret Server Cloud on the disaster recovery configuration page.
- Added a discovery import rule to the new network viewer.
- Added a link to the public SSH keys, when enabled, on both the user preference page and the administration tools section.
- Added a knowledge base link for Platform regions as part of the Platform Optin Experience.
- Added support for LDAP RFC2307 group membership, used in OpenLDAP.
- Discovery rules and dependencies grid can now be filtered by discovery source. Rule grid now also has discovery source available as a column.
- Local Admin column added to new discovery network view.
- Secret template name on the secret general tab is now a direct link to the template.
- The "Send Test Email" button now functions in read only mode.
- The report CSV download is now encoded so that certain Turkish characters appear, and the mime type was changed to text/csv.
- The Unlimited Vault Access page in configuration preview now has a link to open the Unlimited Vault Access audit.
- HSM Integration—RSA OAEP Padding Support. We added OAEP padding as a new configurable option when enabling or rotating the HSM integration. This is in anticipation of the planned deprecation of PKCS padding by NIST. Current configurations are unaffected, but this option is available when rotating the HSM key, or configuring a new integration.

Bug Fixes

Disaster Recovery

- Fixed an issue where DR email alerts were not being sent out.
- Fixed issues for password-requirement character-set data replication in the DR feature.
- Fixed an issue with disaster recovery replication where replicated custom launchers were not visible on their associated secrets.
- Fixed an issue with the disaster recovery logging process so that only error-free data replications are marked as successful.
- Fixed issue when replicating data for disaster recovery where pre-existing users on the replica that do not exist on the source could lose their All Vault Users group membership.
- Fixed replication to allow duplicate names to be replicated individually during disaster recovery. Groups with the same name will still be consolidated during replication when they share values for AD Guid, IsPersonal, IsPlatform, and DomainId.
- Password requirements are now replicated from source to replica as part of disaster recovery.

Other Bug Fixes

- Corrected logic that allowed password requirement consumers to bypass non-replicated secrets
- Dates in the report export no longer include the "Z" for UTC when server time is used and ISO date format is selected because the date/time is the server configured time and not necessarily UTC. That is, the date is ISO format and the server-configured time but does not include the offset. In some specific configurations when user format was selected, the timezone offset would be applied based on the actual server timezone and not the configured timezone.
- Discovery-specific OUs now returns results when the page is initially loaded.
- Due to security reasons, we removed the GET endpoint for /secretserversettings/export and replacing it with a POST endpoint where we can transmit the password securely. The contents of the payload are the same, except for new "password" and "doubleLockPassword" fields, and the entire payload is contained within a parent "data" object.
- Fixed a bug that caused launcher session failure on secrets that were expired on checkout but then disabled checkout via policy. Also, retroactively fixed this situation on secrets.
- Fixed a string truncation error. Expanded the user setting size to resolve issue for some customers with lots of columns for a grid.
- Fixed a timing problem where secret favorites might not initialize if the secret grid loads very quickly.
- Fixed an CSS issue where clicking the "Browse all folders" button caused folder names to overlap.
- Fixed an issue that had platform logout redirecting to a different tenant.
- Fixed an issue where "Web Launcher requires Incognito Mode" was not being respected when enabled. Descriptive text added on web launcher mapping for restricting input fields.

- Fixed an issue where a bulk action was applied to all secrets when select all is checked but a template or folder filter was applied.
- Fixed an issue where a default error page was presented when accessing certain URLs as opposed to a more technical error.
- Fixed an issue where a dependency fails to work when moved to another group or order due to the run condition. When a secret dependency is updated to the first sort order or to a new group, the run condition is cleared. This addresses an issue where a secret dependency with a run condition would not run when it was the first secret dependency in its group.
- Fixed an issue where a Get Folders API call did not returns all descendants, breaking some customer integrations. To retrieve direct children only, use the new LimitToDirectDescendents parameter.
- Fixed an issue where an HSM could not be disabled.
- Fixed an issue where Azure domain accounts were unable to access Secret Server SSH Terminal with a public key. You can now log into Terminal with an Azure Active Directory account using SSH Key Integration. AAD logins to Terminal via password cannot be done.
- Fixed an issue where changing the time zone on the secret audit page did nothing and refreshing the page returned to the default time zone. When the server time zone is different, the time zone picker should show and the date column for audit should render in the selected time zone.
- Fixed an issue where connecting using an SSH key on another secret did not work with "SSH key only" secrets.
- Fixed an issue where data retention under PII removed monitored recordings or user audits related to monitored recordings. Data retention under database size management will still remove monitored recordings and related user audit records.
- Fixed an issue where duplicate user names were throwing an error. When logging in as a local user, we now ignore any Platform native users that may have the same login name, instead of erroring.
- Fixed an issue where event pipeline email notifications were not sent if the email task had an email template selected.
- Fixed an issue where exported computer scan logs were incomplete. Discovery logs now export more than 250 records.
- Fixed an issue where folders and sub-folders were missing secrets with UAM enabled. Left nav max folders default limit increased to 1,000. Setting dialog added to set the user preferred limit. Folder browser now loads 100 records at a time on scroll instead of just 30.
- Fixed an issue where GET /internals/secret-detail/{id}/launcher/{launchertypeid} threw an exception. We now show a friendly error message when launching a secret With Jumpbox Route with RDP that it is missing an SSH launcher
- Fixed an issue where OpenLDAP directory services group-search filter was not working.
- Fixed an issue where PowerShell dependency changer arguments were not being passed into the script.
- Fixed an issue where secret field data over a certain length may be rejected by the database upon replication.
- Fixed an issue where Secret PasswordComplianceCode was not updated after password field/PasswordReq change.

- Fixed an issue where secret template fields of type file no longer showed the drop down options when editing the field.
- Fixed an issue where session monitoring grid view showed the system and not the Secret Server. The secret session search date in the grid and card both now show in the selected time zone and the grid has the timezone picker when relevant.
- Fixed an issue where the folder list disappeared if UAM is enabled and when the "All Folders" toggle is selected in the sidebar. Folders in the tree will now be limited to only show 125 folders per tree. Once there are 125+ subfolders a "Browse all folders" option will appear in the folder tree. This link will take the user to a grid that only shows folders with a search. The grid has paging so it will load 30 folders at a time as the user scrolls. This will help support instances when users have thousands of subfolders. If there are more than 30 subfolders in a folder the secret grid will show a link to the new folder browser. This used to open a dialog to the folder tree which would also run into performance issues when users had over 1,000 subfolders.
- Fixed an issue where the folder tree disappeared when there were more than 1,000 folders accessed and UAM was enabled.
- Fixed an issue where the pipeline activity status stopped updating after the "Send to Email" task
- Fixed an issue where the Preserve Client SSH Process did not appear for process launchers
- Fixed an issue with heartbeat failures if a secret had checkout enabled.
- Fixed an issue with secret search would produce an excessively long URL that would sometimes throw an HTTP 404 error. The secret search API endpoint now accepts a filter param called ExtFieldsCombined, which is a comma delimited list of all extended fields to include in the results. This field is now used by the secret grid to help reduce the size of the URL when many secret fields are exposed for display to avoid the IIS 2k length restriction on GETs.
- Fixed an issue with SSH proxy "Tunnel RDP Connections" performance degradation (high CPU usage).
- Fixed an issue with the data retention page background color.
- Fixed discovery network view to ensure when searching you should be able to find all items under your current levels. However, when looking at a level you only see that level.
- Fixed issue with the password compliance report updating very slowly or not refreshing after either a template or direct PasswordRequirement password field change.
- Fixed issues related to RabbitMQ channel and queue growth and corruption-related issues due to connection interruption causing premature queue deletion.
- Fixed the default timestamp format for CEF.
- The "All Secrets" CSV download now correctly shows the folder name instead of the folder ID.
- The secret policy approvers "default only" option now displays correctly when updated.
- Updated the advanced session recording agent version label on the agent issues page to correctly state that it is the minimum required version, not the current version.
- Fixed an issue where a purge of inactive sessions longer than three minutes was occurring when the Sessions Monitoring page was displayed. It did not take into account the SSH proxy timeout. The page now obeys the timeouts.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.4.000002 GA Release Notes

Release Dates and Notes

On-Premises: March 7, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.3.0

Protocol Handler: 6.0.3.26

Known Issues

The distributed engine (DE) package that came with Secret Server (Cloud and On-Premise) 11.3.x prevents Secret Server from performing a DE auto-upgrade—making a manual upgrade necessary.

Changes Since the Early Availability Release

The following updates focus on improving the stability, performance, and functionality of disaster recovery replication, as well as resolving various issues and bugs that were identified. Additionally, updates were made to localizations and character sets to ensure compatibility and reliability.

The changes are

- The stability and performance of replication of Folder Permissions in disaster recovery has been increased.
- Secret Items from the source are combined with ones from the replica during disaster recovery replication when they have matching SecretIDs and SecretFieldIds.
- Disaster recovery now stops processing and disables replication when it encounters a fatal error and sends a notification of the error to all the disaster recovery admins.
- An issue with disaster recovery folder synchronization selection was resolved, and personal folders can now be selected for either allow or block lists.
- An issue with folder name collisions in disaster recovery synchronization was fixed.
- Localizations were updated.
- Older character sets that failed to replicate when running disaster recovery were fixed.

New Features

User Interface Streamlining: Classic UI Removed

The classic UI is no longer available as an option, and can no longer be enabled. This followed notifications of phased deprecations in prior releases. Several improvements have been made to the UI based on feedback from customers regarding this change.

Checkout Extension Maximum Limit

We created a global configuration setting that allows administrators to set a maximum secret-checkout extension interval. This provides additional admin control by specifying granular limitations to users extending a checked out secret. The time limitation begins at the point of checkout extension and extension time defaults to the set checkout time

Disaster Recovery Enhancements

"Replicated User Status on Disaster Recovery Source" configuration can now be set to:

- Mirror Source, which is the existing behavior
- Disabled by default

New Synchronization Items:

- Character sets
- AD users and groups

Discovery User Experience Improvements

We updated the discovery user experience to reflect the style and design of the application. The legacy pages are still available; however; the new interface items are ready for use, and we welcome feedback on these items. The legacy pages can be accessed by browsing to the relevant new interface and clicking the "View Legacy Page" button. The improvements are:

- Network view is available as a tab on the main Discovery Sources page.
- Network view displays the same results as the legacy page, in a single filterable grid, as opposed to individual tabs for different types of scanners. The new page has the functionality of the legacy page but in a more-responsive and updated design.
- There is a new filter menu, allowing extensive filtering options of this data.
- Each item in the network view list links to a details page allowing review of the discovered data, as opposed to being viewed inline.
- The grid data is exportable as a CSV, similar to other grids.
- Scanner, scan template, command set and search filter configuration are available from the Discovery Configuration Options > Scanner Definition button on the Discovery Configuration page.
- Source scanner configuration is available in the Discovery Source Configuration page as a tab.
- We extensively redesigned the scanner configuration UI to make this experience more intuitive, and scanners are now displayed in a workflow view.

Generated and Created Password Improvements

Password Complexity Indicator

There is a new visual indicator in the password complexity rules that provides the user with a better understanding of the strength of their password. The combined score considers both entropy score (brute force defense) and

character limitations (social engineering defense). In the case that the score is deemed too low, the UI provides recommendations to the user on how to increase password strength.

New Password Rules

We introduced character rules to password complexity selection to enhance the strength of generated and created passwords, if enabled. The new rules provide flexibility in the granularity of the rules. Each selection impacts both entropy and overall strength score. The rules include minimum characters from:

- Lowercase letters
- Symbols
- Numerals
- Uppercase letters

Opt-In Engine Upgrades

Distributed engine upgrades are no longer mandatory for every release. We added a new setting to the Distributed Engine Configuration page to set the minimum required engine version. Modifying this will trigger an automatic update for any engine below this version.

In the action menu for an engine on the Sites page, a manual upgrade can be triggered for individual engines below the latest version, which prompts the engine to update when it next calls in.

When changes are made needing an upgrade, the minimum required version is updated during the update process, and all engines update immediately.

"Run Scripts" Role Permission

We created a new "Run Scripts" role permissions to separate privileges in script management. Holders of the "View Scripts" role permission cannot execute test runs of scripts, and the new role permission must be assigned to perform this task.

Administer Scripts remains unchanged and allows view, edit, and run permissions.

Syslog Timestamps

There is a new setting in Syslog configuration allowing the selection of timestamp formatting. The standard for Syslog indicates that ISO timestamps should be used; however, some consumers use the legacy format. There is now a selection between Syslog and ISO format. Syslog will be the default for upgrades to allow current configurations to retain their behavior, and ISO format is the default in new instances.

Site-Specific FIPS Configuration

Individual sites are now configurable for FIPS compatibility. The setting is available on the Administration > Distributed Engine > Site configuration page, in the Engine Default Settings dialog box. All engines on a site will use this setting, overriding the global setting, which is configured at Administration > Configuration > Security.

Enhancements

- Added a configuration option to disable the SMB heartbeat fallback check.
- Added a secret policy setting to control "Change Password Upon Check-In" behavior. Previously, this was automatically enabled if "Require Check Out" was enabled.
- Added additional debugging output for SSH proxy when using the "ALL" logging level.
- Added audits for emailing and downloading reports.
- Added endpoints for Update Password Type Auth, Get Password Type Auth, and Create Password Type Auth. These allow you to create and update records for the command arguments on RPC command set up.
- Added the configuration setting "Allow Files without Extension" to the configuration preview.
- Added the internal site connector configuration to the configuration preview.
- Added the User parameter to the IBM iSeries Mainframe connection for launching, password changing, and heartbeat.
- Bulk edit share now has a "None" permission which allows removing permissions.
- Changed IIS web.config configuration to disallow access to the file uploads folder.
- Enabled more connection classes to use read-only mode.
- Enhanced secret export logging.
- Improved performance of dependency matching within discovery.
- Improved performance of the role assignment page and added a user panel on the same page.
- Improved performance of the secret to computer matching operation that runs as part of discovery.
- In the data replication summary log now lists in alphabetical order, success and version number will appear before the list of items and any errors are appended at the end.
- Optimized application caching.
- Updated the new UI to allow newly generated SSH keys to have a blank passphrase, which matches legacy UI functionality.

Bug Fixes

- Fixed a memory leak in SSH proxy.
- Fixed a SAML audit error.
- Fixed an error that occurred when multiple identical domains were created.
- Fixed an error where the new SSH proxy custom SSH cipher suite settings were not picked up by distributed engines.
- Fixed an issue in the heartbeat status by day report that would cause the same secret to be counted twice on days where the secret transitions between heartbeat failure and success.
- Fixed an issue where "Days Until Expiration" value on the secrets grid would show a large negative number if expiration is forced. This now displays "Expiration forced."
- Fixed an issue where "requires approval type" could not be set by policy.

- Fixed an issue where a user with edit permissions could not rename a folder.
- Fixed an issue where an "invalid SQL error" was incorrectly displayed when a report timed out.
- Fixed an issue where an error was displayed in an edit field dialog box.
- Fixed an issue where an inbox notification was not clearing in Secret Server Cloud.
- Fixed an issue where completed master encryption key rotation would not show as such.
- Fixed an issue where converting a secret in a folder with a launcher settings policy threw an error.
- Fixed an issue where deleted Active Directory groups were not correctly marked as inactive when synchronized.
- Fixed an issue where disaster recovery would log many password requirement errors.
- Fixed an issue where failing Syslog/SIEM messages did not respect updated Syslog Server configuration.
- Fixed an issue where file contents during SFTP/SCP file transfers were included in the session keystroke recordings.
- Fixed an issue where installation on specific dates on servers with a dd/mm/YYYY localization configuration would prevent some configuration settings from being read.
- Fixed an issue where Local site could not be configured to use Custom SSH Cipher Suite settings when set to process on the Web Site.
- Fixed an issue where manual backup did not work in maintenance mode.
- Fixed an issue where master encryption key rotation would fail due to discovery import rules running at the same time.
- Fixed an issue where missing file attachments caused DR replications to fail.
- Fixed an issue where monitoring and termination of live sessions was not displayed in the UI. This now takes the user to the regular session playback page, which displays the live session.
- Fixed an issue where PowerShell-based dependency changers would not correctly pass arguments.
- Fixed an issue where PuTTY would close immediately following a session error. This was due to a default setting change in PuTTY, which is now explicitly set to remain open on installation or update of the protocol handler. This requires a protocol handler update.
- Fixed an issue where reports generate an application error if users navigated away from the report while it was loading.
- Fixed an issue where scrolling the secrets grid view would deselect items.
- Fixed an issue where Secret Server did not correctly react when two templates have the same field if one had spaces that the other did not.
- Fixed an issue where secrets would not open when users have folder view and secret list permissions. The secret audit within that folder should be accessible.
- Fixed an issue where session recording would sometimes show a 500 error, even though the client would retry. Replaced this with a HTTP 429 response, explicitly informing the client to retry.
- Fixed an issue where session recordings could not be saved to a UNC file path due to missing permissions on the root of the path.

- Fixed an issue where sorting by folder path in the secret grid view would return an error.
- Fixed an issue where SSH dependencies would not process on distributed engines.
- Fixed an issue where SSH Proxy would not allow a launcher to connect in maintenance mode. This is now possible in non-recorded sessions—recording is not possible in maintenance mode.
- Fixed an issue where the advanced session recording agent would attempt to make many reconnections in a short time span.
- Fixed an issue where the 64-bit protocol handler would not function when "Enable Protocol Handler Auto-Update" was enabled.
- Fixed an issue where the folder picker would not populate when adding folders in event pipeline policies while in Unlimited Vault Access mode.
- Fixed an issue where the IBM iSeries password changer was not properly adding the model value to the connection string.
- Fixed an issue where the light/dark mode toggle displayed "Enable Dark Mode" even though the UI was already in dark mode. This was due to a dark mode browser preference and no explicit user preference having been set.
- Fixed an issue where the SAML AuthnRequest was sending a blank RequestedAuthnContext when Authentication Context was set in the Identity Provider Configuration.
- Fixed an issue where the Secret Server website would not load if the internal site connector is unavailable at startup.
- Fixed an issue where the terminate option on the session playback page was missing.
- Fixed an issue where the test buttons would not function for the Oracle Account Ver. 2 password changer.
- Fixed an issue where the UI session monitoring search required additional permissions to load.
- Fixed an issue where the Unlimited Vault Access watermark could block interaction with some page elements.
- Fixed an issue where the wrong error message would be shown when trying to apply an invalid data source key under data replication.
- Fixed an issue where user permissions on replica instances were removed erroneously when data replication ran.
- Fixed an issue with check in when the "Check In Secret on Launcher Close" and "Close Launcher on Check In Secret" settings were both false.
- Fixed an issue with DR replication where some operations would give an error "The incoming request has too many parameters."
- Fixed an issue with excessive CPU usage for RDPWin.exe. Protocol handler and session connector no longer track or record processes using WMI. Now they use native Windows calls, reducing CPU usage of the Windows WMI Provider. The exception is when "Run as secret credentials" is used—it still uses the WMI process tracking.
- Fixed an issue with replicating domain users. This now correctly links the user with the replicated domain.
- Fixed an issue with slow loading sessions failing to load when using session connector. This required an update to the latest protocol handler (RDS) on the session connector server.
- Fixed an issue with the group filter in event pipelines to ensure precise name matching is correctly used.

- Fixed an issue with the SearchSecretsByFieldValue SOAP API function that caused it to return a 500 error.
- Fixed bug where email filters click through approval links.
- Fixed an issue where OIDC platform connection failed for previously imported users after a domain change.
- Mitigated the possibility of an error in SSH Proxy command processing.
- Removed parameters from ASRA installer to accommodate long secret URLs.
- Resolved an issue with RADIUS challenges in Secret Server Cloud.
- Session recordings which are invalid due to no data are now recorded as an error to prevent failure upon playback.
- Updated discovery SSH scanners to handle messages coming back without the stdout marker.
- Updated logging around Azure AD Sync to make it clearer when the sync stops due to configured groups missing in Azure AD.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.4.000000 EA Release Notes

Release Dates and Notes

On-Premises: February 21, 2023 Cloud: February 11, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.3.0

Protocol Handler: 6.0.3.26

Known Issues

The distributed engine (DE) package that came with Secret Server (Cloud and On-Premise) 11.3.x prevents Secret Server from performing a DE auto-upgrade–making a manual upgrade necessary. See the Distributed Engine Auto-Upgrade Does Not Work bulletin for details.

New Features

User Interface Streamlining: Classic UI Removed

The classic UI is no longer available as an option, and can no longer be enabled. This followed notifications of phased deprecations in prior releases. Several improvements have been made to the UI based on feedback from customers regarding this change.

Checkout Extension Maximum Limit

We created a global configuration setting that allows administrators to set a maximum secret-checkout extension interval. This provides additional admin control by specifying granular limitations to users extending a checked out

secret. The time limitation begins at the point of checkout extension and extension time defaults to the set checkout time

Disaster Recovery Enhancements

"Replicated User Status on Disaster Recovery Source" configuration can now be set to:

- Mirror Source, which is the existing behavior
- Disabled by default

New Synchronization Items:

- Character sets
- AD users and groups

Discovery User Experience Improvements

We updated the discovery user experience to reflect the style and design of the application. The legacy pages are still available; however; the new interface items are ready for use, and we welcome feedback on these items. The legacy pages can be accessed by browsing to the relevant new interface and clicking the "View Legacy Page" button. The improvements are:

- Network view is available as a tab on the main Discovery Sources page.
- Network view displays the same results as the legacy page, in a single filterable grid, as opposed to individual tabs for different types of scanners. The new page has the functionality of the legacy page but in a more-responsive and updated design.
- There is a new filter menu, allowing extensive filtering options of this data.
- Each item in the network view list links to a details page allowing review of the discovered data, as opposed to being viewed inline.
- The grid data is exportable as a CSV, similar to other grids.
- Scanner, scan template, command set and search filter configuration are available from the Discovery Configuration Options > Scanner Definition button on the Discovery Configuration page.
- Source scanner configuration is available in the Discovery Source Configuration page as a tab.
- We extensively redesigned the scanner configuration UI to make this experience more intuitive, and scanners are now displayed in a workflow view.

Generated and Created Password Improvements

Password Complexity Indicator

There is a new visual indicator in the password complexity rules that provides the user with a better understanding of the strength of their password. The combined score considers both entropy score (brute force defense) and character limitations (social engineering defense). In the case that the score is deemed too low, the UI provides recommendations to the user on how to increase password strength.

New Password Rules

We introduced character rules to password complexity selection to enhance the strength of generated and created passwords, if enabled. The new rules provide flexibility in the granularity of the rules. Each selection impacts both entropy and overall strength score. The rules include minimum characters from:

- Lowercase letters
- Symbols
- Numerals
- Uppercase letters

Opt-In Engine Upgrades

Distributed engine upgrades are no longer mandatory for every release. We added a new setting to the Distributed Engine Configuration page to set the minimum required engine version. Modifying this will trigger an automatic update for any engine below this version.

In the action menu for an engine on the Sites page, a manual upgrade can be triggered for individual engines below the latest version, which prompts the engine to update when it next calls in.

When changes are made needing an upgrade, the minimum required version is updated during the update process, and all engines update immediately.

"Run Scripts" Role Permission

We created a new "Run Scripts" role permissions to separate privileges in script management. Holders of the "View Scripts" role permission cannot execute test runs of scripts, and the new role permission must be assigned to perform this task.

Administer Scripts remains unchanged and allows view, edit, and run permissions.

Syslog Timestamps

There is a new setting in Syslog configuration allowing the selection of timestamp formatting. The standard for Syslog indicates that ISO timestamps should be used; however, some consumers use the legacy format. There is now a selection between Syslog and ISO format. Syslog will be the default for upgrades to allow current configurations to retain their behavior, and ISO format is the default in new instances.

Site-Specific FIPS Configuration

Individual sites are now configurable for FIPS compatibility. The setting is available on the Administration > Distributed Engine > Site configuration page, in the Engine Default Settings dialog box. All engines on a site will use this setting, overriding the global setting, which is configured at Administration > Configuration > Security.

Enhancements

- Added a configuration option to disable the SMB heartbeat fallback check.
- Added a secret policy setting to control "Change Password Upon Check-In" behavior. Previously, this was automatically enabled if "Require Check Out" was enabled.

- Added additional debugging output for SSH proxy when using the "ALL" logging level.
- Added audits for emailing and downloading reports.
- Added endpoints for Update Password Type Auth, Get Password Type Auth, and Create Password Type Auth. These allow you to create and update records for the command arguments on RPC command set up.
- Added the configuration setting "Allow Files without Extension" to the configuration preview.
- Added the internal site connector configuration to the configuration preview.
- Added the User parameter to the IBM iSeries Mainframe connection for launching, password changing, and heartbeat.
- Bulk edit share now has a "None" permission which allows removing permissions.
- Changed IIS web.config configuration to disallow access to the file uploads folder.
- Enabled more connection classes to use read-only mode.
- Enhanced secret export logging.
- Improved performance of dependency matching within discovery.
- Improved performance of the role assignment page and added a user panel on the same page.
- Improved performance of the secret to computer matching operation that runs as part of discovery.
- In the data replication summary log now lists in alphabetical order, success and version number will appear before the list of items and any errors are appended at the end.
- Optimized application caching.
- Updated the new UI to allow newly generated SSH keys to have a blank passphrase, which matches legacy UI functionality.

Bug Fixes

- Fixed a memory leak in SSH proxy.
- Fixed a SAML audit error.
- Fixed an error that occurred when multiple identical domains were created.
- Fixed an error where the new SSH proxy custom SSH cipher suite settings were not picked up by distributed engines.
- Fixed an issue in the heartbeat status by day report that would cause the same secret to be counted twice on days where the secret transitions between heartbeat failure and success.
- Fixed an issue where "Days Until Expiration" value on the secrets grid would show a large negative number if expiration is forced. This now displays "Expiration forced."
- Fixed an issue where "requires approval type" could not be set by policy.
- Fixed an issue where a user with edit permissions could not rename a folder.
- Fixed an issue where an "invalid SQL error" was incorrectly displayed when a report timed out.
- Fixed an issue where an error was displayed in an edit field dialog box.
- Fixed an issue where an inbox notification was not clearing in Secret Server Cloud.

- Fixed an issue where completed master encryption key rotation would not show as such.
- Fixed an issue where converting a secret in a folder with a launcher settings policy threw an error.
- Fixed an issue where deleted Active Directory groups were not correctly marked as inactive when synchronized.
- Fixed an issue where disaster recovery would log many password requirement errors.
- Fixed an issue where failing Syslog/SIEM messages did not respect updated Syslog Server configuration.
- Fixed an issue where file contents during SFTP/SCP file transfers were included in the session keystroke recordings.
- Fixed an issue where installation on specific dates on servers with a dd/mm/YYYY localization configuration would prevent some configuration settings from being read.
- Fixed an issue where Local site could not be configured to use Custom SSH Cipher Suite settings when set to process on the Web Site.
- Fixed an issue where manual backup did not work in maintenance mode.
- Fixed an issue where master encryption key rotation would fail due to discovery import rules running at the same time.
- Fixed an issue where missing file attachments caused DR replications to fail.
- Fixed an issue where monitoring and termination of live sessions was not displayed in the UI. This now takes the user to the regular session playback page, which displays the live session.
- Fixed an issue where PowerShell-based dependency changers would not correctly pass arguments.
- Fixed an issue where PuTTY would close immediately following a session error. This was due to a default setting change in PuTTY, which is now explicitly set to remain open on installation or update of the protocol handler. This requires a protocol handler update.
- Fixed an issue where reports generate an application error if users navigated away from the report while it was loading.
- Fixed an issue where scrolling the secrets grid view would deselect items.
- Fixed an issue where Secret Server did not correctly react when two templates have the same field if one had spaces that the other did not.
- Fixed an issue where secrets would not open when users have folder view and secret list permissions. The secret audit within that folder should be accessible.
- Fixed an issue where session recording would sometimes show a 500 error, even though the client would retry. Replaced this with a HTTP 429 response, explicitly informing the client to retry.
- Fixed an issue where session recordings could not be saved to a UNC file path due to missing permissions on the root of the path.
- Fixed an issue where sorting by folder path in the secret grid view would return an error.
- Fixed an issue where SSH dependencies would not process on distributed engines.
- Fixed an issue where SSH Proxy would not allow a launcher to connect in maintenance mode. This is now possible in non-recorded sessions—recording is not possible in maintenance mode.

- Fixed an issue where the advanced session recording agent would attempt to make many reconnections in a short time span.
- Fixed an issue where the 64-bit protocol handler would not function when "Enable Protocol Handler Auto-Update" was enabled.
- Fixed an issue where the folder picker would not populate when adding folders in event pipeline policies while in Unlimited Vault Access mode.
- Fixed an issue where the IBM iSeries password changer was not properly adding the model value to the connection string.
- Fixed an issue where the light/dark mode toggle displayed "Enable Dark Mode" even though the UI was already in dark mode. This was due to a dark mode browser preference and no explicit user preference having been set.
- Fixed an issue where the SAML AuthnRequest was sending a blank RequestedAuthnContext when Authentication Context was set in the Identity Provider Configuration.
- Fixed an issue where the Secret Server website would not load if the internal site connector is unavailable at startup.
- Fixed an issue where the terminate option on the session playback page was missing.
- Fixed an issue where the test buttons would not function for the Oracle Account Ver. 2 password changer.
- Fixed an issue where the UI session monitoring search required additional permissions to load.
- Fixed an issue where the Unlimited Vault Access watermark could block interaction with some page elements.
- Fixed an issue where the wrong error message would be shown when trying to apply an invalid data source key under data replication.
- Fixed an issue where user permissions on replica instances were removed erroneously when data replication ran.
- Fixed an issue with check in when the "Check In Secret on Launcher Close" and "Close Launcher on Check In Secret" settings were both false.
- Fixed an issue with DR replication where some operations would give an error "The incoming request has too many parameters."
- Fixed an issue with excessive CPU usage for RDPWin.exe. Protocol handler and session connector no longer track or record processes using WMI. Now they use native Windows calls, reducing CPU usage of the Windows WMI Provider. The exception is when "Run as secret credentials" is used—it still uses the WMI process tracking.
- Fixed an issue with replicating domain users. This now correctly links the user with the replicated domain.
- Fixed an issue with slow loading sessions failing to load when using session connector. This required an update to the latest protocol handler (RDS) on the session connector server.
- Fixed an issue with the group filter in event pipelines to ensure precise name matching is correctly used.
- Fixed an issue with the SearchSecretsByFieldValue SOAP API function that caused it to return a 500 error.
- Fixed bug where email filters click through approval links.
- Fixed an issue where OIDC platform connection failed for previously imported users after a domain change.
- Mitigated the possibility of an error in SSH Proxy command processing.

- Removed parameters from ASRA installer to accommodate long secret URLs.
- Resolved an issue with RADIUS challenges in Secret Server Cloud.
- Session recordings which are invalid due to no data are now recorded as an error to prevent failure upon playback.
- Updated discovery SSH scanners to handle messages coming back without the stdout marker.
- Updated logging around Azure AD Sync to make it clearer when the sync stops due to configured groups missing in Azure AD.

Future and Recent Deprecations

This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server Cloud Release Notes

These are the release notes for Secret Server Cloud versions.

The last published Cloud release was Secret Server Cloud Release July 22, 2025.

Beginning February 2026, new Secret Server Cloud versions will no longer be published on this page. Ongoing Cloud updates, patches, and hotfixes are documented in the Secret Server Change Log.

Secret Server Cloud Release Notes for July 22, 2025

Cloud Release Date: All Regions: July 22, 2025

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.59.0

Protocol Handler: 6.0.3.39

If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

New Features

Azure Key Vault Integration

Azure Key Vault Integration (AKVI) simplifies management and governance of NHI's and secrets from the CSP's native vaults. With AKVI you can centrally manage and update secrets to one or more Azure Key Vaults and rotate passwords or values more frequently. With fine grained roles and permissions, audit and logging, AKVI provides increased governance, visibility, and awareness of secrets managed in Azure Key Vault without affecting development velocity or processes. AKVI is available on Secret Server Cloud, the Delinea Platform, and Secret Server On Premises.

Additional Approval Workflow Type

A new approval workflow type is available, allowing owners to bypass approval while ensuring approvers still require it. The "Standard Including Editors and Approvers (Owners do not need approval)" option offers more flexibility in approval processes to meet organizational needs.

Bulk RPC on Secrets with Checkout Enabled

Bulk RPC actions are available to secrets with checkout enabled. This feature uses random passwords during bulk operations, ensuring that passwords remain secure and hidden, even during bulk updates, without compromising secret integrity.

Bulk Update Secret Fields

Bulk updates for secret fields are now available, enabling users to edit and update multiple fields across secrets in the folder view. This simplifies importing and formatting secrets, streamlining secret management for large datasets.

Global Manual Approver Workflow for Ticketing Systems

A manual approval workflow is now available for scenarios where the primary ticketing system, like ServiceNow, is unavailable. This fallback option ensures that users can still gain access to secrets through a manual approval process, maintaining workflow continuity even during system outages.

PowerShell 7 Support for Scripts

Secret Server now supports PowerShell 7 scripts, allowing users to run both legacy PowerShell scripts and PowerShell 7 scripts. This update ensures compatibility with the latest thycotic.secretserver module and helps avoid disruptions from version conflicts.

PowerShell Ticket Integration—User Information Passed as Arguments

PowerShell ticket integration has been enhanced to pass user information (userID, username, and email) as arguments in scripts. This update provides greater flexibility for ticket validation, enabling more customized and user-specific logic in ticket-related actions.

Pre-Compiled Version of Secret Server On-Premises

A pre-compiled version of Secret Server for on-premises deployments is now available. This version allows files to be signed through catalog signing, addressing code integrity violations and ensuring compliance by maintaining integrity and trust standards for all files.

Secret Icons

Secret Icons allows you to display icons for secrets in the secret list, and secret details page. Icons can be set at both the secret and secret template levels.

Multi-Cloud Security and Integration

- **AWS Secrets Manager Integration** extends our distributed vaulting initiative beyond Azure, providing seamless integration with Amazon's AWS Secrets Manager. Administrators can centrally vault, manage, update, and rotate credentials in AWS Secrets Manager, further addressing secret sprawl challenges across multi-cloud environments. It enables centralized, seamless management of all secrets without sacrificing latency or developer or business agility while managing Non-Human Identities (NHIs) and Artificial Identities (AIs) with maintained security and governance.
- **External vault automatic lists for Azure Key Vault and AWS Secrets Manager** simplifies the vault linking process by automatically presenting available vaults, reducing configuration complexity and potential errors during setup.

Platform Upgrade Center (PIC) Enhancements

Soon to be renamed *Platform Upgrade Center*.

- **Automated, secure Platform access** transforms the previously manual two-step process into an automated workflow when Platform environmental conditions allow, reducing upgrade complexity and potential errors.
- **Enhanced Platform Upgrade Center (PIC) with Entra ID Support** streamlines the upgrade process for organizations using Microsoft Entra ID. The PIC now features automated upgrade steps and application account integration capabilities, making it easier for customers to use the full power of the Delinea Platform. This unblocks a key capability, ensuring customers who federated with Entra ID in Secret Server can seamlessly upgrade to the Delinea Platform via the PIC.
- **Enhanced pre-checks and validation** provide better error messaging and validation throughout the upgrade process, including username validation against Platform regular expression rules and improved group membership handling.
- **Application account support** enables seamless integration of application accounts to the Delinea Platform through the PIC, expanding the scope of automated upgrade capabilities.

Performance and Scalability

- **API performance optimization** addresses excessive launcher session polling that was generating over 120 million monthly API calls, significantly reducing server load and infrastructure costs while maintaining functionality.
- **Secret search performance improvements** deliver a 66% improvement in secret search speed compared to previous versions.
- **Bulk operations performance enhancement** significantly improves reliability and performance for large-scale secret operations. Enhanced secret imports and bulk operations now split large requests into smaller chunks, preventing failures due to message-size limits and boosting performance by up to 20% for operations involving tens of thousands of secrets.

Security and Compliance

- **Security enhancements for auditing** creates separate controls for password view, secret view, and comment-required auditing. This allows customers in higher security environments to audit password view events in real-time while managing business productivity by less aggressively requiring comments.
- **Session management improvements** include better RDP proxy session tracking, automatic session closure when checkout expires, and enhanced keystroke recording capabilities for SSH-tunneled connections. These improvements provide better visibility and control over privileged sessions.

User Experience and Management

- **Personal folder duplicate secret management provides granular control over duplicate secret names** by allowing duplicates in separate personal folders while maintaining restrictions elsewhere. This enhancement uses an improved enumeration-based configuration system that eliminates conflicting Boolean settings.
- **Request forced checkout enhancement** builds upon the 11.8 feature with improved UI display and better handling of secrets in pending status, providing administrators with more control over secret access during incident response scenarios.
- **Increased Windows password changer flexibility** offers increased configurability for authentication methods and their order, with enhanced server message block (SMB) fallback options that provide more granular control over heartbeat and password change operations.

Licensing and Availability

Extended resilient secrets availability to Secret Server Professional resolves licensing issues that previously blocked this feature. Customers with a Secret Server Professional license can now access the resilient secrets pages without encountering license-required error messages.

Improvements

ID	Release Notes
639164	Improved: The legacy license .aspx pages have been removed.
639773	Improved: Added a new report for active users and all users for secrets.
640087	Improved: Added option to allow duplicate secret names in separate personal folders.
640202	Improved: Performance when there are a great number of folders for the following : modifying folders. modifying user display names, or changing the personal folder root name (if personal folders are enabled).
640487	Improved: Added more configurability to the Windows password changer for the method and method order.

ID	Release Notes
640554	Improved: LimitedMode no longer limits AD sync, creating and editing secrets, importing secrets, and web service use.
640556	Improved: UI banner now notifies admins of systems exceeding license limits.
640688	Improved: Scan Template Detail page: an unused scan template can now be deleted. Required Fields now change according to scan type selection.
640783	Improved: $SECRETID and $[x]$SECRETID are now available for scripting
641022	Improved: Folder-detail performance.
641879	Improved: The DR replica now handles events where the DR feature deletes folder(s) assigned to "automatic export" by disabling automatic export.
642042	Improved: Added a PIC pre-check error when a username in Secret Server does not match the regular expression rules defined in Platform.
642213	Improved: Check out, check out extended, and check in Syslog events now contain the UTC times of check out and check in.
642250	Improved: Platform Integration can no longer be disabled when unified mode is enabled and all users are sourced from Platform. This prevents users from locking themselves out of their instance. In the event that Platform Integration can be disabled, a dialog warns the user of the consequences.
643200	Improved: Added a data link between the SDK client account and onboarding rule so when an SDK onboarding rule is deleted all SDK client accounts created from that rule get their access revoked.
643381	Improved: Added a configuration setting under user experience to set the duration for the password mask to begin hiding input again.
643721	Improved: Secret access requests can now be published to the Delinea Platform for other services such as the intelligent authorization agent.
643739	Improved: Users can now use the Platform Upgrade Center to migrate Entra ID domains to Platform.

ID	Release Notes
643793	Improved: The groups precheck in the PIC only warns of group membership and role changes
643866	Improved: Added a tab on the User Management page titled OAuth Expiration that lets users delete previously issued OAuth tokens.
644419	Improved: Added Automatic listing when adding an external vault link to Azure Key Vault added.
644548	Improved: DR button order swapped and grid fixed to have more uniform styling on the status chips.
644589	Improved: Now, during provisioning, we retry validation of Secret Server credentials. If upon retry validation still fails, it notifies the orchestrator that provisioning has failed.
644596	Improved: Performance of session monitor search when HasKeystrokes is enabled.
644755	Improved: Converted the update status endpoint to use a PATCH to prevent unnecessary value changes.
644783	Improved: Consistency of the PIC UI steps.
644847	Improved: A banner now reminds admins when their usage license is exceeded.
644887	Improved: Added QuantumLock actions to the user profile.
645147	Improved: When a user lacks access to a session recording, they see a more informative error page.
646302	Improved: The legacy bookmark pages are now disabled by default. They can be re-enabled from settings > user experience > Disable legacy bookmark pages. These pages will be completely removed in an upcoming release.
646932	Improved: Updated design for adding widgets to the desktop.
647178	Improved: Attempting to create an Active Directory discovery source when discovery is disabled now informs you that discovery is disabled and needs to be enabled.

ID	Release Notes
647190	Improved: Admins now receive a reminder in the UI when license usage has exceeded licensing limits.
647689	Improved: HSM process: When enabling and disabling the HSM or rotating the HSM key a backup of the encryption.config is created. To prevent a bad state where the database has updated and the encryption.config was not, the database changes are rolled back to the prior state. Also, when rotating the HSM key with PKCS11, if selecting the current DLL, the system will prevent changing the token label and user pin. Since the PKCS11 library already has an open session and cannot close, this prevents potentially saving the wrong information.
647936	Improved: Added capability to select from multiple settings with distinct behaviors to set how duplicate secret names are handled in the Permission Options section.
648752	Improved: Performance of resilient secrets excluding all data related to QuantumLocked secrets.
649210	Improved: Protocol handler parameter checking when using install options was extended to address CVE-2024-12908.
649708	Improved: Resilient Secrets now falls under "Professional" licensing without need of an add on.
649863	Improved: Updated workflow and secret approvals to use the template arguments for the ticket system.
649955	Improved: Reduced the likelihood of an incorrect query returning too many results.
650476	Improved: Increased flexibility for the Windows Password Heartbeat. The Enable SMB Fallback option, previously on the remote heartbeat configuration options, has been replaced with options directly under the advanced settings under Windows Password Changer. This allows you to toggle RPC and SMB heartbeat attempts and determine the order. Previous Enable SMB Heartbeat configuration has been translated to the new settings. The new options for flexibility do require DE version 8.4.56.0.
650658	Improved: Legacy bookmarklet pages were removed.
650720	Improved: The legacy session recording search and viewing pages were removed.

ID	Release Notes
650755	Improved: Several legacy message pages, such as a read only mode description, have been removed and replaced with newer versions.
650853	Improved: Reduced CPU use within the website and background worker.
651149	Improved: Added text to the Unified step of the Platform Upgrade Center.
651315	Improved: Removed the HSM legacy .aspx pages.
651333	Improved: Password type audit grid updated to angular.
652518	Improved: Added more prechecks in the PIC for a user with a domain whose AD Guid or UPN is NULL in Secret Server.
653208	Improved: Drop down options added for email configuration.
653299	Improved: The secret view that opens in the right panel has been cleaned up to make the copy icons more visible and keyboard access has been enhanced.
653422	Improved: Added a throttle: "Max Number of Passwords That Can be Changed at One Time setting for Entra ID password changer."
653719	Improved: Adjusted MDI partner API URLs to match the new URL.
655545	Improved: Platform is now running on angular 20.
659980	Improved: Legacy discovery .aspx pages were removed.
661443	Improved: Manage Directory Groups button was removed from the Groups page. It just linked to directory services, which is easily accessed in the left navigation panel.
661831	Improved: The legacy discovery .aspx pages have been removed.

Fixed Issues

ID	Release Notes
638256	Fixed: An inaccurate error message for session recordings when launch is not detected.

ID	Release Notes
638964	Fixed: RDP proxy session tracking. Resolved an issue where RDP proxy sessions that were opened using proxy credentials (not protocol handler) were not being marked as launched, causing them to be missing from session search results.
639151	Fixed: Resolved issue with PostgreSQL password-change functionality.
640392	Fixed: DR replication data loss when the replica encounters save errors. Resolved issue where running "new data since last replication" could result in permanent data loss if the replica encountered errors during save, causing subsequent replications to skip the failed data entirely. Fixed replication state tracking to ensure failed items are retried in future partial replications.
640808	Fixed: Request Force Checkout button is now displayed while the secret is in a pending status and the "request force checkout" feature is enabled
640978	Fixed: The bulk secret field update now works when MFA is enabled on any secret that is selected.
641375	Fixed: Adding and removing fields did not work correctly if none of the new or existing fields were edited.
641376	Fixed: Export CSV on reports and the auto export storage download now work in Platform.
641566	Fixed: The dates of tbPlatformIntegrationStep were either not being set or being reset in certain scenarios. This has been fixed for all of the steps except the Unification step that will be fixed in a separate card.
641630	Fixed: Secret audits did not correctly link to the new session recording UI.
642223	Fixed: A total count issue when searching subfolders and secrets and then checking and unchecking items.
643226	Fixed: Password changes now trigger an external key-vault push for the linked secret.
643304	Fixed: The status of the Customize branding step in the PIC no longer resets from "skipped" to "ready to start" when the page is refreshed.
643492	Fixed: Discovery but where EntraID users or roles would not display properly in "Network TreeView" under the root EntraID tenant node.

ID	Release Notes
643677	Fixed: AFT token validation errors now return an error code instead of a 500 status code with no body.
643715	Fixed: An issue with the "maximum login failures" shortcut leading to the wrong configuration area.
643815	Fixed: TOTP codes from the favorite dashboard in Platform now work.
643841	Fixed: An error with the opt-in step of the PIC if the user refreshed the page once the opt-in process had begun.
643869	Fixed: Save button was enabled when modifying file attachments before any change was made.
644593	Fixed: Corrected workflow email links for Platform to point to Platform URLs not SSC URLs.
644921	Fixed: Discovery source ID was not being read correctly for Entra ID Members, which led to problems viewing and importing accounts.
645106	Fixed: Issue that could sometimes prevent validation of the Platform URL from the Secret Server configuration page.
645923	Fixed: The "ThycoticSystem" internal user now has the display name "Delinea System."
646732	Fixed: Issue where Entra ID discovery would cause errors when field names in the Privileged Secret template were changed.
646957	Fixed: Periodic error when retrieving favicons.
647271	Fixed: Active Directory invites did not get created in Secret Server
647291	Fixed: A new version install could cache old en.json localization files. Language files now include cache-busting tags.
647351	Fixed: Locked users in Platform were not disabled in Secret Server.
647639	Fixed: An issue that could block OIDC authentication.
647691	Fixed: Account scan template was not display after saving on the Scan Template Detail page.
647852	Fixed: A localization issue on the Discovery Rules List page.

ID	Release Notes
648239	Fixed: Template selection issue on discovery rules.
648534	Fixed: Long secret names did not wrap properly when shown as credentials for a discovery scanner.
648665	Fixed: The Validate Connectivity button was not visible when configured to use processing location as the website.
648769	Fixed: 404 error when loading the application load. To prevent this, custom language resources are only loaded if the files exist.
648844	Fixed: The CSV report download button did not work in Platform.
648998	Fixed: The Preview panel, once closed, would not reappear until opened again.
649098	Fixed: Anti-forgery token logic caused pages to refresh in some circumstances.
649167	Fixed: Secrets did not show inherit permissions properly when searching in the grid. Folders now show the inherits permissions column when shown in the grid.
649273	Fixed. The date range filter could be removed from the discovery computer scan results tab.
651907	Fixed: Resolved an upgrade failure to 11.7.25-11.8.1 for on-premises Windows customers using a non-en-us locale.
651955	Fixed: A fresh on-prem install got stuck at the Create Initial User page.
652482	Fixed: Scan template names were not populated in a dropdown on the PasswordChangerEditScanItemTemplateEdit.aspx page.
652648	Fixed: The Edit button is now visible but disabled on non-editable scan templates.
652697	Fixed: in the PIC for the Secure Access step where polling was not occurring in certain situations after the button was pressed leaving the step stuck in the In Progress state.

ID	Release Notes
652855	Fix: Tunneled RDP proxy data could be stored in the database erroneously under certain conditions. This data is encrypted by the RDP protocol and therefore is not useable as keystroke data and should not be stored.
653644	Fixed: Secret policy launcher tab clipped the far right side of the form selects.
654670	Fixed: Secret share no longer adds groups to the Platform Allowed group list when adding from external groups.
655397	Fixed: On-premises edge case where if the web role had a cached valid license the disaster recovery process was allowed to begin but the background worker could not see a valid license and would do nothing. Now a log is generated.
655439	Fixed: Bug where the SAML Metadata Download XML button did not work.
659912	Fixed: The script editor (report, scripts) would sometimes show an error with the text "canceled."
660018	Fixed: A WRONGTYPE issue caused by calling redis.GetList on a "List<string>" type object. Caching once again applies for this value.

Secret Server Cloud Release Notes for April 5, 2025

Cloud Release Date: All Regions: April 5, 2025

This release was previously dated March 29, 2025.

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.43.0

Protocol Handler: 6.0.3.33

If your protocol handler version is 6.0.3.26 or lower, you must manually upgrade to a higher version. Automatic upgrades will not work for versions 6.0.3.26 or below. However, if your protocol handler version is 6.0.3.27 or higher, the automatic upgrade will function properly.

New Features

Azure Key Vault Integration

Azure Key Vault Integration (AKVI) simplifies management and governance of NHI's and secrets from the CSP's native vaults. With AKVI you can centrally manage and update secrets to one or more Azure Key Vaults and rotate passwords or values more frequently. With fine grained roles and permissions, audit and logging, AKVI provides increased governance, visibility, and awareness of secrets managed in Azure Key Vault without affecting development velocity or processes. AKVI is available on Secret Server Cloud, the Delinea Platform, and Secret Server On Premises.

Additional Approval Workflow Type

A new approval workflow type is available, allowing owners to bypass approval while ensuring approvers still require it. The "Standard Including Editors and Approvers (Owners do not need approval)" option offers more flexibility in approval processes to meet organizational needs.

Bulk RPC on Secrets with Checkout Enabled

Bulk RPC actions are available to secrets with checkout enabled. This feature uses random passwords during bulk operations, ensuring that passwords remain secure and hidden, even during bulk updates, without compromising secret integrity.

Bulk Update Secret Fields

Bulk updates for secret fields are now available, enabling users to edit and update multiple fields across secrets in the folder view. This simplifies importing and formatting secrets, streamlining secret management for large datasets.

Global Manual Approver Workflow for Ticketing Systems

A manual approval workflow is now available for scenarios where the primary ticketing system, like ServiceNow, is unavailable. This fallback option ensures that users can still gain access to secrets through a manual approval process, maintaining workflow continuity even during system outages.

PowerShell 7 Support for Scripts

Secret Server now supports PowerShell 7 scripts, allowing users to run both legacy PowerShell scripts and PowerShell 7 scripts. This update ensures compatibility with the latest thycotic.secretserver module and helps avoid disruptions from version conflicts.

PowerShell Ticket Integration—User Information Passed as Arguments

PowerShell ticket integration has been enhanced to pass user information (userID, username, and email) as arguments in scripts. This update provides greater flexibility for ticket validation, enabling more customized and user-specific logic in ticket-related actions.

Pre-Compiled Version of Secret Server On-Premises

A pre-compiled version of Secret Server for on-premises deployments is now available. This version allows files to be signed through catalog signing, addressing code integrity violations and ensuring compliance by maintaining integrity and trust standards for all files.

Secret Icons

Secret Icons allows you to display icons for secrets in the secret list, and secret details page. Icons can be set at both the secret and secret template levels.

Fixed Issues

405016	Fixed: The RPC by Day report is now formatted to user's time zone.
530294	Fixed: Key rotation failure. We now allow a particular password type to be set for account take-over when importing an account into Secret Server.
537916	Fixed: The folder-permission API now requires view or administer folder permissions to query by a folder ID. Previously, you could also do this with the personal folders role permission.
539187	Fixed: Secret access request viewing very slow. Bug fixed with loading large numbers of secret access requests.
546108	Fixed: Add a "Matches" tab on discovery account rules to show computer accounts that match the defined rule condition. This replaces the account rule filter on the network view that has been removed.
556742	Fixed: An issue that prevented empty dependency groups from being deleted.
557774	Fixed: Errant heartbeat every five minutes. When creating a new secret template with heartbeat enabled, if you do not change the interval value it will now correctly assign heartbeat interval of 60 minutes.
559102	Fixed: An issue where large-item-count folder searching was broken.
560138	Fixed: The secret template fields grid would not always load all records properly if there were more than 60 fields on a template.

564689	Fixed: User appearing locked out after the lockout period. On the User General page (admin page), added an Unlock User button and chips and messages to reflect lockout interval for user locked out by failed logins.
566423	Fixed: Resolved an issue where downloaded report names appeared garbled when the language was set to Japanese or Simplified Chinese. Fixed: An issue in the Platform where downloaded reports were incorrectly named "null." Reports now display the correct filenames based on the selected language.
571212	Fixed: Test Script page not working. SQL parameters now work in the new UI.
571231	Fixed: Role audit log error. The Action field of role audit logs now display correctly when the log is created in a language that uses Unicode characters
575503	Fixed: A dependent library used in SAML in Secret Serverhas been updated to close potential security vulnerabilities. It uses a different version of a saml.config when using the legacy SAML configuration, and a conversion process to update saml.config has been added to the upgrade system. Please see Secret Serverdocumentation "Troubleshooting SAML Configuration Errors After Upgrading" if using a saml.config file and having issues.
578291	Fixed: Session recording search times out.
578890	Fixed: Removing a launcher having multiple secrets linked will no longer fail.
580299	Fixed: An issue with /api/v1/launchers/secret endpoint throwing errors with complex URLs.
581180	Fixed: An error when checkout had expired, switching to the settings tab on a secret would throw a red banner error instead of redirecting the user to the checkout page.
582171	Fixed: Double email notifications for access approval request. Access request emails will now indicate a status of the workflow. Viewing a workflow online will also render a visualization of the workflow status.
582538	Fixed: An issue where session messages sent from Secret Serverwould not show during RDP Proxy sessions.

582728	Fixed: An issue where users who had permission to edit secrets could not toggle auto-change using the bulk action on secrets that should have allowed it, based on the permission set in the secret's template.
583939	Fixed: Incorrect active session display. Secret active launcher sessions now updates list when a session is launched from the page.
585609	Fixed: error when removing scanners from a discovery source. Added a custom exception for "scanner X already added" and UI refresh to stay in synch with back end.
591272	Fixed: An issue with the Launcher template when modifying the field "Use SSH Tunneling with SSH Proxy."
593801	Fixed: An issue with SSH key integration expiration configuration.
595169	Fixed: An issue where there was no option to add a step in a workflow. It is no longer possible to delete the last step from a workflow. Existing workflows with no steps will now display a default starting step when opened to edit.
595565	Fixed: An issue where dependency changers in SSC were not passing arguments to scripts, resulting in empty output files. Dependency changers now correctly pass arguments, and the status no longer incorrectly shows as disabled.
599173	Fixed: In active sessions inside a launched secret, when the username that launched the secret contains Unicode characters, they displayed incorrectly.
601706	Fixed: Intermittent Azure message loss. Implemented retry logic for publishing to Azure service bus queues.
603681	Fixed: Resolved a password display Issue (with "comment required" enabled) where, after waiting on the Overview tab for 5+ minutes, the password was displayed as [object Object] instead of prompting for a comment again. Users are now correctly required to re-enter a comment when accessing the password.
603779	Fixed: An issue with category and report permissions showing 0 items when permissions are assigned to users.

605053	Fixed: Heartbeat and password reset failures. Added more support for expired AD account password changers. Secrets that use an AD privileged password changer to rotate the password for an expired AD account will successfully complete the rotation process. Previous behavior involved rotating successfully and then failing the verify step, resulting in the new password not being saved on the Secret Serverside. Subsequent heartbeats may fail for the secret since the account is expired. Password Changes using a secrets own credentials may fail as well.
607434	Fixed: Discovery analysis SQL timeouts. The query that populates the discovered account metrics has been made more efficient. It should no longer have timeout issues.
608395	Fixed: Columns that should have been hidden were selectable in the column selector. If selected, they would (incorrectly) display until page reload. The conditionally available columns are now correctly set visible or hidden in the column selector.
614002	Fixed: Turkish not displaying correctly in email. Turkish characters should publish correctly in email HTMLs.
614465	Fixed: Tooltip location on the Launcher Configuration page.
616185	Fixed: Resolved an issue where users could add members to a migrated group in SSC via individual user modifications. Now, all membership changes must be managed in the Platform, ensuring proper access control.
616221	Fixed: In SSC the from email address field in email configuration settings is restricted to the secretservercloud domain and the TLD excludes .co.uk as a valid option. On premises instances will only validate that it is a valid email address format but will allow any domain to be input.
617344	Fixed: An issue with password that contains username and added a new item to the local-user password configuration area that optionally prevents the password containing the username.
617429	Fixed: An issue where an invalid version number could cause Secret Server to become unresponsive.

617445	Fixed: Updated command sets to no longer add extra spacing between lines, and added validation around comments in command sets, instead of auto-removing extra comments, to reduce confusion on save.
617607	Fixed: Discovery services grid did not sort. Added computer Services API endpoint so the computer services component now has paging and sorting.
618528	Fixed: Resolved an issue where secret policy settings were not properly inherited by secrets, causing discrepancies in the Approval page. Additionally, the "Language Resource Not Found: OnlyOptionViaPolicy" message has been fixed. Secret policy settings now correctly apply as expected.
618869	Fixed: An error with "Default Only" on RPC schedule on a active secret policy.
619554	Fixed: On-Premises Secret Server instances with PRA will now get emails to the Secret Server instead of the Platform instance.
620165	Fixed: Display to show <tenantname>.delinea.app when opting into a prod instance.
620338	Fixed: An issue with "minimum required character count" rules options containing an invalid choice.
621226	Fixed: Resolved an issue where repeated execution of Entra ID secret heartbeats would cause a "Headers too long" error.
621935	Fixed: Resolved an issue where viewing a secret with MFA enabled incorrectly logged "Password Displayed" in audit entries. Now, the audit log correctly records the action as "View" when no other interactions occur.
622254	Fixed: Resolved a bug where when Platform is integrated with Secret ServerCloud and Open ID Connect Platform login is used–in some situations the redirected Platform login page would be incorrect.
622479	Fixed: Error during opt-in in PIC for Europe region.
626465	Fixed: Audit with no notes. Secret policies should no longer create an empty audit log when modifying launcher settings but reverting changes before saving.

626702	Fixed: An issue with users not being re-enabled when logging in through Platform after being disabled by automatic user management.
627109	Fixed: Launchers filter was incorrectly labeled was "Template."
627246	Fixed: The field header example on secret import now wraps correctly.
627291	Fixed: The "All launchers" option of the launcher filter now returns all results as expected.
627619	Fixed: Changed database cleanup logic which was causing some heartbeat/RPC audit records for inactive secrets to be removed before the "Max Secret Log Length" was reached.
627731	Fixed: If an Entra discovery source is created in Secret Server and Platform integration is configured with Inventory Forward enabled, there was a bug when deleting roles from the Discovery Network View in Secret Server. It would cause Entra roles to show up in Platform inventory.
628439	Fixed: Corrected a typo on Launcher Mapping page.
629517	Fixed: Resolved an issue from the previous update where toggling an Active Directory account's expiration status could prevent verification after a password change.
629584	Fixed: An issue with the password compliance check notification on a secret.
630728	Fixed: A bug where saving an approval method for a secret does not persist correctly.
631133	FIxed: An issue with AD privilege password changing partially failing for accounts that had null values for "accountExpires."
634286	Fixed: Issues with dropdown options causing enum values to be displayed for the Secret Security Approval Type so that correct localized strings are displayed.
634484	Fixed: Excessive CPU usage by correcting the SessionKey parameter to varchar, eliminating implicit conversion.
635135	Fixed: The "Ignore permission errors" checkbox is now available without a page refresh.

637136	Fixed: Do not include azure domains or inactive AD domains in group-type precheck.
637139	Fixed: Users missing their ExtendedUserMapping will register as a warning in the precheck instead of an error.
637373	Fixed: Corrected regression where secrets were counted twice in some scenarios. Secrets grid count functionality restored. Count ("# Items") is the sum of the number of first-child subfolders and the number of secrets in the current folder.
637690	Fixed: Incorrect GUI label. Updated Log Level filter label from "Site" to "Log Level."
638073	Fixed: A bug that prevented the secure-platform-access step in the PIC from auto-skipping.

Improvements

546156	Improved: Logging in when MFA setup is required now immediately redirects the user to configure MFA.
566484	Improved: Reports page size minimum has been increased to 60.
575905	Improved: Updated scanner template creation UI to combine both OU Input templates and non-OU Input templates into the same dropdown in categories.
580253	Improved: No dynamic update for active sessions. Active launchers section on secrets now updates every 30 seconds to show an updated list of active launchers.
582378	Improved: Updated grids using timestamps to use datetime in order to properly respect user preferences.
586608	Improved: Password validation failures for common number substitutions. Dictionary now indicates "Dictionary words including common number substitutions."
593543	Improved: Removed time zone tooltips from reports to reduce confusion when time zones are set by the report.
594323	Improved: Empty pinned folders now inform users of the empty sections.

603721	Improved: Resilient secrets log text information and added operation progress percentage estimation.Fixed: An issue where resilient secrets operation was not interrupting on operation timeout.
605210	Improved: Performance of discovery scanner delete: increased timeout to 24 hours, lowered isolation level where possible, and added logging for each delete operation.
609101	Improved: Added a non-configurable 30-second secret password timeout to improve security and reduce stale password issues. The timeout applies to: ■ Show password—hides after 30 seconds (previously visible forever). ■ Copy password—password value cached for 30 seconds only. Copy password icon clicks after that will trigger a fresh API call (to reduce stale password conflicts). Note that this does not affect the value that was already copied to the clipboard, only what will be copied when the user clicks the copy password icon.
610739	Improved: Performance improvements were made to the "Shared with me" Secret, and "Browse All Folders" views for customers with a large amount of folders in a highly nested structure.
611190	Improved: In the secret template list field, list and URL list now have their "dispose for display" boxes checked by default to denote the data's plaintext status. The expose for display control is also disabled so that it can not be unchecked by accident.
611573	Improved: Updates to Discovery Scan Status Report Query.
612177	Improved: Error handling for Platform credentials that become invalid.
612739	Improved: A new setting, "Disable Legacy Bookmark Pages," has been added the admin/user experience section. This setting is false by default. When true, the legacy bookmark pages used by legacy WPF will be disabled. This allows administrators to disable the setting and ensure they do not have any of these legacy clients that require it. This setting will default to disabled in a future release.
614508	Improved: Added the ability to view the Active Directory group type. This is displayed under the General tab of a group. If a group does not have a type, it will display as a hyphen. Otherwise, it will show one of the following: Global, Universal, or DomainLocal.

616620	Improved: Secret export now audits the current "Export" action and a new "Export retrieved" action to indicate that the user actually retrieved the file. Previously, you could close the browser window before retrieving the export file.
618004	Improved: Through the user experience settings, a user can use a new "COMMENT" audit action to separate the VIEW action of a checkout (or ITMS) protected secret from the required comment.
619512	Improved: Event pipeline set-custom-value tasks can now increment or decrement pipeline variables by custom values.
619515	Improved: Added additional group type validation (empty group types and DomainLocal group types) for the Data Sync step in the PIC. If empty group types are detected, users are prompted that there are empty group types and are instructed to run the directory services sync. For any DomainLocal groups found, an error message appears in the pre-check table within the Data Sync step stating that DomainLocal groups are not supported.
626041	Improved: Modifications to build pipeline to precompile, copy and overwrite Secret Serverprecompiled assets to webroot folder. Packaging and installer remain as they were prior to PR.
626668	Improved: With Platform Integration, support for the setting "Create Groups during synchronization" is completely deprecated. Now, all Platform native groups will be created automatically and any directory groups through Platform need manual linking.
626881	Improved: Updated discovery import rules to prevent duplicate account creation and unintended unlinking of service and Active Directory accounts. Added broader test coverage, including integration tests, to ensure correct matching, unmatching, and unchanged behavior when re-running imports.
627169	Improved: Updated discovery analysis layout to emulate dashboard styles and to better accommodate large datasets.
627297	Improved: Added a new date and time range filter to Session Monitoring.
627303	Improved: Added a new state flag to indicate whether the Delinea enablement code has been entered.

627304	Improved: Added a new state flag to indicate the customer has completed the Platform integration.
627344	Improved: The inbox template editor now includes options to select message properties by selecting which message. This helps clarify that only message properties on the targeted message are available to merge into the template.
631776	Improved: The application picker that appears when both Secret Serverand Privilege Manager are installed has an updated design. This slightly increases the speed of the login process.
633054	Improved: Optimized memory management to reduce latency buildup in the US BGW, preventing performance degradation over time. Restored ASP.NET metrics for better visibility into garbage collection and CPU usage.
635732	Improved: Add PasswordTypeIds as a filter on the api/v1/secret-templates-list endpoint.
635803	Improved: Only the users that are migrated are validated.
636130	Improved: When enabled, "Show secret icons" in User Experience will display icons for secrets in grid, card, and detail view.
638928	Improved: Removed legacy secret access request aspx pages.

Secret Server Cloud Release Notes for August 3, 2024

Release Date and Notes

Cloud Release - All Regions August 3, 2024

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.33.0

Protocol Handler: 6.0.3.28

With this version, protocol handler has received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

New Features

Entra ID Discovery

We are excited to introduce Entra ID discovery in Delinea's Secret Server! This enhancement expands our current discovery feature by adding support for Microsoft's Entra ID, alongside our existing AWS and GCP discovery types.

With Entra ID discovery, Secret Server can now scan Microsoft Entra ID for roles and users, importing users as secrets based on the Entra ID User Account template. This completes the suite of features necessary for Secret Server to discover and manage accounts from Microsoft's Entra ID.

Bug Fixes, Changes, and Enhancements

Bug Fixes

Fixed: Discovery runtime summary information is now correctly accessible for screen readers.

Fixed: Mobile logo now displaying properly.

Fixed: The SSH key-expiration configuration value now displays correctly.

Fixed: Updated the distributed engine service to persist the current the web-proxy.config file upon update. When upgrading to version from version 8.4.29.0 or lower, the web-proxy.config will be overwritten, but any upgrades afterwards will preserve it.

Fixed “Secret Erase” translation in some non-English languages.

Fixed a bug where a distributed engine ignored the “tasks Should Respect MaxShells restrictions” setting.

Fixed a bug where distributed engines ignored MaxShells restrictions.

Fixed a bug where distributed engines ignored WinRM quota limits.

Fixed a bug with running disaster recovery data replication from an older source to a newer replica.

Fixed a bug with the export/import settings where it was not resetting after leaving the page.

Fixed a check-in bug that caused a red banner warning.

Fixed an issue during Platform group synchronization where groups with long names would cause an error.

Fixed an issue so users and roles now always show in SSC, even if in unified mode, but still are hidden when using platform.

Fixed an issue to restore configurability of secrets associated with custom launchers.

Fixed an issue where deleting computers from the discovery network view failed to show a confirmation dialog box before continuing.

Fixed an issue where enabling QuantumLock on a secret threw the error “The partner transaction manager has disabled its support for remote/network transactions.”

Fixed an issue where stored data growth impacted proxy sessions. The secret session table is now managed and part of the supported tables of the data retention feature. Secret session records are now truncated in accordance with the existing data retention configuration. Please make sure to review your organization's Data Retention “Max Record Age” settings.

Fixed an issue where the “All time” filter on the inbox might not show all results.

Fixed an issue where users with MFA enabled would be incorrectly sent to the home page on login, instead of the page they were attempting to access.

Fixed content security policy fields for frame-ancestors.

Fixed incorrect access checks concerning reports.

Fixed incorrect Secret search totals when filtering by multiple templates.

Fixed issue where the “su -id” command was failing when the user did not have access to view the password for the secret they were elevating to.

Fixed issue where the maximum log Length was not used to truncate the tbSystemLog.

Fixed issue with “What folder permissions exist” report. Groups with no active users now properly included on the report

Fixed main navigation alignment issues.

Fixed ServiceNow allowed status validation over distributed engine.

Fixed the “view detail” link on the user detail panel.

Fixed The folder tree is now updated when Unlimited Vault Access mode is toggled.

Fixed timeouts for large amounts of data—paging for user audits is now done in the database.

Fixed: A user that did not have the “view launcher password” role permission was unable to create a secret that had a required password because the password field was hidden.

Fixed: Added null checks for username.

Fixed: Added support for Cisco devices when using a question mark after the command or partial command. This allows Cisco to work as normal, while not allowing the blocked commands.

Fixed: Addressed an issue where a launcher type field that was replicated via resilient secrets would not function with all prompt-able field names.

Fixed: Addressed one scenario where a backend process that publishes session information would error.

Fixed: Adjusted secret overview tab to not use a banner for heartbeat failed.

Fixed: Adjusted Secret tab pending password change status to be a chip instead of a banner.

Fixed: Audit handler was missing the “View Configuration Unlimited Admin” permission as an option.

Fixed: Authentication errors are now 401s for API requests and in Platform.

Fixed: Customers who had Easy Move to Platform had duplicate groups created in Secret Server and the existing permissions from the original Secret Server group were not honored. It now disables this new duplicate group and connects the original group to the Platform group as originally expected.

Fixed: During forwarding of inventory data from discovery in Secret Server to Platform inventory, with large amounts of computers, the processes could time out. Made the database calls more efficient and the process no longer times out.

Fixed: Extended the Migration Center to migrate all active roles.

Fixed: Folder path now shows when specified in secret import preview.

Fixed: Heartbeat listed as “pending” when the heartbeat is actually disabled. This occurred when the pending status did not resolve before the secret was disabled.

Fixed: Improved compatibility with Windows high contrast mode.

Fixed: Improved “Regenerate Platform Credentials” to attempt to forward credentials to connected Secret Server Cloud automatically (behind feature flag).

Fixed: In some scenarios only the first 30 subfolders were loaded on initial load for a single folder.

Fixed: In some scenarios the folder tree would not auto-expand when linking directly to a folder.

Fixed: Left navigation expand/collapse toggle incorrectly labeled for screen readers.

Fixed: Login SSH key menu showing properly in cloud when configured.

Fixed: Newer versions of Safari can now play session recordings in Platform.

Fixed: Pinned folders now re-root the tree to the selected pinned folder.

Fixed: Reduced situations where a check-in error could occur when already checked-in.

Fixed: Removed links to legacy create discovery wizard pages.

Fixed: Resolved secret permission issue when many user and groups had been selected and only the 60 were saved when edited again. Resolved for teams selection as well.

Fixed: Searching in all secrets now shows the full folder path for folder search results.

Fixed: Secret password compliance is now calculated when a password is updated to empty and the password is not required. Prior to this, the secret would maintain the compliance flag that was calculated when the password had a value. A password with some characters might fail compliance, but if there is no password and it is not required, then it is compliant.

Fixed: Site name now wraps instead of truncating on the “sites and engines” page so you can read the whole site name.

Fixed: SQL report editor is now properly announced for accessibility.

Fixed: SSH keep-alives sent to the proxy are now relayed to the endpoint server.

Fixed: Teams group membership removed when more than 60 items in Team.

Fixed: Thycotic One Login Link.

Fixed: Unlimited Vault Access mode audit dialog box is now correctly aligned.

Fixed: Updated all the logs to be warnings and information and to state whether they retried or not.

Fixed: Updated Discovery Network view to better handle extremely large record numbers.

Fixed: User username link was sometimes unusable. It is no longer a link. View details link is in menu and preview panel.

Fixed: When viewing folder targets for event pipeline policies the full path is now shown.

Fixed: Remaining KB links now point to `docs.delinea.com` instead of `delinea.center`.

Fixed: About page links not working.

Fixed: Resolved an issue where approvals that cross a day threshold from UTC could not be requested.

Fixed: Resolved a UI issue with discovery import.

Fixed: Resolved an issue that caused SAML logins to fail, resulting in a rollback of the previous update.

Changes

Change: Admin breadcrumb renamed to Settings.

Change: Corrected license expiration banner link.

Change: Platform now specifies “Secret Server” configuration.

Change: Removed the color mode toggle from the top navigation as it is available under user preferences.

Change: The delinea.vault/secretserver/access permission has been removed. This no longer controls Secret Server access for Platform users.

Change: The SSL menu item is removed as it is not an option that can be modified in cloud.

Change: RequirePlatformMfa field is now deprecated.

Enhancements

Enhancement: Added “RPC PRIVILEGED SECRET UPDATED” and “RPC PRIVILEGED SECRET REMOVED” events to audits.

Enhancement: Added “User Lockout Protection” setting to domain.

Enhancement: Added a “Clear cached AD credentials” button in cloud.

Enhancement: Added a “test syslog” button to syslog pages in configuration.

Enhancement: Added a direct link for launching connection manager.

Enhancement: Added AIX support for SSH Proxy su automatic password entry.

Enhancement: Added an OOB RPC template for Okta. Okta requires an “Generic API” secret as the RPC privileged account.

Enhancement: Added an OOB RPC template for ServiceNow. ServiceNow requires an account to have Admin or write permissions to the password field, or an account with those permissions as its RPC privileged account to change the password.

Enhancement: Added DSV links to the Platform settings page.

Enhancement: Added landing page for when the user is unable to access Secret Server instead of showing banners.

Enhancement: Associated secrets will now show “No Access” in the secret name if you do not have access to it.

Enhancement: Converted key management to the latest design and added a verification checkbox confirmation step.

Enhancement: Heartbeat and password-compliance notices now use chips instead of banners.

Enhancement: Improved startup logging for distributed engines.

Enhancement: New import secret page allows you to import when global setting requires that secrets are in folders.

Enhancement: On premise now shows a diagnostics section under settings in the left navigation panel.

Enhancement: The left navigation folder tree now expands on focus to show longer folder names.

Enhancement: Updated password compliance label to a chip.

Enhancement: Updated Putty to version 0.81. Updated version addresses several Putty vulnerabilities, including the Terrapin vulnerability.

Enhancement: Updated Redis library for improved Redis operations.

Enhancement: Updated the server nodes page.

Enhancement: Updated the user profile menu to have more consistent styling and include links to the account details page.

Enhancement: Updated user experience for adding custom logos to Platform instances.

Enhancement: Updated user sorting to cover 2FA.

Enhancement: When a Secret Server is integrated with a Platform tenant, any Platform cloud groups are now automatically and quickly be created in Secret Server to be available for permission delegation.

Enhancement: Aria label added to inline secret-preview copy buttons. Main search category toggles now keyboard accessible.

Secret Server Cloud Release Notes for April 20, 2024

Release Date and Notes

Cloud Release - All Regions April 20, 2024

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.24.0

Protocol Handler: 6.0.3.27

With this version, protocol handler has received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

New Features

Left Navigation Panel

With this release, we have made several improvements to the left navigation sub-menu to provide a better user experience. Some of the most common configuration settings have been moved to the top of the menu. For more information about the latest changes, please see "Main Navigation Drawers" on page 184.

Improved Search

The main search is greatly improved. It now includes content search results as well as users. A status bar shows the full folder path for long secret-folder paths. Highlighted search categories include:

- Content
- Favorites
- Folders
- Secrets
- Users

Entra ID Secret Template for RPC

Secret Server has supported Azure AD remote password changing for several years, this overhaul creates a new password changer and template, Entra ID, that uses Oauth application credentials as a privileged account to change a user password. Entra ID is Microsoft's comprehensive cloud-based identity and access management solution that helps organizations securely manage identities and access across their Microsoft services and applications. Our password changer and template support MFA and conditional-access policies and does not require PowerShell.

Bug Fixes and Enhancements

- Fixed an issue with adding discovery sources that matched the domain of a current secret and were unmatched in the domain-name index table.
- Enhancement: Increased back end performance of event queue processing when there are a large number of inbox rules.
- Fixed an issue where users other than owners could view TOTP backup codes.
- Fixed an issue where OAuth parameters were not validated. The OpenIdConnect flow has been adjusted to validate the redirection URI.
- Fixed issues that could cause incorrect group or user interactions between Secret Server and Platform. We corrected an issue with Platform group synchronization that would not correctly add all group memberships once the number of synchronized groups was over 1000.
- Fixed an issue where a ticket number was not present in SIEM logging.
- Fixed a policy validation issue that occurred when using a $itemvariable.variablename in schedule pipeline minutes.

Secret Server Cloud Release Notes for February 10, 2024

Release Date and Notes

Cloud Release - All Regions February 10, 2024

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.21.0

Protocol Handler: 6.0.3.27

With this version, protocol handler has received changes to core internal functionality that prevents automatically updating to version 6.0.3.27 from a prior version. In environments with protocol handler automatic update enabled, the protocol handler will automatically update to version 6.0.3.26. To use the latest functionality and fixes of protocol handler, you must redeploy or install version 6.0.3.27 to end-user machines. Following that update, the automatic update will continue to work as before.

New Features

QuantumLock

Secret Server's *QuantumLock* is a feature that provides an additional security layer by protecting secret data using asymmetric encryption (a public/private key pair) where the private key is a human-generated password. This feature is independent of regular permissions, Secret Server login access, or physical access to the machine running Secret Server.

A shortcut way of thinking about QuantumLocks is as an extra password for secrets that is held by a set group of users. In addition, both the password and the group of users are reusable for other secrets. In addition, QuatumLocks future-proof our digital security infrastructure against the advancing capabilities of quantum computing.

QuantumLock is an upgrade of the earlier doublelock feature. Besides the name change, the difference is QuantumLock offers the option to use a quantum-safe algorithm for encapsulation to protect the private key, specifically CRYSTALS Kyber-1024, which is designed to counter the potential threat from quantum computers to current encryption methods.

Enhancements

- Enhancement: Added a link to configuration audits on the Remote Password Changing page.
- Enhancement: Added a running log to disaster recovery so progress and duration per table can be tracked during replication.
- Enhancement: Added an event subscription called "Disaster Recovery Replication Success."
- Enhancement: Added auditing of password change schedules.
- Enhancement: Folders in favorites quick access are now filtered when searching.

- Enhancement: Improved HSM cryptography by adding support for AES 256 encryption. This ensures that all keys protecting the secret key will be at the same strength for organizations requiring this level of encryption.
- Enhancement: If an Azure Active Directory configuration in directory services becomes corrupt, you can now view and update the credentials to fix it.
- Enhancement: improved internal security checking around launchers.
- Enhancement: Improved SSH proxy block-command handling in VIM.
- Enhancement: Launching a secret now opens in a dialog allowing launch to occur without leaving the grid or current page. Restricted actions like checkout can be performed in the dialog.
- Enhancement: On the Proxying Configuration page, you can now automatically generate new SSH proxy host keys.
- Enhancement: Platform configuration settings were added to disaster recovery.
- Enhancement: Secret search performance improvements. The secret grid now only requests extended fields that are showing. When column selections are updated, a new request is made only if the extended field choices have changes.
- Enhancement: Secrets grid modal on the Secret Erase Requests search page now auto-scrolls.
- Enhancement: The login policy now supports line breaks.
- Enhancement: The secret search API now has a comma-delimited filter parameter for template IDs, which allows searching beyond IIS URL limits compared to the existing array version. Both are still available.
- Enhancement: The user profile allows for date and time format setting.
- Enhancement: Updated the toast message displayed when saving user preferences to accommodate screen readers.
- Enhancement: Users are no longer redirected from the licensing page.
- Enhancement: When Secret Server Cloud is Platform integrated, there is now an "Add from External Directory" option in secret sharing that allows searching directory sources from Platform to add users or groups.
- Enhancement: Added new optional parameter "nobus=true" to the healthcheck endpoint. This allows a faster response in situations where no lookup of the bus status is required.
- Enhancement: Adjusted the password compliance validation job to process more secrets on each run.
- Enhancement: Discovery port scanner now aborts if elapsed time expires prior to windows TCP handshake. Discovery port scanner will now also log a helpful message if the windows TCP stack aborts due to reaching the windows internal max syn retry count.
- Enhancement: The schedule pipeline task in event pipeline policies now supports using a variable for the schedule delay input.
- Enhancement: Unlimited Vault Access can now check in checked out secrets by other users.
- Enhancement: Added a Computer Scan Results tab to discovery.
- Enhancement: Added a new option to the Distributed Engine page for configuring "pending engines" that allows a pending engine to be assigned to a site without activation.
- Enhancement: Added a note to audits when the system disables a Secret Server user.

- Enhancement: Added an SDK link.
- Enhancement: Added the table tbTerminalConnectionHistory to the list of tables that is handled by the database cleanup consumer. It will periodically delete any records over a certain age, which can be customized by the user.

Bug Fixes

- Added "view all folders" link that appears when folders are filtered in a pin view.
- Added a download button for session recording to Secret Server. The change does not appear for vault sessions in Platform.
- Added aria labels to the notification bell to support screen readers.
- Added new REST API patch method to controller which calls pre-existing latestversion.txt processing code.
- Added protocol handler step-up upgrade. Protocol handler will not try to upgrade versions 6.0.3.26 to newer versions as they must be updated manually. Released new 6.0.3.27 version which will be able to upgrade to future versions.
- Adjusted license tracking for session-recording-enabled secrets so that secrets that have no launchers are excluded.
- Adjusted organization of some administrative menu items in the configuration preview.
- Adjusted permissions on Session Monitoring page so that users with "View Own Session Recordings" permission will only see their own recordings.
- Adjusted the display of administrative items from Platform to avoid perceived duplication.
- Adjusted the log level downward for certain engine messages for syslog to avoid overloading the engine log table.
- Applied a more reasonable default SQL timeout.
- Clarified explanatory information on the Secret Import page to highlight that file fields are ignored.
- Converted dependency template management section to new UI.
- Converted Initial User page to the new UI.
- Corrected an issue where the Distributed Engine page did not respect the "Deleted" filter.
- Disabled the legacy bookmarklet pages.
- Disaster recovery now migrates teams.
- Fixed a client-side error on the Secret Settings page when viewed from Platform.
- Fixed a display issue on the IP Address restrictions page.
- Fixed a missing localization-key issue.
- Fixed a visual bug on secret templates so the password type dropdown no longer appears as "None" if a password type has been set.
- Fixed an edge case that could result in duplicate disabled usernames, possibly causing DR conflicts.
- Fixed an error that could occur on the Advanced Session Recording page.

- Fixed an HTML-encoded document link in discovery scanner.
- Fixed an issue an erroneous warning popup appeared saying a distributed engine is required for Active Directory when the SSC cloud instance has "Azure AD Domain" as the only domain.
- Fixed an issue on the Admin Roles page where the edit button for role permissions was mistakenly requiring "Administer Role Assignment" instead of "Administer Role Permission."
- Fixed an issue that could cause an incorrect error message to display when using the SQL report editor.
- Fixed an issue that could cause the secret picker to display with a horizontal scroll bar.
- Fixed an issue when searching in Secret Share with the "Add from External Directory" option with results of more than 2100 groups would throw an error.
- Fixed an issue where a proper validation message may not display when trying to give a duplicate name to a group.
- Fixed an issue where a secret erase request could no longer be canceled.
- Fixed an issue where banner text referenced only "engine," which was potentially confusing. It now mentions "distributed engine" explicitly.
- Fixed an issue where created hooks would not display on the secret.
- Fixed an issue where enabling RPC on a template through the API could impair the template's functionality.
- Fixed an issue where existing linked groups under the Platform Integration area on the Groups tab would not load.
- Fixed an issue where if a non-local site was used to send syslog to the syslog server any failure was queued back into the database (tbsyslogfailedmessage) and resent indefinitely. This has been resolved. Additionally, we implemented a syslog circuit-breaker system if a non-local site is used to prevent flooding the message queues with syslog messages when failure is expected.
- Fixed an issue where localization load requests would await indefinitely in some cases.
- Fixed an issue where pinned folders would not be removed when the corresponding folder was deleted.
- Fixed an issue where Platform synchronization was running too frequently in some cases.
- Fixed an issue where renaming or copying the "Oracle Account (Template Ver 2)" secret template caused password changes to fail.
- Fixed an issue where Resilient Secrets (DR) sent secret field launchers across the wire for every replication.
- Fixed an issue where selecting Generate New SSH Key on a secret would not generate a new SSH key.
- Fixed an issue where sorting the launchers list by name could display duplicates.
- Fixed an issue where the checkout screen could briefly show while a secret is loading.
- Fixed an issue where the child launcher type was not always visible on the new custom launcher page.
- Fixed an issue where the Everybody group from Platform would not match up properly with the Everybody group from Platform User sync. Corrected the display name of the Platform "Everybody" group.
- Fixed an issue where the light mode collapsed toolbar showed the dark mode logo.
- Fixed an issue where the notification bell could show when there were no notifications.

- Fixed an issue where the Preserve SSH Client Process setting did not correctly display as checked.
- Fixed an issue where the SSH custom cipher was not applied when missing a value from the section.
- Fixed an issue where the synchronized groups displayed could sometimes return all the groups from the domain.
- Fixed an issue where the web launcher would not respect the mapped URL field when multiple URL fields existed on the secret.
- Fixed an issue where unnecessary audits could be written. Fixed an issue where DR Secret Server instances were ignoring licensing updates from Cloud Manager.
- Fixed an issue where upgrade banner was always showing when auto-update was off. Now shows only if at least one engine is lower version than latest.
- Fixed an issue where users could click New Secret multiple times when also uploading files.
- Fixed and incorrect launcher edit field description.
- Fixed buttons that should be grayed out. Run RPC Now can no longer be run when RPC is disabled. Run heartbeat Now can no longer be run when heartbeat is disabled.
- Fixed dark mode IBM password tooltips and banner color-contrast issues.
- Fixed edge case bug if SSH Block Listing causes duplicate sessions that break SSH Proxy.
- Fixed error that could occur when creating a new folder with the folder panel minimized.
- Fixed inconsistent logs between source and replica on partial success. Fatal error is now persisted across the wire so the replica is aware that the source had a fatal error
- Fixed incorrect logging error in AuthenticateWithAdConsumer.
- Fixed issue in directory sync where a search result with an attribute containing an empty list could cause an error.
- Fixed issue where the upper right search bar would not always switch to the selected secret when a selected secret was on a tab other than the General tab.
- Fixed issue with a test script modal where reopening the modal would show the selected secret's ID instead of its name.
- Fixed issue with folder permission editing when updating a path directly.
- Fixed link to dependency templates on the Secret Dependency tab.
- Fixed logic error where the RAS flag was not being referenced before deciding to delete the database entry that reflected additional users.
- Fixed long secret-template names to wrap better in folder edit.
- Fixed missing option. System group in Secret Server Cloud can now have metadata deleted.
- Fixed Platform permissions cached on Secret Server to replicate so they will be respected on a replica instance.
- Fixed query for obtaining services for a directory account in discovery. Fixed check on discovery source name when creating an empty discovery source.

- Fixed secret policies not showing as deleted after deleting a secret. Secret names on the RPC tab of a secret policy will now include "Inactive" if a secret is not active.
- Fixed text alignment. Left aligned the comment text on the MFA security view. The icon and button remain centered.
- Fixed the link to the subscription page from the banner.
- Fixed the REST API token endpoint path. The documentation generator, in removing the "api" string from the beginning of all routes, was also removing embedded occurrences. It now removes it only from the start of the route strings.
- Fixed the secrets grid on the Secret Erase Request Approval page (in a modal opened via a link button) that was obscured in dark mode and nearly indistinguishable in light mode. This is now an inline grid with auto-scroll.
- Fixed visual bug when removing current user's folder owner permissions.
- Folders in "Shared with Me" Quick Access menu are now filtered when searching.
- If a user's encrypted TOTP reset Guid gets corrupted, an administrator is now able to reset their TOTP.
- Improved error handling on the OpenId Configuration page.
- Improved the UI on the Collections Management page for advanced session recording agents.
- In the prior upgrade file set for 11.6.3, fixed an issue with SQL Delta 11.5.000006. Removed a SQL hint on the SQL index that was incompatible with non-Enterprise editions prior to SQL Server 2016 SP1 due to a compatibility issue with data compression. The incompatible hint was not necessary, so the delta was updated. Hashes for upgrade were updated for this change.
- Legacy RPC admin page removed.
- Legacy user and group management aspx pages removed.
- Limited Mode now goes to the correct link in SSC.
- Made performance improvements for the "What Secret Permissions Exist?" report.
- Prevented Thycotic One sync from syncg Platform Native users. This allows Platform native users to log in the rare situation they synced with Thycotic One. Then the administrator clears the system Platform User mappings.
- Queries executed in the chart and SQL editor for custom reports will now take the Use Database Paging setting into account so that the result is the same as if the query was being saved as a report.
- Removed legacy ASPX pages for secret templates.
- Removed link for managing licenses from the Cloud Subscriptions page.
- Secret Server was updated to use the same player for session recordings as platform.
- Set the GET SDK Client Account, SDK Client Audit, and SDK Client Rule API calls to set the operator parameter to 1 if it is not supplied by the caller when a User ID filter is specified.
- Switching pinned folders now resets the text search.
- Updated auditing for users modifying allowed cipher suite algorithms.
- Updated diagnostics page and licensing expiration checks to correctly handle non-US date patterns.
- Updated event subscription and workflow grids.

- Updated password requirement audits to correctly audit missed fields.
- Updated the action-handler secret-launch dialog layout to reflect design changes.
- Updated the Cloud Subscription page to the new UI.
- Updated the Dependency Changes List page to the new UI.
- Updated the Diagnostics page to the new UI.
- Updated the display for secret locked pages to address a wrapping issue with DoubleLock.
- Updated the distributed engine log UI updated. It now remembers your last selected site, system log grid UI updated, and the last selected log level.
- Updated the EventDetails token within Event Subscriptions to correctly capture secret comments.
- Updated the logout.aspx page to avoid errors being generated in rare cases when executing the SAML SLO flow.
- Updated the ticket system list page to the new UI.
- Updated user preferences page for better accessibility.
- web.config now allows explicit definition of allowed HTTP verbs.
- Addressed an issue where discovery rules would not correctly display the selected secret template or password type.
- Adjusted discovery scanning to minimize potential SQL deadlocks during the scanning process.
- Adjusted Secret Server and distributed engine to support 3.x versions of SAP .NET Connector.
- Converted HSM to a new UI page with a new PKCS11 API type. This new option enables you to protect your MEK and secret keys with an AES 256 key, bringing the strength of all keys to AES 256. After setting up PKCS#11 with your HSM vendor, you use the vendor cryptoki library (dll), token label and user pin to integrate with Secret Server. NOTE: You will need to disable the HSM first, to switch to the new PKCS11 API type. See the Hardware Security Module for more details.
- Enable Audit Integration on the Platform Configuration page can now be turned on.
- Extended timeout for some indexing steps for customers with over one million secrets.
- Fixed an issue that caused folder permissions to not update under specific circumstances.
- Fixed an issue where long column names did not wrap in the column selector.
- Fixed an issue where searching for a secret name using a substring within a single word would not always return results.
- Fixed an issue where the Dashboard Overview tab was not selected by default.
- Fixed an issue where the main search did not return content and updated the search design.
- Fixed an issue where the New Folder button would be incorrectly hidden in certain situations when displayed from Platform.
- Fixed an issue where the system log filter preference had an error when all was selected as the last used filter.

- Fixed an issue where the folder tree disappeared when there were more than 1,000 folders accessed and UAM was enabled.
- Fixed an issue with the discovery splash image margin.
- Fixed bug where changing the client ID did not update unless the client secret was updated as well.
- Fixed display issue for Secret edit modal on Discovery scope page.
- Fixed issue with QuantumLock Assign Users grid not displaying correctly after editing then canceling.
- Fixed the folder audit download to show the correct title.
- Improved exception logging for certain scenarios related to launching.
- License requirement message for secret policies updated to Pro Edition or higher.
- Removed no-longer-used bookmarklet login pages.
- Updated API documentation for updating team membership.
- Updated the Secret Import to handle a trailing whitespace in the folder path to prevent bug where created the child folder at the root level.
- Updated the ticket system detail page to the modern UI framework.

Secret Server Cloud Release Notes for September 23, 2023

Release Date and Notes

Cloud Release - All Regions Except United States of America (U.S) September 9, 2023

Cloud Release - United States of America (U.S) September 23, 2023

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.16

Protocol Handler: 6.0.3.26

Note: Step Upgrade Required (11.5.2). Versions prior to 11.5.2 will need to first upgrade to 11.5.2. The automatic downloads in the product will get the right versions for the step upgrade and then allow the 11.6 upgrade. But if offline and using the file upload method, versions prior to 11.5.2 will get an error message saying, "Integrity Check failed - Security Catalog is signed by thumbprint that is not specifically trusted." The remedy is to first upgrade to 11.5.2 and then do the upgrade to 11.6.

Feature Enhancements

View Own Session Recordings Permission

A new permission has been added "View Own Session Recordings". With this permission, a user can be restricted to only viewing the recordings that they initiated. If the user with this permission clicks on a recording initiated and owned by another user, they will get an Access Denied window. In addition, the "View Session Recordings" permission has been renamed to "View All Session Recordings".

Session Monitoring Playback Page UI Conversion

The Session Recording playback page has been updated to the new UI, including a new video player with additional controls. The SSH keystroke-only playback page and the video playback page have been merged, and the available elements will be shown. The legacy player is still available as a link from the new video playback page.

Note: The activity graph and download button have not yet been implemented for the new page, although they are available on the legacy page if needed.

Manual Password Change for Checked Out Secrets

Secrets with Change Password on Checkin configured now have the "Change Password Now" functionality available. This will enable the standard functionality of a password change, and the secret will also complete the automatic password change on checking in. This is to allow maintenance and testing of secrets protected in this manner, and a pending password change must be completed before the check-in process is allowed to begin in order to maintain a secure order of operations.

Updated User Selection Interface

Various locations around the product provide a user selection interface to provide the ability to select a user as the target of a particular configuration, such as the permissions, groups, and roles pages. These have been updated throughout the product to provide more data about the users in the list. You may now view, filter, and search for users by their Username, Display Name, or Email.

Automated Password Change on Import

An option has been added to the Import Secret function to mark each secret's password to immediately change after import. With this option enabled, a user who has had access to view the list of secrets will no longer know the password of the secrets once they have completed the import. The option is available for CSV and XML and can be flagged via the UI and API.

Enhancements

- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: (Disaster Recovery/Resilient Secrets):Data replication will now create personal folders for replicated users in cases where the replica blocks or does not allow personal folders to be replicated. This is only if personal folders are enabled on the replica.
- Improvement: User tooltips in both Secret Server and Delinea Platform now highlight the Platform Integration Types.
- Improvement: Fixed issues with user and group syncing between Secret Server Cloud and the Delinea Platform.
- Improvement: Added a "Managed" field to the Discovery Network view to show when a discovery item is managed.
- Improvement: The Password Requirement Audit has been converted to the new UI.

- Improvement: The Secret Dependency Changers editor has been converted to the new UI.
- Improvement: Dependency Templates are now available in the new UI.
- Improvement: Session playback player UI has been updated.
- Improvement: The Launcher Audits page has been migrated to the new UI.
- Improvement: Discovery Service Accounts Detail Page now shows services that run as the directory account as well as the computers on which that service runs
- Improvement: Added a Quick Access link to see all secrets you currently have checked out.
- Improvement: Updated Createuser.aspx to redirect to the new user creation page.
- Improvement: Updated the group role assignment UI.
- Improvement: Group membership assignment UI updated.
- Improvement: Group role assignment UI updated.
- Improvement: Updated process for populating a forthcoming computer-centric view.
- Improvement: Session recording search now uses updated filter pattern.
- Improvement: The built-in "Everyone" group was renamed "All Vault Users."
- Improvement: Enhanced new Discovery Area to include some additional fields and added logic for the error chip being displayed
- Improvement: Added a Copy button for Data Source URL on Disaster Recovery - Outgoing Setup Steps modal.
- Improvement: New Vault User Details in the Platform overview for Users tab. It requires a Vault to be successfully connected and configured for the details to appear, otherwise the section does not appear.
- Improvement: Added banners to various Roles/Permissions pages in Secret Server Cloud and Platform with links to help navigate between the two.
- Improvement: Secret Share tab UI has been updated to match the permission setting experience for setting folder permissions. Domain name is now displayed for users on the secret share tab.
- Improvement: Fixed an issue where the folder permissions tab would load slowly with large numbers of users.
- Improvement: Updated group membership management pages to use new design patterns.
- Improvement: The display name of the secret Vault is now set via the Platform. The Vault subcategories for Reporting, Inbox, and administration have been updated to reflect Secret Server.
- Improvement: Analysis tab of Discovery no longer includes disabled Discovery Sources in managed/unmanaged counts.
- Improvement: Administration Configuration Launcher Settings now displays the Enable Protocol Handler Auto-Update setting in cloud.
- Improvement: View Log was hidden for Directory Accounts since there's no computer associated to show the log of.
- Improvement: Added Application from tbAuditSecret to session search results model and session model.

- Improvement: When discovery is running the network view performance would timeout depending on SQL locks. This should no longer happen.
- Improvement: Discovery scanners added an option to "Add child scanner" which filters available scanners to show only applicable child scanners.
- Improvement: Disaster Recovery Add-On Licensing handling added.
- Improvement: Secret template fields table has been updated and has an improved drag and drop experience.
- Improvement: Secret panel is more mobile friendly.
- Improvement: Syslog/CEF logging enhanced to capture more detailed metadata for secrets that contain fields/data that map to the following SIEM fields: Account Name, Account Domain, Target Server, Request ID (that is from Ticketing System). Additionally, failed attempts to access secrets due to Ticket Validation errors are now also logged to Secret Audits.
- Improvement: New inbox notification bell with panel, allows for viewing and approving inbox items without having to navigate through the site.
- Improvement: The Security Audit Log page has been converted to the latest UI.
- Improvement: A donut chart showing different Operating Systems in discovery has been added to the Analysis tab of discovery.
- Improvement: Live viewing has been added to the new session monitoring.
- Improvement: The new UI Discovery Rules page now shows the correct Secret Template name.
- Improvement: Secret policy now links to the policy on the secret general tab.
- Improvement: A loading indicator now shows when opening the discovery add scanner dialog.
- Improvement: The main top left logo will link to the users preferred login home if it is the dashboard or all secrets.
- Improvement: The COM+ scanner will be able to be added, but there will be a note in the preview panel letting the user know that the scanner will not work for a site that is set to UseWebsite.
- Improvement: A preview chip has been added to Multifactor Authentication on Secrets and its supporting configuration pages.
- Improvement: A new field "Full Name" has been added to the discovery network view to give a more detailed version of the item's name.
- Improvement: Default columns have been added per Item Type in the discovery network view.
- Improvement: Dependency Tokens are now available on the dependency edit screen.
- Improvement: Enhanced loading times of Secret Server elements in Delinea Platform.
- Improvement: REST API documentation has links to individual services that load quickly.
- Improvement: Added filter on recorded-sessions endpoint to filter out applications, particularly 'RemoteAccessService' when in platform
- Improvement: Implemented a message shim in the Vault Broker to inform Secret Server that a user's platform permissions have changed.

- Improvement: Updated the Vault Settings and Vault User Detail Tabs with some UI changes.
- Improvement: Converted the creation of a Password Changer when Create Password Changer is selected from the Password Changers list in Remote Password Changing.
- Improvement: Added a filter of secretIDs to the Secret Search endpoint to that Secrets can be filtered by SecretID.
- Improvement: Terminate, limit to 5 minutes, and message only have been added to live viewing in the new session monitoring
- Improvement: The heading for Vault within Platform User Management details has been updated to read its value from within Platform.
- Improvement: The text for page title, breadcrumbs, and navigation for Secret Server Reporting have been updated in Platform to match.
- Improvement: Added Search Groups column to Discovery Network View.
- Improvement: Added more instructions regarding Disaster Recovery's data storage path configuration setting.
- Improvement: Added configuration setting to determine which secret permission is required to change Remote Password Changing settings on a Secret. Owner or Edit.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Added a WMI Service Timeout setting to the cloud advanced configuration page to help with dependency changes that take more time than the allotted 60 seconds.
- Improvement: The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- Improvement: Improved performance of Secret Search for customers with large numbers of Secrets.
- Improvement: Updated data type to support frequent users of session recording that was crashing the encoding process.
- Improvement: Secrets with text field based URL lists are now searchable.
- Improvement: Platform users can login to Terminal using SSH Key Integration.
- Improvement: Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- Improvement: When Platform integration is active the integration page will now have a button to reset mappings from Delinea Platform.
- Improvement: AD Privilege Password changer now has Remote Password Change timeout minutes Advanced Setting.
- Improvement: Better handling of unexpected heartbeat behavior to mitigate reported Distributed Engine stalling.
- Improvement: Connect As Credentials on Secret works better with SSH Keys for su user switching.
- Improvement: Updated links on the Security Hardening Report to new UI pages
- Improvement: When creating a new send to syslog task you no longer get a default schedule. Most of the templates didn't create a schedule, now they're all consistent.

- Improvement: Session monitoring search now supports searching by a single secret.
- Improvement: When a Secret is assigned to a site the user does not have access to due to Teams restriction, they will see the word "Restricted" instead of "Site Name (Inactive)".
- Improvement: Mitigated issue in large bulk secret actions.
- Improvements: The "Synchronization Running" message for DR will now only appear if there is a recorded start time for DR in the past and a finish time that is in the future.
- Improvement: Added Secret Field validation on the Template level to ensure users cannot create a "Secret Name" field on a template.
- Improvement: Default values for Secret Fields such as port will now be replicated for Disaster Recovery.
- Improvement: A user with only direct access to a report and the "browse reports" role permission can add that report to the dashboard.
- Improvement: The breadcrumbs within the RPC administration pages have been standardized. The links within Platform Vault Configuration Overview no longer cause the page to reload.
- Improvement: Report column preferences will be saved and applied when viewing a report.
- Improvement: The Secrets grid now updates displayed data and selected columns simultaneously.
- Improvement: Improved error logging and efficiency for calls coming from Delinea Platform.
- Improvement: Quick access filters now both apply when updated.
- Improvement: Knowledge base links within Platform Vault now link to their intended location.
- Improvement: Corrected edge case that could result in a session view audit being placed on the incorrect Secret.
- Improvement: The Parent Scan Template will be filtered to the type and will default to the first item in the list on create. The proper fields will be shown based on the type.
- Improvement: If a secret is inactivated after initially viewing the secret, a user that cannot view inactive secrets will no longer get an error from secret heartbeat.
- Improvement: Clicking cancel when editing folder permissions will clear any active filters.
- Improvement: Editing folder permissions now has a split button that allows for directly entering edit or add group/user mode.
- Improvement: The Secrets Quick Access link when collapsed, now targets the correct destination.
- Improvement: The Platform Opt In modal styling has been adjusted to no longer display with scroll bars.
- Improvement: Secret Share and Folder Permissions: Show disabled edit button until filters are loaded since split button does not yet support disabled.
- Improvement: API calls to /v[1/2]/secrets/{id} now update the Recents secrets data source.
- Improvement: When viewing Event Pipeline Activity details, selecting an Activity Detail record from the grid now displays the selected Activity's details.
- Improvement: Added query parameter for PipelineId to pass back when viewing specific pipeline activity
- Improvement: Minimum Heartbeat interval reduced from 15 to 5 minutes.

- Improvement: Discovery Scanner will not allow deletion until Secret selection is changed.
- Improvement: Remote Password Changing: Check for DNS Mismatch now visible and functional in Cloud.
- Improvement: EventTime token is available in pipeline scripts. $EventTime - event date and time of the event ("yyyy'-'MM'-'dd'T'HH':'mm':'ss").
- Improvement: The preview chips for Multifactor on Secrets have been removed.
- Improvement: Creating a User SSH Key in Platform downloads the private key with a proper filename.
- Improvement: Cipher Suite Configuration now allows configuration of allowed Host Key Algorithms.

Bug Fixes

- Fixed an issue where Viewing Session Connector Custom Launchers without access to the RDS Credentials secret would show an error.
- Fixed an issue where unplayable session recording videos would display an infinite load instead of the appropriate error.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where Pause times for ODBC Remote Password Changers were not adhered to. If you feel your RPC's are running slowly, check the pause times and remove them if they are not needed for the RPC action.
- Fixed an issue where Web Password Filler didn't work in certain instances due to an ambiguity in interpreting the Secret Server URL.
- Fixed an issue where setting custom expiration dates in all time zones did not work correctly.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where the secret name would incorrectly display on the New Discovery Import Rules page.
- Fixed an issue with negative numbers exporting incorrectly when exporting to a CSV file.
- Fixed an issue where a large number of SSH terminal connection history records causing timeouts.
- Fixed an issue with hidden days until deletion field when enabling deletion in the retention schedule. Added localization to error when trying to submit days less than or equal to the archive retention value.
- Fixed an issue with passwords being uneditable if RPC is set to use a Privileged Secret to which the user has no access to. Restored explanatory banner.
- Fixed an issue where secrets aren't synced with DevOps in cloud with when triggered by pipelines.
- Fixed issue in discovery where computer scans were sometimes throwing string truncation exceptions.
- Fixed an issue where TOTP Secret Settings edit button was available to users who could not edit the settings.
- Fix an issue with editing Session Connector Custom Launcher Port.
- Fixed a UI issue with the launcher popup window showing an option the user didn't have permission for.
- Fixed an issue where configuring a new session connector launcher might not show all available launcher types.
- Fixed an issue where configuring "Use Additional Prompt" on launchers might prevent save.
- Fixed an issue with the TemplateCreateSecret role link.

- Fixed an issue with View Launcher Password.
- Fixed an issue where users with only 'View' access on a Secret would be unable to view the Password if there was a custom launcher with arguments configured for that Secret Template.
- Fixed an issue with DSV sync for secret with file type fields and no file set.
- Fixed an issue with localization on folder Metadata page.
- Fixed an issue with sorting for Checkout User Id and Checkout User.
- Fixed an issue with ODBC password changing that broke postgres and mySQL changing.
- Fixed a logging issue with Dependency changes ran through Distributed Engine being skipped due to conditions.
- Fixed an issue where the generate SSH key returns a 500 exception.
- Fixed an issue where the SSHCipherSuiteModel GetAsync returned a 500 exception.
- Fixed an issue where the CreatePublicSSHKey returned a 500 Exception.
- Fixed an issue where Discovery Scanners could not be removed until the associated secrets had been edited.

Secret Server Archive

This section contains release notes for unsupported versions of Secret Server On-Premises and older versions of Secret Server Cloud.

For changes pushed to cloud between major releases, see the Secret Server Change Log.

On-Premises Archived

This section contains unsupported versions of Secret Server On-Premises.

Secret Server: 11.3.000003 Release Notes

11.3.000004 is a retroactive patch for this release. Please see "Secret Server 11.7.000001 Release Notes" on page 1692 for details.

Important security release—we recommend all affected Secret Server on-premise customers upgrade as soon as possible.

Release Date: February 8, 2023

An unauthorized access vulnerability was found in Secret Server. This issue is rated **High** with an 8.5 Common Vulnerability Scoring System (CVSS) score. Please see the CVSS Calculator for details.

> 11.3.000003 is a security update only.

> This vulnerability has been patched in Secret Server Cloud, so there is no additional update to address it.

Secret Server: 11.3.000002 Release Notes

Release Dates and Notes

On-Premises: November 15, 2022

Cloud: November 11, 2022

Component Versions

Distributed Engine: 8.3.1.0

Protocol Handler: 6.0.3.23

New Features

None

Enhancements

Discovery

- Improved discovery dependency matching performance.

Secrets, Policies, and Templates

- Added a secret policy setting to control "Change Password Upon Check-In" behavior. Previously, this was enabled if "Require Check Out" was enabled.
- Optimized Performance of /api/v2/secrets endpoint when searching by secret name.

Session Recording and Monitoring

- Added a terminate option to the session playback page

Bugs

Access Requests, Checkout, Secret Workflows, and Doublelocks

- Check in now works as expected if settings "Check In Secret on Launcher Close" and "Close Launcher on Check In Secret" are both false.

Alerts, Auditing, and Logs

- Fixed an error in SAML audits.

Authentication, Login, and Directory Services

- Fixed an issue where deleted Active Directory groups would not be reflected as disabled during Active Directory synchronization. This now correctly registers as a disabled group and is disabled in Secret Server if configuration is set to mirror the AD status.
- Fix an issue with RADIUS challenges in Secret Server Cloud.
- Fixed an issue where installation on specific dates on servers with a dd/mm/YYYY localization configuration would prevent reading some configuration settings.

Encryption, Passwords, and Certificates

- Fixed an issue where longer passwords with spatial pattern complexity rules enabled would fail to generate. Spatial patterns are now compared at a length of four characters if the password is above 50 characters.

General

- Fixed an issue where the Secret Server website would not load if the internal site connector is unavailable at startup.

Remote Password Changing

- Added the User parameter to the IBM iSeries Mainframe Connection for launching, password changing and heartbeat functionality.
- Fixed an issue where PowerShell-based dependency changers would not correctly pass arguments.
- Fixed an issue where removing an RPC schedule from a secret policy does not update a secret assigned to the policy.
- Fixed an issue where the IBM iSeries password changer was not properly adding the model value to the connection string.

Secrets, Policies, and Templates

- Fixed an error when converting a secret in a folder with a launcher settings policy.
- Fixed an issue where the test buttons would not function for the Oracle Account Ver. 2 password changer.
- Fixed an issue where "Days Until Expiration" value on the secrets grid would show a large negative number if

expiration is forced. This now displays "Expiration forced."

- Fixed an issue where sorting by folder path in the secret grid view would return an error.

Session Recording and Monitoring

- Fixed an issue where the advanced session recording agent would attempt to make many reconnections in a short time span.
- Fixed an issue where monitoring and termination of live sessions was not appearing in the New UI. This now takes users to the regular session playback page, which displays the live session.
- Fixed an issue where file contents during SFTP/SCP file transfers were not included in session keystroke recordings.
- Fixed an issue where the new UI session monitoring search required additional permissions to load.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.3.000001 Release Notes (GA)

Release Dates and Notes

Early Access: October 4, 2022 (On-Premises)

General Availability: October 25, 2022 (On-Premises)

Note: The following release notes apply to both EA (11.3.000000) and GA (11.3.000001). The bug fixes that only apply to GA are prefaced with *GA only*.

Note: The protocol handler version for this release is RDPWin_6_0_3_23.

New Features

Additional Custom Logo Variations

You can now upload more custom interface logos. This includes an optional larger logo for the login page. Each logo includes alternative images for light and dark modes. This results in six logo variations.

The settings are available in the configuration preview. Enable the configuration preview and then locate the new settings in the **Administration > Configuration > General > User Interface** area.

Advanced Session Recording Agent

The advanced session recording agent (ASRA) MSI is now self-contained and based on .NET Core, which does not need a .NET SDK installed; however, installing an ASRA from the advanced session recording page using the installer still requires that the .NET Framework redistributable components are installed.

To install or deploy the agent without the framework, follow the customization steps here: "Installing the Advanced Session-Recording Agent" on page 1271 .

Configurable Global Banner

You can now configure a multipurpose global banner for all users. You can use it for maintenance, security, or policy notifications. You can set the severity level, text, a hyperlink, and an in-theme color, which is determined by the severity.

The settings are available in the configuration preview. Enable the configuration preview and then locate the new settings in the **Administration > Configuration > General > User Interface** area.

Classic User Interface

We enhanced the new UI experience, and all new features only appear in that UI. The classic UI is deprecated and no longer maintained. For this release, the classic UI is disabled by default but temporarily still available. You can enable it at **Administration > Configuration > General > User Interface settings.** As of the next minor release, the classic UI will be permanently removed.

Disaster Recovery Synchronization Improvements

We improved the disaster recovery (DR) feature to synchronize additional items, including:

- Local and domain users
- Groups
- File attachments
- Secret and folder permissions

This enables replication of the permissions structure to the replica server, providing a readily available standby with permissions in place.

Event Pipeline Enhancements to Sending Emails

Users can now select an inbox email template in the event-pipeline send-email tasks. This gives the user access to event-pipeline and inbox tokens within the predefined email template.

Once the event pipeline is triggered, it sends an inbox notification and processes any inbox rules. The inbox rules send an email to the task recipients.

Protocol Handler Process Tracking

We renamed launcher settings from "Record Multiple Windows" and "Record Additional Processes" to "Track Multiple Windows" and "Track Additional Processes." These are now both used for process tracking, regardless of whether recording is enabled. This improves session termination, either triggered or automatic, applying to child and specified processes, per the launcher settings.

Refreshed Administration Page

We updated the administration page with a new categorized view where users can pin commonly used items to a list. To pin an item on the new administration page, hover over or focus it, revealing a pin icon. Click the icon to add the item for quick access.

Session Monitoring Page

We converted the session monitoring search page to the new UI. The functionality remains essentially the same; however, we removed role restrictions on filters. We also optimized both the front- and back-ends.

SFTP Tunneling

Added an SFTP tunnel setting to the SSH proxied process launcher for use with SFTP client custom launchers. This was tested with FileZilla and WinSCP.

SSH Cipher Suite Configuration

We added a configuration page that sets the Secret Server SSH ciphers used when making SSH connections for various tasks, such as heartbeat, password changing and discovery. This does not apply to SSH password changers using the "Legacy" runner type. This is at **Administration > SSH Cipher Suite Configuration**.

With this feature, users can set availability and application order for key exchange, MAC, and encryption algorithms via an easy-to-use list. To use the list, go to the configuration page for the site, and enable the SSH cipher suite setting.

Enhancements

Alerts, Auditing, and Logs

- Better error logging during disaster recovery.
- Added a "Session Recording Downloaded" audit event.
- Updated email templates with new brand headers.
- Added a saved history for TOTP fields on secrets.
- Converted the user audit report page to the new UI.
- Added support for Unicode characters in email addresses.

Authentication, Login, and Directory Services

- Renamed the "What computers in Active Directory no longer exist?" report to "What Computer Accounts found by Discovery are not managed?" to reflect the results more accurately.

Backup, DR, and HA

- Added file attachment fields to disaster recovery sync.
- GA only: Improved replication by adding extended data mappings.

Dashboard and UI

- Searches now work correctly for usernames with non-alphanumeric characters such as % _ and [].
- Updated Inbox page to allow for low screen resolution or high zoom settings.

Encryption, Passwords, and Certificates

- Generated SSH private keys are now saved with AES128 encryption instead of DES.

General

- Updated several third-party libraries to remediate vulnerabilities.
- Added DPAPI and SAML pages to the configuration preview.
- Office 365 Template and Password Changer have been renamed to Azure AD Account and Azure AD respectively.

Heartbeats

- Office365 heartbeats now detects if you provide the domain in the username.

Launchers and Protocol Handlers

- We now include the required Visual C++ runtime with the protocol handler.
- Updated the PuTTY version distributed with the protocol handler from v0.74 to v0.77.
- Launcher mappings and restrictions are only validated when they have changed.

Localization

- Increased localization performance in Cloud by caching additional language files.

Remote Access and Proxies

- Added a "use SFTP tunnel setting" to the SSH proxied process launcher to support using SFTP client custom launchers. This was tested with FileZilla and WinSCP.

Reports

- Added "new report " and "add category " action buttons to the reports page.
- Moved reports audit to a tab for consistency, replacing the existing button.

Secrets, Policies, and Templates

- Added more tooltips to the secret template page.
- Added a new public endpoint for secret template conversion.
- Increased an individual secret list field to 500 characters.
- Secret erase now completes without errors when the secret has an associated list.

Session Recording

- Adjusted SSH keystroke recordings to not display VTY special commands to clean up the output and to show control commands used in the client output.
- Converted the advanced session recording agent to .NET Core.

- Advanced session recording agent will now only register if the latest agent is installed (or any future versions). This supports a change in the registration process.

Teams

- Added "include all users from domain" setting to the team configuration, which directly maps the users synchronized from a domain to that team.

Users, Groups, Roles, and Permissions

- Viewing the password requirement page now requires the "view password requirements " permission.

Web Password Filler

- Added a Safari link for Web Password Filler to the launcher tools page.

Bugs

Access Requests, Checkout, Secret Workflows, and Doublelocks

- Fixed an issue where no notification appeared if a secret view interval expires while the user was viewing the secret.
- Fixed the secret session extension to also extend launcher sessions and not just checkout sessions.
- Fixed an issue where adding a workflow to a secret could not be saved.
- Fixed an issue where users could not check out a secret when the internal site connector was unavailable, even if they did not have checkout hooks or pipelines actions that rely on the site connector.
- Fixed an issue where workflow items in secret policies would not save.

Alerts, Auditing, and Logs

- Fixed an issue where the secret-template password-type field-mapping audits were not recording the correct fields
- Fixed an issue where viewing a secret list would record that the password was displayed in the audit log.
- Fixed an issue where removing a user from a group did not show up in the event log.
- Fixed issue where "expire secrets on user audit report" was deactivating secrets.

API and Scripting

- Fixed an issue where secretPath in the API would not work with secrets having a single forward or back slash in their name.
- Fixed an issue where the diagnostics API showed an incorrect value for the upgradeAvailable property. We also added the latestVersion property.
- Fixed issue with secret search v1 API throwing a 400 error.
- Fixed issue where the secret policy SOAP API would throw an error when using the professional license.

Authentication, Login, and Directory Services

- Fixed an issue where SSH terminal authentication with RADIUS two-factor authentication would incorrectly audit login failure.
- Fixed an issue where SSH terminal authentication would not correctly process RADIUS logins.
- Fixed an issue where changing the distinguished name field on directory services displayed inaccurately in audit logs.

Background Services

- Fixed an issue where running a change-password bulk operation required an SSH key on secrets set up for both key and password changes.
- Fixed an issue where bulk operations would fail if too many target secrets were specified.
- Fixed an issue where a bulk change-password operation threw an "empty private key" error.
- Fixed an issue where the "set privileged account" bulk operation would display an error when attempting to set the "credentials on secret " option.
- Fixed an issue where applying a bulk operation checkout would also enable "change password on check In."

Backup, DR, and HA

- GA only: Fixed an issue where pre-existing non-replicated folder ACLs were deleted on replication.
- GA only: Fixed an issue where during DR ProtoObjectCollectionServiceBase.SaveDtos (secret launcher) threw a fatal error when too many characters were inserted.
- GA only: Fixed an issue where PasswordRequirementConsumer threw errors during replication when bringing in large numbers of secrets.

Bulk Operations

- Fixed an issue where running a change-password bulk operation required an SSH key on secrets set up for both key and password changes.
- Fixed an issue where bulk operations would fail if too many target secrets were specified.
- Fixed an issue where a bulk change-password operation threw an "empty private key" error.
- Fixed an issue where the "set privileged account" bulk operation would display an error when attempting to set the "credentials on secret " option.
- Fixed an issue where applying a bulk operation checkout would also enable "change password on check In."

Cloud

- Fixed an issue where cloud pages were returned in a previously cached language.

Dashboard and UI

- Fixed an issue where changing the address bar from one secret ID to another would not update the display of the associated secrets list.
- Fixed an issue where the "Restrict SSH Commands Edit" link was not showing.
- Fixed an issue where the password on a secret was not displayed when "Edit Requires Owner" was set on the field and the user had edit permissions.
- Fixed an issue where the script editor on various pages would act as a keyboard trap, and there was no way to change focus without a mouse. Enabled an escape combination and detailed it alongside the editor.
- Fixed an issue where the script editor on various pages would represent a tab with a single space. Changed to 4 spaces.
- Fixed an issue where text formatting was not displaying on the in-line secret preview in the secret grid.
- Fixed an issue where breadcrumbs were not displaying on several pages.
- Fixed an issue where custom Logos would not display correctly.
- Fixed an issue where a long secret field name would overflow the label area and obscure the value in the secret preview panel.
- Fixed an issue where page layout would change the location of buttons on the password changer configuration page.
- Fixed an issue where setting the UI inactivity timeout value to 0 caused an exception. This value now disables UI inactivity as expected.
- Fixed an issue where the secret list view would not scroll to the bottom of the list.
- Fixed an issue where secrets view would not remember the last setting between grid or list options.

Discovery

- Fixed an issue where you could not set a discovery source to inactive if the sync secret was no longer valid.
- Fixed an issue where discovery rules would not function correctly when organization units had brackets in their names.
- Fixed an issue where secret search filters were not saved to a discovery scanner when searching "All Folders."

Distributed Engines and Site Connectors

- Fixed an issue where a site connector could not be disabled if it was assigned to the local site when it is configured for website processing.

Encryption, Passwords, and Certificates

- GA only: Fixed an MEK rotation error when rotating deleted session recordings.
- Fixed an issue that could cause an index error during master key rotation.
- Fixed an issue where a password rules validation message did not appear when exceeding the maximum

allowed characters for a ruleset.

- Fixed an issue where some validator options were not visible when creating a new password requirement.

Event Subscriptions and Pipelines

- Fixed issue where users could not click pipeline buttons when in Unlimited Vault Access mode.
- Fixed an issue where the "Move to Folder" event pipeline task would throw an error when editing.
- Fixed an issue where event subscriptions could only target secrets with view permission or higher. Secrets with list view are now selectable.

Folders

- Fixed issue that allowed sharing personal folders when using "Username and Domain" as the display name.
- Fixed an issue where a new pinned folder view would default to all secrets instead of the expected default active secrets.
- Fixed an issue where folders would unintentionally display in reverse alphabetical order in the secrets list.
- Fixed an issue where expanding the details of a folder would sometimes display the details for a secret in the secrets grid view.
- Fixed an issue where the folder picker would not display when selecting from a list of collapsed folders in secret list view. When there are many subfolders, they collapse into a single item showing the number of subfolders. Clicking this opens a folder picker to choose the desired folder.
- Fixed an issue where the last viewed secret folder was not retained when the user preference was set to remember it.
- Fixed an issue where secret policy inheritance would not propagate down the folder structure when importing folders.
- Fixed an issue where moving a child folder to a location with a subfolder of the same name would throw an error.

General

- Fixed an issue where Secret Server On-Premises unsuccessfully attempted to connect to our cloud monitoring platform.
- Fixed an issue where dependency scan messages would not expire when not consumed, causing a large queue to form.

Heartbeats

- Fixed an issue where heartbeats intermittently failed when run while storing account details for multiple Office 365 tenants.
- Fixed an issue where heartbeat could be queued while a remote password change operation was still in progress. This would cause the heartbeat to fail.
- Fixed an issue where Oracle usernames with the hyphen character would fail to heartbeat. This now wraps the username in quotes, as is required by Oracle.

Import and Export

- Fixed an issue where automatic export would not run every day as configured.
- Fixed an issue where secret export did not trigger the appropriate event subscriptions or pipelines.
- Fixed an issue where extended fields in the secrets view grid would not be present in the export.

Launchers and Protocol Handlers

- Fixed an issue where the protocol handler for session connector download would fail.

Licensing and Activation

- GA only: Fixed an error during license activation.

Localization

- Fixed an issue with slow page loading when the browser language was set to a language that is not an available localization option.
- Fixed an issue with localization not applying to some labels on inbox notifications.

Remote Access and Proxies

- GA only: Fixed an issue with SSH proxy where WinSCP in SCP mode with block lists did not connect as expected. In addition, the session recording log no longer records file content.
- Fixed an issue where system tray notifications would not show in session connector sessions.
- Fixed an issue where duplicate jumpbox route options were sometimes shown.

Remote Password Changing

- Fixed an issue where custom PowerShell password changers would not evaluate the $CURRENTPASSWORD token.
- Fixed an issue where changing the remote password changing schedule by policy would not happen until after the next previously configured schedule attempt. This now immediately takes effect.
- Fixed an issue where monthly remote password changing schedules could not be saved.
- Fixed an issue where remote password changing schedules would display time in an incorrect time zone.

Reports

- Fixed an issue where built-in remote password changing reports were excluding items without configured expiry fields. Added a new field to the secret table to track the last password change and updated the reports.
- IBM Only: Fixed an issue where the report editor was not usable.
- Fixed an issue where report results could not be downloaded from the view report page.

Secrets, Policies, and Templates

- GA only: Fixed an error where rendering secret list pages threw a SQL error.
- GA only: Fixed an error where a user could create a secret using a secret template the user does not have access to.
- GA only: Fixed an issue where the secrets reporting card description was missing.
- Fixed an issue so only secret owners can see the test option for a dependency.
- Fixed an issue where service dependency changers failed because Windows used a different naming format from the secret. We added more-robust handling for several cases.
- Fixed an issue where an imported dependency would persist even if the machine no longer existed.
- Fixed an issue where a user could change the active state of a secret template when not authorized to do so.
- Fixed an issue where you could save a secret with no owner set.
- Fixed an issue where setting permissions on a secret would result in an error.
- Fixed an issue where converting a secret to a template would remove metadata.
- Fixed an issue where an error occurred when changing the autochange schedule on a policy from default to enforced.

Session Recording and Monitoring

- GA only: Fixed an issue where session monitoring did not save a column preference.
- Fixed an issue with the advanced session recording agent installer generation.
- Fixed an issue where large numbers of recorded keystrokes would affect performance in the secret audit page.

Ticketing System

- Added better logging and error handling for ticket system integrations.

Users, Groups, Roles, and Permissions

- Notification: System roles are no longer editable. If you need to enable a system role, please contact Delinea Support.
- Fixed an issue where the inactive message would show when a user had view only permission on a secret.
- Fixed an issue where users could not access the secret settings page without the "view advanced secret settings" role permission.
- Fixed an issue where users could not define a domain when creating a user.
- Fixed an issue where only 30 of the user management IP restrictions would load.
- Updated secret share to not show users without permission on the secret.

Web Password Filler

- Fixed an issue where forward slashes were removed from Web Password Filler URLs. This broke redirect URLs.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.3.000000 Release Notes (EA)

Important: EA release notes are combined with the "Secret Server: 11.3.000001 Release Notes (GA)" on page 1821.

Release Dates and Notes

Early Access:

October 4, 2022 (On-Premises)

General Availability:

October 22, 2022

Note: Technically, the release number for 11.3 EA is 11.2.000050. GA will have the correct numbering.

Secret Server: 11.2.000003 Release Notes

11.2.000004 is a retroactive patch for this release. Please see "Secret Server 11.7.000001 Release Notes" on page 1692 for details.

Important security release—we recommend all affected Secret Server on-premise customers upgrade as soon as possible.

Release Date: October 4, 2022

A SQL Injection vulnerability was found in the Secret Server REST API. This issue is rated **High** with a 8.8 Common Vulnerability Scoring System (CVSS) score. Please see the CVSS Calculator for details.

11.2.000003 is a security update only.

This vulnerability has been patched in Secret Server Cloud, so there is no additional update to address it.

Secret Server: 11.2.000002 Release Notes (GA)

Release dates:

General Availability:

June 7, 2022 (On-Premises)

June 11, 2022 (Cloud)

Note: The following release notes apply to both EA (11.2.000000) and GA. The bug fixes that only apply to GA are prefaced with *(GA only)*.

Note: The known issue with the replication process of the new disaster recovery feature launched in 11.2.000002 (June 7th, 2022) has been fixed.

New Features and Enhancements

New Branding

Thycotic and Centrify are now Delinea, and we have updated the interface styling to reflect the new company branding. Both light and dark mode are updated with new colors and component styles.

Improved Secret Browsing Experience

Note: The classic UI was scheduled for removal in this release. Based on feedback, we deferred it to a later release. This section details the changes made to address the feedback on this change.

The secrets menu item in the new UI now has a collapsible folder tree panel that occupies the full height of the page. This replaces the folder tree at the bottom of the left navigation bar and delivers a significantly improved folder browsing experience.

Clicking a secret in the secret table view now opens an in-line card with details and actions. A launch button now appears when hovering over the row, where launchers are available, allowing launching without viewing secret details.

You can now pin a folder, limiting the folder tree to showing the contents of that pinned folder. With this, you can limit navigation to the folder and streamline navigation. Applying filters to the table in one pinned folder will not affect others, and the settings are remembered upon returning to that pinned folder.

We moved "favorites," "recent secrets," and "shared with me" to a widget bar, globally available in the top right in the new UI, allowing immediate access to your most important items.

New Secret Policy UI

We converted secret policy configuration to the new interface, adding a few changes. Policy settings are now grouped into tabs, grouping related settings together.

The "enforced" or "default" dropdowns are now checkboxes, improving usability.

New Administration Side Panel

A new administration menu is now available as a global side panel, allowing quick access to administration pages through a searchable list.

You can also pin pages in the list, creating a tailored quick-access list specific to a user. If the pinned item list is empty, there is a button to populate it with the default items that appeared on the previous list, which was available in the bottom-left "Admin" menu.

New Configuration Preview

A new configuration page is almost ready, and we need feedback on the new experience before making the page live. There is a new link to enable it in the top right-hand corner of the current configuration page.

Enabling the configuration preview changes the behavior of the new left administration panel, mentioned above, to include a new configuration section where the subsections are listed. Accessing any of these subsections navigates to the new configuration page, which has a dedicated search. This searches for configuration items by label, tooltip, and value content, displaying the search results and providing a link to a configuration section.

To disable the configuration preview, browse to the new configuration page, and disable the configuration preview in the top right-hand corner.

New Disaster Recovery Replication

There is now an efficient data replication method between multiple instances of Secret Server. This is typically used for replicating secret data into a backup vault for disaster recovery or business continuity. Currently, this is limited to secrets, templates, and launchers. Currently, DR replication does not include any other data, such as permissions, users, or policies, which future Secret Server versions will likely have.

Important: There is a known issue with the replication process of the new disaster recovery feature launched in 11.2.000002 (June 7th, 2022). A resolution is in progress and will be available soon. Please delay testing or implementing this feature until we release an update.

Note: DR replication is available in Secret Server Platinum.

New Oracle Password Changer

A new Oracle password changer is available with new templates pre-configured for various configurations. The new password changer does not require installing any additional components on web servers and distributed engines, unlike the existing changer, which required Oracle ODAC components.

The new changer supports Oracle AS SYS, Oracle DataSource, and Oracle TCPS connections, and the new templates are pre-configured for these.

New Marking and Obfuscating PII

There is a new option available to enable the marking or obfuscation of Personally Identifiable Information (PII) in audit exports. This allows for data exportation for review by third parties without including any PII. Marking PII prepares exports for external cleanup, and obfuscation automatically removes it during exportation.

PII includes many internal stored attributes, such as IP addresses, usernames, and email addresses. Metadata fields can be flagged on creation as potentially containing PII, which aids applying the same filtering to user-configured metadata fields.

This feature currently only applies to audit tables available in the interface.

New Password Complexity Rules

We have added two new optional features to password requirement configuration:

- Variable Rule Matching: Passwords must match a specific number of your password character sets. Previously, all defined character sets must match. Now, you can define that one or more sets must match. For example, three of four sets must match.
- Must End With: A password's final character must match a defined character set. This support compatibility with systems with similar requirements.

New Secret Checkout Expiration Notification

There is now a globally configurable checkout expiration that notifies users with a checked-out secret via their Secret Server inbox and inbox rules when a defined checkout period percentage has elapsed. For example, setting checkout expiration to 80% notifies users when 20% of the checkout interval remains.

This setting is available under "user experience" in the configuration page.

New Role-based Access Control for Reports

We have added a "Browse Reports" role that allows access to reports restricted by permissions. Permissions are configurable at the category and report levels and share a similar inheritance model to secrets and folders. You can define users or groups with "view" or "edit" permissions for each category or report.

Users with the existing "view reports" and "edit reports" roles are not restricted by the permissions set.

New Extendable Access Requests

You can now request future access to a secret you currently have access to—no need to wait for the current access to expire before asking for more time. A new access window is granted using the existing approval method. The new window's start time is automatically set to the end time of the current one.

General

- Secret exports now support using a doublelock password instead of a local password, providing a method for federated users to manage passwords.
- RDP Settings, such as accessing the clipboard, are now enforceable on secrets by policy.
- Web Password Filler now supports URL lists. You can map a list to the URL field in web launcher mappings.
- Restored support for AES-*-ctr algorithms in Secure Blackbox when running in FIPS mode. SSH heartbeat, RPC, and proxy can once again connect to machines using –ctr algorithms.
- Added new tokens for recipient time, server time, and UTC time to inbox templates.
- Syslog messages are now sent to SIEM systems in UTF-8 encoding, which supports non-ASCII characters. Users who wish to view UTF-8 characters, such as Cyrillic or Korean, in their SIEM system will need to configure their SIEM servers to receive UTF-8 messages.
- Updated the protocol handler for session connector.
- Optimized SQL queries around RPC scheduling to increase performance.
- Web launcher support for HTTP: Web launchers by default force HTTPS, regardless of the protocol scheme in the URL field. Advanced configuration now as a "Web Launcher Forces HTTPS" setting to disable this for http:// URLs.
- Optimized performance of APIs related to Web Password Filler.

- Added a "preserve client process" setting to SSH-proxied process launchers that preserves the session if the launched process closes. This allows tabbed SSH clients to operate correctly as launched sessions.

UI/UX

- Log in autocomplete is now always on. We deleted the "allow autocomplete" setting from Admin > Configuration > Login.
- SSH Terminal now displays the last heartbeat status of a secret in the output of the "cat" command.

API

- Created a more usable version of the secret policy API.
- Adjusted /api/v1/folders sort order to return deterministic results.

Bug Fixes

Access Requests, Secret Workflows, and Doublelocks

- Fixed an issue where extend checkout would fail for users with view permission.
- Fixed an issue that did not allow custom check out intervals when set to maximum values.
- Fixed an issue with the Revoke button being invisible in the approval and requests inbox. It is now visible for basic approvals but not for workflow approvals as these do not support revocation.
- Fixed an issue where doublelock access would be intermittent if requests hit different web nodes.
- Fixed an issue where a workflow could be created and activated with no approvers

API and Scripting

- Fixed an issue where an empty "items" property existed on the api/v1/lists/{categorizedListid} endpoint.
- Fixed an issue where applying a policy with "Web launcher requires Incognito mode" set during API secret creation caused creation failure.
- Fixed an issue where an empty "items" property existed on the api/v1/lists/{categorizedListid}.
- Fixed an issue where JSON values could not be used as script arguments. These are now handled correctly in PowerShell.
- Fixed a SQL timeout issue from the adjusted data retention cleanup of the SDK client table.
- Fixed an issue where duplicate metadata fields could be created via the API.
- Fixed an issue with the DomainStatus value not being correctly populated in calls to the GET /api/v1/directory-services/synchronization endpoint.
- Fixed an issue where the /api/v1/directory-services/synchronization/log endpoint would not return data. This endpoint was renamed to /logs and now returns appropriate data.

Alerts, Auditing, and Logs

- Fixed an issue where an IP address was not displaying in the user audit page in the new UI.
- Fixed an issue where incorrect messaging was logged due to an IP address change. The log no longer references user location.
- Fixed bug where a "value cannot be null." error was written to the logs when updating node records during upgrade.
- Fixed an issue with URL generation for inbox notification emails.
- Fixed an issue where an incorrect IP address could be sent to syslog.
- Fixed an issue where verbose logging in distributed engines that indicates which key it is encrypting and decrypting communications with Secret Server specified it is logging a hash of the key, not the key itself.
- Fixed an issue where operational logs for multiple processes would not clean up due to the database table being too large.
- Fixed an issue where dual controls would not insert correct audits for launch events.

Authentication, Login, and Directory Services

- Fixed an issue where privileged password changing would not work for a user defined by the user principal name. The Active Directory password change now works with both UPN and SAM account name formats.
- Fixed an issue where SAML logins would not reset login failures for account lockout policies.
- Fixed an issue where OpenLDAP directory synchronization would not accept a custom port.
- Fixed an issue where the login page would load slowly when using HSM integration.
- Fixed an issue where CAPTCHA would sometimes fail due to session persistence.
- Fixed an issue with SAML SLO failing when the identity provider failed to log out.
- Fixed an issue where an incorrect identifying IP address was sent to Duo. This now sends the client address.
- Fixed an issue where Azure AD directory synchronization failed due to an unexpected value for OnPremisesImmutableId. These values are now anticipated.
- Fixed an issue where SAML login could be attempted for users assigned to disabled domains.
- Fixed an issue where the download service-provider metadata in SAML configurations showed even though there was not any metadata to download.
- Fixed an issue where engine logs would be cleaned up in a single transaction that could time out.
- Fixed an issue where Azure AD synchronization would incorrectly map users that had their username changed.

Disaster Recovery

Note: The known issue with the replication process of the new disaster recovery feature launched in 11.2.000002 (June 7th, 2022) has been fixed.

- (GA only) Fixed an issue with disaster recovery synchronization not updating synchronized folder names.
- (GA only) Fixed an issue with disaster recovery synchronization not synchronizing secrets predating a new synchronization folder.
- (GA+ only) Fixed an issue where the CLR detected an invalid program.
- (GA+ only) Fixed an edge case issue where data may fail to replicate if edits occur while a replication is taking place.
- (GA+ only) Fixed an edge case issue where editing a secret field launcher may cause a null reference during DR replication.
- (GA+ only) Fixed an InvalidCastException that was introduced in the fix for RC13.
- (GA+ only) Fixed an issue where launcher sessions expired immediately when launched from the DR replica.

Discovery

- Fixed an issue where changing the secret on a discovery import rule would not save.
- (GA only) Fixed an issue where GCP discovery would return no results and not create the source organizational structure if errors to certain calls were received.

Encryption, Passwords, and Certificates

- Fixed an issue where credentials were not correctly supplied to "post change failure" or "post change success" commands, resulting in a failed connection instead of these commands running.

Event Subscriptions and Pipelines

- Fixed an issue where a secret metadata filter in an event pipeline would not work unless another task or filter had a $ token.
- Fixed the language resource for event pipeline policies.
- Fixed an issue where group name was not present when an event subscription was created for "User - Removed from group."
- Fixed an issue where subscribers could not be removed from an event subscription notification rule.
- (GA only) Fixed an issue with event pipelines not running with certain date formats.

Folders

- Optimized folder tree loading when over 1000 folders are displayed.
- Fixed an issue where "delete folder" was not available in the row options menu for folder items.
- (GA only) Fixed an issue where folder edit view would not update when editing one folder following another.

General

- Fixed an issue with custom dictionaries attached to password requirements not updating correctly.
- Fixed an issue where a problem with a single site caused messages to stop processing for multiple sites.
- Fixed an issue where the session connector would not install on non-English language systems.

- Fixed a CVE-2018-1185 vulnerability in the log4net package, which was updated to 2.0.14.
- Updated the time zone database library with the latest information.
- Fixed the Connection Manager download Links for IBM tenants.
- Fixed an issue where large emails would fail to send due to RabbitMQ maximum message size.
- Fixed an issue where user personally identifiable information PII removal would not erase the UserPrincipalName from the database.
- Fixed an issue where license expiration comparison was not considering local date formatting and displaying an activation error when parsing dates.
- Fixed an issue that caused large domain-synchronization messages to not send, creating partial result sets for directory synchronization.
- Fixed an issue where email would not send from a web node with the background worker disabled.
- Custom dictionaries now support two-character entries.
- Fixed an issue where all IP address restrictions would not display more than 30 entries.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue with high command throughput against SAP systems causing issues with logging those commands. We throttled the SAP password changers send-commands rate, which is configurable at Admin > Remote Password Changing > Configure Password Changing > SAP Account (or SAP SNC Account) > Advanced Settings. This delay defaults to 500 ms.
- Optimized the distributed engine administration page.
- Fixed an issue where distributed engines would fail to connect to the Azure service bus after updating.
- Fixed an issue where disabling RPC globally would also disable heartbeat globally for distributed engine sites.
- Fixed an issue where the distributed engine setup assistant page would show, even after a site connector had been created.
- Fixed an issue where successful password changes with failed dependencies would show as canceled.
- Fixed an issue where automatic user management may not be processed on an engine site.
- Fixed an issue where heartbeat would fail if a valid client certificate existed for the LDAP connection used to heartbeat. Heartbeat now attempts Kerberos first.

Installation, Upgrade, and Uninstall

None

Integration

- Fixed an issue where a CredSSP generic error returned when a ticketing system integration script failed. This now returns the specific error.
- Fixed an issue where using HSM integration without having performed a master encryption key rotation would cause performance issues.
- Resolved an issue where Connection Manager would not correctly present fields requiring a user prompt.

- Fixed an issue with misleading settings for ticket system configuration. It now always prompts for a site.
- Fixed an issue where "RADIUS default username" could not be set on existing users when enabling RADIUS.

Launchers and Protocol Handlers

- Fixed an issue where mapping a launcher port field failed with the error "this field must be a number."
- Fixed an issue where launcher restrictions were not letting users limit user input in some scenarios.
- Fixed an issue where using "run process as secret credentials" launcher option and enabling session recording could result in launcher startup failure due to an access denied error.
- Fixed an issue where session connector RDP launchers would fail if there was no domain on the secret.
- Fixed an issue that caused proxied launchers to not display the port field if the launcher was modified after creation.
- Fixed an issue where protocol handler would downgrade if a newer version than the version available from the server is used.
- Fixed an issue where the 64-bit installer of protocol handler would include a 32-bit executable. This could start a race condition, causing launchers to close.
- Fixed an issue where the session-connector protocol handler could update to the normal client version, disabling some session recording features.
- (GA only) Fixed an issue where some configurations of "hide launcher password" and "field view permissions" would evaluate incorrectly.

Networking

- Fixed an issue where checking for WinRM service status required administrative privileges.

Remote Access and Proxies

- Fixed an issue where SSH terminal froze when launching secrets with failing heartbeats.
- Fixed an issue where RDP proxy endpoints would respond as available even with an invalid configuration, causing proxy connection failures. Endpoints no longer respond as available if the configuration is invalid.
- Fixed an issue where SSH and RDP proxy connections failed due to Unicode characters in connection credentials.
- Fixed an issue where the jumpbox route connection forwarding could not forward across different network segments.
- Fixed an issue with SSH proxy performance related to the "hide passwords from SSH keystroke capture" setting.
- Fixed an issue where master encryption key rotation would fail if RDP proxy credentials were created but not used.
- Fixed an issue where the "hide Password from SSH keystroke capture" setting was always enabled.
- Fixed an issue where using GUI applications in an SSH session would not work with restricted command lists enabled.

- Fixed an issue where pressing the down arrow key in an SSH proxy session could crash the SSH proxy.
- Fixed an issue where SSH key authentication to SSH terminal would display incorrect prompts.
- Fixed an issue where the jumpbox route port range setting was not used correctly by engine proxies.
- (GA only) Fixed an issue where SSH key rotation would fail on the first attempt.

Reports

- Fixed an issue where the report "What folder permissions exist?" would not run on newer SQL Server versions.
- Fixed an issue with reports failing with a "not valid for reporting" error with older versions of SQL Server.
- Fixed issue causing the "reports" option to be incorrectly hidden.
- Fixed an issue with reports failing to send to email when no start date is defined but the stacked-column chart type is used.
- Fixed an issue where the "secrets with failed password change" report would show an incorrect value for DateRecorded.
- (GA only) Fixed an issue where reports could not be selected in the left navigation on some pages.

Secret Server Cloud

- Fixed a Secret Server Cloud issue where engines were incorrectly set to enable FIPS compliance, causing SSH cipher issues.

Secrets, Policies, and Templates

- Fixed an issue where secret erase would not run on a secret that had a previously changed password.
- Fixed an issue where user could not add a list field if the other non-list secret fields were not correctly configured.
- Fixed an issue where editing a secret template launcher mapping would remove the port. To restore the port to affected launchers, edit the mapping and re-save it.
- Fixed an issue where password fields would display as empty on the duplicate secret dialog box.
- Adjusted timeout behavior with bulk operations to provide more accurate statuses.
- Fixed an issue with exporting secret templates failing under some conditions.
- Fixed an issue where long URLs would affect page layout in the secret details view.

Session Recording

- Fixed an issue with advanced session recording agent installs always showing as a new entry. The entry now persists between upgrades.

Users and Groups

- Fixed an issue where column headings would disappear on the group membership assignment page.

UX/UI

None

Web Password Filler

- Fixed an issue where web password filler would default to the username field, regardless of the field mapping template settings.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server: 11.2.000000 Release Notes (EA)

Release dates:

Early Availability May 5, 2022 (On-Premises)

Please see the "Secret Server: 11.2.000002 Release Notes (GA)" on page 1831 for EA too. On that page, any bug fixes that only apply to GA are marked as such.

Secret Server: 11.1.000012 Release Notes

Release date:

May 13, 2022 (On-Premises)

Important: We recommend all affected Secret Server on-premise customers upgrade immediately to version 11.1.000012.

The 11.1.000012 update resolves a **security vulnerability** that was discovered internally. The Common Vulnerability Scoring System (CVSS) rates the issue high (7.6). It impacts Secret Server On-Premises up to 11.1.000011.

This vulnerability has been patched in Secret Server Cloud, so there is no additional update to address it.

This vulnerability is patched in the version 11.2.000000 Early Adopter release.

Note: This release also includes some high priority bug fixes that have been through our full QA process.

Bugs

- Added a DataDeliveryTolerance application setting for distributed engines for troubleshooting proxy keystroke-recording issues.
- Fixed an issue where column headings would disappear on the group membership assignment page.
- Fixed an issue with reports failing with a "not valid for reporting" error with older versions of SQL Server.
- Fixed an issue where master encryption key rotation would fail if RDP proxy credentials were created but not used.
- Fixed an issue where "hide password from SSH keystroke capture" was always enabled.

- Fixed an issue where the login page would load slowly when using HSM integration.
- Fixed an issue where extend checkout would fail for users with view permission.
- .Fixed an issue where mapping a launcher port field would fail with the error "This field must be a number."
- Fixed a bug where updating node records during an upgrade upon application start or restart would log a "value cannot be null" error logs.
- Fixed an issue where launcher restrictions were not letting users restrict user input in some scenarios.
- Fixed an issue with SSH proxy performance related to the "hide Passwords from SSH keystroke capture" setting.
- Fixed an issue where the jumpbox route connection forwarding could not forward across different network segments.
- Fixed an issue that caused proxied launchers to stop working if modified after creation. A port field in the template was not visible in UI.
- Fixed an issue where attempting to cancel a character set validation rule and then saving resulted in an error.
- Fixed an issue where attempting to save a secret after the require comment timeout had expired would cause the interface to hang.
- Fixed an issue where the port would be removed from a secret template launcher mapping when edited. To restore the port to affected launchers, users had to edit the mapping and re-save it.
- Fixed an issue where applying a policy with the "web Launcher requires Incognito mode" setting during secret creation using the API would cause the creation to fail.
- Made changes to stop SSH terminal from freezing when a secret heartbeat is failing.
- Fixed an issue where an empty "items" property existed on api/v1/lists/{categorizedListid}.
- Fixed an issue where a CredSSP generic error would be returned when a ticketing system integration script failed. This now returns a more specific error.
- Fixed an issue where an incorrect identifying IP address was sent to Duo. This now sends the client address.
- Fixed an issue a single malfunctioning site would cause messages to stop processing for multiple sites.
- Fixed an issue where using HSM integration without having performed a master encryption key rotation would cause slow responsiveness.
- To address performance issues, we reduced the number of folders displayed in a folder tree when there are more than 1000 items.
- Updated the time zone database library with the latest time zone information.
- Optimized the distributed engine administration page.

Secret Server: 11.1.000007 Release Notes

> 11.1.000008 is a retroactive patch for this release. Please see "Secret Server 11.7.000001 Release Notes" on page 1692 for details.

Release dates:

January 25, 2022 (On-Premises)

January 15 2022 (Cloud) (unchanged from 11.1.000006)

Important: The 11.1.000007 update resolves a security vulnerability that was discovered during third-party penetration testing. The Common Vulnerability Scoring System (CVSS) rates the issue high (7.4). It impacts Secret Server On-Premises up to 11.1.000006. We recommend all affected Secret Server on-premise customers upgrade immediately to version 11.1.000007. This vulnerability does not apply to Secret Server Cloud, so there is not an update to address it.

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

New Features and Enhancements

Master Encryption Key Rotation

Secret Server can now generate new master encryption keys via a rotation process. Previously, the master encryption key was generated at installation and rotation was not possible.

This feature is at Admin > Configuration on the Security tab in the Master Encryption Key Rotation section.

Note: Secret encryption uses a different key, and the independent secret key rotation is still available.

SSH Jumpbox Route Support

SSH jumpbox routes allow SSH terminal and proxy to connect through one or more jumpbox servers in line to a final connection when launching from that target server's secret. An *SSH jumpbox*, a type of *bastion host*, is a regular Linux server, accessible from the Internet, that is a gateway to other Linux machines on a private network using the SSH protocol.

Note: *Bastion* means *a projecting part of a fortification*. Bastion hosts are hardened and monitored servers that reside outside of an organization's security zone, usually exposed to the internet. SSH jumpboxes are also called *bastion hosts*, *jump hosts*, *jump boxes*, or *jump servers*. All jumpboxes are bastion hosts, but all bastion hosts are not necessarily jumpboxes.

RDP Clipboard and Drive Mapping

Gives the owner of a secret control of the RDP clipboard and drive mapping settings, restricting users from using their alternative settings. This provides administrators enforcement control over secrets and users' RDP launcher settings.

Checkout Time Indicator

There is now an indicator within secret details that shows the remaining time on a checkout and can extend the checkout if required. The indicator is color coded and counts down in days, hours, or minutes.

Click the timer for an option to extend the checkout if this is enabled. The setting to enable checkout extension is at Admin > Configuration on the General tab. Enable the "Enable Secret Check Out Extension" check box after clicking the Edit button.

Enhanced Diagnostic and Logging Functionality

The logging level of Secret Server web nodes and distributed engines are now centrally configurable and collectable. This feature is especially useful for large systems with many nodes and engines.

Configuration for the web nodes is found on the Server Nodes configuration page, alongside role settings. Configuration for distributed engines is found in the Distributed Engine configuration page. Log levels include: All, Debug, Info, Warn, Error, Off, and Not Set (the default). Previously, manual configuration file changes were required. “Not Set” relies on the configuration files for the logging level, which was the previous default behavior.

The diagnostic feature for collecting logs is improved and now gathers logs from all nodes and engines. This feature is at Admin > Diagnostics.

API Automatic Checkout

There are now automatic check in and check out parameters for secret API calls that can check in and out, leave comments, and force check in. The parameters are:

- `autocheckout=true` checks out the secret before performing any operations and then checks the secret back in afterwards.
- `forcecheckin=true` checks in the secret if it is currently checked out before performing any operations.
- The combination of `autocheckout=true` and `autocheckin=false` leaves the secret checked out after the operation completes.
- The combination of `autocheckout=true` and `autocheckin= true` checks out the secret before performing any operations and then checks the secret back in afterwards.
- `autocomment=[comment]` adds a check out or in comment. The comment must be in a URL-escaped format. For instance spaces are changed to `%20`.

This functionality is currently available on the following endpoints:

- `api/v1/secrets/{id}/`
- `api/v1/secrets/{id}/change-password/`
- `api/v1/secrets/{id}/email`
- `api/v1/secrets/{id}/expiration`
- `api/v1/secrets/{id}/expire/`
- `api/v1/secrets/{id}/fields/{slug}/`
- `api/v1/secrets/{id}/fields/{slug}/`
- `api/v1/secrets/{id}/fields/{slug}/list`
- `api/v1/secrets/{id}/fields/{slug}/listdetails`
- `api/v1/secrets/{id}/general`

- api/v1/secrets/{id}/heartbeat/
- api/v1/secrets/{id}/restricted/
- api/v1/secrets/{id}/restricted/fields/{slug}/
- api/v1/secrets/{id}/rpc-script-secrets
- api/v1/secrets/{id}/security-general
- api/v1/secrets/{id}/settings
- api/v1/secrets/{id}/ssh-restricted-commands
- api/v1/secrets/{id}/state
- api/v1/secrets/{id}/summary/
- api/v1/secrets/{secretId}/update-ssh-restricted-commands
- api/v1/secrets/rdpproxy
- api/v1/secrets/sshproxy
- api/v1/secrets/sshterminal
- api/v2/secrets/{id}/email
- api/v2/secrets/{id}/general
- api/v2/secrets/{id}/rpc-script-secrets
- api/v2/secrets/{id}/security-general
- api/v3/secrets/{id}/security-approval
- api/v3/secrets/{id}/security-checkout

General

- Added support for RabbitMQ version 3.9.5 with RabbitMQ Helper.
- Updated syslog over TCP to meet the requirements of RFC-6587. Added a newline terminator at the end of each syslog message per RFC 6587. You can disable this by setting the "System Log force line feed end of line" advanced configuration setting to "False."
- Upgraded RADIUS authentication to include EAP-TTLS-PAP.
- Added options to prevent login via OAuth if SAML is enabled.
- Improved audit logs with addition of username and display name data.
- Added token (such as `$EventUsername`) translation to the input value for the secret field filter in event pipeline policies.
- The "Restrict by" setting in launchers and now use notes, text fields, or list fields.

UI/UX

- Added accessibility controls across Secret Server.
- Added a "quick launcher" feature to the secret table view, providing faster access to the launchers from search results or folders.
- Added screen reader hints.
- Improved wording in the UI description for managed directory services groups.
- UI description for user preference email settings now says users with view permissions see secret notifications.
- Improved the UI for assigning multiple groups to a user from the user management page.
- Improved the UI adding permissions to folders.
- Improved the secret template administration pages.
- Added a copy password button to the secret password history (Secret Item Value History popup). The history now has a multi-line text box, making it easier to manipulate text strings.
- Added a `#TIMEZONE` parameter to the custom report builder. This inserts the user time zone (formatted for SQL) into the report. This can be used with SQL syntax for converting dates, such as `CONVERT(DATE, DateRecorded AT TIME ZONE ''UTC'' AT TIME ZONE #TIMEZONE) as DateRecorded`
- Added a folder search to the folder picker.

API

- The `GET /folders` API endpoint can now optionally return only root folders by using the new query parameter `filter.OnlyIncludeRootFolders=true`.

Bug Fixes

Access Requests and Secret Workflows

- Fixed an issue where comments for checked-out secrets appear in the preview panel.
- Fixed an issue when including owners as reviewers was only updated if another part of the step was updated.
- Fixed the issue where the max allowed approvers setting was being reset to 1 instead of the number of approvers.

API

- Fixed an issue with API secret endpoints not returning a 400 bad request statement when an approval workflow is used.

Alerts, Auditing, and Logs

- Fixed an issue where auto export would report an error in the system log when it is not enabled.
- Fixed an issue with the historical data import for Privileged Behavior Analytics not working.
- Fixed an issue where inbox templates would not load if they were in a language different to the application.

- Fixed a performance issue when retrieving secret audits with large numbers of audits and secret sessions associated with the secret.
- Fixed an issue where AccessConfigs is null for some customers. The fix checks before using the values in AccessConfigs and creating additional logs.

Authentication, Login, and Directory Services

- Fixed an issue where OAuth tokens generated with a maximum lifetime would sometimes return an error.
- Increased the size limit of SAML certificate storage to accommodate larger certificates.
- Fixed an issue where certain LDAP directories could not synchronize because they did not support the SearchOptions control.
- Fixed an issue with bulk operations to disable two-factor authentication not running on the User Administration page.
- Fixed an Secret Server Cloud error when users attempted to use the "lost my phone" feature.
- Improved the AD sync error messaging by separating users from domains that failed to sync from those whose domains have no users in the latest sync, delivering separate error messages for each.
- Fixed a login issue by enforcing an existing restriction of application accounts from logging into the UI for SAML authentication.
- Fixed an issue with AD and LDAP Secret Server users not being able to successfully authenticate with a public key over SSH Terminal.
- Fixed an issue when 2FA was enabled for users with no entry in the tbuser fields causing login failure.
- Fixed an issue where duplicate item rows were added when generating a SSH key and passing to the passphrase. The duplicate caused an error in validation that expected only one row per field.
- Fixed an issue with AD sync over a distributed engine with "TLS error auditing" enabled that caused "disable user management" to stop working.

Discovery

- Fixed an issue with discovery host-range mapping validation.
- Fixed an issue where a mouseover tool tip was not showing the full OU path on the Discovery Domain Scope page for excluded OUs.
- Fixed an issue where previously scanned Linux machines were not displayed in discovery network view.
- Fixed an issue with discovery import rules for windows local account templates that prevented successful account import.
- Fixed an issue where an invalid secret template configuration caused a page load error when navigating to the Discovery Network View page.

Encryption, Passwords, and Certificates

- Fixed an issue with the password report in the dashboard UI to properly update the date.
- Fixed an issue where the "Prevent Username in Password" setting was not working for a password template.

Event Subscriptions and Pipelines

- Reduced the EventQueue "maximum batches per job" default from unlimited to 100. This is an advanced configuration item.
- Fixed an issue that prevented recording an audit log and sending an event subscription when "Require Two Factor for these Login Types" is set to "Web Services Login Only."

Folders

Fixed an issue where folder owners cannot move secrets to a folder if the owner does not have access to the folder's parent folder.

General

- Added table monitoring for DIM for new tables.
- Fixed an incorrect error code displayed when navigating to a URL containing invalid characters. Navigating to the URL now displays a 404 error.
- Fixed an issue with unclear licensing errors. Highlighted the error and clarified working.
- Fixed an issue with non-English languages displaying the product name incorrectly.
- Fixed a CVSS 7.4 security issue. It impacts Secret Server On-Premises up to 11.1.000006. See the important note at the top of these release notes.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue where changes to proxy endpoint settings would not be audited on distributed engine proxy endpoints.
- Fixed an issue with distributed engine activation requiring MSDTC to be enabled.
- Fixed an issue with dropped connections to RabbitMQ causing worker process connections to RabbitMQ to accumulate additional connection channels, impacting connectivity.
- Fixed an issue where changing a dependency group site assignment to "Use Site from Secret" would throw an application error.
- Fixed an issue where a secret would be queued for password changing every password changing interval due to an invalid change schedule setting.
- Fixed an issue on the Secret Remote Password Changing settings tab where the option to remove associated secrets would not display.
- Fixed an issue with the Test Dependency button on the Secret Dependency view did not work correctly on the New UI.
- Fixed an issue where bulk operation "Assign to Site" required heartbeat or remote password changing to be enabled on the template
- Fixed an issue on the RPC configuration auto-change schedule not honoring a scheduled "when password expires" change.

- Fixed an issue that occurred when running RPC on a secret and then switching to view another secret–if the first secret's RPC fails, the information is displayed on the second secret.
- Fixed an issue where RPCNextAttemptTime does not update when adjusting the auto change schedule after a failed RPC attempt.
- Fixed an issue in discovery where the Secret Type field does not provide dropdown options in the UI if RPC is disabled on the secret template's password changer.
- Fixed an issue with the application path of Secret Server being used in a distributed engine for ComPlus dependencies.

Installation, Upgrade, and Uninstall

None

Launchers

- Fixed an issue where the "Hide Launcher Password" setting would hide the password field from a secret owner when the field also has "View Requires Edit" enabled.
- Fixed an error when a machine list restricts an input field on a secret launcher.
- Fixed an issue with protocol handler that caused certificate errors from the IDP or delays in validating the CRL.

Remote Access and Proxies

- Fixed an issue with proxied SSH connections to slow devices where "Connect As" commands were not inputted correctly.
- Fixed an issue where some key-exchange algorithms were not supported for various SSH tasks, including proxy, discovery, heartbeat and password changing.
- Fixed an issue where SSH command restrictions using allowed command lists would close the connection when trying to navigate the command restrictions menus.
- Fixed an issue with automatic sudo elevation during SSH proxy sessions identifying password prompts incorrectly and attempting to enter the password.
- Fixed an issue with SSH proxy session performance when sending or receiving large quantities of data.
- Fixed an issue where using SSH Blocked Command lists prevented exiting text editors in an SSH session.
- Fixed an issue with reports using date range filters. The local timezone is now correctly filters the report, as opposed to UTC.
- Fixed a memory leak issue in SSH proxy on Web node connections.
- Fixed an issue where PuTTY did not load the default session logging location.
- Fixed an issue where SSH Terminal was locked out due to an authorization issue when launching a secret.

Reports

- Fixed an issue with users not receiving report emails.
- Fixed an issue where scheduled reports failed to send emails when the report file size was too large, producing an error.

Secret Server Cloud

Fixed an issue where secret key rotation could trigger database growth when used with KMS key protection.

Secrets, Policies, and Templates

- Fixed an issue with the secret template interface that prevented users from setting a default deprived secret. This was possible in the Classic UI.
- Clarified an error when changing the field type on a secret template that occurs if the field is mapped to the "Restrict By" setting of a launcher.
- Fixed an issue on the Secret General tab where the icon indicating that a session is not recorded did not display on Web Password Filler launchers.
- Fixed an issue with secret search where results appeared to be matching any word in the search text instead of all words.
- Fixed an issue with secret import not using the site from the import XML unless the site was also added during the same import. Import will now use the site ID on the secret if sites were not also imported.
- Fixed an issue where a checked-in secret's password is visible. Secret Server now displays an error if the user tries to click the view password link on a the secret.
- Fixed an issue that prevented access to a secret in "Unlimited Vault Access mode" if the secret is checked-out and requires a comment.
- Fixed an issue with secret search when searching an encrypted secret field with partial matches of some terms.
- Fixed an issue with the Secret Settings interface showing incorrect settings when a secret policy was enforced.

Session Recording

None

Users and Groups

- Fixed an issue with automatic user management not correctly enabling or re-enabling users in some configurations during SAML login.
- Fixed an issue in the UI where groups with long names obscured permission dropdown-list options. Long group names now text wrap to allow viewing.

UX/UI

Fixed an issue where switching languages would display the incorrect OEM logo and product name in the classic UI.

Web Password Filler

None

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

- Internet Explorer 11. Support for Internet Explorer 11 ends on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI. The Classic UI option in Secret Server is scheduled to be removed in Q2 2022. After that time, the New UI will be the only available UI option in Secret Server.

Secret Server: 11.1.000006 Release Notes

Release dates:

January 11, 2022 (On-Premises)

January 15 2022 (Cloud)

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

New Features and Enhancements

Master Encryption Key Rotation

Secret Server can now generate new master encryption keys via a rotation process. Previously, the master encryption key was generated at installation and rotation was not possible.

This feature is at Admin > Configuration on the Security tab in the Master Encryption Key Rotation section.

Note: Secret encryption uses a different key, and the independent secret key rotation is still available.

SSH Jumpbox Route Support

SSH jumpbox routes allow SSH terminal and proxy to connect through one or more jumpbox servers in line to a final connection when launching from that target server's secret. An *SSH jumpbox*, a type of *bastion host*, is a regular Linux server, accessible from the Internet, that is a gateway to other Linux machines on a private network using the SSH protocol.

Note: *Bastion* means *a projecting part of a fortification*. Bastion hosts are hardened and monitored servers that reside outside of an organization's security zone, usually exposed to the internet. SSH jumpboxes are also called *bastion hosts*, *jump hosts*, *jump boxes*, or *jump servers*. All jumpboxes are bastion hosts, but all bastion hosts are not necessarily jumpboxes.

RDP Clipboard and Drive Mapping

Gives the owner of a secret control of the RDP clipboard and drive mapping settings, restricting users from using their alternative settings. This provides administrators enforcement control over secrets and users' RDP launcher settings.

Checkout Time Indicator

There is now an indicator within secret details that shows the remaining time on a checkout and can extend the checkout if required. The indicator is color coded and counts down in days, hours, or minutes.

Click the timer for an option to extend the checkout if this is enabled. The setting to enable checkout extension is at Admin > Configuration on the General tab. Enable the "Enable Secret Check Out Extension" check box after clicking the Edit button.

Enhanced Diagnostic and Logging Functionality

The logging level of Secret Server web nodes and distributed engines are now centrally configurable and collectable. This feature is especially useful for large systems with many nodes and engines.

Configuration for the web nodes is found on the Server Nodes configuration page, alongside role settings. Configuration for distributed engines is found in the Distributed Engine configuration page. Log levels include: All, Debug, Info, Warn, Error, Off, and Not Set (the default). Previously, manual configuration file changes were required. "Not Set" relies on the configuration files for the logging level, which was the previous default behavior.

The diagnostic feature for collecting logs is improved and now gathers logs from all nodes and engines. This feature is at Admin > Diagnostics.

API Automatic Checkout

There are now automatic check in and check out parameters for secret API calls that can check in and out, leave comments, and force check in. The parameters are:

- `autocheckout=true` checks out the secret before performing any operations and then checks the secret back in afterwards.
- `forcecheckin=true` checks in the secret if it is currently checked out before performing any operations.
- The combination of `autocheckout=true` and `autocheckin=false` leaves the secret checked out after the operation completes.
- The combination of `autocheckout=true` and `autocheckin= true` checks out the secret before performing any operations and then checks the secret back in afterwards.
- `autocomment=[comment]` adds a check out or in comment. The comment must be in a URL-escaped format. For instance spaces are changed to `%20`.

This functionality is currently available on the following endpoints:

- api/v1/secrets/{id}/
- api/v1/secrets/{id}/change-password/
- api/v1/secrets/{id}/email
- api/v1/secrets/{id}/expiration
- api/v1/secrets/{id}/expire/
- api/v1/secrets/{id}/fields/{slug}/
- api/v1/secrets/{id}/fields/{slug}/
- api/v1/secrets/{id}/fields/{slug}/list
- api/v1/secrets/{id}/fields/{slug}/listdetails
- api/v1/secrets/{id}/general
- api/v1/secrets/{id}/heartbeat/
- api/v1/secrets/{id}/restricted/
- api/v1/secrets/{id}/restricted/fields/{slug}/
- api/v1/secrets/{id}/rpc-script-secrets
- api/v1/secrets/{id}/security-general
- api/v1/secrets/{id}/settings
- api/v1/secrets/{id}/ssh-restricted-commands
- api/v1/secrets/{id}/state
- api/v1/secrets/{id}/summary/
- api/v1/secrets/{secretId}/update-ssh-restricted-commands
- api/v1/secrets/rdpproxy
- api/v1/secrets/sshproxy
- api/v1/secrets/sshterminal
- api/v2/secrets/{id}/email
- api/v2/secrets/{id}/general
- api/v2/secrets/{id}/rpc-script-secrets
- api/v2/secrets/{id}/security-general
- api/v3/secrets/{id}/security-approval
- api/v3/secrets/{id}/security-checkout

General

- Added support for RabbitMQ version 3.9.5 with RabbitMQ Helper.

- Updated syslog over TCP to meet the requirements of RFC-6587. Added a newline terminator at the end of each syslog message per RFC 6587. You can disable this by setting the "System Log force line feed end of line" advanced configuration setting to "False."
- Upgraded RADIUS authentication to include EAP-TTLS-PAP.
- Added options to prevent login via OAuth if SAML is enabled.
- Improved audit logs with addition of username and display name data.
- Added token (such as `$EventUsername`) translation to the input value for the secret field filter in event pipeline policies.
- The "Restrict by" setting in launchers and now use notes, text fields, or list fields.

UI/UX

- Added accessibility controls across Secret Server.
- Added a "quick launcher" feature to the secret table view, providing faster access to the launchers from search results or folders.
- Added screen reader hints.
- Improved wording in the UI description for managed directory services groups.
- UI description for user preference email settings now says users with view permissions see secret notifications.
- Improved the UI for assigning multiple groups to a user from the user management page.
- Improved the UI adding permissions to folders.
- Improved the secret template administration pages.
- Added a copy password button to the secret password history (Secret Item Value History popup). The history now has a multi-line text box, making it easier to manipulate text strings.
- Added a `#TIMEZONE` parameter to the custom report builder. This inserts the user time zone (formatted for SQL) into the report. This can be used with SQL syntax for converting dates, such as `CONVERT(DATE, DateRecorded AT TIME ZONE ''UTC'' AT TIME ZONE #TIMEZONE) as DateRecorded`
- Added a folder search to the folder picker.

API

- The `GET /folders` API endpoint can now optionally return only root folders by using the new query parameter `filter.OnlyIncludeRootFolders=true`.

Bug Fixes

Access Requests and Secret Workflows

- Fixed an issue where comments for checked-out secrets appear in the preview panel.
- Fixed an issue when including owners as reviewers was only updated if another part of the step was updated.
- Fixed the issue where the max allowed approvers setting was being reset to 1 instead of the number of approvers.

API

- Fixed an issue with API secret endpoints not returning a 400 bad request statement when an approval workflow is used.
- Fixed an issue with the SOAP API Method `AddNewSecret` that threw an object reference error when setting `SecretSettings.IsChangeToSettings = $true`.

Alerts, Auditing, and Logs

- Fixed an issue where auto export would report an error in the system log when it is not enabled.
- Fixed an issue with the historical data import for Privileged Behavior Analytics not working.
- Fixed an issue where inbox templates would not load if they were in a language different to the application.
- Fixed a performance issue when retrieving secret audits with large numbers of audits and secret sessions associated with the secret.
- Fixed an issue where AccessConfigs is null for some customers. The fix checks before using the values in AccessConfigs and creating additional logs.

Authentication, Login, and Directory Services

- Fixed an issue where OAuth tokens generated with a maximum lifetime would sometimes return an error.
- Increased the size limit of SAML certificate storage to accommodate larger certificates.
- Fixed an issue where certain LDAP directories could not synchronize because they did not support the SearchOptions control.
- Fixed an issue with bulk operations to disable two-factor authentication not running on the User Administration page.
- Fixed an Secret Server Cloud error when users attempted to use the "lost my phone" feature.
- Improved the AD sync error messaging by separating users from domains that failed to sync from those whose domains have no users in the latest sync, delivering separate error messages for each.
- Fixed a login issue by enforcing an existing restriction of application accounts from logging into the UI for SAML authentication.
- Fixed an issue with AD and LDAP Secret Server users not being able to successfully authenticate with a public key over SSH Terminal.
- Fixed an issue when 2FA was enabled for users with no entry in the tbuser fields causing login failure.
- Fixed an issue where duplicate item rows were added when generating a SSH key and passing to the passphrase. The duplicate caused an error in validation that expected only one row per field.
- Fixed an issue with AD sync over a distributed engine with "TLS error auditing" enabled that caused "disable user management" to stop working.

Discovery

- Fixed an issue with discovery host-range mapping validation.
- Fixed an issue where a mouseover tool tip was not showing the full OU path on the Discovery Domain Scope page for excluded OUs.
- Fixed an issue where previously scanned Linux machines were not displayed in discovery network view.
- Fixed an issue with discovery import rules for windows local account templates that prevented successful account import.
- Fixed an issue where an invalid secret template configuration caused a page load error when navigating to the Discovery Network View page.

Encryption, Passwords, and Certificates

- Fixed an issue with the password report in the dashboard UI to properly update the date.
- Fixed an issue where the "Prevent Username in Password" setting was not working for a password template.

Event Subscriptions and Pipelines

- Reduced the EventQueue "maximum batches per job" default from unlimited to 100. This is an advanced configuration item.
- Fixed an issue that prevented recording an audit log and sending an event subscription when "Require Two Factor for these Login Types" is set to "Web Services Login Only."

Folders

Fixed an issue where folder owners cannot move secrets to a folder if the owner does not have access to the folder's parent folder.

General

- Added table monitoring for DIM for new tables.
- Fixed an incorrect error code displayed when navigating to a URL containing invalid characters. Navigating to the URL now displays a 404 error.
- Fixed an issue with unclear licensing errors. Highlighted the error and clarified working.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue where changes to proxy endpoint settings would not be audited on distributed engine proxy endpoints.
- Fixed an issue with distributed engine activation requiring MSDTC to be enabled.
- Fixed an issue with dropped connections to RabbitMQ causing worker process connections to RabbitMQ to accumulate additional connection channels, impacting connectivity.
- Fixed an issue where changing a dependency group site assignment to "Use Site from Secret" would throw an application error.

- Fixed an issue where a secret would be queued for password changing every password changing interval due to an invalid change schedule setting.
- Fixed an issue on the Secret Remote Password Changing settings tab where the option to remove associated secrets would not display.
- Fixed an issue with the Test Dependency button on the Secret Dependency view did not work correctly on the New UI.
- Fixed an issue where bulk operation "Assign to Site" required heartbeat or remote password changing to be enabled on the template
- Fixed an issue on the RPC configuration auto-change schedule not honoring a scheduled "when password expires" change.
- Fixed an issue that occurred when running RPC on a secret and then switching to view another secret—if the first secret's RPC fails, the information is displayed on the second secret.
- Fixed an issue where RPCNextAttemptTime does not update when adjusting the auto change schedule after a failed RPC attempt.
- Fixed an issue in discovery where the Secret Type field does not provide dropdown options in the UI if RPC is disabled on the secret template's password changer.
- Fixed an issue with the application path of Secret Server being used in a distributed engine for ComPlus dependencies.

Installation, Upgrade, and Uninstall

None

Launchers

- Fixed an issue where the "Hide Launcher Password" setting would hide the password field from a secret owner when the field also has "View Requires Edit" enabled.
- Fixed an error when a machine list restricts an input field on a secret launcher.
- Fixed an issue with protocol handler that caused certificate errors from the IDP or delays in validating the CRL.

Remote Access and Proxies

- Fixed an issue with proxied SSH connections to slow devices where "Connect As" commands were not inputted correctly.
- Fixed an issue where some key-exchange algorithms were not supported for various SSH tasks, including proxy, discovery, heartbeat and password changing.
- Fixed an issue where SSH command restrictions using allowed command lists would close the connection when trying to navigate the command restrictions menus.
- Fixed an issue with automatic sudo elevation during SSH proxy sessions identifying password prompts incorrectly and attempting to enter the password.
- Fixed an issue with SSH proxy session performance when sending or receiving large quantities of data.
- Fixed an issue where using SSH Blocked Command lists prevented exiting text editors in an SSH session.

- Fixed an issue with reports using date range filters. The local timezone is now correctly filters the report, as opposed to UTC.
- Fixed a memory leak issue in SSH proxy on Web node connections.
- Fixed an issue where PuTTY did not load the default session logging location.
- Fixed an issue where SSH Terminal was locked out due to an authorization issue when launching a secret.

Reports

- Fixed an issue with users not receiving report emails.
- Fixed an issue where scheduled reports failed to send emails when the report file size was too large, producing an error.

Secret Server Cloud

Fixed an issue where secret key rotation could trigger database growth when used with KMS key protection.

Secrets, Policies, and Templates

- Fixed an issue with the secret template interface that prevented users from setting a default deprived secret. This was possible in the Classic UI.
- Clarified an error when changing the field type on a secret template that occurs if the field is mapped to the "Restrict By" setting of a launcher.
- Fixed an issue on the Secret General tab where the icon indicating that a session is not recorded did not display on Web Password Filler launchers.
- Fixed an issue with secret search where results appeared to be matching any word in the search text instead of all words.
- Fixed an issue with secret import not using the site from the import XML unless the site was also added during the same import. Import will now use the site ID on the secret if sites were not also imported.
- Fixed an issue where a checked-in secret's password is visible. Secret Server now displays an error if the user tries to click the view password link on a the secret.
- Fixed an issue that prevented access to a secret in "Unlimited Vault Access mode" if the secret is checked-out and requires a comment.
- Fixed an issue with secret search when searching an encrypted secret field with partial matches of some terms.

Session Recording

None

Users and Groups

- Fixed an issue with automatic user management not correctly enabling or re-enabling users in some configurations during SAML login.
- Fixed an issue in the UI where groups with long names obscured permission dropdown-list options. Long group names now text wrap to allow viewing.

UX/UI

Fixed an issue where switching languages would display the incorrect OEM logo and product name in the classic UI.

Web Password Filler

None

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

- Internet Explorer 11. Support for Internet Explorer 11 ends on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI. The Classic UI option in Secret Server is scheduled to be removed in Q2 2022. After that time, the New UI will be the only available UI option in Secret Server.

Secret Server: 11.0.000008 Release Notes

Release date:

- September 30, 2021 (on-premises and cloud)

Important: The 11.000008 update resolves a **serious security vulnerability**. Please carefully read the following *High Security Issue* section. **We strongly recommend all affected Secret Server customers upgrade at their earliest opportunity**.

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

High Security Issue

Overview

The 11.000008 update resolves a high security vulnerability for customers using OpenLDAP directory services with Secret Server.

This issue is rated **High** with a 8.6 Common Vulnerability Scoring System (CVSS) score. Please see the CVSS Calculator for the issue.

Scope

This vulnerability applies when all of the following are true:

- The user is authenticated via an OpenLDAP domain.
- The user is accessing Secret Server via the API or a tool that uses the API, such as Connection Manager, Web Password Filler, or the Secret Server mobile app.
- The LDAP domain is configured to allow unauthenticated bindings. For example, the presence of `allow bind_anon_cred` in the OpenLDAP configuration.

Remediation

Installing the update resolves the issue. In the meantime, as a temporary workaround, we suggest disabling unauthenticated binding in your OpenLDAP directory configuration.

Known Issues

Note: All the original release notes for 11.0.000007 have been moved below for convenience and clarity.

Connection Manager Version 1.6.2 Required for Customers Using Secret Server 11.0

Details:

- Intermittent Issue: On a macOS, when run in protocol handler mode, copy and paste does not work. The app does not crash but the copy and paste action is not successful. If the app is “unlocked,” copy, cut, and paste work. For your Secret Server connection to “unlock” it, expand the left navigation panel, and double click on the “lock” icon.
- Intermittent Issue On a macOS, while connected to any Secret Server, if the user edits the same Secret Server name (via the Secret Server connections menu), the app could get stuck in a “connecting…” state.
- Intermittent Issue: On a macOS, some users may experience issues connecting to Secret Server via a Web login (SAML) where the connection stays in a “connecting…” state.
- Upgrade Issues: In some situations, the automatic upgrade may not run the installer after downloading the MSI or package files. On macOS, when upgrading from v1.6.0, the automatic update fails to launch the installer. On Windows, the auto update may not launch the installer. In that case, please download and run the installer manually or via a software deployment tool.

New Features and Enhancements

API

Secrets are now searchable by the full path. This removes the need to know the ID to locate the intended secret.

Encrypted Secret Export

Secret Server now allows you to schedule encrypted exports of secret data to external storage.

General

- Updated ESXi integration support via an update of PowerCLI 12.
- Updated PuTTY to version .074.

- Added SNC support for communication between SAP and Secret Server for heartbeat and remote password changing.
- Added support for metadata filters on event pipelines.
- Added the ability to intercept a sudo or su command in a proxied session and inject the session password directly from Secret Server, not disclosing the password to the user.
- Added support for displaying both username and display name in audit logs.
- Added SMB fallback support for local Windows account heartbeats.
- Added a discovery threshold configuration that controls when a dependency is deactivated if it is not found in a scan. The threshold is set to the times a dependency can be missing prior to deactivation. It can also be set to "never" to prevent deactivation.

Inbox

The inbox now provides a customizable toolset to manage how email and notifications are sent and received by users. Inbox allows for configuration of notification scheduling, collecting notifications into digests, creation of message templates and rules, and more.

Lists

Secrets now support configurable data lists. Users with the "apply lists to secrets via secret policies" permission can create a list. This provides an easy mechanism for secret owners to simply choose from provided lists, such as a list of machines the user can select. Additionally, lists can be used for allow and blocklists allowing for control over what the secret owner can access.

Proxy Generic Connections

Secret Server can now securely tunnel a connection to servers operating on a variety of protocols.

Secret Erase

Users with the permissions to use the secret erase feature can permanently erase data from a secret. This provides Secret Server a method to purge secret data without reconciliation of the erased data. The existing "delete" function (now called "deactivate") allows you to "undelete" (reactivate). Secret erase can be audited as an event.

SSH Key Discovery

Secret Server discovery can now discover SSH public keys by scanning key locations on Linux and Unix servers.

User Interface

- Added dependency status reports. The reports are:
  - Overview: Shows how many dependencies failed, succeeded, and were not run.
  - Status: Shows how many dependencies failed, succeeded, and were not run by clickable secret, secret dependency group, and site.

  - Failed by secret: Shows doughnut graphic with secret and fail count.
  - Not run by secret: Shows the not run count by secret.
- Renamed the "Viewing Password Requires Edit" setting to "Hide Launcher Password" in the secret policies editor to improve clarity.

Bug Fixes

Note: The same line item may appear in more than one section when it applies to both.

Access Requests and Secret Workflows

- Fixed an issue where the "Revoke" button was being displayed in the UI after a request had already expired. The button should not be available to users past expiration.
- Fixed an issue where a "No Permission" page is displayed incorrectly when checking-in a secret with "change on check-in" enabled.

Alerts, Events, and Logging

- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries. For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.

API

- Fixed an issue where API was returning null for createDate on SecretSummary queries.
- Fixed an issue that resulted in receiving a 500 error when using the REST API to enable check-in on a secret using the PATCH method /secrets/{id}/security-checkout.
- Fixed an issue where the REST API was returning "Object reference not set to an instance of an object." against the /directory-services/domains/{domainid}/group.
- Fixed an issue for the API endpoint, workflow, or template throwing an exception when the take parameter was not specified.
- Fixed a POST issue in secret-templates REST endpoint that did not properly validate the editablePermission property on fields.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.

Authentication, Login, and Directory Services

- Fixed an issue with post authentication for SAML.
- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries. For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.

- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue where occasionally users that synced via Active Directory were not getting assigned default role (s).
- Fixed an issue with Active Directory synchronization throwing a credential validation error when the sync credentials are from another domain after creating relationship between domains.
- Added a notice in the UI for directory services group sync search results being limited to 1000 groups.
- Fixed an issue where Active Directory group names were showing with their pre-Windows 2000 name instead of the group name.
- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.

Discovery

- Fixed an issue in discovery when using LDAPS where discovery attempts to use port 389 despite the user having selected LDAPS port 636.
- Fixed an issue with saving IP addresses additions to the manual host range within the discovery scanner. A message is now provided to inform the user that the manual host ranges should be set on the discovery source scanner, rather than as a default setting on the scanner itself.
- Fixed an issue that could occasionally cause dependencies to get disabled by a computer discovery scan. The fix adds a discovery configuration for a threshold to improve control when a dependency is deactivated if not found in a scan. The threshold can be set to ‘Never’ to prevent disabling or a count for times a dependency is not found.
- Fixed a discovery issue that could cause background processes to stop.
- Fixed an issue where discovery was retaining too many historical records for each host. We added an advanced configuration setting to define the number of records.
- Fixed a discovery issue where when the discovery sourceid was equal to 9 or 10, after the domain scan completed to get machines, the Service Account tab in the UI would not load re-scan buttons.
- Fixed an issue where the schedule task scanner did not work for the domain discovery source with two UPNs.
- Fixed an issue with discovery for scheduled task scanning across multiple trusted domains.
- Fixed a discovery issue where similar OU names resulted in discovery importing accounts from an OU with a similar name to the targeted OU.

Event Subscriptions and Pipelines

- Fixed an issue that could be encountered with event subscriptions after converting a secret's template. An improved message is now provided in the UI when converting secret templates to inform the user what actions needs to take place to prevent the issue.
- Fixed an issue with event pipelines receiving an application error when trying to add tasks in a policy if the policy

has a deactivated pipeline.

- Fixed an event subscriptions issue of not initiating for engine events.

Folders

- Fixed an issue when editing folder permissions and receiving no search results for groups that contained a '+' in the group name.
- Fixed an issue that prevented the ability to sort folders by alphabetical order on name in the Favorites tab.
- Fixed an issue where the folder name may not display in the secret grid.
- Fixed an issue where right clicking secret folders in the UI did not have the "View Details" option available for users with view permissions.
- Fixed an issue where editing folder sharing permissions removed restricted template options in the new UI.
- Fixed an issue that caused an application error when changing a folder's secret permissions to "none."

General

- Fixed an issue that caused a 500 error if certain password sequences were used when password validation settings were enabled to prevent password sequences.
- Fixed an issue that prevented content deletion in metadata fields.
- Fixed an issue where pressing enter on the keyboard when using the main application search box did not display results in the secret grid but only in the dropdown.
- Fixed an issue where the "Copy to Clipboard" button was not appearing on fields that contained a character count beyond the max field character display.
- Fixed an issue where the "Options" menu on pages is automatically hidden in the UI if no options are present to display to the user.
- Fixed an issue where sessions created through the Secret Server terminal "Launch" command were not getting returned by session search when filtering by secret name, secret field value, or user.
- Fixed an issue where on the home page engine status widget was not displaying the correct status in the "Connection Status 1" column. In the fix, this column has been renamed to 'Activation Status'.
- Fixed an invalid audit message entry when a user initiates "Change Password Now" using the "Randomly Generated" option.
- Fixed an issue where changing the name of a launcher did not update the name of the launcher on the secret.
- Fixed a mouseover label on "RADIUS User Name" on the Users page. Mouseover tooltip now displays "The user name of your RADIUS user."
- Fixed an issue with password requirement validation. When a password policy specified that the username must not be included in the password, the validation was too aggressive. Now at least three consecutive characters in the password must match a section of the username for a password to be rejected.
- Fixed an issue that caused locks to hang in tbDatabaseCache.
- Fixed an issue where an account is not being used as a "Privileged Secrets for Scripts" when importing for discovery for RPC and heartbeat.

- Fixed an issue where RDP proxy may experience intermittent connectivity when using the Mac version of Connection Manager.
- Fixed an issue causing Secret Server-BWSR errors from UDP Syslog datagrams exceeding RFC3164/5424 specifications. Note that TCP or SecureTCP, is preferred over UDP for reliability purposes.
- Fixed an issue when editing the default password requirement when using a language other than English. It set the default to false.
- Fixed an issue when syncing AzureAD where deleting a sync group in AzureAD would result in members of all groups being synchronized.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue that resulted in a "Phantom.JS.exe not found" error when trying to run a heartbeat on a Web password with a distributed engine.
- Fixed an issue where password changing for secrets was not being triggered after a forced check-in.
- Fixed an issue when creating custom dependencies that produced an invalid error when adding a parent field of 'Machine.'
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue where a "Last Heartbeat Status" error was displayed in the UI that indicated the user's Web browser stopped polling the server. An improved error message is provided in cases where polling timeout still occurs.
- Fixed an issue with password changing for SAP secrets that caused failures at password change due to an issue with the check-in.

  For SAP servers where rfc/reject_expired_passwd = 1, a new option was added to the Advanced Settings in the SAP password changer. This new option, "Use Single Destination (SAP)" is false by default, but, when set to true, it allows privileged password changing to succeed on these servers by using the privileged credentials in both steps of the privileged password change.

  For servers where rfc/reject_expired_passwd = 0, this option may be set to true or false and password changing will succeed.
- Fixed an issue where previously inactive custom scripts were still displayed as available for RPC.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.
- Fixed an issue that displayed the distributed engine count incorrectly based on previously deleted distributed engines.
- Fixed an issue that could prevent the privileged account password from changing by a distributed engine if a child secret were deleted while it was being processed for RPC.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.

- Fixed an issue for the ODBC password changer with verification opening the connection but not executing custom commands. The fix allows for: CheckFor, CheckContains, and CheckNotContains to be used in custom commands. Additional logging has also been added when verbose logging is enabled.
- Fixed an issue with RPC on scheduled tasks that have a secret ID on a different trusted domain.
- Fixed an issue where the distributed engine automatic upgrade would fail if the OS account HKU{GUID} entry does not have permission to stop the distributed engine service.

Installation, Upgrade, and Uninstall

- Fixed an issue where ThycoticSetup.exe failed to install SQL Express when selected for the installation.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.

Launchers

Fixed an issue with SAP launcher where record "Additional Processes" stops recording if it was opened from another process within "Process Arguments" and that process is closed.

Reports

Fixed an issue where duplicate report emails were received when a report schedule was not removed after a report with the same name was deleted. The fix does not allow two active reports to have the same report name when creating or updating a report.

Secret Server Cloud

- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.
- Fixed an issue in Secret Server Cloud where personal folders were not being created for new users created through Delinea One.
- Fixed an issue for Secret Server Cloud where after entering the PIN for Duo and attempting login, Secret Server would activate the Duo Push button in the UI, rather than proceeding with the login.

Secrets, Policies, and Templates

- Fixed an issue by adding more robust permission checks to determine when template conversion options should be available to users, rather than displaying generic access denied errors when users attempted making conversions on a template without the right user roles.
- Fixed an issue by providing additional detail in a warning message to alert the users when duplicating templates that changes must be applied to all secrets intended to use the new template.
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.

- Fixed an issue that prevented record retrieval on secret permissions if the application account has owner permissions at the secret level. Now, if you have view access to the secret in the filter you can retrieve the permissions. Queries that do not have secret ID still require the secret owner.
- Fixed an issue where a secret template with a duplicate name in fields would cause a failure when exported, due to the field name match. We recommend using an available slug on the XML for handling fields which have the same name.
- Fixed an issue in the UI when searching of the secrets grid where the search text box covered the first result in the grid.
- Fixed and improved reference labeling to secrets when a secret template changes on deleted secrets. A (deleted) reference is added to secrets used in a secret policy that have been deleted. Added a note to let the user know that deleted secrets are included in the secret count.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue preventing applying a secret policy without access to the required privileged account. Users can now assign a new role that allows users with "list" permissions on the secret to pass the secret access permissions check for privileged and associated secrets when the privileged or associated secrets are enforced by secret policy.

Session Recording

- Fixed an issue causing Session Recording failures to record multiple sessions to the same target with MobaXTerm.
- Fixed an issue where older session recording keystroke logs were not deleted after the configured retention period. Session recording using SSH or RDP Proxy to capture keystroke metadata was not running the cleanup job after the data retention period expired.
- Fixed an issue where searching for recorded sessions could produce an execution timeout error.
- Fixed an issue with the SAP launcher only recording part of the screen.

SSH Proxy and Terminal

- Fixed an issue where SSH proxy sessions via SSH terminal would close within approximately five minutes after launch.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue when launching SSH secrets via SSH terminal that have 'check out' and 'change on check in' enabled. When exiting the launched session, the secret does not check in.
- Fixed an issue with proxied SSH custom launchers using a "Connect As" secret failing to launch successfully.
- Fixed an issue using private ECDSA SSH keys generated in the OpenSSH format that produced an error when uploading the key on a SSH key template.
- Fixed an issue that caused premature closure of proxied SSH processes when opening multiple sessions of MobaXterm.
- Fixed an issue where the SSH proxy tunnel would not take $password from Xshell client on a custom launcher.

- Fixed an issue where the supported SSH key exchange algorithms would fail to negotiate (ecdh-sha2-nistp256, ecdh-sha2-nistp384, and ecdh-sha2-nistp521).
- Fixed an issue where the keyboard did not operate for users on SSH RDP PuTTY sessions via proxy.

Users and Groups

Fixed an issue with the "Users Migrate to AD" function producing an invalid error when canceling.

Web Password Filler

Fixed an issue where Web Password Filler did not prompt token generation for users on Windows 10 version 20H2.

Fixes made since Early Adopter Version 11.0.000000

- Fixed a high, CVSS 8.6, security issue. See the important note at the top of these release notes.
- Fixed a critical, CVSS 9.9, security issue. It impacts Secret Server 10.9.000032 to 11.0.000006. See the important note at the top of the 11.000007 release notes.
- Fixed an issue with secret access requests not allowing the administrator to approve via the inbox.
- Fixed an issue where SSH blocklist caused user keystrokes to be echoed back in the session.
- Fixed an issue with SSH blocklist that caused all su sessions to quit when issuing an exit command.
- Fixed an issue with SSH blocklist where the control-c input does not quit running the program when SSH blocklist is enabled.
- Fixed an issue with SSH blocklist where ESC input on a session with SSH blocklist terminates the session.
- Fixed an issue with SSH blocklist where all su sessions terminate when issuing an exit command.
- Fixed an issue with the lists feature where a user with own or edit permission on a secret were not given access to add or remove lists.
- Fixed date parsing logic for license dates. License dates are in U.S. date format, but default parsing logic uses local-server time-format settings to parse the date and could fail if the expected format is in a different order, for example, in the U.K. where the format is dd/mm/yyyy instead of mm/dd/yyyy. We forced the parser to use the U.S. date format.

Pending Deprecations

This section describes planned feature or platform-support deprecations in Secret Server.

- Internet Explorer 11. Support for Internet Explorer 11 ends on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI. The Classic UI option in Secret Server is scheduled to be removed in Q1 2022. After that time, the New UI will be the only available UI option in Secret Server.

Secret Server: 11.0.000007 Release Notes

Release date:

- September 7, 2021 (on-premises only)
- September 11, 2021 (Cloud: US)

> This release addresses a security issue that was recently discovered during third-party penetration testing. See "Secret Server 11.1.000007 Security Update" below for details.

> If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:
>
> - PM agents will not register.
> - When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.
>
> If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

Secret Server 11.1.000007 Security Update

This release addresses a security issue that was recently discovered during third-party penetration testing. The security issue is rated High severity on the standard CVSS scale and impacts all previous versions of Secret Server On-Premise. It impacts Secret Server**10.9.000032** to **11.0.000006**. We recommend all affected Secret Server on-premise customers upgrade immediately to version **11.0.000007**.

It does not impact Secret Server Cloud and there were no version updates to Secret Server Cloud.

CVSS Summary:

NTLM Hash Leak:

Short Description: A highly privileged user on the same network as Secret Server could potentially cause an unauthorized NTLM hash leak. The vulnerability is given a score of 7.4 by CVSS v3.1 Vector AV:N/AC:H/PR:N/UI:N/S:U/C:N/I:H/A:H.

> Delinea thanks Filip Magic and Florian Coman from TDC NET Security for identifying the security issue leading to the 11.0.000007 release.

> We deployed a security patch for this same issue to all Secret Server Cloud regions on September 3rd. The update was independent of the 11.000007 feature update, which occurs on September 11.

Known Issues

Connection Manager Version 1.6.2 Required for Customers Using Secret Server 11.0

Details:

- Intermittent Issue: On a macOS, when run in protocol handler mode, copy and paste does not work. The app does not crash but the copy and paste action is not successful. If the app is “unlocked,” copy, cut, and paste work. For your Secret Server connection to “unlock” it, expand the left navigation panel, and double click on the “lock” icon.
- Intermittent Issue On a macOS, while connected to any Secret Server, if the user edits the same Secret Server name (via the Secret Server connections menu), the app could get stuck in a “connecting…” state.
- Intermittent Issue: On a macOS, some users may experience issues connecting to Secret Server via a Web login (SAML) where the connection stays in a “connecting…” state.
- Upgrade Issues: In some situations, the automatic upgrade may not run the installer after downloading the MSI or package files. On macOS, when upgrading from v1.6.0, the automatic update fails to launch the installer. On Windows, the auto update may not launch the installer. In that case, please download and run the installer manually or via a software deployment tool.

New Features and Enhancements

API

Secrets are now searchable by the full path. This removes the need to know the ID to locate the intended secret.

Encrypted Secret Export

Secret Server now allows you to schedule encrypted exports of secret data to external storage.

General

- Updated ESXi integration support via an update of PowerCLI 12.
- Updated PuTTY to version .074.
- Added SNC support for communication between SAP and Secret Server for heartbeat and remote password changing.
- Added support for metadata filters on event pipelines.
- Added the ability to intercept a sudo or su command in a proxied session and inject the session password directly from Secret Server, not disclosing the password to the user.
- Added support for displaying both username and display name in audit logs.
- Added SMB fallback support for local Windows account heartbeats.
- Added a discovery threshold configuration that controls when a dependency is deactivated if it is not found in a scan. The threshold is set to the times a dependency can be missing prior to deactivation. It can also be set to "never" to prevent deactivation.

Inbox

The inbox now provides a customizable toolset to manage how email and notifications are sent and received by users. Inbox allows for configuration of notification scheduling, collecting notifications into digests, creation of message templates and rules, and more.

Lists

Secrets now support configurable data lists. Users with the "apply lists to secrets via secret policies" permission can create a list. This provides an easy mechanism for secret owners to simply choose from provided lists, such as a list of machines the user can select. Additionally, lists can be used for allow and blocklists allowing for control over what the secret owner can access.

Proxy Generic Connections

Secret Server can now securely tunnel a connection to servers operating on a variety of protocols.

Secret Erase

Users with the permissions to use the secret erase feature can permanently erase data from a secret. This provides Secret Server a method to purge secret data without reconciliation of the erased data. The existing "delete" function (now called "deactivate") allows you to "undelete" (reactivate). Secret erase can be audited as an event.

SSH Key Discovery

Secret Server discovery can now discover SSH public keys by scanning key locations on Linux and Unix servers.

User Interface

- Added dependency status reports. The reports are:
  - Overview: Shows how many dependencies failed, succeeded, and were not run.
  - Status: Shows how many dependencies failed, succeeded, and were not run by clickable secret, secret dependency group, and site.
  - Failed by secret: Shows doughnut graphic with secret and fail count.
  - Not run by secret: Shows the not run count by secret.
- Renamed the "Viewing Password Requires Edit" setting to "Hide Launcher Password" in the secret policies editor to improve clarity.

Bug Fixes

Note: The same line item may appear in more than one section when it applies to both.

Access Requests and Secret Workflows

- Fixed an issue where the "Revoke" button was being displayed in the UI after a request had already expired. The button should not be available to users past expiration.
- Fixed an issue where a "No Permission" page is displayed incorrectly when checking-in a secret with "change on check-in" enabled.

Alerts, Events, and Logging

- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries.

For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.

API

- Fixed an issue where API was returning null for createDate on SecretSummary queries.
- Fixed an issue that resulted in receiving a 500 error when using the REST API to enable check-in on a secret using the PATCH method /secrets/{id}/security-checkout.
- Fixed an issue where the REST API was returning "Object reference not set to an instance of an object." against the /directory-services/domains/{domainid}/group.
- Fixed an issue for the API endpoint, workflow, or template throwing an exception when the take parameter was not specified.
- Fixed a POST issue in secret-templates REST endpoint that did not properly validate the editablePermission property on fields.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.

Authentication, Login, and Directory Services

- Fixed an issue with post authentication for SAML.
- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries. For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue where occasionally users that synced via Active Directory were not getting assigned default role (s).
- Fixed an issue with Active Directory synchronization throwing a credential validation error when the sync credentials are from another domain after creating relationship between domains.
- Added a notice in the UI for directory services group sync search results being limited to 1000 groups.
- Fixed an issue where Active Directory group names were showing with their pre-Windows 2000 name instead of the group name.
- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.

Discovery

- Fixed an issue in discovery when using LDAPS where discovery attempts to use port 389 despite the user having selected LDAPS port 636.

- Fixed an issue with saving IP addresses additions to the manual host range within the discovery scanner. A message is now provided to inform the user that the manual host ranges should be set on the discovery source scanner, rather than as a default setting on the scanner itself.
- Fixed an issue that could occasionally cause dependencies to get disabled by a computer discovery scan.
- Fixed a discovery issue that could cause background processes to stop.
- Fixed an issue where discovery was retaining too many historical records for each host. We added an advanced configuration setting to define the number of records.
- Fixed a discovery issue where when the discoverysourceid was equal to 9 or 10, after the domain scan completed to get machines, the Service Account tab in the UI would not load re-scan buttons.
- Fixed an issue where the schedule task scanner did not work for the domain discovery source with two UPNs.
- Fixed an issue with discovery for scheduled task scanning across multiple trusted domains.
- Fixed a discovery issue where similar OU names resulted in discovery importing accounts from an OU with a similar name to the targeted OU.

Event Subscriptions and Pipelines

- Fixed an issue that could be encountered with event subscriptions after converting a secret's template. An improved message is now provided in the UI when converting secret templates to inform the user what actions needs to take place to prevent the issue.
- Fixed an issue with event pipelines receiving an application error when trying to add tasks in a policy if the policy has a deactivated pipeline.
- Fixed an event subscriptions issue of not initiating for engine events.

Folders

- Fixed an issue when editing folder permissions and receiving no search results for groups that contained a '+' in the group name.
- Fixed an issue that prevented the ability to sort folders by alphabetical order on name in the Favorites tab.
- Fixed an issue where the folder name may not display in the secret grid.
- Fixed an issue where right clicking secret folders in the UI did not have the "View Details" option available for users with view permissions.
- Fixed an issue where editing folder sharing permissions removed restricted template options in the new UI.
- Fixed an issue that caused an application error when changing a folder's secret permissions to "none."

General

- Fixed an issue that caused a 500 error if certain password sequences were used when password validation settings were enabled to prevent password sequences.
- Fixed an issue that prevented content deletion in metadata fields.
- Fixed an issue where pressing enter on the keyboard when using the main application search box did not display results in the secret grid but only in the dropdown.

- Fixed an issue where the "Copy to Clipboard" button was not appearing on fields that contained a character count beyond the max field character display.
- Fixed an issue where the "Options" menu on pages is automatically hidden in the UI if no options are present to display to the user.
- Fixed an issue where sessions created through the Secret Server terminal "Launch" command were not getting returned by session search when filtering by secret name, secret field value, or user.
- Fixed an issue where on the home page engine status widget was not displaying the correct status in the "Connection Status 1" column. In the fix, this column has been renamed to 'Activation Status'.
- Fixed an invalid audit message entry when a user initiates "Change Password Now" using the "Randomly Generated" option.
- Fixed an issue where changing the name of a launcher did not update the name of the launcher on the secret.
- Fixed a mouseover label on "RADIUS User Name" on the Users page. Mouseover tooltip now displays "The user name of your RADIUS user."
- Fixed an issue with password requirement validation. When a password policy specified that the username must not be included in the password, the validation was too aggressive. Now at least three consecutive characters in the password must match a section of the username for a password to be rejected.
- Fixed an issue that caused locks to hang in tbDatabaseCache.
- Fixed an issue where an account is not being used as a "Privileged Secrets for Scripts" when importing for discovery for RPC and heartbeat.
- Fixed an issue where RDP proxy may experience intermittent connectivity when using the Mac version of Connection Manager.
- Fixed an issue causing Secret Server-BWSR errors from UDP Syslog datagrams exceeding RFC3164/5424 specifications. Note that TCP or SecureTCP, is preferred over UDP for reliability purposes.
- Fixed an issue when editing the default password requirement when using a language other than English. It set the default to false.
- Fixed an issue when syncing AzureAD where deleting a sync group in AzureAD would result in members of all groups being synchronized.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue that resulted in a "Phantom.JS.exe not found" error when trying to run a heartbeat on a Web password with a distributed engine.
- Fixed an issue where password changing for secrets was not being triggered after a forced check-in.
- Fixed an issue when creating custom dependencies that produced an invalid error when adding a parent field of 'Machine.'
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue where a "Last Heartbeat Status" error was displayed in the UI that indicated the user's Web browser stopped polling the server. An improved error message is provided in cases where polling timeout still

occurs.

- Fixed an issue with password changing for SAP secrets that caused failures at password change due to an issue with the check-in.

  For SAP servers where rfc/reject_expired_passwd = 1, a new option was added to the Advanced Settings in the SAP password changer. This new option, "Use Single Destination (SAP)" is false by default, but, when set to true, it allows privileged password changing to succeed on these servers by using the privileged credentials in both steps of the privileged password change.

  For servers where rfc/reject_expired_passwd = 0, this option may be set to true or false and password changing will succeed.
- Fixed an issue where previously inactive custom scripts were still displayed as available for RPC.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.
- Fixed an issue that displayed the distributed engine count incorrectly based on previously deleted distributed engines.
- Fixed an issue that could prevent the privileged account password from changing by a distributed engine if a child secret were deleted while it was being processed for RPC.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.
- Fixed an issue for the ODBC password changer with verification opening the connection but not executing custom commands. The fix allows for: CheckFor, CheckContains, and CheckNotContains to be used in custom commands. Additional logging has also been added when verbose logging is enabled.
- Fixed an issue with RPC on scheduled tasks that have a secret ID on a different trusted domain.
- Fixed an issue where the distributed engine automatic upgrade would fail if the OS account HKU{GUID} entry does not have permission to stop the distributed engine service.

Installation, Upgrade, and Uninstall

- Fixed an issue where ThycoticSetup.exe failed to install SQL Express when selected for the installation.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.

Launchers

Fixed an issue with SAP launcher where record "Additional Processes" stops recording if it was opened from another process within "Process Arguments" and that process is closed.

Reports

Fixed an issue where duplicate report emails were received when a report schedule was not removed after a report with the same name was deleted. The fix does not allow two active reports to have the same report name when creating or updating a report.

Secret Server Cloud

- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.
- Fixed an issue in Secret Server Cloud where personal folders were not being created for new users created through Delinea One.
- Fixed an issue for Secret Server Cloud where after entering the PIN for Duo and attempting login, Secret Server would activate the Duo Push button in the UI, rather than proceeding with the login.

Secrets, Policies, and Templates

- Fixed an issue by adding more robust permission checks to determine when template conversion options should be available to users, rather than displaying generic access denied errors when users attempted making conversions on a template without the right user roles.
- Fixed an issue by providing additional detail in a warning message to alert the users when duplicating templates that changes must be applied to all secrets intended to use the new template.
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue that prevented record retrieval on secret permissions if the application account has owner permissions at the secret level. Now, if you have view access to the secret in the filter you can retrieve the permissions. Queries that do not have secret ID still require the secret owner.
- Fixed an issue where a secret template with a duplicate name in fields would cause a failure when exported, due to the field name match. We recommend using an available slug on the XML for handling fields which have the same name.
- Fixed an issue in the UI when searching of the secrets grid where the search text box covered the first result in the grid.
- Fixed and improved reference labeling to secrets when a secret template changes on deleted secrets. A (deleted) reference is added to secrets used in a secret policy that have been deleted. Added a note to let the user know that deleted secrets are included in the secret count.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue preventing applying a secret policy without access to the required privileged account. Users can now assign a new role that allows users with "list" permissions on the secret to pass the secret access permissions check for privileged and associated secrets when the privileged or associated secrets are enforced by secret policy.

Session Recording

- Fixed an issue causing Session Recording failures to record multiple sessions to the same target with MobaXTerm.
- Fixed an issue where older session recording keystroke logs were not deleted after the configured retention period. Session recording using SSH or RDP Proxy to capture keystroke metadata was not running the cleanup job after the data retention period expired.

- Fixed an issue where searching for recorded sessions could produce an execution timeout error.
- Fixed an issue with the SAP launcher only recording part of the screen.

SSH Proxy and Terminal

- Fixed an issue where SSH proxy sessions via SSH terminal would close within approximately five minutes after launch.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue when launching SSH secrets via SSH terminal that have 'check out' and 'change on check in' enabled. When exiting the launched session, the secret does not check in.
- Fixed an issue with proxied SSH custom launchers using a "Connect As" secret failing to launch successfully.
- Fixed an issue using private ECDSA SSH keys generated in the OpenSSH format that produced an error when uploading the key on a SSH key template.
- Fixed an issue that caused premature closure of proxied SSH processes when opening multiple sessions of MobaXterm.
- Fixed an issue where the SSH proxy tunnel would not take $password from Xshell client on a custom launcher.
- Fixed an issue where the supported SSH key exchange algorithms would fail to negotiate (ecdh-sha2-nistp256, ecdh-sha2-nistp384, and ecdh-sha2-nistp521).
- Fixed an issue where the keyboard did not operate for users on SSH RDP PuTTY sessions via proxy.

Users and Groups

Fixed an issue with the "Users Migrate to AD" function producing an invalid error when canceling.

Web Password Filler

Fixed an issue where Web Password Filler did not prompt token generation for users on Windows 10 version 20H2.

Fixes made since Early Adopter Version 11.0.000000

- Fixed a critical, CVSS 9.9, security issue. It impacts Secret Server 10.9.000032 to 11.0.000006. See the important note at the top of these release notes.
- Fixed an issue with secret access requests not allowing the administrator to approve via the inbox.
- Fixed an issue where SSH blocklist caused user keystrokes to be echoed back in the session.
- Fixed an issue with SSH blocklist that caused all su sessions to quit when issuing an exit command.
- Fixed an issue with SSH blocklist where the control-c input does not quit running the program when SSH blocklist is enabled.
- Fixed an issue with SSH blocklist where ESC input on a session with SSH blocklist terminates the session.
- Fixed an issue with SSH blocklist where all su sessions terminate when issuing an exit command.
- Fixed an issue with the lists feature where a user with own or edit permission on a secret were not given access to add or remove lists.

- Fixed date parsing logic for license dates. License dates are in U.S. date format, but default parsing logic uses local-server time-format settings to parse the date and could fail if the expected format is in a different order, for example, in the U.K. where the format is dd/mm/yyyy instead of mm/dd/yyyy. We forced the parser to use the U.S. date format.

Pending Deprecations

This section describes planned feature or platform-support deprecations in Secret Server.

- Internet Explorer 11. Support for Internet Explorer 11 ends on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI. The Classic UI option in Secret Server is scheduled to be removed in Q1 2022. After that time, the New UI will be the only available UI option in Secret Server.

Secret Server: 11.0.000006 Release Notes

Release date:

- July 21, 2021 (early release, on-premises only)
- August 17, 2021 (on-premises version)
- August 28, 2021 (Cloud: CA, SG, AU, EU)
- September 11, 2021(Cloud: US)

Note: These dates are tentative. Please see the main release note page for the actually dates as they happen.

Important: If you are in a Secret Server Cloud region that has not yet received the 11.0.x release, please use the "Secret Server: 10.9.000064 Release Notes" on page 1896 notes instead.

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

Known Issues

Connection Manager Version 1.6.2 Required for Customers Using Secret Server 11.0

Details:

- Intermittent Issue: On a macOS, when run in protocol handler mode, copy and paste does not work. The app does not crash but the copy and paste action is not successful. If the app is “unlocked,” copy, cut, and paste work. For your Secret Server connection to “unlock” it, expand the left navigation panel, and double click on the “lock” icon.

- Intermittent Issue On a macOS, while connected to any Secret Server, if the user edits the same Secret Server name (via the Secret Server connections menu), the app could get stuck in a “connecting…” state.
- Intermittent Issue: On a macOS, some users may experience issues connecting to Secret Server via a Web login (SAML) where the connection stays in a “connecting…” state.
- Upgrade Issues: In some situations, the automatic upgrade may not run the installer after downloading the MSI or package files. On macOS, when upgrading from v1.6.0, the automatic update fails to launch the installer. On Windows, the auto update may not launch the installer. In that case, please download and run the installer manually or via a software deployment tool.

  Installer download links:

  - macOS
  - Windows

New Features and Enhancements

API

Secrets are now searchable by the full path. This removes the need to know the ID to locate the intended secret.

Encrypted Secret Export

Secret Server now allows you to schedule encrypted exports of secret data to external storage.

General

- Updated ESXi integration support via an update of PowerCLI 12.
- Updated PuTTY to version .074.
- Added SNC support for communication between SAP and Secret Server for heartbeat and remote password changing.
- Added support for metadata filters on event pipelines.
- Added the ability to intercept a sudo or su command in a proxied session and inject the session password directly from Secret Server, not disclosing the password to the user.
- Added support for displaying both username and display name in audit logs.
- Added SMB fallback support for local Windows account heartbeats.
- Added a discovery threshold configuration that controls when a dependency is deactivated if it is not found in a scan. The threshold is set to the times a dependency can be missing prior to deactivation. It can also be set to "never" to prevent deactivation.

Inbox

The inbox now provides a customizable toolset to manage how email and notifications are sent and received by users. Inbox allows for configuration of notification scheduling, collecting notifications into digests, creation of message templates and rules, and more.

Lists

Secrets now support configurable data lists. Users with the "apply lists to secrets via secret policies" permission can create a list. This provides an easy mechanism for secret owners to simply choose from provided lists, such as a list of machines the user can select. Additionally, lists can be used for allow and blocklists allowing for control over what the secret owner can access.

Proxy Generic Connections

Secret Server can now securely tunnel a connection to servers operating on a variety of protocols.

Secret Erase

Users with the permissions to use the secret erase feature can permanently erase data from a secret. This provides Secret Server a method to purge secret data without reconciliation of the erased data. The existing "delete" function (now called "deactivate") allows you to "undelete" (reactivate). Secret erase can be audited as an event.

SSH Key Discovery

Secret Server discovery can now discover SSH public keys by scanning key locations on Linux and Unix servers.

User Interface

- Added dependency status reports. The reports are:
  - Overview: Shows how many dependencies failed, succeeded, and were not run.
  - Status: Shows how many dependencies failed, succeeded, and were not run by clickable secret, secret dependency group, and site.
  - Failed by secret: Shows doughnut graphic with secret and fail count.
  - Not run by secret: Shows the not run count by secret.
- Renamed the "Viewing Password Requires Edit" setting to "Hide Launcher Password" in the secret policies editor to improve clarity.

Bug Fixes

Note: The same line item may appear in more than one section when it applies to both.

Access Requests and Secret Workflows

- Fixed an issue where the "Revoke" button was being displayed in the UI after a request had already expired. The button should not be available to users past expiration.
- Fixed an issue where a "No Permission" page is displayed incorrectly when checking-in a secret with "change on check-in" enabled.

Alerts, Events, and Logging

- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries.

For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.

API

- Fixed an issue where API was returning null for createDate on SecretSummary queries.
- Fixed an issue that resulted in receiving a 500 error when using the REST API to enable check-in on a secret using the PATCH method /secrets/{id}/security-checkout.
- Fixed an issue where the REST API was returning "Object reference not set to an instance of an object." against the /directory-services/domains/{domainid}/group.
- Fixed an issue for the API endpoint, workflow, or template throwing an exception when the take parameter was not specified.
- Fixed a POST issue in secret-templates REST endpoint that did not properly validate the editablePermission property on fields.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.

Authentication, Login, and Directory Services

- Fixed an issue with post authentication for SAML.
- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries. For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue where occasionally users that synced via Active Directory were not getting assigned default role (s).
- Fixed an issue with Active Directory synchronization throwing a credential validation error when the sync credentials are from another domain after creating relationship between domains.
- Added a notice in the UI for directory services group sync search results being limited to 1000 groups.
- Fixed an issue where Active Directory group names were showing with their pre-Windows 2000 name instead of the group name.
- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.

Discovery

- Fixed an issue in discovery when using LDAPS where discovery attempts to use port 389 despite the user having selected LDAPS port 636.

- Fixed an issue with saving IP addresses additions to the manual host range within the discovery scanner. A message is now provided to inform the user that the manual host ranges should be set on the discovery source scanner, rather than as a default setting on the scanner itself.
- Fixed an issue that could occasionally cause dependencies to get disabled by a computer discovery scan.
- Fixed a discovery issue that could cause background processes to stop.
- Fixed an issue where discovery was retaining too many historical records for each host. We added an advanced configuration setting to define the number of records.
- Fixed a discovery issue where when the discoverysourceid was equal to 9 or 10, after the domain scan completed to get machines, the Service Account tab in the UI would not load re-scan buttons.
- Fixed an issue where the schedule task scanner did not work for the domain discovery source with two UPNs.
- Fixed an issue with discovery for scheduled task scanning across multiple trusted domains.
- Fixed a discovery issue where similar OU names resulted in discovery importing accounts from an OU with a similar name to the targeted OU.

Event Subscriptions and Pipelines

- Fixed an issue that could be encountered with event subscriptions after converting a secret's template. An improved message is now provided in the UI when converting secret templates to inform the user what actions needs to take place to prevent the issue.
- Fixed an issue with event pipelines receiving an application error when trying to add tasks in a policy if the policy has a deactivated pipeline.
- Fixed an event subscriptions issue of not initiating for engine events.

Folders

- Fixed an issue when editing folder permissions and receiving no search results for groups that contained a '+' in the group name.
- Fixed an issue that prevented the ability to sort folders by alphabetical order on name in the Favorites tab.
- Fixed an issue where the folder name may not display in the secret grid.
- Fixed an issue where right clicking secret folders in the UI did not have the "View Details" option available for users with view permissions.
- Fixed an issue where editing folder sharing permissions removed restricted template options in the new UI.
- Fixed an issue that caused an application error when changing a folder's secret permissions to "none."

General

- Fixed an issue that caused a 500 error if certain password sequences were used when password validation settings were enabled to prevent password sequences.
- Fixed an issue that prevented content deletion in metadata fields.
- Fixed an issue where pressing enter on the keyboard when using the main application search box did not display results in the secret grid but only in the dropdown.

- Fixed an issue where the "Copy to Clipboard" button was not appearing on fields that contained a character count beyond the max field character display.
- Fixed an issue where the "Options" menu on pages is automatically hidden in the UI if no options are present to display to the user.
- Fixed an issue where sessions created through the Secret Server terminal "Launch" command were not getting returned by session search when filtering by secret name, secret field value, or user.
- Fixed an issue where on the home page engine status widget was not displaying the correct status in the "Connection Status 1" column. In the fix, this column has been renamed to 'Activation Status'.
- Fixed an invalid audit message entry when a user initiates "Change Password Now" using the "Randomly Generated" option.
- Fixed an issue where changing the name of a launcher did not update the name of the launcher on the secret.
- Fixed a mouseover label on "RADIUS User Name" on the Users page. Mouseover tooltip now displays "The user name of your RADIUS user."
- Fixed an issue with password requirement validation. When a password policy specified that the username must not be included in the password, the validation was too aggressive. Now at least three consecutive characters in the password must match a section of the username for a password to be rejected.
- Fixed an issue that caused locks to hang in tbDatabaseCache.
- Fixed an issue where an account is not being used as a "Privileged Secrets for Scripts" when importing for discovery for RPC and heartbeat.
- Fixed an issue where RDP proxy may experience intermittent connectivity when using the Mac version of Connection Manager.
- Fixed an issue causing Secret Server-BWSR errors from UDP Syslog datagrams exceeding RFC3164/5424 specifications. Note that TCP or SecureTCP, is preferred over UDP for reliability purposes.
- Fixed an issue when editing the default password requirement when using a language other than English. It set the default to false.
- Fixed an issue when syncing AzureAD where deleting a sync group in AzureAD would result in members of all groups being synchronized.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue that resulted in a "Phantom.JS.exe not found" error when trying to run a heartbeat on a Web password with a distributed engine.
- Fixed an issue where password changing for secrets was not being triggered after a forced check-in.
- Fixed an issue when creating custom dependencies that produced an invalid error when adding a parent field of 'Machine.'
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue where a "Last Heartbeat Status" error was displayed in the UI that indicated the user's Web browser stopped polling the server. An improved error message is provided in cases where polling timeout still

occurs.

- Fixed an issue with password changing for SAP secrets that caused failures at password change due to an issue with the check-in.

  For SAP servers where rfc/reject_expired_passwd = 1, a new option was added to the Advanced Settings in the SAP password changer. This new option, "Use Single Destination (SAP)" is false by default, but, when set to true, it allows privileged password changing to succeed on these servers by using the privileged credentials in both steps of the privileged password change.

  For servers where rfc/reject_expired_passwd = 0, this option may be set to true or false and password changing will succeed.
- Fixed an issue where previously inactive custom scripts were still displayed as available for RPC.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.
- Fixed an issue that displayed the distributed engine count incorrectly based on previously deleted distributed engines.
- Fixed an issue that could prevent the privileged account password from changing by a distributed engine if a child secret were deleted while it was being processed for RPC.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.
- Fixed an issue for the ODBC password changer with verification opening the connection but not executing custom commands. The fix allows for: CheckFor, CheckContains, and CheckNotContains to be used in custom commands. Additional logging has also been added when verbose logging is enabled.
- Fixed an issue with RPC on scheduled tasks that have a secret ID on a different trusted domain.
- Fixed an issue where the distributed engine automatic upgrade would fail if the OS account HKU{GUID} entry does not have permission to stop the distributed engine service.

Installation, Upgrade, and Uninstall

- Fixed an issue where ThycoticSetup.exe failed to install SQL Express when selected for the installation.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.

Launchers

Fixed an issue with SAP launcher where record "Additional Processes" stops recording if it was opened from another process within "Process Arguments" and that process is closed.

Reports

Fixed an issue where duplicate report emails were received when a report schedule was not removed after a report with the same name was deleted. The fix does not allow two active reports to have the same report name when creating or updating a report.

Secret Server Cloud

- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.
- Fixed an issue in Secret Server Cloud where personal folders were not being created for new users created through Delinea One.
- Fixed an issue for Secret Server Cloud where after entering the PIN for Duo and attempting login, Secret Server would activate the Duo Push button in the UI, rather than proceeding with the login.

Secrets, Policies, and Templates

- Fixed an issue by adding more robust permission checks to determine when template conversion options should be available to users, rather than displaying generic access denied errors when users attempted making conversions on a template without the right user roles.
- Fixed an issue by providing additional detail in a warning message to alert the users when duplicating templates that changes must be applied to all secrets intended to use the new template.
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue that prevented record retrieval on secret permissions if the application account has owner permissions at the secret level. Now, if you have view access to the secret in the filter you can retrieve the permissions. Queries that do not have secret ID still require the secret owner.
- Fixed an issue where a secret template with a duplicate name in fields would cause a failure when exported, due to the field name match. We recommend using an available slug on the XML for handling fields which have the same name.
- Fixed an issue in the UI when searching of the secrets grid where the search text box covered the first result in the grid.
- Fixed and improved reference labeling to secrets when a secret template changes on deleted secrets. A (deleted) reference is added to secrets used in a secret policy that have been deleted. Added a note to let the user know that deleted secrets are included in the secret count.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue preventing applying a secret policy without access to the required privileged account. Users can now assign a new role that allows users with "list" permissions on the secret to pass the secret access permissions check for privileged and associated secrets when the privileged or associated secrets are enforced by secret policy.

Session Recording

- Fixed an issue causing Session Recording failures to record multiple sessions to the same target with MobaXTerm.
- Fixed an issue where older session recording keystroke logs were not deleted after the configured retention period. Session recording using SSH or RDP Proxy to capture keystroke metadata was not running the cleanup job after the data retention period expired.

- Fixed an issue where searching for recorded sessions could produce an execution timeout error.
- Fixed an issue with the SAP launcher only recording part of the screen.

SSH Proxy and Terminal

- Fixed an issue where SSH proxy sessions via SSH terminal would close within approximately five minutes after launch.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue when launching SSH secrets via SSH terminal that have 'check out' and 'change on check in' enabled. When exiting the launched session, the secret does not check in.
- Fixed an issue with proxied SSH custom launchers using a "Connect As" secret failing to launch successfully.
- Fixed an issue using private ECDSA SSH keys generated in the OpenSSH format that produced an error when uploading the key on a SSH key template.
- Fixed an issue that caused premature closure of proxied SSH processes when opening multiple sessions of MobaXterm.
- Fixed an issue where the SSH proxy tunnel would not take $password from Xshell client on a custom launcher.
- Fixed an issue where the supported SSH key exchange algorithms would fail to negotiate (ecdh-sha2-nistp256, ecdh-sha2-nistp384, and ecdh-sha2-nistp521).
- Fixed an issue where the keyboard did not operate for users on SSH RDP PuTTY sessions via proxy.

Users and Groups

Fixed an issue with the "Users Migrate to AD" function producing an invalid error when canceling.

Web Password Filler

Fixed an issue where Web Password Filler did not prompt token generation for users on Windows 10 version 20H2.

Fixes made since Early Adopter Version 11.0.000000

- Fixed an issue with secret access requests not allowing the administrator to approve via the inbox.
- Fixed an issue where SSH blocklist caused user keystrokes to be echoed back in the session.
- Fixed an issue with SSH blocklist that caused all su sessions to quit when issuing an exit command.
- Fixed an issue with SSH blocklist where the control-c input does not quit running the program when SSH blocklist is enabled.
- Fixed an issue with SSH blocklist where ESC input on a session with SSH blocklist terminates the session.
- Fixed an issue with SSH blocklist where all su sessions terminate when issuing an exit command.
- Fixed an issue with the lists feature where a user with own or edit permission on a secret were not given access to add or remove lists.
- Fixed date parsing logic for license dates. License dates are in U.S. date format, but default parsing logic uses local-server time-format settings to parse the date and could fail if the expected format is in a different order, for

example, in the U.K. where the format is dd/mm/yyyy instead of mm/dd/yyyy. We forced the parser to use the U.S. date format.

Pending Deprecations

This section describes planned feature or platform-support deprecations in Secret Server.

- Internet Explorer 11. Support for Internet Explorer 11 ends on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI. The Classic UI option in Secret Server is scheduled to be removed in Q1 2022. After that time, the New UI will be the only available UI option in Secret Server.

Secret Server: 11.0.000005 Release Notes

Release date:

- July 21, 2021 (early release, on-premises only)
- August 17, 2021 (on-premises version)
- August 28, 2021 (Cloud: CA, SG, AU, EU)
- September 11, 2021(Cloud: US)

Note: These dates are tentative. Please see the main release note page for the actually dates as they happen.

Important: If you are in a Secret Server Cloud region that has not yet received the 11.0.x release, please use the "Secret Server: 10.9.000064 Release Notes" on page 1896 notes instead.

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

Known Issues

Connection Manager Version 1.6.2 Required for Customers Using Secret Server 11.0

Details:

- Intermittent Issue: On a macOS, when run in protocol handler mode, copy and paste does not work. The app does not crash but the copy and paste action is not successful. If the app is “unlocked,” copy, cut, and paste work. For your Secret Server connection to “unlock” it, expand the left navigation panel, and double click on the “lock” icon.
- Intermittent Issue On a macOS, while connected to any Secret Server, if the user edits the same Secret Server name (via the Secret Server connections menu), the app could get stuck in a “connecting…” state.

- Intermittent Issue: On a macOS, some users may experience issues connecting to Secret Server via a Web login (SAML) where the connection stays in a “connecting…” state.
- Upgrade Issues: In some situations, the automatic upgrade may not run the installer after downloading the MSI or package files. On macOS, when upgrading from v1.6.0, the automatic update fails to launch the installer. On Windows, the auto update may not launch the installer. In that case, please download and run the installer manually or via a software deployment tool.

  Installer download links:

  - macOS
  - Windows

New Features and Enhancements

API

Secrets are now searchable by the full path. This removes the need to know the ID to locate the intended secret.

Encrypted Secret Export

Secret Server now allows you to schedule encrypted exports of secret data to external storage.

General

- Updated ESXi integration support via an update of PowerCLI 12.
- Updated PuTTY to version .074.
- Added SNC support for communication between SAP and Secret Server for heartbeat and remote password changing.
- Added support for metadata filters on event pipelines.
- Added the ability to intercept a sudo or su command in a proxied session and inject the session password directly from Secret Server, not disclosing the password to the user.
- Added support for displaying both username and display name in audit logs.
- Added SMB fallback support for local Windows account heartbeats.
- Added a discovery threshold configuration that controls when a dependency is deactivated if it is not found in a scan. The threshold is set to the times a dependency can be missing prior to deactivation. It can also be set to "never" to prevent deactivation.

Inbox

The inbox now provides a customizable toolset to manage how email and notifications are sent and received by users. Inbox allows for configuration of notification scheduling, collecting notifications into digests, creation of message templates and rules, and more.

Lists

Secrets now support configurable data lists. Users with the "apply lists to secrets via secret policies" permission can create a list. This provides an easy mechanism for secret owners to simply choose from provided lists, such as a list

of machines the user can select. Additionally, lists can be used for allow and blocklists allowing for control over what the secret owner can access.

Proxy Generic Connections

Secret Server can now securely tunnel a connection to servers operating on a variety of protocols.

Secret Erase

Users with the permissions to use the secret erase feature can permanently erase data from a secret. This provides Secret Server a method to purge secret data without reconciliation of the erased data. The existing "delete" function (now called "deactivate") allows you to "undelete" (reactivate). Secret erase can be audited as an event.

SSH Key Discovery

Secret Server discovery can now discover SSH public keys by scanning key locations on Linux and Unix servers.

User Interface

- Added dependency status reports. The reports are:
  - Overview: Shows how many dependencies failed, succeeded, and were not run.
  - Status: Shows how many dependencies failed, succeeded, and were not run by clickable secret, secret dependency group, and site.
  - Failed by secret: Shows doughnut graphic with secret and fail count.
  - Not run by secret: Shows the not run count by secret.
- Renamed the "Viewing Password Requires Edit" setting to "Hide Launcher Password" in the secret policies editor to improve clarity.

Bug Fixes

Note: The same line item may appear in more than one section when it applies to both.

Access Requests and Secret Workflows

- Fixed an issue where the "Revoke" button was being displayed in the UI after a request had already expired. The button should not be available to users past expiration.
- Fixed an issue where a "No Permission" page is displayed incorrectly when checking-in a secret with "change on check-in" enabled.

Alerts, Events, and Logging

- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries. For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.

API

- Fixed an issue where API was returning null for createDate on SecretSummary queries.
- Fixed an issue that resulted in receiving a 500 error when using the REST API to enable check-in on a secret using the PATCH method /secrets/{id}/security-checkout.
- Fixed an issue where the REST API was returning "Object reference not set to an instance of an object." against the /directory-services/domains/{domainid}/group.
- Fixed an issue for the API endpoint, workflow, or template throwing an exception when the take parameter was not specified.
- Fixed a POST issue in secret-templates REST endpoint that did not properly validate the editablePermission property on fields.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.

Authentication, Login, and Directory Services

- Fixed an issue with post authentication for SAML.
- Fixed an issue where if the browser is set to a non-English language, a failed login attempt causes invalid system logging. The fix changes the character type from text to nvchar to produce successful logging entries. For this data type conversion, we recommend that customers with lots of data may want to run the SQL delta ahead of an upgrade to prevent potential SQL timeouts during upgrade.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue where occasionally users that synced via Active Directory were not getting assigned default role (s).
- Fixed an issue with Active Directory synchronization throwing a credential validation error when the sync credentials are from another domain after creating relationship between domains.
- Added a notice in the UI for directory services group sync search results being limited to 1000 groups.
- Fixed an issue where Active Directory group names were showing with their pre-Windows 2000 name instead of the group name.
- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.

Discovery

- Fixed an issue in discovery when using LDAPS where discovery attempts to use port 389 despite the user having selected LDAPS port 636.
- Fixed an issue with saving IP addresses additions to the manual host range within the discovery scanner. A message is now provided to inform the user that the manual host ranges should be set on the discovery source scanner, rather than as a default setting on the scanner itself.
- Fixed an issue that could occasionally cause dependencies to get disabled by a computer discovery scan.

- Fixed a discovery issue that could cause background processes to stop.
- Fixed an issue where discovery was retaining too many historical records for each host. We added an advanced configuration setting to define the number of records.
- Fixed a discovery issue where when the discoverysourceid was equal to 9 or 10, after the domain scan completed to get machines, the Service Account tab in the UI would not load re-scan buttons.
- Fixed an issue where the schedule task scanner did not work for the domain discovery source with two UPNs.
- Fixed an issue with discovery for scheduled task scanning across multiple trusted domains.
- Fixed a discovery issue where similar OU names resulted in discovery importing accounts from an OU with a similar name to the targeted OU.

Event Subscriptions and Pipelines

- Fixed an issue that could be encountered with event subscriptions after converting a secret's template. An improved message is now provided in the UI when converting secret templates to inform the user what actions needs to take place to prevent the issue.
- Fixed an issue with event pipelines receiving an application error when trying to add tasks in a policy if the policy has a deactivated pipeline.
- Fixed an event subscriptions issue of not initiating for engine events.

Folders

- Fixed an issue when editing folder permissions and receiving no search results for groups that contained a '+' in the group name.
- Fixed an issue that prevented the ability to sort folders by alphabetical order on name in the Favorites tab.
- Fixed an issue where the folder name may not display in the secret grid.
- Fixed an issue where right clicking secret folders in the UI did not have the "View Details" option available for users with view permissions.
- Fixed an issue where editing folder sharing permissions removed restricted template options in the new UI.
- Fixed an issue that caused an application error when changing a folder's secret permissions to "none."

General

- Fixed an issue that caused a 500 error if certain password sequences were used when password validation settings were enabled to prevent password sequences.
- Fixed an issue that prevented content deletion in metadata fields.
- Fixed an issue where pressing enter on the keyboard when using the main application search box did not display results in the secret grid but only in the dropdown.
- Fixed an issue where the "Copy to Clipboard" button was not appearing on fields that contained a character count beyond the max field character display.
- Fixed an issue where the "Options" menu on pages is automatically hidden in the UI if no options are present to display to the user.

- Fixed an issue where sessions created through the Secret Server terminal "Launch" command were not getting returned by session search when filtering by secret name, secret field value, or user.
- Fixed an issue where on the home page engine status widget was not displaying the correct status in the "Connection Status 1" column. In the fix, this column has been renamed to 'Activation Status'.
- Fixed an invalid audit message entry when a user initiates "Change Password Now" using the "Randomly Generated" option.
- Fixed an issue where changing the name of a launcher did not update the name of the launcher on the secret.
- Fixed a mouseover label on "RADIUS User Name" on the Users page. Mouseover tooltip now displays "The user name of your RADIUS user."
- Fixed an issue with password requirement validation. When a password policy specified that the username must not be included in the password, the validation was too aggressive. Now at least three consecutive characters in the password must match a section of the username for a password to be rejected.
- Fixed an issue that caused locks to hang in tbDatabaseCache.
- Fixed an issue where an account is not being used as a "Privileged Secrets for Scripts" when importing for discovery for RPC and heartbeat.
- Fixed an issue where RDP proxy may experience intermittent connectivity when using the Mac version of Connection Manager.
- Fixed an issue causing Secret Server-BWSR errors from UDP Syslog datagrams exceeding RFC3164/5424 specifications. Note that TCP or SecureTCP, is preferred over UDP for reliability purposes.
- Fixed an issue when editing the default password requirement when using a language other than English. It set the default to false.
- Fixed an issue when syncing AzureAD where deleting a sync group in AzureAD would result in members of all groups being synchronized.

Heartbeat, Distributed Engines, and RPC

- Fixed an issue that resulted in a "Phantom.JS.exe not found" error when trying to run a heartbeat on a Web password with a distributed engine.
- Fixed an issue where password changing for secrets was not being triggered after a forced check-in.
- Fixed an issue when creating custom dependencies that produced an invalid error when adding a parent field of 'Machine.'
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue where a "Last Heartbeat Status" error was displayed in the UI that indicated the user's Web browser stopped polling the server. An improved error message is provided in cases where polling timeout still occurs.
- Fixed an issue with password changing for SAP secrets that caused failures at password change due to an issue with the check-in.

For SAP servers where rfc/reject_expired_passwd = 1, a new option was added to the Advanced Settings in the SAP password changer. This new option, "Use Single Destination (SAP)" is false by default, but, when set to true, it allows privileged password changing to succeed on these servers by using the privileged credentials in both steps of the privileged password change.

For servers where rfc/reject_expired_passwd = 0, this option may be set to true or false and password changing will succeed.

- Fixed an issue where previously inactive custom scripts were still displayed as available for RPC.
- Fixed an issue where a secret policy which enforces 'View Password Requires Edit' prevents API access to the view the password.
- Fixed an issue that displayed the distributed engine count incorrectly based on previously deleted distributed engines.
- Fixed an issue that could prevent the privileged account password from changing by a distributed engine if a child secret were deleted while it was being processed for RPC.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.
- Fixed an issue for the ODBC password changer with verification opening the connection but not executing custom commands. The fix allows for: CheckFor, CheckContains, and CheckNotContains to be used in custom commands. Additional logging has also been added when verbose logging is enabled.
- Fixed an issue with RPC on scheduled tasks that have a secret ID on a different trusted domain.
- Fixed an issue where the distributed engine automatic upgrade would fail if the OS account HKU{GUID} entry does not have permission to stop the distributed engine service.

Installation, Upgrade, and Uninstall

- Fixed an issue where ThycoticSetup.exe failed to install SQL Express when selected for the installation.
- Fixed an issue producing an error during a distributed engine install when the hostname was more than 50 characters.

Launchers

Fixed an issue with SAP launcher where record "Additional Processes" stops recording if it was opened from another process within "Process Arguments" and that process is closed.

Reports

Fixed an issue where duplicate report emails were received when a report schedule was not removed after a report with the same name was deleted. The fix does not allow two active reports to have the same report name when creating or updating a report.

Secret Server Cloud

- Fixed an issue where Secret Server Cloud users were presented with a misleading tooltip for user synchronization interval options in directory services configuration. An improved tooltip has been provided to inform the user the limitations of the configuration more accurately in Secret Server Cloud.
- Fixed an issue in Secret Server Cloud where personal folders were not being created for new users created through Delinea One.
- Fixed an issue for Secret Server Cloud where after entering the PIN for Duo and attempting login, Secret Server would activate the Duo Push button in the UI, rather than proceeding with the login.

Secrets, Policies, and Templates

- Fixed an issue by adding more robust permission checks to determine when template conversion options should be available to users, rather than displaying generic access denied errors when users attempted making conversions on a template without the right user roles.
- Fixed an issue by providing additional detail in a warning message to alert the users when duplicating templates that changes must be applied to all secrets intended to use the new template.
- Fixed an issue when setting the auto change schedule on a secret policy to monthly that caused a UI issue that prevented viewing the Remote Password Changing tab.
- Fixed an issue that prevented record retrieval on secret permissions if the application account has owner permissions at the secret level. Now, if you have view access to the secret in the filter you can retrieve the permissions. Queries that do not have secret ID still require the secret owner.
- Fixed an issue where a secret template with a duplicate name in fields would cause a failure when exported, due to the field name match. We recommend using an available slug on the XML for handling fields which have the same name.
- Fixed an issue in the UI when searching of the secrets grid where the search text box covered the first result in the grid.
- Fixed and improved reference labeling to secrets when a secret template changes on deleted secrets. A (deleted) reference is added to secrets used in a secret policy that have been deleted. Added a note to let the user know that deleted secrets are included in the secret count.
- Fixed an issue preventing a scheduled password change if the secret template expiration is disabled.
- Fixed an issue preventing applying a secret policy without access to the required privileged account. Users can now assign a new role that allows users with "list" permissions on the secret to pass the secret access permissions check for privileged and associated secrets when the privileged or associated secrets are enforced by secret policy.

Session Recording

- Fixed an issue causing Session Recording failures to record multiple sessions to the same target with MobaXTerm.
- Fixed an issue where older session recording keystroke logs were not deleted after the configured retention period. Session recording using SSH or RDP Proxy to capture keystroke metadata was not running the cleanup job after the data retention period expired.

- Fixed an issue where searching for recorded sessions could produce an execution timeout error.
- Fixed an issue with the SAP launcher only recording part of the screen.

SSH Proxy and Terminal

- Fixed an issue where SSH proxy sessions via SSH terminal would close within approximately five minutes after launch.
- Fixed an issue where when a distributed engine was used as a proxy server the SSH terminal gave an invalid error during authentication for public keys.
- Fixed an issue when launching SSH secrets via SSH terminal that have 'check out' and 'change on check in' enabled. When exiting the launched session, the secret does not check in.
- Fixed an issue with proxied SSH custom launchers using a "Connect As" secret failing to launch successfully.
- Fixed an issue using private ECDSA SSH keys generated in the OpenSSH format that produced an error when uploading the key on a SSH key template.
- Fixed an issue that caused premature closure of proxied SSH processes when opening multiple sessions of MobaXterm.
- Fixed an issue where the SSH proxy tunnel would not take $password from Xshell client on a custom launcher.
- Fixed an issue where the supported SSH key exchange algorithms would fail to negotiate (ecdh-sha2-nistp256, ecdh-sha2-nistp384, and ecdh-sha2-nistp521).
- Fixed an issue where the keyboard did not operate for users on SSH RDP PuTTY sessions via proxy.

Users and Groups

Fixed an issue with the "Users Migrate to AD" function producing an invalid error when canceling.

Web Password Filler

Fixed an issue where Web Password Filler did not prompt token generation for users on Windows 10 version 20H2.

Fixes made since Early Adopter Version 11.0.000000

- Fixed an issue with secret access requests not allowing the administrator to approve via the inbox.
- Fixed an issue where SSH blocklist caused user keystrokes to be echoed back in the session.
- Fixed an issue with SSH blocklist that caused all su sessions to quit when issuing an exit command.
- Fixed an issue with SSH blocklist where the control-c input does not quit running the program when SSH blocklist is enabled.
- Fixed an issue with SSH blocklist where ESC input on a session with SSH blocklist terminates the session.
- Fixed an issue with SSH blocklist where all su sessions terminate when issuing an exit command.
- Fixed an issue with the lists feature where a user with own or edit permission on a secret were not given access to add or remove lists.

Pending Deprecations

This section describes planned feature or platform-support deprecations in Secret Server.

- Internet Explorer 11. Support for Internet Explorer 11 ends on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI. The Classic UI option in Secret Server is scheduled to be removed in Q1 2022. After that time, the New UI will be the only available UI option in Secret Server.

Secret Server: 10.9.000064 Release Notes

> 10.9.000065 is a retroactive patch for this release. Please see "Secret Server 11.7.000001 Release Notes" on page 1692 for details.

Release date:

- April 13, 2021 (on-premises version)
- April 3 - May 15th, 2021. Release date is dependent on region (cloud version)

Important: These notes cover the General Availability release of version 10.9.000064. The general release is not till April 13, 2021 for the on-premises version and between April 3rd and May 15th 2021, depending on region, for the cloud version. If you are not part of the early release program, or are in a Secret Server Cloud region that has not yet received the 10.9.00064 release, please use the "Secret Server: 10.9.000005/33 Release Notes" on page 1906 notes instead.

Updates:

- April 3rd: 10.9.000064 released to Secret Server Cloud in the Canada and Southeast Asia regions. Secret Server
- April 10th: 10.9.000064 released to Secret Server Cloud in the Australia region.
- April 13th: 10.9.000064 On-Premises is released.
- April 24th: 10.9.000064 released to half of the United States region customers.

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

Upgrade Notes

Delinea encourages all customers to upgrade at the earliest opportunity.

New Features and Enhancements

SSH Command Blocklisting

SSH command blocklisting allows administrators to configure lists of commands that a user may not enter during a proxied SSH session.

Pre-Check-in Pipeline Trigger

An additional trigger condition is available for secret event policy pipelines. Pre-check-in triggers apply when a secret check in is requested, before the check in occurs. The trigger can stop the pipeline with an error message or run commands.

Configuration Management

Configuration management adds export and import of Secret Server configuration settings.

This facilitates transferring configurations from test to production environments. It also makes setup and configuration of new Secret Server instances easier for customers and partners with multiple installations.

Timeouts for Tiered Workflow

Workflow templates have new timeout configuration options. They allow a workflow to automatically advance to the next step if insufficient responses are received during a configurable period.

Selectable Workflow Steps

Workflow approvals now allow an administrator to choose the next action when a step of the workflow is approved. Available actions are:

- Approving the entire workflow, disregarding any later steps
- Moving to the next step of the workflow
- Moving to a later step in the workflow

CSV Scheduled Reports

Scheduled report configuration now includes the option to attach the report to the scheduled email in a spreadsheet-friendly comma-separated value (CSV) file.

User Interface

- Migrated to an Angular framework which better supports usability and accessibility.
- Left navigation menu is now a menu role, which helps accessibility and quickens keyboard navigation.
- Updated color palette for accessibility.
- Updated numerous buttons and links that were previously inaccessible with keyboard to improve keyboard navigation and accessibility.
- Fixed an issue that caused selection and drop-down components to clip behind scrollable elements.
- Improved labeling and tool tips for Connection Manager configuration.

- Added a column in the new UI for admins in the users grid for 2FA. The same was added to API user search results.
- The secret detail side menu now stays present in the UI after navigating away from secret.

General

- Added user-defined metadata sections and field values on users, groups, folders, or secrets.
- Updated and expanded the "custom launcher arguments" field character limit to prevent impact on scripted launchers.
- Added a redirect service to direct Secret Server internal hyperlink traffic to the updated Delinea documentation portal.
- Clarified the heartbeat status message on the secret page.
- Added additional license key support for the Privilege Manager Unix/Linux Server.
- Improved user data entry input security during Connect As sessions.

Bug Fixes

API

- Fixed an issue when creating workflow steps due to the template step stub not being available for the configuration object.
- Fixed an issue returning a 500 error when getting the triggers for an event pipeline (`/api/v1/event-pipeline/{id}/trigger`).
- Corrected the documentation on the endpoint for OAuth to obtain a refresh token.
- Corrected the documentation to properly cite that a description is required for ReportCreateArgs to create reports.

Heartbeat and RPC

- Fixed an issue with heartbeat on an AD Sync that prompted an exception.
- Fixed an issue where the test action of SSH RPC configuration could not handle a dollar sign as the first character of the password.
- Fixed an issue with a RPC and heartbeat PowerShell script that failed when a privileged account lacked additional permissions.
- Fixed an issue that caused RPC to have "invalid" failures if values in the password changer were blank, even though the fields were not mandatory according to the configuration.

SSH Terminal

- Fixed an issue where the SSH terminal did not honor host restrictions for secret launches.
- Fixed an issue where SSH command menu commands through the SSH terminal did not reset the SSH proxy's timer, causing an inactivity timeout.

- Fixed an issue where the UI component for the SSH terminal blocklist settings was not visible when the SSH terminal setting was set to "No."
- Fixed an issue that locked Secret Server user accounts when Unix connections to SSH terminal were made with a keypair and no passphrase. Authentication prompts are determined by Secret Server > Admin > Config > Login > Enable SSH Key Integration (for SSH terminal). If this check box is left unchecked (assuming SSH proxy and terminal are enabled), the user is prompted for a password after trying to SSH into Secret Server. If the box is checked, no attempts to log on with a private key are allowed if "Password Only" is selected. If one of the three other Unix authentication methods are selected, the private key is attempted first (or exclusively, in the case of "Public Key Only").

User Interface

- Fixed an issue where the UI would freeze when attempting to edit the manual host range on the discovery scanners page.
- Fixed an issue where in the UI it did not properly display a site after being disabled from a discovery source on a domain.
- Fixed an issue where the UI would not automatically adjust to display scrolling in modal windows.
- Fixed an issue in the new UI where moving a folder would not correctly inherit the new parent folder's permissions as displayed.
- Fixed an issue in the new UI where a validation error was not displayed when a folder was moved to a folder containing a folder of the same name. The fix provides an error message to notify the user and allows the user to pick a new destination.
- Fixed an issue in the new UI where a group search was not restricted by owner.
- Fixed an issue with the RPC's associated secrets table hiding columns after a column was resized beyond the workspace.

General

- Fixed an issue impacting proper display of last login record in audits for OpenID Connect.
- Fixed an issue that could cause discovery logs to take longer than usual to load and display.
- Fixed an issue in Active Directory domain settings that caused the synchronization secret to revert to a previous entry.
- Fixed an issue that prevented using some identifiers on the distinguished name in directory services. Added a base distinguished name code in the LDAP field configuration to ensure some identifiers do not cause an error.
- Fixed an issue for Okta SAML login failures due to accounts being re-enabled.
- Fixed an issue for RDP proxying where the remote host name was not being passed to the protocol handler for the RDP client to display.
- Fixed an issue where additional DLL files were removed when a distributed engine was upgraded. A data directory "ignore list" file was added to list files that shall not be deleted during the upgrade process.
- Fixed an issue that prevented a secret's security settings from being edited when an event pipeline policy was set through a secret policy.

- Fixed an issue that prompted a file upload error on a folder when attempting to attach a file. This occurred when the folder included a secret policy with an event pipeline policy.
- Fixed an issue with protocol handler where an encoder was initializing even if session recording was disabled. Now the encoder is loaded only if screenshots are taken.
- Fixed an issue with the C# SDK returning a null after the cache has expired for CacheThenServerAllowExpired.
- Fixed an issue that could prevent users from logging in using SAML.
- Fixed an issue in the new UI that prevented domain selection when creating a new user.
- Fixed an issue where the site connector for a local site would not accept changes to the configuration in the UI. This only applied to system sites.
- Fixed a permissions issue that occurred when enabling "view requires edit" on a password field that caused a user with only view permissions on a secret to no longer view the one-time password.
- Fixed an issue with the SAML log on workflow that caused an invalid login page redirection loop with OpenID Connect.
- Fixed an issue when using the move folder command causing removal of secret policy settings and inherit permissions.
- Fixed an issue with SDK client management in client onboarding improperly displaying disabled application accounts when editing a user.
- Fixed an issue with session recording the caused inactivity timeouts when activity timeout was not enabled.
- Fixed an issue that caused SMTP send failures when the mail server was configured for implicit SSL.
- Fixed an issue affecting 2FA login when OATH was not properly configured for the user. Log on now redirects to an error page with indication of the configuration issue.
- Fixed an issue when disabled users were removed from local groups when new members were added to the group.
- Fixed an issue where browsers can become unresponsive when producing long-running reports.
- Fixed an issue where Secret Server was not sending metadata to PBA when assigned to a site with a distributed engine, preventing SSO.
- Fixed an issue where a permissions error is incorrectly prompted when setting a favorite folder.
- Fixed an issue with SecureBlackbox TISSHClient not being compatible with -etm MAC algorithms. An update for SecureBlackbox has resolved this.
- Fixed an issue where in SSC where the SSH proxy port was not being accepted.
- Fixed an issue in 10.9 Upgrade where SQL was missing the DBO schema when creating the table tbEngineServerCapabilties, producing an "object not found" error when verifying the deltas.
- Fixed an intermittent issue causing an error when using RDP proxy session recording with keystroke recording enabled. The error was intermittent based on which engine handled the connection.
- Fixed an issue where custom logos set in Secret Server did not display correctly caused by browser-level caching.
- Fixed an issue where secrets were not checking in after the launcher is closed while using RDP proxy.

- Fixed an issue where setting the "Allow Duplicate Secret Names" permission option to "No" caused a bulk delete action to produce an error.

Fixes made since Early Adopter Version 10.9.000063

- Fixed an issue where execution times were longer than expected (waiting for a full timeout) for SSH scripts via the password changers (heartbeat and RPC), discovery, or checkin and checkout hooks.
- Fixed an issue in the Early Adopter 10.9.000063 version where possible memory leaks could occur.

Pending Deprecations

This section describes planned feature or platform-support deprecations in Secret Server.

- Internet Explorer 11: Support for Internet Explorer 11 will end on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI: The Classic UI option in Secret Server is scheduled for removal in Q1 2022. After the announced date, the New UI will be the only on in Secret Server.

Secret Server: 10.9.000063 Release Notes

Release date:

- March 23, 2021 (On-Premise Early Adopter)
- April 13, 2021 (On-Premises)
- April 3 to May 15, 2021 (Cloud–depends on region)

Important: These notes cover the Early Adopter version 10.9.000063. The general availability release is not till April 13, 2021 for the on-premises version and between April 3rd and May 15th 2021, depending on region, for the cloud version. If you are not part of the early release program, please use the "Secret Server: 10.9.000005/33 Release Notes" on page 1906 notes instead.

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

Upgrade Notes

Delinea encourages all customers to upgrade at the earliest opportunity.

New Features and Enhancements

SSH Command Blocklisting

SSH command blocklisting allows administrators to configure lists of commands that a user may not enter during a proxied SSH session.

Pre-Check-in Pipeline Trigger

An additional trigger condition is available for secret event policy pipelines. Pre-check-in triggers apply when a secret check in is requested, before the check in occurs. The trigger can stop the pipeline with an error message or run commands.

Configuration Management

Configuration management adds export and import of Secret Server configuration settings.

This facilitates transferring configurations from test to production environments. It also makes setup and configuration of new Secret Server instances easier for customers and partners with multiple installations.

Timeouts for Tiered Workflow

Workflow templates have new timeout configuration options. They allow a workflow to automatically advance to the next step if insufficient responses are received during a configurable period.

Selectable Workflow Steps

Workflow approvals now allow an administrator to choose the next action when a step of the workflow is approved. Available actions are:

- Approving the entire workflow, disregarding any later steps
- Moving to the next step of the workflow
- Moving to a later step in the workflow

CSV Scheduled Reports

Scheduled report configuration now includes the option to attach the report to the scheduled email in a spreadsheet-friendly comma-separated value (CSV) file.

User Interface

- Migrated to an Angular framework which better supports usability and accessibility.
- Left navigation menu is now a menu role, which helps accessibility and quickens keyboard navigation.
- Updated color palette for accessibility.
- Updated numerous buttons and links that were previously inaccessible with keyboard to improve keyboard navigation and accessibility.
- Fixed an issue that caused selection and drop-down components to clip behind scrollable elements.
- Improved labeling and tool tips for Connection Manager configuration.

- Added a column in the new UI for admins in the users grid for 2FA. The same was added to API user search results.
- The secret detail side menu now stays present in the UI after navigating away from secret.

General

- Added user-defined metadata sections and field values on users, groups, folders, or secrets.
- Updated and expanded the "custom launcher arguments" field character limit to prevent impact on scripted launchers.
- Added a redirect service to direct Secret Server internal hyperlink traffic to the updated Delinea documentation portal.
- Clarified the heartbeat status message on the secret page.
- Added additional license key support for the Privilege Manager Unix/Linux Server.
- Improved user data entry input security during Connect As sessions.

Bug Fixes

API

- Fixed an issue when creating workflow steps due to the template step stub not being available for the configuration object.
- Fixed an issue returning a 500 error when getting the triggers for an event pipeline (`/api/v1/event-pipeline/{id}/trigger`).
- Corrected the documentation on the endpoint for OAuth to obtain a refresh token.
- Corrected the documentation to properly cite that a description is required for ReportCreateArgs to create reports.

Heartbeat and RPC

- Fixed an issue with heartbeat on an AD Sync that prompted an exception.
- Fixed an issue where the test action of SSH RPC configuration could not handle a dollar sign as the first character of the password.
- Fixed an issue with a RPC and heartbeat PowerShell script that failed when a privileged account lacked additional permissions.
- Fixed an issue that caused RPC to have "invalid" failures if values in the password changer were blank, even though the fields were not mandatory according to the configuration.

SSH Terminal

- Fixed an issue where the SSH terminal did not honor host restrictions for secret launches.
- Fixed an issue where SSH command menu commands through the SSH terminal did not reset the SSH proxy's timer, causing an inactivity timeout.

- Fixed an issue where the UI component for the SSH terminal blocklist settings was not visible when the SSH terminal setting was set to "No."
- Fixed an issue that locked Secret Server user accounts when Unix connections to SSH terminal were made with a keypair and no passphrase. Authentication prompts are determined by Secret Server > Admin > Config > Login > Enable SSH Key Integration (for SSH terminal). If this check box is left unchecked (assuming SSH proxy and terminal are enabled), the user is prompted for a password after trying to SSH into Secret Server. If the box is checked, no attempts to log on with a private key are allowed if "Password Only" is selected. If one of the three other Unix authentication methods are selected, the private key is attempted first (or exclusively, in the case of "Public Key Only").

User Interface

- Fixed an issue where the UI would freeze when attempting to edit the manual host range on the discovery scanners page.
- Fixed an issue where in the UI it did not properly display a site after being disabled from a discovery source on a domain.
- Fixed an issue where the UI would not automatically adjust to display scrolling in modal windows.
- Fixed an issue in the new UI where moving a folder would not correctly inherit the new parent folder's permissions as displayed.
- Fixed an issue in the new UI where a validation error was not displayed when a folder was moved to a folder containing a folder of the same name. The fix provides an error message to notify the user and allows the user to pick a new destination.
- Fixed an issue in the new UI where a group search was not restricted by owner.
- Fixed an issue with the RPC's associated secrets table hiding columns after a column was resized beyond the workspace.

General

- Fixed an issue impacting proper display of last login record in audits for OpenID Connect.
- Fixed an issue that could cause discovery logs to take longer than usual to load and display.
- Fixed an issue in Active Directory domain settings that caused the synchronization secret to revert to a previous entry.
- Fixed an issue that prevented using some identifiers on the distinguished name in directory services. Added a base distinguished name code in the LDAP field configuration to ensure some identifiers do not cause an error.
- Fixed an issue for Okta SAML login failures due to accounts being re-enabled.
- Fixed an issue for RDP proxying where the remote host name was not being passed to the protocol handler for the RDP client to display.
- Fixed an issue where additional DLL files were removed when a distributed engine was upgraded. A data directory "ignore list" file was added to list files that shall not be deleted during the upgrade process.
- Fixed an issue that prevented a secret's security settings from being edited when an event pipeline policy was set through a secret policy.

- Fixed an issue that prompted a file upload error on a folder when attempting to attach a file. This occurred when the folder included a secret policy with an event pipeline policy.
- Fixed an issue with protocol handler where an encoder was initializing even if session recording was disabled. Now the encoder is loaded only if screenshots are taken.
- Fixed an issue with the C# SDK returning a null after the cache has expired for CacheThenServerAllowExpired.
- Fixed an issue that could prevent users from logging in using SAML.
- Fixed an issue in the new UI that prevented domain selection when creating a new user.
- Fixed an issue where the site connector for a local site would not accept changes to the configuration in the UI. This only applied to system sites.
- Fixed a permissions issue that occurred when enabling "view requires edit" on a password field that caused a user with only view permissions on a secret to no longer view the one-time password.
- Fixed an issue with the SAML log on workflow that caused an invalid login page redirection loop with OpenID Connect.
- Fixed an issue when using the move folder command causing removal of secret policy settings and inherit permissions.
- Fixed an issue with SDK client management in client onboarding improperly displaying disabled application accounts when editing a user.
- Fixed an issue with session recording the caused inactivity timeouts when activity timeout was not enabled.
- Fixed an issue that caused SMTP send failures when the mail server was configured for implicit SSL.
- Fixed an issue affecting 2FA login when OATH was not properly configured for the user. Log on now redirects to an error page with indication of the configuration issue.
- Fixed an issue when disabled users were removed from local groups when new members were added to the group.
- Fixed an issue where browsers can become unresponsive when producing long-running reports.
- Fixed an issue where Secret Server was not sending metadata to PBA when assigned to a site with a distributed engine, preventing SSO.
- Fixed an issue where a permissions error is incorrectly prompted when setting a favorite folder.
- Fixed an issue with SecureBlackbox TISSHClient not being compatible with -etm MAC algorithms. An update for SecureBlackbox has resolved this.
- Fixed an issue where in SSC where the SSH proxy port was not being accepted.
- Fixed an issue in 10.9 Upgrade where SQL was missing the DBO schema when creating the table tbEngineServerCapabilties, producing an "object not found" error when verifying the deltas.
- Fixed an intermittent issue causing an error when using RDP proxy session recording with keystroke recording enabled. The error was intermittent based on which engine handled the connection.
- Fixed an issue where custom logos set in Secret Server did not display correctly caused by browser-level caching.
- Fixed an issue where secrets were not checking in after the launcher is closed while using RDP proxy.

- Fixed an issue where setting the "Allow Duplicate Secret Names" permission option to "No" caused a bulk delete action to produce an error.

Pending Deprecations

This section describes planned feature or platform-support deprecations in Secret Server.

- Internet Explorer 11: Support for Internet Explorer 11 will end on 31 August 2021. Secret Server releases after that date will not support Internet Explorer 11.
- Secret Server Classic UI: The Classic UI option in Secret Server is scheduled for removal in Q1 2022. After the announced date, the New UI will be the only on in Secret Server.

Secret Server: 10.9.000005/33 Release Notes

Release date:

- December 14, 2020 (on-premises version)
- December 12, 2020 (cloud version)

Important: If you installed Secret Server as your default or top-level website and you have Privilege Manager (PM) and Secret Server installed together, you may experience the following issues after upgrading to .NET Framework 4.8:

- PM agents will not register.
- When a PM agent updates itself (using the agent utility), it states that there are zero policies to download.

If you believe this scenario applies to you, please contact Delinea Support **before** performing a .NET, Secret Server, or PM upgrade.

Important: This release corrects a critical issue discovered in Secret Server version 10.9.000032. Delinea encourages all customers to upgrade any 10.9.00032 installations to 10.9.000033 as soon as possible. For more information, including remediation (if you have been affected), see the "Secret Server: 10.9.000005/32 Release Notes" on page 1912.

Note: All the original release notes for 10.9.000032 have been moved here for convenience and clarity.

Upgrade Notes

Delinea encourages all customers to upgrade at the earliest opportunity.

Note: This version of Secret Server uses a two-step upgrade. See Secret Server: 10.9.000005/33 Release Notes.

New Features and Enhancements

HSM Key Rotation

This feature enables customers using a Hardware Security Module (HSM) to rotate their root encryption key. Secret Server supports using an HSM to store the root encryption key for all data in the Secret Server database. Some customers have security policies requiring rotation of all encryption keys. Until now this was a manual process.

DSV Integration: SSH Key Synchronization

Further enhancing the integration between DevOps Secrets Vault (DSV) and Secret Server, the integration now supports customers using DSV to provide PAM services to their DevOps teams. DevOps teams may use SSH keys to access portions of their infrastructure.

SSH Key Authentication to SSH Terminal

SSH terminal in Secret Server provides SSH access for users who do not want to use the Secret Server UI. This is particularly useful for Linux users. These users commonly use SSH keys to authenticate to servers and services. Providing SSH key authentication to SSH terminal allows them to continue to use their preferred access tools with Secret Server.

User Interface

- Secret Server now uses the terms allowlist and denylist. See Delinea shifts the language used in products and materials to promote inclusivity.
- New content has been added to "empty" user interface pages to explain initial actions to be taken by new users to streamline the onboarding experience. There is now more information about what they are able to do with helpful links to the knowledge base and corresponding technical documentation, giving them more confidence as they navigate Secret Server for the first time.
- Ongoing new user interface updates include pages such as User Management, Login, Reports, and Distributed Engine configuration.

General

- Added the ability to trigger event pipelines on the heartbeat UnableToConnect status. This feature adds a new advanced configuration setting, "Heartbeat: Include UnableToConnect as Heartbeat Failure Event". When toggled to true, this setting allows a user to include UnableToConnect as part of the heartbeat failure event subscriptions. It defaults to false.
- Improved handling of site-based requests in relation to heartbeats and remote password changer.
- Secret Server now integrates with Slack, allowing for notifications and workflow handling. This includes approval requests, recently used secret notifications, and launching secrets.

Security

- Added protection against malicious remote code execution through CEF log file tampering.

  Note: Only applies to Secret Server on-premise.
- Added protection against malicious argument injection in SSH launcher.

API

- Fixed an issue to properly display API_AccessDenied as a 403-error code.
- Updated error handling and prompts when editing a group via Active Directory sync. The error for the add has been changed to API_CannotAddRemoveUsersFromDirectoryManagedGroups for clarity. The remove has also

been updated to throw that error when the group is from AD sync.

- Created the following new endpoints:
  - Distributed engine
  - Dual controls
  - Report schedule
  - Secret policy search
  - Slack
  - Ticket System
  - User and group management

Integrations

- Fixed an issue with ServiceNow validation that caused tickets in "Active" status to fail validation. Added an active status to the default allowed statues for ServiceNow. This auto-populates when ServiceNow is setup.
- Fixed an issue when creating a ServiceNow ticket without a secret caused a failure. The system now validates the secret field being required before proceeding.

Protocol Handler

Protocol handler is updated for this release. Added Secret Server protocol handler administrative settings that you can configure through Microsoft's Group Policy Objects (GPOs) or through Secret Server itself. One setting controls which domains, URLs, or IP addresses the protocol handler installation may connect to. The other setting ensures protocol handler will never auto-update itself, even if told to by the Secret Server installation that it connects to.

Bug Fixes

- Fixed an issue causing duplication of tbOAuthExpiration. Added process that deletes a tbOAuthExpiration object if one was created earlier in the same request and another one is about to be created.
- Fixed an issue where the date format displays incorrectly according to the date preference set by the user.
- Fixed an issue in RPC where a space in the character set fails PowerShell password changes. We now enclose all parameters that go to the PowerShell Password Changer in double quotes.
- Fixed an issue preventing authentication to VMware with API via PowerShell. All fields of associated secrets are available in RPC scripts now.
- Fixed an issue causing the discovery start time to increase after each interval based on extending completion times. Changed the logic for both discovery and computer scan to run based upon the start date and not run if a scan is in process.
- Fixed an issue with UNIX discovery search filter not matching the machine scanner. Modified a tool tip indicating that $machine filters cannot be used with host range and machine scanners.
- Fixed a script issue for ParseDataItems not handling edge case—System.NullReferenceException: Object reference not set to an instance of an object. Added a null check for the return object in ParseDataItems.
- Fixed an event subscription issue where the engine offline email alert was not being sent.

- Fixed an issue for SSH-proxied secret's audit log where no results are displayed when selecting "Show Proxy Credentials."
- Fixed an issue for RDP-proxied secret's audit log where no results are displayed when selecting "Show Proxy Credentials."
- Fixed an issue that when navigating manually to an enabled secret from a deleted secret erroneously retained the deleted banner.
- Fixed an issue where users are not automatically re-enabled while using "Automatic User Management" with SAML.
- Fixed an issue that caused inability to bulk assign privileged accounts for Unix secrets. Added new "Update Associated Secrets" bulk operation which sets the associated secret list on any selected secrets.
- Fixed an issue where the folder search was not functioning when importing accounts to a folder.
- Fixed an issue causing Oracle scripts to not execute successfully on remote distributed engine.
- Fixed an issue with the left navigation folder tree navigation causing the horizontal scroll to function incorrectly.
- Fixed an issue with Office 365 and Azure AD causing a wrong heartbeat status code and preventing consecutive attempts. Added code to differentiate authentication errors coming back from Office 365 from other errors. Authentication Errors will continue to create a "LoginFailed" error on the result while all other errors will generate "UnableToConnect".
- Fixed an issue where the user is unable to see the "Check In" button when browser is maximized.
- Fixed an issue that caused ClickOnce and protocol handler PuTTY to not load default session logging location.
- Fixed an issue that may crash the Web interface when a dependency forces check-in, prompting error "Global Catch: Secret requires checkout."
- Fixed an issue when adding parameters to SSH scripts where the dependencies are not updated to reflect the changes that are made. When populating the dependency details modal, a check is made to ensure the script's parameters match the parameters in its definition.
- Investigated an issue when RDP proxy is enabled causing a connection issue with using NTLMv1. NTLMv2 is required and is the default on Windows Server 2008 and later.
- Fixed an issue where database integrity monitoring sent false-positive alert emails for database rows changed by Secret Server.
- Fixed an issue where NULL NetBIOSName breaks IWA and causes spurious IP connections. The fix adds a step during the login process, specifically along the IWA path, that checks if the domain about to be checked has a NetBIOSName and, if not, fills it in.
- Fixed an issue in the UI with the drop-down menu with a predefined URL field values for secret template when creating a new secret.
- Fixed an issue in the UI where the incorrect folder menu was displayed on the favorites page.
- Fix issue where custom discovery account scanners that had "organizational unit" as their input where changed to "computer" if the scanner was updated.
- Fixed an issue when setting up a domain on a site that uses DE processing breaking Windows Authentication for that domain.

- Fixed an issue where the error message would not show for GCP and AWS scanner when the selected secret did not have a mapped password changer.
- Fixed an issue in the UI where "days until expiration" showed "expired" instead of a negative number to indicate time since expiration was met.
- Fixed an issue in the UI where the selected columns are only saved per folder, rather than across all folders. An "apply as default" check box was added to the column selector for folders. This allows the user to set up a default column setting for folder columns. It will be used when the columns are not set on a specific folder.
- Fixed an issue with live session viewing affecting Secret Server version 10.9.
- Fixed an issue where Connection Manager was not getting redirected to "get token" page when logged in with SAML.
- Fixed an issue that displayed an incorrect status message is displayed along with the error message. The "password verify was successful" message is no longer displayed along with the error message while checking heartbeat for invalid Active Directory password changes.
- Fixed an issue where the login screen was not remembering the last selected domain despite default login being set to "last selected."
- Fixed an issue with database integrity monitoring service Tablesnapshot exceptions not being handled.
- Fixed an issue where SSH proxy could fail and require a DE restart.
- Fixed an issue when saving an Active Directory domain, a 500 error on POST was prompted.
- Fixed an issue in the UI when using Internet Explorer that prevented adding a privilege account in a secret policy.
- Fixed a bug that was preventing searches on partial URLs from matching the secrets containing the partial URL. All parts of the URL host name, as well as any specified port, path, and query string are now parsed into terms according the indexing separators and are fully searchable in the UI and REST API.
- Fixed an issue where the "expire all secrets" and "delete all secrets" buttons were not present in reports in the new UI.
- Fixed an issue in the classic UI where a secret's URL path capitalization was being displayed incorrectly.
- Fixed an issue assigning a password on the secret if a username has consecutive special characters, such as `./` or `-_`.
- Fixed an issue that allowed local Secret Server users to log in without a synchronization group to Azure AD.
- Fixed an issue that prevented OUs from being added to the discovery scope with a message indicating the OU was already included due to its parent, which was invalid.
- Fixed an issue with updating associated dependencies when converting a secret template of a privileged account.
- Fixed an issue where a password change on RPC stays in pending status after meeting the retry threshold. We updated RPC functionality to stop the RPC, fix the RPC button to allow retry, and removed the pending password banner when the max attempts were reached.
- Fixed an issue with database integrity monitor not adding a separator for AggregateKey.

- Fixed a bug in extended search indexing that did not index all parts of the URL field, causing searches that contained non-indexed text to not return matches.
- Fixed a timing issue with Active Directory sync when processing results on a "synchronization now" event for groups.
- Fixed an issue where undeleting a secret did not honor the setting to not allow duplicate names.
- Fixed an issue where enabling proxy setting was not available in the secret policy with RDP proxy.
- Fixed an issue where OU exclusion does not allow different credentials underneath included a domain-specific OU.
- Fixed an issue with dependency bulk operations failing to run on privileged secrets.
- Fixed an issue with downloading system logs from the UI only listing what was shown in the UI. Implemented record ranges for all grids that implement the paging interface.
- Fixed an issue that caused an error when protocol handler MSI 6.0.0.33 did not overwrite the sslauncher registry key.
- Fixed an issue that prevented running a custom report in the UI.
- Fixed an issue where "view next password" was triggered when showing current password in the audit UI.
- Fixed an error when adding many groups or users to the folder permissions and saving.
- Fixed a permission to "view scanners link" in the menu UI.
- Fixed an issue when creating a secret in the UI it did not honor the default field values changed by the secret template.
- Resolved an issue that prevented RDP connections with non-standard port numbers when connecting via an SSH tunnel.
- Fixed an issue where scheduled task dependencies were disabled after an RPC on Windows Server 2008 R2 and 2012 R2.

Secret Server Cloud

Note: The following only apply to Secret Server Cloud (SSC). Other issues and features are assumed to affect both on-premises and cloud unless otherwise noted.

Azure ServiceBus Transport Type Setting

We added a new cloud-only setting called "Azure Service Bus Transport Type" in the global engine settings. This defaults to "Web Sockets," so the outbound port for engines communicating with SSC will only use port 443. Customers may change the setting to "AMQP," which changes the outbound ports to 5671 and 5672.

Other Issues

- Resolved an issue with Delinea One user synchronization.
- Resolved an issue that could cause repeated errors when accessing the OTP value for a secret.
- Changed some log entry types to warnings instead of errors.

- Fixed a bug that caused a SQL "incorrect parameter order" error when more than 2000 secrets were processed by RPC.

Known Issues

Important: If you encounter any of these known issues, please contact Delinea Support for assistance.

Note: These issues no longer apply to Secret Server Cloud as of December 19th.

- When used with Connection Manager, secrets that have a configured allow list for server connections will not display the allow list in the Connection Manager UI. This issue will be resolved in Connection Manager 1.4, scheduled for release on Dec 15, 2020.
- Secret Server on-premises installations may experience memory leak issues, which can be remedied by performing an IIS reset or application pool recycle.
- When creating a new user, the ability to select a domain is not displayed.
- The site connector for a local site cannot be changed in the UI. A workaround is possible via a manual edit in tbSite.
- Users configured for SAML are not correctly directed to the SAML login page when attempting to log in. Users will have to select "Local Login". This also applies to users that have MFA enabled in Secret Server–the user is incorrectly redirected after SAML login.
- SAML messages may not contain a necessary attribute, preventing users from successfully logging in via SAML. An available workaround is to select "Disable InResponseTo Check" in the Identity Provider settings of SS.
- Users with view permissions can no longer see generated OTP codes on secrets.

Secret Server: 10.9.000005/32 Release Notes

Release date:

- December 8, 2020 (on-premises version)

Critical Issue–Please Update to 10.9.000033 As Soon As Possible

We discovered a critical issue in Secret Server version 10.9.000032 shortly after releasing it. We encourage you to update to 10.9.000033 as soon as possible.

Important: If you have been affected by this issue, you may need to take corrective action in addition to updating. Please see below.

> **Note:** All the original notes for 10.9.000032, all of which still apply, appear in the "Secret Server: 10.9.000005/33 Release Notes" on page 1906.

Specifics appear below:

Issue

The issue occurs when managing local groups, users or roles in the User Management section of the New UI. This affects pages with URLs starting with `https://<Secret Server>/app/#/admin/user-management/...` When

editing lists, the number of items in the list is erroneously limited to the number displayed in the UI. If the list previously contained additional items, they are removed when the list is edited.

Impact Examples

- When editing a local group, the number of users in the group is limited to 30.
- When editing the roles assigned to a group, the list of roles is limited to 30.
- When editing the roles assignments for a user, the list of roles is limited to 10.
- When editing the group memberships for a user, the list of groups is limited to 30.
- When filtering a group member list by domain and then editing the members, the member list only shows the filtered domain members, hiding the members from other domains.

Workarounds

If you cannot immediately update to 10.9.000033 or you have already been affected by the issue, please use the classic user interface when making changes to group membership, role assignment, or editing user roles or groups.

Secret Server 10.9.000032 automatically redirects attempts to edit users in the classic UI to the new UI, so you must directly navigate to the user management page by going to `https://<Secret Server>/users.aspx?legacyui=true` to edit them.

Versions Affected

Secret Server 10.9.000032 is affected.

Secret Server Cloud trials and new instances provisioned on or after 10 December 2020 are affected. Instances provisioned before 10 December 2020 are not affected.

Resolution

Customers impacted by this issue must manually restore their group and role assignments. Secret Server audit logs contain the required recovery information, such as which users were removed from a group. Use the classic UI (via the above mentioned URL) for doing this.

Notes

We removed Secret Server 10.9.000032 from our download sites.

Secret Server: 10.9.000002 Release Notes

September 22, 2020

Note: The system requirements last changed with version 10.7.000000. See Secret Server: 10.9.000002 Release Notes for details.

Upgrade Notes

Delinea encourages all customers to upgrade at the earliest opportunity.

Security

Security update to resolve a SQL injection vulnerability that an authenticated administrative user could exploit to achieve remote code execution on the Secret Server host system.

Common Vulnerability Scoring System (CVSS) v3.1 score: 8.0 (High).

CVSS v3.1 Vector AV:N/AC:H/PR:H/UI:N/S:C/C:H/I:H/A:H

Secret Server Cloud has been updated to include this security fix.

New Features and Enhancements

None

Bug Fixes

The following bug fixes apply to non-cloud Secret Server only. Secret Server Cloud has not been updated to include these fixes.

- Fix to Discovery rules to correctly handle OUs with bracketed names.
- Secret names in reports are now links to the corresponding secret.
- Logout from Secret Server no longer sends the `Clear-Site-Data` header, which could previously log users out of unrelated Web applications.
- SSH connections via SSH proxy now close correctly.
- Fixed an SSH proxy connection timeout when connecting via a distributed engine.

Secret Server: 10.9.000000 Release Notes

August 7-9, 2020

> **Note:** The system requirements last changed with version 10.7.000000. See Secret Server: 10.9.000000 Release Notes for details.

Upgrade Notes

- Delinea encourages all customers to upgrade at the earliest opportunity.
- Secret Server now requires .NET 4.8 or later.

New Features and Enhancements

Alerts, Events, and Logging

- Added an event subscription for when a backup event fails or another exception is encountered.
- Changed log-level messaging in ClientToServerConnection to improve supportability.

API and Scripting

Added a parameter for an API endpoint to identify inactive users that may be members of a given group.

Authentication and Encryption

- Added validators to prevent passwords using keyboard sequences and patterns, dictionary words, and usernames.
- Added configuration setting to define the length of time to which users are locked out of Secret Server after the maximum login failure configuration setting is met.
- Created a more user-friendly experience when entering Time-Based One-Time Passwords (TOTP) generation keys.
- Added a password display option when viewing secrets using SSH Terminal.

Azure AD Synchronization

You can now synchronize users and groups in Secret Server with user and groups in an Azure AD. Does not require an on-premises AD for synchronization.

Connection Manager

Replaced the MacOS protocol handler. Secret Server no longer includes a MacOS version of the protocol handler for session launching. Instead, the Connection Manager free version is packaged with Secret Server for MacOS users.

DevOps Secrets Vault Integration

Added integration to allow Secret Server to create secrets in DSV and periodically push updates to those secrets. This allows customers to use DSV for fast API access and CI or CD pipeline integration while benefiting from the additional capabilities of Secret Server, such as credential rotation.

Discovery

- Updated discovery of scheduled tasks to no longer require Windows version compatibility between target and Secret Server's machine Windows version.
- Updated scriptable discovery to match all parameters to any field of a secret.
- Discovery can now be performed on AWS instances. This allows for OUs to be pulled from the AWS region scanner, machine detection from AWS Windows machine scanner, and machine detection from AWS SSH machine scanner.

Event Pipelines for Groups

Added triggers, filters, and tasks for group events to event policy pipelines.

Google Cloud Discovery

Note: GCP account and instance discovery requires that projects belong to an organization.

Implemented discovery across Google Cloud infrastructure including:

- Discovery and password changing of IAM service account users
- Discovery of instances associated to the projects

- Heartbeat and password changing of Google Cloud Platform (GCP) service accounts
- Token rotation for GCP service accounts

Heartbeat

- Added two values to the Web node health check to indicate when a node is in the process of an upgrade.
- Performance improvement: Added two advanced configuration settings for heartbeat consumer distribution across multiple nodes.
- Significantly increased heartbeat and RPC message publishing rates by allowing distributing work across nodes.

Integrations

ServiceNow integration now allows users to specify the ticket statuses that are accepted by Secret Server.

Launchers

Added a "Run Launcher using SSH key" configuration setting to secret policies. The selected secret will be applied to all PuTTY launchers attached to the secret.

LDAP Synchronization

Synchronize users and groups in Secret Server with users and groups in an LDAP directory.

Performance Improvements

- Added a new advanced configuration setting for the background worker process that requires higher publish rates. Setting configures the minutes to wait for the background workers to publish the secret to the queue before retrying.
- Improved efficiency of the expire secret background runner processes.
- Created a generic pre-processor for publishing batched secret lists to background workers.
- Implemented a performance enhancement to the FQDN lookup time per domain.
- UI now caches localization files for up to one hour, saving up to five seconds when the UI initializes.

RPC

Significantly increased heartbeat and RPC message publishing rates by allowing distributing work across nodes.

Security

Added a process to find lock keys that are over an hour old and subsequently remove them from the various caches.

Session Connector

You can now record video and keystroke data for sessions that do not use Delinea components at the user's client or target server.

Note: Removing the possibility of recording at a user's client or target server means that connections must be routed through a jump host running Microsoft RDS as part of the deployed PAM infrastructure. Connection recording occurs at a jump host running Microsoft RDS and additional Delinea software.

Session Recording

Changed behavior so viewing a session recording no longer opens a new tab in the browser from the UI.

User Interface

- Enhanced the new UI to present Admin > Folders via the left navigation panel and context menus. The dedicated Folders page is no longer available in the new UI.
- Added the ability for admins to set the default view used on the Admin page.
- Backup configuration tool and page now displays in the new UI.
- Launcher tool and page now displays in the new UI.
- Indexing Service page now displays in the new UI.
- Audit tab of the Admin Group Assignment page now displays in the new UI.
- About page now displays in the new UI.
- Discovery tool now displays in the new UI.
- New UI can no longer be disabled.
- Admin page can now preserve view selection.
- Discovery is no longer directly associated with the Active Directory page in the UI. Admin > Discovery is the updated location for discovery. "Directory Services" is the retitled page to manage Active Directory domains, as well as other directory services supported by Secret Server 10.9.

Bug Fixes

Alerts, Events, and Logging

- Fixed an issue where an event subscription is not triggered when a copy to clipboard event occurs.
- Fixed an issue where event subscriptions did not send a message when a login failure occurred due to two factor authentication failure.
- Fixed a verbose logging statement to correctly list "Windows Service" rather than "Scheduled Task" for service dependency scanning.
- Fixed an issue affecting the system event log entries for when Windows Authentication is enabled in IIS but is not enabled in Secret Server.
- Fixed an issue that displayed username (PII) in event logs when a password change was aborted.
- Fixed an issue that displayed incomplete information in the system logs when showing the Windows Account Login Failure error message.
- Fixed an issue where an Event Subscription or Event Pipeline did not trigger an event when copying a password to clipboard in the UI. Trigger is modified to be Password Displayed.

API and Scripting

- Fixed an issue with the SOAP API that could add permissions when InheritPermissionsEnabled is set. The call now removes inheritance when the permissions are updated.
- Fixed an issue that caused a 400 error when attempting to activate a license using API calls.
- Fixed an issue where the API was returning a server error rather than an access denied statement when making the call without the proper role assignment.
- Secret Server Cloud: Fixed an issue causing a failure when creating a secret in a folder via REST with a Secret Policy assigned.
- Fixed an issue with the API audit record statement for a password displayed event.
- Fixed an issue with the SSH exit command not working as expected.
- Updated tokens used for SSH fields in secret template extended mappings to match tokens used by the corresponding password changer fields: `$PRIVATEKEY`, `$PUBLICKEY`, and `$PASSPHRASE`. Properties on associated secrets can be consistently referenced using these tokens, regardless of whether the fields are mapped on the associated secret's password changer or on its template's extended mappings.

Authentication and Encryption

- Fixed inconsistent login issue when using SAML and two-factor authentication.
- Fixed an issue causing 'remember me' function to fail, prompting login after closing a browser window.

Checkout

- Fixed secret check in to no longer check password compliance immediately after check in. System now sets the compliance to pending, and the next time the compliance check happens it will be updated.
- Fixed an error in the workflow template for secret checkout when the reason field contained a large amount of characters.

Database

Fixed an issue with SQL not connecting due to high frequency schedules causing a timeout. Added a retry message to assist when a lock cannot be cleared.

Discovery

- Fixed an issue where the wrong field is passed to the dependency changer when a template field has a space in its name.
- Fixed an issue where the discovery host scanner was not substituting a token from an associated secret. Now, Discovery will try to match all parameters to any field of a secret.
- Secret Server Cloud: Fixed a sorting issue in the new UI on the discovery network view.
- Fixed an issue where accounts without an OU would be processed and removed by another discovery source.
- Fixed an issue where the Discovery page displays "please wait" if the site it is set to is disabled.
- Fixed an issue where some discovery dependency scanners were unable to be deleted within a domain.

- Fixed an issue that caused stack trace on discovery pages when making a copy of a template that has an inactive RCP mapping field.

Distributed Engine and Clustering

Fixed an issue where Distributed Engine would not reestablish a new connection after encountering an exception.

Export and Import

- Fixed an issue with CSV secret import using regex name patterns that caused import failures.
- Fixed an issue with importing secret to provide a more detailed error message to reflect the Secret Server environment used.
- Fixed an issue when exporting the user list where the exported CSV file did not contain a column for DisplayName data.
- Fixed an issue when exporting personal folders for users that had the same name. The fix introduces a toggle setting in the admin configuration of folders to allow the user to change their personal folders to either their display name or username and prefix.

General

- Fixed an issue with inactivity timeout.
- Fixed an issue in diagnostics where the internet connectivity check was still performed when disabled.
- Fixed a permissions issue for assigning secret policies to folders.
- Fixed an issue that caused an error when running asynchronous calls when reading and writing to CacheClient.
- Fixed an issue with secrets where proxying was enabled on secrets when RDP proxying was disabled.
- Fixed an issue where RDP proxy did not allow custom ports. Secret Server now checks the port number as appended to the computer name and uses the supplied port, if present.
- Fixed an access error for users with "view deleted secrets" role permission when converting a secret to a different template the original secret is not deleted.
- Fixed an issue where favorited secrets could not be removed from favorites after the user's access to the secret was downgraded to "list."
- Re-posted the clipboard Utility extension for Secret Server in the Chrome Web Store after policy changes made it temporarily unavailable.
- Added a setting to support web password filler's ability to autofill on multiple login page sequences and remediate users being redirected to the wrong URL. This launcher setting, by default, will send an extra parameter in the call to assist with multiple URLs.
- Fixed a memory leak appearing when the SSH port receives too many connection attempts in a short time. A third-party code library was not properly releasing memory used during failed connection attempts. Now, when an IP address makes too many (the default is over five) connection attempts over a specified time (the default is 30 minutes), that address is automatically denylisted in the database, and future connections are denied. When this occurs, notifications appear in the Secret Server logs. The solution also prevents targeted DOS attacks on the SSH port.

Heartbeat

- Fixed an issue where users with the edit permission were unable to perform a bulk operation to enable or disable heartbeat.
- Fixed an issue that displayed a misleading error on heartbeat failure. System now returns underlying error message when custom PowerShell password changer fails instead of a generic PowerShell error message.

Integrations

- Fixed an issue that caused issue with the TwoSense integration which causes Attempt User Password to fail.
- Fixed an issue with the scheduling task for the Quartz monitor.
- Fixed an issue where the site URL was not accepted on ConnectWise configuration if using http or https on the URL.

Installation and Upgrade

Updated the installer to configure worker roles to automatically start after a restart of Secret Server or IIS.

Launchers

- Fixed an issue where a secret containing a field named "Port" does not pass the value to the launcher.
- Fixed an issue that causes the browser to crash when a secret has a process launcher associated with session recording.
- Fixed an issue with the protocol handler not recording multiple processes when using the Web UI.
- Fixed an issue where protocol handler 6.0.0.23 launched sessions stopped shortly after launch when recording was enabled.

Remote Password Changing

- Fixed an issue with RPC not changing a dependency when running as a local admin.
- Fixed an issue with RPC where background tasks in the default task scheduler met a limit on active background tasks, causing a queue for new background tasks.
- Fixed an issue affecting new installations of Secret Server 10.7—the setting for "Change Password Using Privileged Account" did not appear in the new UI.
- Fixed an issue that could cause a duplicated password change when RPC is set to only change password when secret is expired.
- Fixed an issue when using a complex set of SSH commands for executing a password change by providing additional settings to accommodate various customer command needs.
- Fixed an RPC failure caused by replication latency for large Active Directory environments. Fix provides two additional advanced password types settings that allow for delaying and bypassing verification upon successful password change.
- Fixed an issue where Azure password changing failed during verification. Added two advanced password type settings for every password changer.

Reports

Fixed a display issue with pie charts not displaying correctly when the chart needed to display a large number of unique values.

Session Recording

Fixed an issue with session recording for SSH and RDP proxied secrets.

User Interface

- Fixed an issue in the new UI where the Secret List failed to reload and show values when adding a column containing a space.
- Fixed an issue where an error was produced when navigating from the Upgrade Secret Server page to the System Log page.

Webservices

Resolved IIS header conflicts for the X-Frame-Options header.

Secret Server: 10.8.000004 Release Notes

June 8, 2020

Note: The system requirements last changed with version 10.7.000000. See Secret Server: 10.8.000004 Release Notes for details.

Upgrade Notes

- **Delinea encourages all customers to upgrade at the earliest opportunity.**
- Security advisories are under review and will be published at the end of that review process. The link to that advisory will appear here.
- Delinea thanks Jay Huang from Insomnia Security for identifying the security issues leading to this release.

Security

High Priority Security Fix

Addressed incorrect user permissions validation.

- Common Vulnerability Scoring System (CVSS) v3.1 score: 8.8 (High).
- CVSS v3.1 Vector AV:N/AC:L/PR:L/UI:N/S:U/C:H/I:H/A:H.

Additional Security Fixes

- Added Custom "URL Security Check" to the Secret Server Security Hardening report. Delinea recommends configuring the Custom URL.
- Added host and port validation when using a proxied secret.
- Remediated potential cross-site scripting vulnerability.

- Modified user access controls to limit low-privilege application user access to administrative features.
- Implemented SHA-512 hashes for the launcher, replacing an older hash algorithm.
- Removed disclosure of internal IP addresses during authentication process of proxied connections.
- Modified when cookies are set during authentication.

Secret Server: 10.8.000000 Release Notes

April 3, 2020

Note: The system requirements last changed with version 10.7.000000. See Secret Server: 10.8.000000 Release Notes for details.

Upgrade Notes

- RMQ Helper was updated to install the latest RMQ version (3.8.2). See RabbitMQ and RabbitMQ Helper documentation for more details.
- Enabled the "port scan enable" configuration by default for discovery scanners.

New Features and Enhancements

RDP Proxy

Secret Server now includes an RDP proxy that facilitates third-party session management tools without exposing connection credentials. RDP proxy also enables optional keystroke recording for an RDP session without the need for the advanced session recording agent.

Event Pipelines

- Pipelines provide event-driven process automation within Secret Server. Users and administrators can save time by creating tailored workflows which are triggered automatically by events affecting secrets within Secret Server. Pipelines can be applied broadly across Secret Server or restricted by folder, secret template, group, site, or a combination of these and other criteria. For example, a pipeline could be configured to automatically change the password on an Active Directory secret when heartbeat fails.
- Infinite loops: By default, pipelines are configured to consider any event that executes five tasks within five minutes from the same trigger as an infinite loop. For example, "secret edit" is selected as a pipeline trigger, and "remote password change" is selected as the task. After the first edit is made on a secret, an RPC is triggered. Every time the RPC completes, a new edit is triggered, which, in turn, triggers another RPC. If this happens five times within five minutes, then an infinite loop is declared. If the RPC is slow, taking more than five minutes for five password changes to occur, then an infinite loop is **not** declared. In this case, use the "configuration advanced" page to change "event pipelines infinite loop time (minutes)" to a longer time.

Session Recording

Can now record multiple windows, including child processes, when session recording. Some applications used for session management open multiple GUI windows at once or launch child processes to render the session to the user. Secret Server can now record more than the main window of the parent process to ensure all user activity during a session is captured.

Web Password Filler

Note: This section covers the release notes for Web Password Filler (WPF) version 2.0.0, which is released with Secret Server 10.8.

This release includes updates for the following web browsers:

- Chrome
- Mozilla Firefox
- Edge (Chromium version)
- Opera

Enhancements:

- Web session recording is now supported in the WPF (please see the below section on Web Session Recording).
- Improved support for the refresh token. We improved the refresh token to better support SAML-configured Secret Server environments, and the WPF is updated to use this improved token. This also makes better use of the timeout settings for the SAML token. Secret Server
- Added timing restriction to the refresh button on the "sign in as" pop-up window in the WPF. This is to limit the number of calls that can be made in a 10-second time frame from going back to Secret Server to update the list of secrets.
- Added a new feature to match URLs by exact path. This option looks at the domain value in the URL and will only list secrets that have an exact match. During Web session recording, this option exactly matches the values between `//` and the first `/` in the URL. For example, in `http://Company.Sub.Primary.Domain.TopDomain/subsite` it matches `Company.Sub.Primary.Domain.TopDomain`.
- Improved support for sites that have second-level subdomains in the URL, such as sites that have ".co.uk" or ".online.com.
- Added handling when fetching secrets from Secret Server for common second-level subdomains when filtering for applicable secrets on a website.

Bug fixes:

- Fixed an issue that returned a 500 error in the background when users tried to save a new secret (using WPF) when the new user interface is disabled in Secret Server. Secret Server.
- Fixed an issue that did not display the "Add Accounts to Secret Server" dialog if you entered credentials (that are not in a secret) into a site and try to automatically save it as a secret when "personal folders" are disabled for the Secret Server instance.
- Fixed an issue where not all folders were being returned when adding a secret, if the user had access to more than 1,000 folders.

Web Session Recording

- Added web session recording to the WPF browser extension. If a Web secret is configured for recording, WPF will now record the web session and display a recording icon at the top of the tab. Any additional Web browser tabs that are opened from that session (provided they stay on URLs that require recording) will also be recorded. All recordings will be available in Secret Server.
- If Web session recording is configured to run for a site, but the site prevents the recording icon from being placed in the browser tab's title bar, the WPF instead displays a pop-up message that the session is being recorded.

Connection Manager

Added two new settings for Connection Manager users on the Admin > Connection Manager page. Users with the "administer configuration" permission can modify these settings:

- Allow local connections
- Allow Connection Manager to save Secret Server user passwords

Note: These configuration options require Connection Manager 1.2 or later.

Integrations

- Added support for Devolutions Remote Desktop Manager integration, which allows users to retrieve passwords from Secret Server directly within Remote Desktop Manager. See https://updates.thycotic.net/secretserver/documents/SS-INTG-Devolutions.pdf. Secret Server
- Added support for WitFoo Precinct to integrate with SS, which allows users to view incident or event logs. See https://updates.thycotic.net/secretserver/documents/SS-INTG-Witfoo.pdf.

Smartcard Authentication

Added support for CAC/PIV smartcards pass-through authentication for RDP launchers.

Compliance and User Data

Personally Identifiable Information (PII) for inactive user data in Secret Server can now be anonymized to help organizations meet compliance regulations for GDPR.

Roles

- Added a new role permission, "session recording auditor," which allows a user to audit session recordings but not access the corresponding secrets.
- Added a new user role, "view secret password history," that allows users to have access to a password without granting them access to the password history. Users with edit or owner permissions on a secret who do not have this new role will be able to view and update the current secret password but will not be able to view previous passwords on the secret.

  Note: User roles that previously had the "view secret" permission will automatically gain "view secret password history" during the upgrade process.

Discovery

Added an extensible discovery "run as" privilege credential. Users can now specify a secret for the default credentials for running all PowerShell scripts on a site. This allows sites in different data centers to have different default credentials. This applies to remote password changing, checkout hooks, and discovery PowerShell scripts. If you want a specific secret checkout hook, secret password changer, or discovery scanner to use different credentials, you can still provide credentials in those areas, which take precedence over the secret set for the site. See "Discovery Overview" on page 534.

Performance Improvements

- Redesigned the "secret dependencies" page. Updates include database paging and filtering to fix page load performance issues in the new UI.
- The audit REST API was improved to increase performance when viewing the secret audit log in the new UI
- Added optimizations to improve secret search performance with very large secret sets. These include modifications to the secret list page, folder secret listings, search terms and other filters, the secret picker, and REST API endpoints. Endpoint improvements include options to not automatically count matching secrets and a method to count matching secrets rather than returning the set, both designed to remediate the overhead of secret filter set paging.

  Note: The optimizations may cause issues when upgrading, so they are not on by default. They may also cause issues with extremely long secret names (400+ characters). Please contact technical support for more information if you believe you might benefit from the optimizations.
- Altered the MS SQL Server collation used for secret name search to improve performance. As a result, secret names starting with numeric values now return before secret names starting with symbols. An advanced setting (contact Delinea Support) is available to revert this back to the original sort order at the cost of some of the performance gains.

Security

- Fixed an issue where a local user could log in to the Secret Server SSH terminal despite an expired password.
- Fixed a reflected cross-site scripting (XSS) vulnerability.
- Extended the default HSTS max age to one year and extended it to cover subdomains.
- Fixed a cross-site scripting (XSS) issue.
- Fixed an issue preventing a security header from being returned in certain locations within the application.
- Secret Server no longer allows any cross origin (CORS) calls.

API

- The rest API documentation has a new look and feel, including a table of contents.
- Added 67 new endpoints. See The "REST API Reference Download" on page 1522 for details.
- Added the ability to autogenerate API clients for PS, C#, Java, Postman, and Insomnia.
- Added PATCH API call methods, which are designed to update only values that are passed through the call. New object types include:

```
/secrets/{id}/email/secrets/{id}/general/secrets/{id}/security-checkout/secrets/
{id}/security-general
```

An example of a PATCH call is:

```
PATCH/secrets/{id}/general{{secretPolicy: 1}}
```

or more descriptive:

```
PATCH/secrets/{id}/general{{secretPolicy: {value: 1, dirty: true}}}
```

Logging

- Added verbose logging for:
  - Active Directory password changers
  - SQL Server password changers
  - MySQL password changers
  - Oracle password changers
  - Sybase password changers
  - LDAP Privileged password changers
  - Mainframe password changers
  - Windows password changers
  - SSH password changers
  - AppPool dependency
  - SSH dependency
  - SQL dependency
  - PowerShell dependency
  - ComPlus dependency
  - FlatFile password changers
  - ScheduledTask password changers
  - WindowsService password changers
- Added a correlation ID to every request generated by new UI pages. This ID is tracked by the API and is included in the server log when relevant. To get the IDs, users can go to the new UI diagnostics page to download a log of all HTTP requests made within the past two days.
- Updated error handling to process unknown errors as "UnknownError." Previously unknown errors logged as "LoginFailed."

Cloud

- Fixed a caching issue where discovery scanning sometimes did not find an existing organizational unit (OU) for SSC instances.
- Significantly improved shutdown and restart times for engines connected to SSC.

- Added a new configuration setting to allow SSC admins to opt non-admin users out of seeing the SSC upgrade notification banner before a release. Access this "display maintenance message To administrators only" setting at Admin > Configuration > General tab > User Experience.
- Removed the legacy Web Password Filler bookmarklet.

General

- Updated the layout for configuration pages to include more details about page sections.
- Removed options such as "import secrets" and "launcher tools" from the grid icon menu. All menu items are available from the admin page.
- Redesigned the "user preferences" page. Click the profile icon in the upper right, and then select User Preferences.
- Added actions that allow a user to cancel an existing request in the request log grid.
- Added auditing for changes made to discovery source pages.
- Application requests made from the API can now be approved or denied on the inbox page.
- Added a checkbox to the settings of the scheduled task and Windows service scanners to use NETBIOS name instead of UPN when matching domains.
- On secrets that require both check out and comment, users are no longer required to submit two comments. We combined the check out and comment prompts.
- Added a "next password reveal" audit for secrets that are manually updated with a next password.
- Converted active templates to new UI.

Bug Fixes

- Fixed an issue to Web Password Filler to have the URL encoding match what is configured in the secret. Issue related to handling of ampersands contained in the launcher URL.
- Fixed an issue where request access emails did not send to some approvers.
- Fix to address accuracy of login time stamps when using SAML Active Directory Federated Services.
- Fixed an issue where copying custom reports sometimes did not allow a user to save.
- Fixed an issue where some secrets did not display when picking associated secrets for a secret policy or event subscription. Associated secrets on secret policy edit will now default to not filtering by password type configured on the template. The "show all" button will also no longer filter by this setting.
- Fixed an issue where folder permissions could be changed via REST API despite the "inherit permissions from parent" setting being enabled. Changes to folder inheritance through the API will now be reflected in the UI and will be messaged in the API.
- Added a new advanced configuration advanced setting, OffloadRunNowToDifferentNode. If true, offloads the "run now" commands to nodes with background worker enabled. This only applies if Secret Server nodes have different RabbitMQ site connectors.
- Fixed an issue where filter parameters were ignored when using `filter.searchField` in the API method. Users are now able to perform partial searches through the API.

- Fixed an issue where users with edit permission on a folder were unable to perform the "convert template" bulk operation on secrets they owned within that folder.
- Fixed an issue where deleted engines were still shown on the engine status widget.
- Fixed an issue where RADIUS two-factor authentication access challenge prompts did not work with Integrated Windows Authentication.
- Fixed an issue where the time format in the secret access request form page did not match the default time format in Admin > Configuration.
- Fixed an issue in the new UI where the dependencies tab was not displayed correctly.
- Added a notification message when a secret is forced to check in by another user.
- Fix made for RPC password changes getting stuck in the processing state, after disabling RPC.
- Fixed an issue where a folder name is truncated to 50 characters when imported via XML.
- Fixed an issue where the audit log showed duplicate view instances for secrets
- Fixed an issue where Unicode characters would display as question marks on the SSH proxy session data page.
- Enhanced search logic so that an exact match for folder or secret name will appear first in the search results list.
- Fixed an issue where proxied sessions (RDP or SSH) did not properly terminate if session recording was previously disabled for the secret.
- Fixed an issue where the "inherit permission from folder" setting was disabled when sharing a newly created secret in the old UI.
- Fixed an issue where other users' personal sub-folders were still visible to users who did not have View permissions on them despite the "require view permission on specific folder for visibility" setting being enabled. This only occurred on the Admin > Folder Permissions & Audit page.
- Fixed an issue where different time zones were shown when editing the RPC settings of a secret.
- Fix made to address error when attempting to export diagnostic logs which resulted in incomplete records.
- Fixed the "value cannot be null" error message after clearing a report filter.
- Fixed an issue where the `POST /secret-templates/generate-password/{secretfieldId}` endpoint did not properly handle password fields.
- Fixed an issue where the web password filler could not login local users through SAML authentication.
- On the security hardening report page, increased the maximum size of the zero-information disclosure message.
- Fixed an issue where AD sync processed a disabled domain.
- Updated the distributed engine "processing" status query to exclude inactive secrets in its data count on the SiteView.aspx page.
- Fixed an issue where duplicate secrets could be linked to a discovery scanner.
- Fixed an issue where edits to a dependency modal did not save.

- Fixed an issue where the "automatic user management" setting did not re-enable Integrated Windows Authentication (IWA) users properly.
- Fixed an issue with attaching files while creating a new secret that had check-out or require comment enabled.
- Fixed an issue with the REST API `POST /secret-templates/` endpoint, which did not work.
- Fixed an issue in folders that contain over 30 sub-folders where clicking to maximize the folder list threw an error.
- Fixed an issue where converting a secret template failed after modifying the secret template without first saving the template.
- Fixed an issue in the new UI where require approval logic on a secret policy blocked users from creating secrets in a folder where the policy was assigned.
- Fixed a new UI issue where copying a secret template failed when using the Internet Explorer browser.
- Fixed an application error message when secret access was revoked by its owner, while another user was attempting to check it out.
- Fixed inaccuracies displayed in "last accessed" and "created" column data in secret grids.
- Fixed an issue in the way IP addresses in URL fields were indexed and how indexed searching was conducted. Searching by partial IP address now correctly matches against URL fields for any substring of the IP address, as long as the search term starts with a whole octet of the field.
- Fixed a display issue for drop-down grid menus in the new UI.
- Fixed an issue when sharing a secret where a message incorrectly stated that the user would no longer be owner of the secret.
- Fixed an issue where duplicate groups populated when selecting from the "add Group/user" dropdown on the Admin > Groups page.
- Secret folder tree expansion is no longer lost when editing a folder.

Secret Server: 10.7.000059 Release Notes

December 9, 2019

Note: The system requirements last changed with version 10.7.000000. See Secret Server: 10.7.000059 Release Notes for details.

Upgrade Notes

- Fixed an issue with Legacy SAML. Customers are encouraged to migrate to Secret Server's updated SAML if still using the Legacy version.
- This release launches a new web password filler. To update your web password filler extension, go to the extension download site for your browser and platform.
- Customers with multi-node environments using Advanced Session Recording will need to update all ASR agents after your Secret Server upgrade to take advantage of the RabbitMQ failover updates in this release. We recommend doing so, but not doing so will not impact current functionality. See the "RMQ Failover" note below and the Secret Server Advanced Session-Recording Agent Installation KBA.
- Users will be directed to the dashboard Overview tab for their first login after upgrading.

New Features

Data Retention

Secret Server now allows administrators to permanently delete audit records for tables that either contain Personal Identifiable Information (PII) or tables that can grow large in enterprise environments. To configure these settings admins need to add the permission "Administer Data Retention" to the user's role and then the user can Search for **Data Retention**. Only users with the "Unlimited Vault Access" permission can assign this new permission.

Manual Rolling Upgrades

A new "Manual Rolling Upgrade" feature is available when upgrading from Secret Server version 10.7.000059 or above. Using this process, customers using clustered web nodes with a load balancer can experience little-to-no downtime during the upgrade process, but this process requires manual steps by an admin with Web node and database access.

RMQ Failover

Updated Secret Server to support durable exchanges for RabbitMQ (RMQ). This allows clustered site connectors to failover without impacting Secret Server's processing. Distributed engines will auto-update after Secret Server's upgrade to also support durable exchanges through RMQ.

Note: Older Advanced Session Recording Agents (ASRA) can be used with this version of Secret Server but ASRAs will not benefit from this change to failover handling. To include failover capability for ASRA an updated agent must be deployed.

Technical Details: The ExchangeDeclare logic in MessageQueue client was altered to attempt to create durable exchanges with logging. A durable exchange is automatically re-created if RabbitMQ restarts for any reason. Non-durable exchanges disappear when RMQ goes down and can only be re-created by some external action. If the new logic detects that creating the durable queue failed, it will log an error and attempt to create a non-durable queue.

Note: The presence of legacy non-durable exchanges can prevent the automatic creation of durable exchanges. See "RabbitMQ Durable Exchanges" on page 786

Time-Based One-Time Passwords (TOTP)

Added a new feature where Secret Server can now generate time-based one-time passwords (TOTP) for web secrets. This allows users to implement TOTP on shared secrets. Configuring secrets for TOTP begins at the secret template level.

Truncated Log Data

Added the ability to truncate table logs for several types of data that log to the "Status Message" table. These messages can contribute to excessive log data and slow performance. The option to truncate each message type is called "Days to Keep Operational Logs" and is under the "Advanced" sections on the following list of configuration pages. Minimum message retention time is one day and the default is 30 days. The logs include:

- AdminDiscovery.aspx (**Admin > Discovery**)
- AdminSearchIndexer.aspx (**Admin > Search Indexer**)

- ConfigurationActiveDirectory.aspx (**Admin > Active Directory**)
- ConfigurationPasswordChanging.aspx (**Admin > Remote Password Changing**)
- ConfigurationSshProxy.aspx (**Admin > Proxying**)
- ConnectWiseConfiguration.aspx (**Admin > Folder Sync**) Setting only available when using the "Database" Folder Synchronization Method on this page.

Technical details: A background task was added that scans the status message table every 12 hours and checks the status messages against configured values for how long they should be retained. These configured values were added to applicable UI pages.

Web Browser Plugins

The Web browser plugins for Secret Server were rebuilt with a new look and feel and now have additional browser and site support. These new plugins are available for:

- Google Chrome
- Mozilla Firefox
- Microsoft EdgeKeep Secret Name History
- Opera

These features from the old browser plugins have been improved to allow more flexibility:

- Create secrets
- Select secret template
- Generate complex password

Users can now authenticate to Secret Server directly from the Web plugin, including support for 2FA options, such as DUO. Log in via Secret Server is also available for users with single sign-on, SAML, or other multi-factor authentication mechanisms. Web plugins automatically identify manual entry of new credentials in a Web page and offer to save the credentials as a secret. There is also improved support for sites that use multi-page login mechanisms.

Enhancements

Advanced Session Recording

Added a new setting to disable keystroke data from advanced session recording metadata. The new setting is called "Default Keystroke Recording Configuration" and can be configured under **Admin > Configuration > Session Recording > Configure Advanced Session Recording.** Click **Collection name** to edit individual collection settings or agent settings. By default, advanced session recording keystrokes are enabled.

Remote Password Changing upon Regex-Defined Error

Added a new regex setting to automatically retry a remote password change (RPC) with a regenerated password if the original RPC failed due to a specific type of error.

Search for **Remote Password Changing**, click **Advanced** under the **Configure Password Changers** section. The new setting is **Attempt Password Change with new password when error contains (regex)**. Edit it to provide the regex failure code that will trigger the automatic next password RPC.

Discovery

Added messaging for when computer or dependency scans do not run due to having no scanners configured for a discovery source.

Distributed Engine Offline Status

Updated the definition of distributed engines' offline status to be the configured heartbeat interval times three. For instance, if your heartbeat interval is configured at 5 minutes, the engine will report offline if Secret Server and the engine do not successfully communicate within a 15-minute time period. Engine online and offline states were also added to subscription actions to allow notification to admins when engine states change.

New User Interface

- Redesigned the Admin landing space. Click **Admin > "See All"** to explore the new layout.
- Redesigned DoubleLock.
- Added new "Recent Activity" section to the Home dashboard page to display recent activity at a glance.
- Updated the Security Hardening tab in the Reports page.
- Updated the IP Address Management pages under Admin.
- Added custom logos. Added custom "full-sized" and "collapsed" logos for the new UI in **Admin > Configuration** under in the **User Interface** section.
- Added dark mode theme option in the new UI. To change theme mode preferences, go to **Account Settings > Color Mode**. Options include Light Mode, Dark Mode, or Default (mode will update based on user's OS color mode settings).
- Added a new setting to configure the inactivity time before the new UI goes into dark screen "sleep mode." To configure Search for **UI Inactivity Timeout**.
- Converted the Groups page to the new UI.
- Updated error messaging in the new UI to display folder synchronization and deletion errors.
- Updated the date picker to allow for future start dates and time selection without first adjusting the end date when requesting secret access. End dates are automatically adjusted to align with the start date +1 hour.
- Updated grid downloads in the new UI to download according to new options. User options now include choices to download all data or specific rows of data, and specify date format. You can also choose time zone options of UTC, server time zones, or the local browser time zones.

  Note: for downloaded reports users' time zone options are limited to UTC or the server time zone.
- Updated behavior of new UI so that clicking the "Select All" check box at the top of a secret grid selects all rows. Previously the check box selected only the items currently loaded on the page.
- Added the "View Audit" button to the reports page of new UI.

- Added the "Upgrade Available" banner to display in the new UI.
- Added the ability to drag-and-drop child folders into the root folder. Folders will automatically re-order alphabetically in the left navigation pane.

  Note: This action is only allowed if users have the "Create root folder" permission and own folders that they are attempting to move.
- Added folders to the "Shared With Me" page.
- Added new inbox notifications including "getting started" notifications for new installs and administrator alerts when an instance is close to hitting licensing limits.
- Added the ability to mark Inbox notifications as read or unread for most notification types.
- Added the ability to browse by folder name using the URL format `[SecretServerURL]/SecretServer/app/#/lookup?folderPath=[FolderName]`. If multiple folders exist with the same name, this URL search schema only directs users to the first folder listed within the left navigation pane.
- Updated Favorite star icons to remain in column view when the Name column is resized.
- Expanded file-size allowance on file uploads. File uploads can now be up to 10 MB.
- Grid results updated to auto-load 30 results instead of 15.

Licensing

A second distributed engine is now available, by default, for the local site.

Reports

- Updated several reports to no longer show deleted secrets.
- A new out-of-the-box report called "Secret Templates without an expiration field" was added to display any secret templates that have a password field but do not have an expiration field set.

Secret Template Import and Export

Updated secret template settings for importation and exportation to include:

- Is Required?
- Edit Requires
- Hide on View
- Secret template icon
- Keep Secret Name History
- Validate Password Requirements on Create/Edit
- Field Slug Name
- Type Description
- One Time Password settings

The secret template settings that do **not** transfer include:

- Launcher settings
- Password changing settings
- Session recording enabled
- Associated secrets

SSH Proxy

- Updated "connect as" to accept key-based SSH authentication without also requiring a manual password.
- For SSH proxy sessions, added the option set:
  - Only record keystrokes
  - Only record video for sessions.

  By default new installs will only record keystrokes on SSH proxy sessions to preserve disk space. To configure this setting go to **Admin > Configuration > Session Recording tab > Secret Server Proxy Session Recording**. Edit the **SSH Proxy Session Recording Options** dropdown list. The options include:
  - Record keystrokes and video
  - Record keystrokes only
  - Record video only
  - Do not record

Verbose Logging

Added Verbose Logging for:

- AWS password changers
- AWS discovery scanner
- ComPlus dependency scanner
- PowerShell discovery scanner
- Flat file discovery scanner
- ODBC discovery scanner
- SSH discovery scanner
- ESX discovery scanner

Terminal

- Added terminal instructions for how to view SSH proxy credentials in the new UI under **Secret Options > Show SSH Terminal Details**.
- Removed restrictions from the allowed number of concurrent logins for SSH terminal. Previously, terminal logins were tied to the "Maximum concurrent logins per user" setting that establishes this number for UI-based users.
- Added Unicode support for SSH command menu items (names and descriptions).
- Added "clear" command to terminal.

Database SQL Indexes

Added new SQL indexes for the following areas:

- Column LauncherSessionGuid on the Launcher Session Video (tbLauncherSessionVideoSegment)
- Event Queue Monitor (tbEventQueue)
- Expired Secret Monitor (tbSecretDependency table)
- Folders (tbFolder, tbFolderGroupPermissions)
- General Navigation (tbUserSession)
- Launcher Activities (tbSecretSession)
- Log In (tbUser)
- Node Activation Check (tbNodeLicenseActivation)
- Secret Log table (tbSecretLog)
- System Reports (tbAuditUser, tbAuditSecret)

Unique Field Slug IDs

Added a new "Unique Field Slug" ID column for secret templates to allow users to create secrets with duplicate field names without compromising the ability to target each field name with a unique identifier for API calls.

User Variables for Scripting

Added the following user-based script variables to be used in API calls as arguments:

- `$SECRETSERVERUSERID`
- `$SECRETSERVERUSERNAME`
- `$SECRETSERVERDISPLAYNAME`
- `$SECRETSERVEREMAILADDRESS`

This allows, for example, that when a specific user runs a check-out hook, they can pass a user email, ID, username, or display name as a parameter into the script to use a check-out hooks and related AD functionality in Secret Server through the API.

API and Scripting

API General

Added a setting that allows users with view permission on a secret to get the secret's "autoChangeNextPassword" field in the API. This setting is enabled under **Admin > Configuration > Permission Options**. Set **Allow View User To Retrieve Auto-Change Next Password** to **Yes**.

New API Calls

- Get one time password code and seconds: `GET /one-time-password-code/{id}`
- Search secrets by URL: `POST /secret-extensions/search-by-url`

- Get AutoFill values for URL by secret ID: `POST /secret-extensions/autofill-values`
- Update secret field: `PUT /secrets/{id}/fields/{slug}`
- Update secret: `PUT /secrets/{id}/restricted`
- Get SSH Terminal details: `POST /secrets/sshterminal`
- Get extended regex values by secret: `GET /extended-fields/regex/{secretId}`

Removed API Calls

- Search app clients: `GET /app-clients`
- Update secret: `PUT /secrets/{id}`
- Update secret field: `PUT /secrets/{id}/restricted/fields/{slug}`

Integrations

- Added support for Open ID Connect to integrate with Secret Server authentication.
- Added Connection Manager as a tools option in the grid menu and under the Admin space in the new UI.

Performance Improvements

- Added server-side paging to reports in the new UI to address performance issues when attempting to load reports with large numbers of records.
- The new UI will no longer load the subfolders If a parent folder has more than 30 subfolders within it on the grid page. Instead, a folder picker will display above the folder's secrets that will allow users to select a specific subfolder.
- Applied enhanced SQL querying logic on the groups pages so that environments with large groups no longer experience page timeouts when processing group data.
- Improved the shutdown performance in distributed engine.
- Removed the welcome widget from the dashboard on the classic UI due to page load issues in large environments.
- Enhanced SQL query for the Unlimited Vault Access report to improve performance for large environments.
- Added a new "use database paging" setting for the custom reports page. Database paging allows the database to load large reports more quickly. We recommend database paging if the query is expected to pull large amounts of data for the report. Implementing database paging may not work if the SQL query uses some keywords, including TOP, OPTION, INSERT, UNION, WITH, or aliases containing the word FROM.

  Example queries:

  - Works using database paging: `SELECT * FROM tbSecret WHERE NAME LIKE 'Test%'`
  - Does not work using database paging: `SELECT TOP 10 * FROM tbSecret WHERE SecretName LIKE 'Test%'`

Security

- Updated PuTTY to version 0.73. Updated version addresses several PuTTY vulnerabilities, including one critical and two high severity items. CVE-2019-17067, CVE-2019-17068, CVE-2019-17069
- Addressed a vulnerability with the SDK client account handler.
- Fixed a permissions issue in the new UI where password requirements did not obey the "administer custom password requirements" permission.
- Added audits and event subscriptions for viewing passphrases and SSH keys.
- Addressed a Remote Code Execution (RCE) vulnerability that allowed parameter changes for an action without validating user permissions.
- Resolved an issue for SSH scripts and SSH remote password changers where sensitive information was being written to log files:
  - SSH remote password changers will now only log the comment for each command as it runs.
  - SSH scripts will only log that they ran because they have no comment for each command.

  Note: If you manually test an SSH script or password changer, the full output will still be shown for debugging purposes, because you just entered the credentials yourself.
- Resolved a URL redirection vulnerability.
- Added configurable parameter quoting for custom launchers.
- Resolved three cross-site scripting (XSS) vulnerabilities.
- Fixed an XML external entity (XXE) injection vulnerability.
- Removed user information that was returned in an API call.
- Added auditing for changes made to the session recording configuration page on the **Admin > Configuration > Session Recording** tab.
- Added auditing for test script actions in the **Custom Command Edits** section in the **Admin > Scripts** pages.
- Added auditing to the **Admin > Configuration > Ticket System** tab. Audits are logged under **Admin > Configuration > General tab > View Audit.**
- Updated missing secure cookie attributes when "Force HTTPS" is enabled.
- New installs running 10.7.000059 or later will now automatically apply zero information disclosure.
- Added SHA1 and SHA256 hashes for protocol handler.
- All Delinea DLLs and EXEs are now signed with the Delinea Software certificate including distributed engine, advanced session recording agent, and MemoryMQ applications.

Bug Fixes

- Fixed an issue where creating folders through the API failed to set a secret policy.
- Fixed a memory leak issue where leaving Mac launcher sessions open for extended periods of time consumed increasing amounts of memory on the machine hosting the session. This issue was incorrectly believed to be fixed in the Secret Server version 10.7.000002 release.

- Fixed an issue where an access approval email link did not work if Integrated Windows Authentication (IWA) and two-factor authentication were enabled.
- Fixed an issue where Unix secrets were not reported in the "Password Last Changed" report because the Unix Account template did not have a password expiration field by default. Unix password fields are now set to expire at 30 days by default.
- Fixed an issue where pressing Enter with the cursor in the Search bar on the Discovery Network View page would open the create rule dialog.
- Fixed an issue where new users were not adequately loading in the dropdown option for subscribers in the "discovery rule alerts" setting if users increased from under 40 to over 40 users.
- Added clear error and validation in entering credentials for a discovery scanner.
- Fixed an issue where localized language customization did not apply to some product pages due to default cache keys or inconsistent HtmlHelper methods implemented on those pages.
- Fixed a bug where some pages in the old UI did not follow customized headers from CSS stylesheets.
- Fixed an issue where extended search terms were not applied for URLs. Updated BookmarkletSecretSearcher so that it will not do extended hashes on URLs that might result in many erroneous matches. For instance, facebook.com would match face.org.
- Fixed issue where non-AD discovery sources (ESX, PowerShell) would not match dependencies with domain to an existing AD Domain. If the dependency scan item has a field called "domain," it will attempt to map to an existing domain.
- Fixed a bug where the REST API "daysUntilExpiration" field returned a blank value when calling for a secret summary.
- Added a query to resolve sort ordering issues for dependency numbering.
- Fixed an issue in the new UI where deleted secrets remained on display on the favorites widget in the home tabs.
- Fixed a "bad token" error on login for mobile apps (Windows Desktop, iOS, or Android) for local users.
- Fixed an issue where SSH keystroke data was not searchable from the session playback page due to proxy session data not being correctly hashed in the database.
- Fixed a ticketing system bug where the option to require users to either provide a ticket number or a comment for requesting access incorrectly required both a comment and a ticket number to access the secret. This issue existed when requesting access to the secret through the UI, workflows, or terminal.
- Fixed a bug where hashed terms were intermittently slow to return search results in the new UI.
- Fixed a rendering issue for the group edit page when using the IE browser.
- Fixed a localization issue in the SSH command menus where setting non-English as the global or user preference threw an exception when trying to save a secret policy.
- Fixed an issue where an "object disposed" exception was thrown when navigating away from the new UI soon after application pools were recycled. This occurred because of an incorrect re-use of a service that is for processing the first Web request to the application.

- Fixed a bug in the new UI where personalized preferences for launcher settings on a secret were not allowing users with view access to save.
- Fixed a bug where custom columns on grids in the new UI occasionally tried to display the same column twice and threw an error.
- Fixed an issue where a syslog header was missing the hostname when logging from an engine.
- Fixed an issue where Duo authentication was not checking for valid fallback device options when the configured "default device" failed to authenticate.
- Updated the "find new dependencies" feature to be available to users with edit permissions on the secret. Previously the new UI required users to have owner permissions.
- Resolved a timing issue where secrets with scheduled password changes enabled would get erroneous heartbeat fails due to remote password change (RPC) expiration and heartbeat occurring at the same time. Now heartbeats are skipped for an interval of five minutes before and after a scheduled password change to allow password change completion before heartbeat is attempted.

Secret Server Release Notes 10.7.000002

October 8, 2019

Note: The system requirements last changed with version 10.7.000000. See Secret Server Release Notes 10.7.000002 for details.

Note: Secret Server 10.7 and later no longer support using SQL Server 2008 R2 as the database for Secret Server.

General Bug Fixes

- Fixed an issue where automatic password changes (including scheduled password rotations) did not run on environments with distributed engines.

  Note: Using the "Run Now" button (Admin > Remote Password Changing) to manually start the process was unaffected.

- Fixed an intermittent PuTTY crash with the RDP Launcher caused by PuTTY version updates in Secret Server not properly disposing named-pipe-related entities after the 10.7 release.
- Fixed an issue where writing to the local CEF log file threw exception errors, causing deadlocks, due to a missing allowlist for local CEF logging.
- Fixed an issue where the "Generate New SSH Key" button did not generate a public key when creating a new SSH key secret.
- Fixed an issue where disabling two-factor authentication using the "Lost Phone" option did not trigger a "Two-Factor Changed" event, resulting in the event logs not recording the reset of the user's two-factor authentication mechanism. Added two new events, one for a successful and one for an unsuccessful TOTP reset.

Mac Launcher Fixes

- Fixed an issue where copy actions in a launched session would drop the last letter in the copied string.
- Resolved an issue where a Mac RDP session could crash if left open for a long, inactive period.

- Fixed an issue where right-clicking within a PowerShell window terminated the Mac RDP session with the server.
- Fixed an issue where turning off custom resolution in "Launcher Settings" caused a crash on next launch.
- Added a check to ensure a non-zero height and width are used. If the width is set to 0, then a width of 1024 is used. If height is set to 0, then as height of 768 is used. These were the previous default settings.
- Enhanced messaging when sessions are disconnected due to server-side tasks. The user now receives a dialog notification letting them know that the session was closed from the server.
- Fixed an issue where pressing the Option key during a Mac RDP Launcher session malfunctioned as if the user was indefinitely holding down the key.
- Added scrollbars to the FreeRDP window to improve mouse scrolling. The mouse wheel now scrolls windows inside the connected server but does not scroll the FreeRDP window. Users must drag the FreeRDP scrollbars to move the content.
- Made window resizable down to 100×100 pixels and up to the specified dimensions.
- Fixed a memory leak where leaving Mac launcher sessions open for an extended period consumed ever-increasing memory on the machine hosting the session.
- Fixed a session recording issue in the Mac Launcher when multiple recorded sessions occurred at the same time. If a recorded session began while another session was already recording, the original recording would not be saved.

Secret Server Release Notes 10.6.000027

Secret Server 10.6.000027 Release Notes

This is a security release for Secret Server On-Premises. Released on June 18, 2019.

Security Advisory

Bug Fixes

MS SQL Server 2008R2

*	Fixed an issue for MS SQL 2008R2 users that caused search to fail in the New UI.
*	Fixed an issue for MS SQL 2008R2 users when loading the "Manage Secret Access Requests" page from updates in the New UI.

Secret Server Release Notes 10.6.000026

The second minor release after 10.6 for Secret Server On-Premises. Released on May 29, 2019.

Upgrade Notes

•	After upgrading to 10.6.000026, the first admin who logs in to Secret Server is prompted with a wizard that walks through the new user interface (UI) configuration settings for their instance. Users can adjust these settings at any time from **Admin > Configuration** in the **User Interface** section.
•	Enterprise customers who use load balancing with RabbitMQ may want to delete queues after upgrading Secret Server from versions earlier than 10.6. If customers using RabbitMQ do not delete their queues, they will **not** lose functionality, but old queues that were renamed in a 10.6 architectural update will continue to fill up with messages.

New Features

New User Interface

•	In the 10.6.26, Secret Server's user interface was updated, featuring a black left-hand navigation pane. The look and feel and user experience updates were based on user feedback from the beta version.
•	As noted in the upgrade notes section, after upgrading the first admin who logs in to Secret Server is prompted with a wizard that walks through the new UI configuration settings for their instance. Users can adjust these settings at any time from **Admin > Configuration** in the **User Interface** section. After settings are saved, users with access to the new UI are shown a short demonstration of switching between new and classic user interfaces upon their first login.

We are incrementally introducing feature parity between the new and classic UIs. In this upgrade the new UI added support for:

•	Emailing reports to users.
•	Deleting reports.
•	Converting secret templates.
•	Uploading files to secrets.
•	Copying and converting file attachments.
•	Setting automatic password change rotations when creating new secrets.
•	Rotating SSH Keys and Passphrases for SSH secrets.
•	Rotating SSH Keys and SSH passwords using a bulk operation.
•	Displaying custom columns in the folder view.

•	Updated the Secret Picker to include a folder tree browser when selecting a privileged secret for Remote Password Changing.
•	Added a password complexity indicator that displays when editing a Secret's password.
•	Updated Search functionality to include folders.
•	Users can now "favorite" folders by clicking stars on folders in a table view or by right-clicking folders in the left navigation pane.
•	Additional "View" audits were added to the new UI to track users who view Next Passwords, SSH Keys, and Passphrases.
•	Optimized SQL queries when searching for secrets in the new UI. This includes: Faster searches, the paging and sorting is now performed in the database instead of the web server Ability to filter by secret permission, extended type id, password type id, RPC enabled, recently used date range Can now return extended fields Sorting by an invalid field now returns an exception instead of sorting by the secret ID

Advanced Session Recording Without Launcher

•	Added video recording capability to the Advanced Session Recording agent, with a new configuration setting that can enable recording of a video on an endpoint even when a launcher is not used to begin a session.
•	Advanced "headless" session recordings will show a 'Session Minimized' notification for periods during which the session was minimized, or otherwise hidden from the user such as during the final stages of logging out.
•	To prevent unnecessarily long session recording sessions, added a "Max Session Length" setting for recorded videos. The default for this setting for on-premises instances will stop a session after 24 hours of no activity. Administrators can set this to a maximum of 48 hours.

New Secret Templates

•	Added a new "No Password" template for SSH/Linux Key rotation. These templates allow users to rotate SSH and Linux keys without the password field requirement that exists on other Unix secret templates in Secret Server. When creating a new secret, select "**Unix Account (SSH Key Rotation - No Password)**" as the Template to use this new feature.
•	Added a native Amazon (IAM key) rotation template. When creating a new secret, select "**Amazon IAM Key**" as the Template to use this new feature.

Integrations

•	Added a new biometrics eWBM integration for FIDO2 authentication with Secret Server. eWBM's website at http://www.ewbm.com/.
•	A connector application is now available to link Secret Server to identity management tools using the System for Cross-Domain Identity Management (SCIM) standard.

System Support Updates

•	Secret Server now supports Azure SQL as its database server but only if the Web server is hosted in the same geographical datacenter as the Azure SQL database (because of latency issues). Secret Server does not support Azure SQL if the Web server is hosted on-premises. **Note:** Azure SQL users are unable to use the Secret Server database backup setting. For information about Azure SQL backup please see Microsoft documentation. (https://docs.microsoft.com/en-us/azure/sql-database/sql-database-automated-backups)
•	Secret Server System Requirements have been updated to include Support for Windows Server 2019 and SQL Server 2017.

Enhancements

Session Recording

•	Updated the "View Session Data" feature for session recording to keep users from viewing session data on any ongoing session.
•	Added searching by date and time for session recording videos.
•	Updated the advanced session recording agent (ASRA) so that the SecretLauncherSessionMatchingService can now match the ShortName to the NETBIOS name of domain objects in Secret Server. * Windows terminal sessions report the pre-2000 domain NetBIOS name, which is relayed from the ASR agent to Secret Server and used for matching Windows terminal sessions to secret launcher sessions. This is an issue if the domain on the secret is the domain FQDN or friendly name and matching fails. For example: You have the ASR agent installed on a machine which is joined to a domain (mydomain.com) with a pre-2000 NetBIOS domain name "SOMETHINGELSE" Your secret has the domain name "mydomain.com" When you launch into the machine, Secret Server attempts to match "mydomain.com" (from the secret) with "SOMETHINGELSE" (the domain NetBIOS which the ASR agent relays) and fails. Secret Server resolves this issue by trying multiple methods to get the appropriate FQDN for the Windows terminal session and using the best result from those methods, which should result in matching correctly more frequently.

•	Updated advanced session recording matching by automatically mapping to the secret template's RDP fields automatically. Matching was improved by checking the secret template's RDP launcher mappings. Now, no matter what the fields are named on the secret template, the correct username and domain fields are used, based on the launcher mappings.
•	Advanced session recording can now match sessions using DNS resolution. When using an RDP launcher on a secret with a machine or computer name, instead of an IP address, the protocol handler does a DNS resolution of the hostname and reports the IP back to Secret Server, which is saved for the entry in tbSecretSession. This helps advanced session recording find additional matches when the hostname does not match the computer name, only if the hostname resolves to an IP address found directly on the target computer. If there is any NAT used, this will still fail to find a match because the NAT IP is not found on the target computer.

Secret Folder Import and Export

•	Added subfolder creation during secret importation.

Secret Templates

•	Updated launcher and password changing for the IBM iSeries secret template.

Search

•	Added default index separators to include the following characters: ? Question mark ! Exclamation point @ At symbol # Pound symbol (left parenthesis) right parenthesis [left square bracket] right square bracket { left brace } right brace ' apostrophe " double quotation mark - hyphen Configure indexing separators at **Admin > Search Indexer**.

Discovery

•	Updated the ESX discovery scanner to updated versions of the VMWare/VSphere SDK.

Logs

•	Enhanced verbose logging. Added additional logging for the Scheduled Task Scanner, Discovery Classes, Active Directory, and Password Changer logs.

Bug Fixes

Launchers

•	Fixed an issue where the Mac launcher was not automatically populating unique password prompts when connecting with PuTTY.
•	Fixed an issue where the Custom Launcher screen resolution setting for Mac Launchers was not properly applied. Previously, custom launcher sessions used full-screen resolution. **Note:** If there are no custom values set, session resolution will default to 1024x768.
•	Fixed an issue where using a Windows account launcher with a domain account would fail if the launcher was configured with an IP address in the machine field. The logic detected the computer name as an IP address and then returned before setting the domain field.
•	Updated the Mac Launcher to hide the session recording indicator for users when **Configuration > Session Recording > Hide Recording Indicator** is enabled for the launcher. The mac launcher now uses the "hideRecordingIndicator" variable stored in the sessionInfo object. Initially, there was no logic involving hiding the indicator. Added the "hideRecordingInidicators" function to the object ALaunchedTask. Updated logic under "refreshRecordingIndicator" under TaskMonitor to call "hideRecordingIndicators" when determining if it should show any icon for active watchdogs. Updated watchdog to contain a public property that is passed on instantiation–"hideWatchdogMessages". On watchdog start or stop, it now validates the "hideWatchdogMessages" is false before displaying alerts about the session being recorded.
•	Fixed a custom URL issue where launcher images did not properly display when accessing Secret Server from different sites. The custom URL was a different sub-domain from the URL that the site was accessed from. The images were served from the custom URL and our content security policy was blocking those requests. The content security policy is used to prevent cross-site scripting attacks. The solution uses the URL given instead of the custom URL.
•	Updated the Mac launcher to include support of TLS versions 1.2 and 1.3.
•	Changed the default launcher setting for RDPUseComputerForDomain to "True" to allow the launcher to work on all Windows versions currently supported by Microsoft upon install. This was tested on Windows 8.1, 10, Server 2008, Server 2012, Server 2016, as well as on MacOS 10 Sierra, High Sierra, and Mojave. It prevents launchers from failing unintentionally when connected to some Windows OS versions.
•	Updated launchers to accept upper case characters in URL strings on a Web password secret. Previously, launchers set all uppercase characters to lowercase before launching, which caused launch failures for URLs that are case sensitive.
•	Fixed an issue where a user launched a session recording but then immediately exited, Secret Server still attempted to record the session, resulting in inaccessible videos that were 00:00 seconds long. To resolve, zero-length sessions are no longer turned into videos and now returns the error: "Session too short - no video."

New User Interface

•	Fixed a bug in Internet Explorer for the new UI where the Download File button threw an "access denied" error.
•	Fixed a bug where the dependency log view did not sort correctly on the Date Recorded column.
•	Fixed a bug in the new UI where users with "edit" and "administer folders" permissions were unable to create subfolders within a parent folder.
•	Fixed a bug in the new UI where users without the "Assign Secret Policy" role permission were unable to create new secrets in a folder. The internal logic for validating whether a user may assign a secret policy to a secret did not consider the special case of secret creation. The user's personal permission to assign a secret policy should be ignored during the creation process if they did not assign one, but the code acted as if the user had assigned the policy, not that the policy was assigned by the folder.
•	Fixed a bug in the new UI where breadcrumbs for the Workflow and Teams audit pages displayed "audit" instead of the component's name. This issue also caused breadcrumbs to reload when switching between tabs on the page.

Time Conversion

•	Fixed a date-time issue where abbreviations for the month of the year in languages other than English were not properly logging to Syslog.
•	Fixed an issue where records in custom reports were logging as the UTC time zone rather than a user's local time zone.

Scripting

•	Updated REST API call "Get Folder Permissions" parameter for filter.userId to return all user permission information.
•	Added enhanced error logging for Oracle scripts.
•	Fixed a bug where the API incorrectly required Owner permissions on a secret to change the password on that secret. Edit permissions are now required when changing a password through the API.

•	Fixed an issue where the "Webservice Password Displayed" audit was logged incorrectly when non-password-related API calls to "Get Secret Fields" occurred. The REST endpoint **GET /secrets/{id}/fields/{slug}**, when used to view a non-password secret's field was incorrectly recording an audit stating "WEBSERVICE PASSWORD DISPLAYED." This was due to the endpoint's implementation using the existing **GetSecret** REST logic, which manages the creation of this audit. This logic assumed you would respond or display to the user with the secret's fields (items and data) when getting a secret that contains a password, recording an audit. To correct this, the **GetSecret** logic now supports an optional parameter that specifies which of the secret's fields (items or data) you will be responding with (displaying) to the user. If the items supplied to this method do not contain a password field, then the password displayed audit is not recorded. The corresponding **GET /secrets/{id}/fields/{slug}** endpoint was then updated to supply this method with the requested secret field, fixing this bug.
•	Fixed a bug where Web services incorrectly returned SecretDependencyTemplateIDs as null. The SecretDependencyTemplateId is now returned with every dependency found by GetDependencies in SSWebServiceHandler.
•	Fixed a bug where an "Application Account License limit has been reached" error was incorrectly displayed after editing existing application accounts, instead of only when creating new user accounts. This bug was due to a flaw in the user license logic where application account licenses were incorrectly returning the API_MetApplicationAPILimit error code when editing and attempting to save an existing application account user, while at the current application account user limit. Specifically, the logic assumed the addition of a new application account user—it did not support editing an existing user. The error occurred at the application account user limit where adding a new user is not permitted. The fix was to check if users were adding a new application account user or editing an existing user when determining whether to return the error code, API_MetApplicationAPILimit.
•	Fixed a bug where API group membership changes were not properly audited. This bug was due to a lack of auditing logic in the CreateGroupUser and DeleteGroupUser REST endpoints. The fix was to observe what audits the UI were doing upon adding and removing users to and from groups, then applying that same logic to the CreateGroupUser and DeleteGroupUser REST endpoints. Some extra logic was added to prevent recording audits if no operation was executed, such as moving a user to a group it already belonged to or removing a member from a group it was not a member of.
•	Fixed a bug where users were unable to create subfolders that inherit folder permissions through the REST API, despite the user having "Edit Folder" permission.

Authentication

•	Fixed a SAML login issue that could cause login failures if multiple users had the same User Principle Name (UPN) in Secret Server. The account that was created first would be prompted for SAML authentication even if that account was in a disabled state. This caused login failures with an error saying the user's account was disabled. Updated GetUserByUserPrincipalName to return a user only if there was exactly one user found with that UPN that was active. If there is not exactly one, it returns null. Handled a few logic flows where a GetUserByUserPrincipalName request is followed with a request to GetUserbyUsername. In cases where a valid UPN is entered, an error is produced at GetUserByUsername. These errors are now handled and logged.
•	Fixed a bug where if an instance had two users with the same username (one active user, one disabled user) across different domains two-factor authentication (2FA) enabled for login, a user trying to reset their login might get a validation error because the reset code they entered would be checked against the code of the other user with the same name. Secret Server now checks the domain of the user who is trying to login when determining which user account should be used for the 2FA reset request. This removes ambiguity when users in different domains have the same username, thus ensuring the correct 2FA validation is used.
•	Fixed an issue where 2FA failures were not showing up in the "Failed login attempts" report. The 2FA failure message was different from a normal login failure message. The report SQL was changed to display any login failure message.
•	Corrected a configuration error that changed the 'Disable Radius NAS-IP-Address Attribute' setting to have the opposite effect. The logic using the DisableRadiusNasIpAddressAttribute setting was set to return if false instead of true. This was an old application setting that would normally be false for most customers. When it was added to the UI configuration pages, the setting was implemented incorrectly, reversing the logic. In versions 10.5.14, 10.6 and 10.6.1, it is being disabled by default due to the backwards logic. This release corrects the configuration setting to work as described in the UI.
•	Fixed a bug where the authentication function for the "Attempt User Password" Radius setting did not work when using the REST API.

Discovery

•	Updated the PowerShell local account and dependency scanners to timeout after a set timeout. The application settings DiscoveryScannerTimeout and DependencySearchTimeout have been moved to settings on the individual scanners. If this setting was only set in an application setting, it needed to be reset on the scanner setting. Wrapped the PowerShell dependency and local account scanners in a System.Task to cancel after a timeout period.
•	Fixed an issue where out-of-the box dependency scanners (scheduled tasks, application pools, and service accounts) were not correctly copying as the same specified scanner's type.
•	Fixed an issue where discovery imported group-managed service accounts (gMSAs) as new computers and subsequently attempted to scan them for accounts.

Password Changing

•	Fixed an issue with Oracle privileged password changers. Before this update, Oracle password changing logic for privileged accounts was not correctly using the designated privileged secret to perform password rotations, leading to failed password change attempts.
•	Fixed an issue where missing parameters in the Sonic Wall password changer resulted in multi-factor-authentication (MFA) failure. The info sent to the Sonic Wall password changer now includes default values for MFA code and future MFA codes so those do not reference null. The PhantomJS script for Sonic Wall now looks for the host name at a different place in the parameters list.
•	Fixed a bug where the IBMi mainframe password changer timed out during process cleanup. IBM iSeries password changer has two threads during a session, the primary thread processing the session or request and a subsequent one that is spooled up during the process to ensure the interface framework (ws3270) does not get stuck in the wait state when the wait command is called. The second thread may detect false stuck wait states and attempt to close the session. If this happens after the primary session has completed the wait and has already closed, an "Access Denied" exception occurs. That exception can still be due to permissions, so it is worth checking, but most of the time this is the error thrown by the .Net Process framework when attempting to exit a process that has already exited.
•	Resolved issues with error handling, command pause handling, and session termination / logoff when using remote password changing (RPC) with IBM z/OS and IBM iSeries. IBM z/OS and IBM iSeries utilize the same base architecture within RPC to manage and execute commands. In some cases the password change process did not correctly resume after a pause command. In others the pause did not take effect, causing commands to execute prematurely and showing incorrect fails. Code was also added to clean up failed RPC / Heartbeats once a user is logged in. An identifier to the logoff command now informs RPC of the correct command to kill sessions in cases where it needs to terminate prematurely.
•	Fixed an issue after a Google update where changing Google account passwords returned incorrect messaging whether a password change failed or succeeded. Important Notes: The Google RPC only works if the user has previously logged into the Google account from the IP address that is trying to change it. In other words, the user needs to log into their Google account from a Web browser and allow the sign-in from an unrecognized IP address before attempting to rotate the password from that IP. If there are too many failed login attempts, Google may block the login for some time. If Google prompts a reCAPTCHA field to verify a human is changing the password, the RPC for the Google account will fail. Technical Details: Updated the URL check for the password changed test to fix the failed password change when it was a success. Updated the missing error code to fix the successful password change when it was failing. Also added better error checks to inform the user of the specific password change error.
•	Added logging to provide details when password change attempts for Google accounts fail, including: NewPasswordLengthTooShort NewPasswordLengthTooLong InvalidCharactersInNewPassword NewPasswordNotComplex IsAPreviousPassword SameAsCurrentPassword

Secret Import and Export

•	Fixed an issue where a user was able to edit the error message in the "Import Secrets' dialog box after importing a secret.
•	Fixed an issue where secrets were not displaying for users when a left bracket appeared in the parent folder name. We replaced any instance of [in a LIKE clause with [[] The first [opens the character comparison list. The second [is the character we allow for comparison. Finally, the closing] closes the character comparison list. It is unnecessary to replace additional instances of] because they mean nothing without a matching [
•	Fixed an exportation issue where the double quotation mark (") was not included in CSV files.

Security

•	Resolved a security issue in the protocol handler.
•	Fixed a security issue where users retained Unlimited Vault Access permissions for a short time after the Unlimited Vault Access Mode was turned off, due to a caching issue in the background worker. The issue was related to caching configuration data for 5 minutes and how the cache was being managed by the ServiceLocator used by the background worker. Turning Unlimited Vault Access Mode on or off would clear the configuration from the cache used by the UI, but the background worker had its own cache, which did not get cleared. The fix was to reinitialize the cache provider on the ServiceLocator whenever starting a bulk operation or secret importation to ensure these functions get a fresh copy of the configuration and Unlimited Vault Access setting.
•	Resolved inconsistent behaviors in role-based permissions.

Other Bug Fixes

•	Updated Session Recording to address an issue where video recordings intermittently returned black frames during the session's video playback. This was observed on older laptops running Windows 7 (either 32-bit or 64-bit) with integrated Intel graphics. Neither metadata nor keystroke logging (for advanced session recordings) were affected by this issue, only the viewing experience of the video, which could be interrupted by black frames. The fix was to use a different Windows API call as a fallback whenever a black frame is returned from the original screen capture attempt. A drawback to this approach is that fallback API simply captures the whole window including whatever might be on top of it. To counter this, logic was added to ensure that the RDP window is topmost during image capture. There remains a small possibility of capturing an isolated black frame or two if another window is moved on top of the maximized RDP window when an image is captured.

•	Fixed an issue where some Secret Server background threads attempted to perform tasks when Secret Server was disconnected from its database. The issue was that some background threads would exit their continuous monitoring loop. Specific conditions caused new SQL server connections to time out, but the open connections continued working. This resulted in Secret Server working normally but caused the monitoring loop to exit and fail to restart, breaking the monitoring of the thread. This was fixed by catching the error that caused the loop's exit, allowing the monitoring process to continue.
•	Fixed a bug where removing an event subscription item deleted the wrong item. When editing the events to trigger the event subscription, the ID of the event stored in the database identified which event to remove when an item was deleted. If an item was added, but the updated event subscription had not been saved, that ID was not generated yet. This caused the first event in the list to be deleted every time a newly added event was removed while editing. A temporary ID is now generated when a new item is added to the list so that if the item has not been saved to the database, the correct item in the list can now be identified.
•	Resolved an issue where backups were unable to complete if a Web application file was in use by a worker process. When looping through the files to be backed up, we now catch errors for any files that cannot be accessed by the backup process due to being locked by another process. When an error is caught, the issue is logged, and the backup process continues to the next file.
•	Fixed a bug in the old UI where a Safari browser repeatedly prompted Mac users to download and install the plug-in when attempting a copy-to-clipboard action. The old UI prompts for our Safari plug-in to be downloaded for using the user's clipboard. This is no longer used in the new UI. The link to the plug-in was removed. Now, the user loads the password by clicking the "load" image and then can copy the secret's value to the clipboard by clicking the copy image.
•	Fixed an issue where a Distributed Engine would return "Unknown Error" for a secret heartbeat if there was a transient error publishing the real secret heartbeat result back to Secret Server.
•	Fixed a bug where sorting groups by the "Created" field did not properly order groups in the table.
•	Improved page size restrictions when assigning roles and editing groups for customers with large numbers of users.
•	Fixed a bug where searching from a tab did not correctly output search results until the user navigated back to the Home Dashboard. To fix this bug, users now are automatically redirected to the Home tab when performing a search.
•	Fixed a bug that allowed Secret Server Professional Edition users to set a Workflow Access Request secret policy that should be unavailable in Professional Edition, causing an error when adding secrets to folders using that policy.

•	Lengthened the default maximum value for the transaction timeout on the installer from 10 to 90 minutes to prevent installs from failing due to longer database setup. The issue was caused by lengthy transaction times when running the installer against an Azure SQL database. The default maximum value for a transaction timeout is 10 minutes. We added code to allow us to make the transaction larger and set the timeout to 90 minutes.
•	Fixed a bug where converting a secret to a different template created two active copies of the secret: one converted, one unconverted. Inside the SecretDataCopier, when setting permissions, the code did not know it was due to a conversion. It then copied the folder permissions down onto the secret, instead of using the secret permissions that were on the secret originally. This meant that in the scenario above, the user did not have edit rights, throwing an "Access Denied" error.
•	Fixed an issue where launcher-based sessions were not displaying proper messaging during session recording. Message boxes are now correctly bound to their parent process (the launched process), and message box behavior has changed. Before this update, message boxes launched without a proper parent process would be minimized and would not display or block input if you restored the launched process, because they did not belong to the launched process. After this update, message boxes are launched with a proper parent process always appearing on top of that process and preventing input to that process until the message box is acknowledged.
•	Fixed a bug where Distributed Engines configured to callback to multiple Web servers did not work if the server names were separated by semicolons.
•	Fixed an issue where after an SSH key expiration occurred, uploading a new key remained in an expired state instead of properly updating the key.
•	Resolved an exception error that occurred when closing an RDPWin session window after a secret-checkout session ended.
•	Fixed an issue in customer environments configured with ticketing systems where approving a request from an event notification email caused an exception error to occur, rather than completing the approval.
•	Fixed an issue where reports containing the #CUSTOMTEXT dynamic parameter failed to send emails.

Secret Server Release Notes 10.6.000001

Release Date: 2019-03-20

Enhancements

Enhanced the Secret Server Login Assist plugin for Chrome browsers. Changed the mechanism that displays the Login Assist icon in the password field so that it is not obscured by other visible elements of the page. This update also reduced the size of the Login Assist downloaded package.

Download the updated version at https://chrome.google.com/webstore/detail/secret-server-login-assis/pbemhiacephlgacdahceanbbiokmgldb .

Bug Fixes

- Moving dependencies into groups more than once caused a JavaScript error. Fixed a bug where a JavaScript "page unresponsive" error occurred after editing many dependencies without leaving or reloading the page. To resolve this issue, we fixed a memory leak that slowed the page down and caused the error.
- Converting a single Unix Account (SSH Key Rotation) template to the same template type incorrectly populated the Private Key and Public Key File Type drop-down lists. Bulk operations doing the same thing worked fine. Fixed. Note: The customer needed the source and destination templates to be the same because they had a custom template based on it.
- Issues appeared with editing and creating administration scripts after upgrading from Secret Server 9.1.000001 to 10.5.000003. Fixed issue when upgrading from versions 9.1.000001 or earlier. Secret Server
- Fixed: Mac RDP Proxy did not work in Secret Server 10.6.
- Fixed: Custom proxied SSH process provided the wrong $HOST or $MACHINE field values.
- Fixed: An incorrect domain name appeared in the RDP launcher log on window.
- User and group "Send Email Alert for Accounts Found" drop-down did not display correctly on the Discovery Rules Alert page. Fixed an issue where the "Send Email Alert for Accounts Found" user and group "auto completion" drop-down did not display correctly. This occurred on the Discovery Rules Alert page when an SMTP server was configured for the instance.
- Fixed: Bulk 'Edit Share' option erroneously added additional users to share the secret with.
- Mac Custom launcher did not work. Fixed a bug where the Custom launcher failed to launch when configured to use the "Terminal" or "Text Edit" processes.
- Importing secrets into a folder the user owns or can edit erroneously required"Administer Folder" permission. Fixed an issue where a user without the "Administer Folder" permission was unable to import secrets into a folder that they had "Owner" or "Edit" permissions on.
- Mac Unix SSH Key launcher did not work with SSH proxy. Fixed a bug where an SSH proxy did not connect to server from a Mac launcher.
- Custom launchers incorrectly parsed the input prompt. Fixed an issue where Custom launchers (Process, PowerShell, or Batch) did not correctly parse the input prompt.
- Mac Custom proxied executable ran PuTTY instead of a process. Fixed a bug where a custom proxied launcher for Mac attempted to launch on PuTTY instead of SecureCRT.
- Mac launcher was unable to connect to some endpoints after trusting the server fingerprint. Fixed a bug where the Mac launcher was unable to connect to some endpoints due to an issue processing the target machine fingerprint.
- Session recording did not handle HSM encryption properly for video playback. Fixed a session recording issue where video decryption for playback and downloads was not handled correctly when using an HSM. Decryption was incorrectly attempting to use the HSM, rather than the master, key for decryption.
- Dependency group numbering was incorrect when adding dependencies to groups. Fixed. The dependency listing could display multiple dependencies with the same number. This could cause the incorrect impression that dependencies would be run in parallel.

- Copying a secret did not copy file attachments. Fixed an issue where file attachments were not copied when copying a secret or converting to a new secret template.
- When changing the parent folder, the API did not update the folder path for subfolders. Fixed an issue where changing the parent folder ID of a folder in the API did not update the folder path for subfolders.
- Assigning secret permissions to a group threw a secret template permissions "Bad Request" error in Secret Server 10.6. Fixed. Attempting to remove permissions from the All Vault Users group or assigning permissions to a different group threw the error. Assigning permissions to individual users still worked; however, any group-based assignment failed. Secret Server
- In Secret Server 10.6, Execute and other keywords were not filtered from custom reports, creating a security vulnerability. Fixed a security issue where some keywords were not filtered properly from custom reports. This allowed database modification by knowledgeable attackers.
- Hide Launcher Password setting did not work in all cases. Fixed an issue where the Display option was visible in the preview pane of the new UI when a user had Edit permissions on a secret, even with the Hide Launcher Password setting enabled. The password itself was never shown to users who did not have Edit permissions, so there was not a security issue.
- Web services session expired after upgrading to Secret Server 10.6. Fixed issue where the Session Timeout for Webservices setting was overridden by the Allow Remember Me setting for REST and SOAP sessions.

Secret Server Release Notes 10.6.000000

Release Date: 2/12/2019

Upgrade Notes

Manual Updates When Using Integrated Windows Authentication with Distributed Engine

Customers using the Integrated Windows Authentication (IWA) feature with a Distributed Engine need to perform a workaround when upgrading to Secret Server 10.6. IWA is the Windows feature where users log on their Windows domain only once—once logged on, any additional domain logons are done automatically without having to reenter a user name and password.

*Installing New Advanced Session Recording Agent***

Customers using Advanced Session Recording need to deploy the new agent when upgrading to Secret Server 10.6. Secret Server 10.6 does not support the RDP Monitoring Agent from Privilege Manager for recording keystrokes or process auditing.

New Features

Workflows

- Added a new enterprise feature to allow multi-tiered secret approvals. Workflow Administrators can setup secret access to be granted to users only after meeting multiple layers of approver requirements. This feature is available in Secret Server's new UI only.
- Added two new Roles to support multi-tiered secret approval workflows:

- Workflow Administrator – Can administer workflow permissions.
- Workflow Designer – Can create new workflow templates.

Advanced Session Recording

- Enhanced speed and performance for both Basic Session Recording and Advanced Session Recording.

  Added a new agent to Secret Server for Advanced Session Recording that captures metadata from launcher sessions to targets.

  Customers using Advanced Session Recording need to deploy the new agent when upgrading to Secret Server 10.6. Secret Server 10.6 does not support the RDP Monitoring Agent from Privilege Manager for recording keystroke or process start data.

  New Advanced Session Recording Agent includes functionality to uninstall themselves when deactivated from Secret Server.
- Added new configuration setting for storing session recordings based on site. Search for **"Archive Location Dependent on Site."**

  Note: "Enable Moving to Disk" must be checked to reveal the new setting. You may then specify folder path locations based on each site that the Session Recording secret uses.

  Secret Server must have appropriate permissions required to access all file paths listed for saving the configuration and recordings.

  When creating a new site, a specific site-to-folder-path relationship won't be created automatically, the secret will instead use the default path (i.e. whatever path is used for the local site).

  When you edit, a row will show up with the default value per site already loaded.
- Added a warning for Session Recording experiencing many unprocessed videos.

Teams

- Added a new "Teams" feature so that Secret Server administrators can segment users and groups within one Secret Server instance.

  Designed as a convenience feature, users that lack an elevated role permission within a team will not be able to select users, groups, or sites that exists outside their team, including in dropdown options and searches.

  Added three new roles to support teams:

  - Administer Teams - Can create, edit, and view teams.
  - Unrestricted by Teams - Can view all users, groups, and sites. The default User role in Secret Server now has this permission, so role permission customization is needed for Teams to take effect.
  - View Teams - Can view all teams.

FIDO2 (YubiKey) Authentication

- Added a new integration with Yubico. Secret Server can now be configured to use FIDO2 tokens (YubiKeys) as a method for multi-factor authentication.

Launcher Compatibility

- Added backwards and forwards compatibility to the Secret Server Launcher Protocol Handler.

Telemetry

- Added a new feature that sends anonymized usage data to help guide future research and development plans at Delinea.

Remote Password Changing

- Added the ability to use Secret Server's API for Remote Password Changing on AWS secrets. That is, support for PowerShell script password and dependency changes for AWS IAM token rotation. Generated values are passed back for saving on the secret. This useful for tokens generated by an external system during rotation. **Note:** this is only the underlying architecture for use via PowerShell scripts, not a full password changer.
- Added a new IBM iSeries Password Changer template to enhance 5280/IBM Series 7.1-7.3 Systems support including additional features like program functions.
- Added the ability to use a $$Pause Command for the custom SSH Password Changer so that administrators have the option to prevent run commands executing immediately after login, which can cause failed executions.
- Added support for VMware Password Changing and Discovery to work with updated versions of PowerCLI up to 10.1.1.
- Increased default RPC Retry Interval to run every 15 minutes and to cap at 10000 consecutive tries. "Unlimited max attempts" is no longer an available option. Retry Interval can be manually configured by 5-minute increments. Heartbeat interval is also now capped at minimum of 15 minutes.

SDK

- New version of the SDK released on nuget.org that supports targeting for .NET Framework 4.5.1 in all packages. The only external dependency is Newtonsoft.Json (v11.0.2). https://www.nuget.org/packages/Thycotic.SecretServer.Sdk

RabbitMQ Helper

- Added Federation Support and Clustering functionality for RabbitMQ Helper.
- Federation: https://thycotic.github.io/rabbitmq-helper/usecases/federation/
- Clustering: https://thycotic.github.io/rabbitmq-helper/usecases/clustering/

Enhancements

- Added the ability to download a recorded session from the API.

  This new API call will not download metadata, only applies to Basic Session Recordings. The call is api/v1/recorded-sessions/{id}/session-recordings.
- Added a PrefetchCount app setting to allow customization of engine response message processing and enhance processing speed.
- Enhanced load performance for Discovery.

Added a cache for Session Configuration to prevent excessive callbacks to SessionRecordingConfigurationProvider.Load during Discovery scanning.

- Added a new setting for configuring the SSH Remote Password Changing timeout interval to all applicable SSH Secret Template Settings' pages.

  Prior to this fix, users were not notified when a group name exceeded the maximum character length and instead experienced a web session hang.

- Added a setting to Discovery that can check whether IIS is installed before scanning for Application Pools. The "Verify IIS is Installed" Setting can be enabled by navigating to **Admin > Discovery > Edit Discovery Sources > [Select a source] > Scanner Settings >** Scroll down to under the "**Find Dependencies**" section and click the **edit icon** next to the **"Application Pool" Scanner > "Settings – Application Pool"** page.

  In Extensible Discovery, scanners are setup to run in consecutive order across many organizational units within large environments. This setting was added to allow Secret Server to skip the process of scanning for application pools whenever a machine does not have IIS already installed to enhance performance and cut down on run times.

- Added support for a RADIUS challenge in web services. Secret Server will now return a "RadiusUSAccessChallenge" error if an additional prompt is needed. To use this functionality, on-premises Secret Server needs to connect to the same node on both authentication calls.

  Previously, Secret Server could only handle a single request from RADIUS' authentication process. This enhancement uses caching, which means that authenticating scripts need to hit the same web node to use a challenge authentication. This fails when using REST + Secret Server On-Prem + Load Balancing + RADIUS Challenge Authentication combined. The workaround is to hardcode REST scripts by IP or FQDN.

- Added various enhancements to the Upgrader. Enhancements will not take effect until your next upgrading process.

  Upgrade enhancements include updated logging, the removal of unchanged files during the upgrade process, re-ordering of tasks to improve performance, and enhanced messaging.

- Enhanced error messaging when Heartbeats fail due to an unavailable machine state.

  Prior to this enhancement, when Heartbeats failed on a machine due to disconnection it flagged an "Unknown Error." Now the machine will return an "Unable to Connect" status.

- Added and enhanced the Custom SSH Password Changer's console output logging for debugging.

  Prior to this issue, command set logging was removed from Custom SSH Password Changers due to a security concern in the logging messages. To resolve this issue the original security messaging was addressed, then debug logging was reinstated.

- Fixed an issue where Heartbeat failed when changing a AS/400 Mainframe secret due to versioning requirements.

  When setting up an AS400 Password Changer for V7R1 or V7R2 systems, the page erred due to a timeout response from the password changing that failed to manage the WS3270 utility properly. Updated the supported versioning for the IBM iSeries Password Changer template to resolve this issue.

- Added the option to include subfolders when configuring event subscriptions.

Users can now optionally apply event subscriptions to subfolders, previously folder subscriptions were limited to individual folders.

- Enhanced performance of the Event Subscriptions' page.

  Page performance on the event subscription page in Secret Server was increased by rearranging the logic and ordering of the event subscription processes.

- Increased default LDAP processing throttling limit on Distributed Engine from 100 to 1000.

  Distributed Engine's performance was slowed down by the low throttling threshold. Increasing the limit allows faster performance for Engine tasks like heartbeat or password changing.

- Enhanced audit logging messages when viewing and displaying secrets and Passwords.

  Unmasking a password or viewing a password's History is only logged in Secret Server every five minutes when the same user performs the same action on a secret within a short period of time. Prior to this update the description of behavior on the Audit View page did not include the action for "Password Displayed."

- Two-Factor Authentication now supports the User Principal Name (UPN).

  Two-Factor Authentication now supports using the User Principal Name (UPN) as a default for usernames when logging into Secret Server. Configure this setting in **Admin > Configuration > Login > RADIUS Default Username** when RADIUS is enabled.

- Renamed the "Google Authenticator" dropdown option for Multi-Factor Authentication to "TOTP Authenticator" (Time-based One-time Password algorithm) for accuracy.

- Updated Distributed Engine to use REST instead of Windows Communication Foundation (WCF) when using HTTP to contact Secret Server. WCF is no longer a prerequisite installing Distributed Engines.

- Added log message buffering.

  By default, log messages are not buffered and are written to logs immediately. For very active systems, log message buffering can increase performance. In the web-log4net.config file, the Delinea.BufferingForwardingAppender parameter should be uncommented and then IIS reset. Buffer size can be configured using the bufferSize parameter in that configuration file.

Bug Fixes

- Fixed a bug where manually added fields in custom templates would not display in the table view.

  Prior to this fix, when creating a custom template with the "expose for display" option selected the field would not display in the table as a new column.

- Corrected error messaging when deleting a dependency on secrets with large numbers of dependencies.

  When a secret had 1000+ dependencies, deleting one of them resulted in a "Failed to Execute" error prior to this fix.

- Fixed error reporting when a user enters a group name that exceeds the max character length.

- Fixed an issue where background threads could go into wait mode indefinitely during a manual upgrade.

  Added detection for when the "upgrade in progress" indicator remains active after a completed manual upgrade. This could cause background tasks to remain paused indefinitely during a manual upgrade. Now, the user is notified and can reset the indicator, allowing background tasks to resume.

- Resolved an issue with Amazon secret heartbeats and rotations because of a change in Amazon login page layout and flow. To create a new Amazon Web Services (AWS) secret: create a new web password secret, then select **Remote Password Changing tab > Password Type** (Amazon, Google, and Salesforce options).
- Fixed an issue where a RADIUS Authentication timeout would block other RADIUS requests from authenticating to Secret Server, causing login delays for RADIUS users.

  Prior to this update there was a lock in the RadiusUSRequest.GetResponse() that only allowed one connection at a time. This fixes an issue when making more than one UDP connection to the same client port.
- Removed unnecessary logging on the OperationCanceledException in the System Log.
- Fixed a bug where SSH Key rotation commands were not properly authenticating.

  The "Verify" command for password changing was ignored if no "Post Change" command existed in a Custom SSH key rotation template, resulting in being able to use the same key to connect for the verify command and the password change in certain cases.
- Fixed a broken documentation link on the Server Nodes page.
- Fixed a bug where duplication errors occurred if scheduling a report with the same name as another, already disabled, report in Custom Reports.

  The workaround for this issue was to undelete the original report and rename it before deleting it, but users are now able to delete and create reports with the same name, if the duplicated reports are not both active.
- Fixed an issue that prevented users from creating or editing an SSH Command Menu on individual secrets.
- Fixed an issue where the "Allowed" and "Available" Secret Templates' columns did not populate on the "Create New Folder" page when restricting secret templates.
- Fixed a bug where editing checkout hooks saved changes instead of allowing users to cancel out of the edit page.

  After clicking cancel on the checkout hooks edit page, the updated data was not saved to the database but was updated on the page behind the UI modal.
- Edited PUT /secrets/{id}/fields/{slug} parameters in API documentation to use Secret ID instead of the secret name.
- Edited /secrets/{id}/check-in REST API call in API documentation.

  In this script, "Force Checkin" could bypass the Access responses, then successfully check-in the secret, before attempting to return the access responses it previously skipped. This failed.
- Fixed a bug where ProcessShouldScanComputers resulted in collation conflicts after running Discovery on OUs with incorrect server collation settings.

  Specifically, this occurred if a server's default collation was set to "Latin1_General_CI_AS" because it conflicts with "Latin1_General_CI_AS" collation on Secret Server SQL database's collation settings when running SQL commands on specific tables.
- Fixed an issue where ExpiredSecretMonitor stopped running in certain conditions due to a session recording call.

Users were experiencing several days in between these issues. The SessionRecordingBlobWriter registered an exception error that stopped background threads from processing. This SQL call was irrelevant, and its elimination allowed the ExpiredSecretMonitor to update every minute as normal.

- Fixed an issue where "Language Resource Not Found" errors were thrown on the Themes page under the Advanced section.

This issue resulted from missing resource strings on the page.

- Fixed an issue where the SSMS launcher did not send the correct password if a caret symbol (^) was in the password.

  This issue was specific to SQL Server Management Studio (SSMS.exe). The fix for this involved updating the SSMS process launcher configuration to allow for an optional escape character to be added, now configurable in the advanced section when setting up a launcher for a SQL Server Account secret.

- Fixed a bug where failed password changes on custom SSH secrets would not stop processing when CheckContains command failed.

  This issue stemmed from the CheckContains command script in the Custom SSH password changer.

- Fixed a bug where environments using geo-replication threw errors when attempting to re-send failed syslog messages.

  Prior to this fix, geo-replication environments with failed Syslog messages resulted in large numbers of error messages because Syslog created triggers on the tables and would try to update the items repeatedly.

- Fixed an issue where items could be imported into the root personal folder.

  Prior to this fix, administrators were able to migrate secrets into the Personal Folder (root) using the upload XML tool, which allowed all users to see the imported items.

- Fixed an issue where a language setting caused errors.

  Some language settings could cause an IIS crash with HTTP Error 503: The Service is Unavailable.

- Edited tooltip wording for the advanced "Auto Change Schedule Interval" setting.

- Fixed an issue where SSH key rotations were not properly rotating and then deleting the old SSH key at endpoint when the SSH Custom Password Changer was configured in a specific way.

  Key rotations for Linux SSH keys failed to cleanup old SSH keys on target machines after a key rotation occurred due to a missing command in the success script.

- Fixed an issue where users were unable to delete Reports.

  Deleting and undeleting Reports threw an exception error due to a database ReportCategoryId mismatch.

- Fixed an issue where the API call "GET /secret-templates" did not support the inactive filter ("filter.includeinactive").

- Updated API Rest documentation to not label a Dictionary object (enumerated KeyValuePair) as an object[].

- Fixed an issue where scheduling Reports failed if the time zone was set to time zones ahead of UTC.

  Prior to this fix, any time zone that was UTC+x failed to properly populate ScheduleCustomReportEdit.aspx "Recurrence Scheduled Start Time."

- Fixed an issue with the API Folder Create method where folders created through the API would error when trying to access permissions.

  After creating a new folder via the REST API, a Get command for the new folder would return null permissions prior to this fix.

- Fixed a bug where Basic Users were not able to use the "Create New" secrets template when Active Directory template permissions were revoked.

  In Basic User mode the "Create New" secret templates drop down list incorrectly started with `<Active Directory>`, causing permissions errors when the Active Directory Template was revoked for Basic users. The drop-down list now starts with `<Select>` in all user modes.

- Fixed a bug where searching for a subfolder would not return results when the user did not have permissions to view its parent folder.

- Fixed a bug where the bulk operation mode did not move multiple secrets to a folder.

  This issue specifically involved the search feature on the bulk operation dropdown when filtering for the folder location. Users were required to manually select the folder rather than being able to find it through search.

- Fixed issue where "Require Approval Access" on a secret policy did not follow default settings to not enforce the policy.

- Fixed a bug where a user's display name could be left null when creating new users.

- Fixed an issue where Discovery Computer Scans using a "machine only" resolution type resulted in an exception error rather than completing the scan.

  A null exception was thrown when scanning for machine names rather than using the "Use Fully qualified name (recommended)" setting in Discovery.

- Enhanced error messaging when running Dependency scans in Discovery.

- Error message fixes included:

- If all scanners worked but did not find anything: "No Dependencies."

- If one scanner fails, then it shows a failure message for the scanner.

- If multiple scanners fail, it only has room to show one failure.

- If a scan fails but no failure message exists, it will show "Unknown Error."

- Updated two collation settings in session recording tables to allow case insensitivity on table names and prevent collation errors when the SQL server collation mismatches.

- Fixed an issue from a patch update where scanning for scheduled tasks in Discovery failed due to an auto-appended domain in the authentication string.

  This issue only affected customers who deployed the December Patch, v 10.5.14.

- Fixed a bug where the "Only change password when Secret is expired" checkbox would not save if Auto-Change Schedule was set to None.

- Fixed an issue where SAML authentication check could not be disabled.

  Prior to this fix, some accounts would receive an 'Invalid Relay State' error when logging in. This had to do with disabling the "SAML authn context" in Secret Server.

- Enhanced error messaging when Heartbeat is not assigned to a PowerShell Script Password Changer.
- Fixed a bug where log file exports were not downloading from the Manage Secret Access Request page.
- Fixed a bug where the "Use Custom Window Size" Launcher setting was not implementing the correct resolution.

  Prior to this fix, when attempting to launch at a smaller 1024 x 768 resolution, a session launched instead as full screen.
- Fixed an issue where if the Response Bus Site Connector disconnected, it prevented the web site from loading.

  Updates were made to BackgroundScheduler, BackgroundWorker, and the EngineWorker. If a role cannot connect to its response bus an error will now be logged and the site will still load.
- Fixed a bug where Heartbeat on local administrator accounts on Windows Server 2012 pre-R2 was not compatible with PowerShell v3.0.

  Added output logging to file and operating system information.
- Fixed a bug where reports were saved in UTC time rather than in local server time.
- Fixed a bug where API calls against restricted secrets threw an object reference error.

  This fix allows accessing "require comment," checkout, or other restricted secrets through the API. These secrets were returning errors due to a null reference linked to a "ViewTracker" secret attribute.
- Fixed an issue where a WinRM warning message displayed even when WinRM is running and correctly configured on a server if authentication account did not have access to running services.

  Prior to this fix the WinRM warning message saying the service isn't running displayed on the PowerShell maintenance window even though WinRM was running and correctly configured on the server according to instructions at: http://support.thycotic.com/KB/a303/configuring-winrm-for-powershell.aspx PowerShell scripts ran successfully, but the misleading message remained.
- Fixed an issue where Web Password secrets caused Bookmarklet JQuery Exceptions when the Web Password Filler was used in the IE11 browser.
- Fixed a bug where EnableFrameBlocking was not respected on certain pages in Secret Server.

  Middleware was added to send X-Frame-Options / SameOrigin header for everything but the bookmarklet if not installed, no one was logged in, or FrameBlocking was enabled. MainLayout also changed for MVC pages so that they will render with the frame blocking script.
- Fixed a bug where email configurations were not properly saving applied settings.

  Prior to this fix, changes to Email configuration page did not properly update the database.
- Fixed workflow issue where users were directed to the Setup Home page after saving changes on the Email configuration page.
- Fixed an issue where AD users were not receiving approval emails after an access request for a secret in some environments.
- Fixed a bug which caused audit tables to display date and time in UTC rather than the configured time zone.
- Fixed a bug that could cause bulk operations to fail in environments using geo-replication.
- Fixed a bug that could cause a "Failed to load history" error when viewing the history data for a secret.

- Fixed a timeout on secret audit when there are very many audit entries.

  Audits with very large result sets only display the top 1000 entries.

- Resolved an error reporting issue with Unix Account (SSH) and Unix Account Custom (SSH) account types so that connection failures and login failures are correctly reported.

  Previously, Unix Account (SSH) would report login failure as UnknownError and Unix Account Custom (SSH) would report login failure as UnableToConnect.

Secret Server Release Notes 10.5.000003

Release Date: 9/24/2018

Enhancements

Session Recording

- Updated Session Recording to support H.264/MP4 video encoding with resolutions up to 4K (now the default).

  Customers are now able to configure the time when Session Recordings are moved from the database to disk to suit business needs. Previously this move was hard coded to run at 02:00 UTC. Time is configured through an AppSetting.

User Interface

- Preview Mode for the new and improved redesign of Secret Server has been enabled. Please contact UX@thycotic.com to gain access to the Preview Mode.
- Included a "24 hours" option to the expiration Quick Picker.

APIs

- Updated the UserCreateArgs to include AD Guid to account for possible duplicate users in Active Directory through the API.
- Added API call for Check Out Secret.

Time Zone Enhancements

- Enhanced time zone functionality on the backend to account for daylight savings time.

Bug Fixes

- Fixed a bug where users with the "Administer Configuration" Role Permission could see but not access option settings under Admin > Configuration.
- Fixed a bug where the Application Pool scanner and IIS tester do not properly initialize the ManagementScope for WMI calls to Local Machines.
- Fixed a bug where only one Discovery Scanner worked when Active Directory had more than one local account scanner setup.
- Fixed a bug where valid REST/SOAP API tokens did not permit login access.
- Fixed an issue that allowed personal folders to be moved to the top level of the folder tree.

- Fixed an issue where after adding and saving an identity provider in advance settings (SAML), the user observed an error stating 'Object reference not set to an instance of an object.'
- Fixed a bug where a user was unable to delete an approved user from the Edit Secret Policy page.
- Fixed a bug where there were inconsistencies in the time zone handling.
- Fixed a bug where there was an error message of 'Connection Failed' during Custom Unix (SSH) Remote Password Changing but the password changed successfully.
- Fixed a configuration issue with the SSH Key Rotation Privileged Account Password Changer that is used by the Unix Account (Privileged Account SSH Key Rotation) template and caused RPC to fail with an error saying Associated Secret is required.

Security Fixes

- Fixed an issue with Request Access when set to be required for Owners and Approvers where an Approver could approve their own request through JavaScript manipulation. Note an email detailing the approval would have been sent to all other approvers.
- Fixed a Security Vulnerability that allowed Cross-Site Scripting.

Secret Server Release Notes 10.5.000001

Release Notes 10.5.000001

Release Date: 8/15/2018

Security Fixes

- Secret data is now authenticated with HMAC-SHA-256. This addresses CVE-2018-18002.
  - Security Issue Discovered by: Jarrod Farncomb of TSS (https://dtss.com.au)
- SOAP API updated to use the same token generation as the REST API.
- Security Issue Discovered by: TSS (https://dtss.com.au)

Enhancements

- Customers are now able to configure the time when session recordings are moved from the database to disk.

Bug Fixes

- Fixed issue where after 10.5 upgrade, session recording could not be configured to use a file share.
- Fixed an issue where there was an intermittent first login fail on fresh install.
- Fixed issue where selecting "Now" for a password change in Autochange Schedule could set the incorrect time in situations where the user's computer is in a different time zone than the Secret Server host.
- Fixed issue where dependency scanning would miss Scheduled Task dependencies in situations where two domains with the same name (ex: customer.com and customer.net) were used.
- Fixed issue where the password for an account would be changed multiple times in a row if the "Only Change password when Secret is expired" box was selected in Autochange Schedule.
- Fixed issue where bulk operations could cause database deadlocks.

- Fixed issue where Distributed Engine callbacks could cause a race condition.
- Added a warning to the schedule page that specified the time will be saved is Secret Server configuration time.
- Fixed an issue where after adding and saving an identity provider in advance settings (SAML), the user observed an error stating 'Object reference not set to an instance of an object.'

Secret Server Release Notes 10.5.000000

Release Date: 7/10/2018

Enhancements

SAML

- Added a new SAML configuration page so SSO providers can be configured without modifying the saml.config file.

UI Updates

- Subfolders can now be created within a user's Personal Folder.
- The login screen domain dropdown menu can now be disabled for customers that wish to hide the list of domains.
- Added auditing for the following configuration changes: Character Sets, Password Requirements, Event Subscriptions, Role names, Backups, Custom Password Changers, Licenses, and Database Connections.
- Added export functionality for Heartbeat logs, Remote Password Changing logs, Discovery logs, and Computer Scan logs.
- Failed password changes now display an error within the Secret View UI.
- If using multiple devices per user in Duo Security for two factor logins, Secret Server will now show the Device Name set in the Duo admin portal next to each device.

Discovery

- Added Discovery settings to scan for open ports on target machines, connect to specific ports, and set a default timeout for port scanning.
- Added a Discovery scanner setting for excluding services, tasks, or application pools by name.
- Added new Diagnostic logs to address duplicate Discovery Scan items.

Password Changing

- Auto Change Schedules can now be configured so that they will trigger a password change even if the Secret is not expired.
- Added the ability to rotate SSH Keys with no passphrase required.

Reporting

- Added Session Revocations to the User Audit report.
- Added IP addresses to the login failure report.

- Added new chart options for custom SQL reports.
- Added the ability to configure AS400 Password Changers.
- Enhanced Secret Server's ability to process larger message sizes. Secret Server'
- Distributed Engines now send operation results back to Secret Server through the Site Connector instead of sending them via website.
- Ticket System Integration can now be configured to work over Distributed Engine.
- Improved System Log Searching in active environments.
- Added new Syslog event messages for SIEM integration and enhanced log messaging.

Security Enhancements

- Added a configuration setting to change the default role that a new user receives.
- Added the ability to audit certificate verification errors for Active Directory calls over LDAPS and syslog connections using Secure TCP.
- Added the ability to send a client certificate with Active Directory calls over LDAPS or syslog connection using Secure TCP.

Bug Fixes

- Fixed issue where Secret Policy changes would not apply to all Secrets.
- Fixed issue where Service Account Discovery could timeout and flag Secret Dependencies for removal.
- Fixed issue where Two Factor could prevent a "Login Failed" audit on the user; added new logging details in the Audit User Log if errors do occur from Two Factor authentication.
- Fixed issue where excluding OUs from Discovery scans prevented computers from being deleted when they were removed from AD.
- Fixed condition in certain environments where the auto-change Secrets were not changing properly.
- Improved performance of the Discovery Stored Procedure for specific OUs scanning to avoid timeout in large environments.
- Fixed a logging exception in Monitor Logging.
- Resolved a permission error in certain environments that occurred during Local Account Discovery Scans.
- Fixed issue where integrated Windows login requests were building up in the tbOauthExpiration table.
- Fixed issue where columns could not be sorted in Discovery Network View.
- Fixed issue where queued RabbitMQ messages were lost if RabbitMQ was restarted.
- Fixed bug where an email config port change was logging the new port as the old port.
- Fixed an issue with SQL Replication where indexes on indexed views were not replicated.
- Fixed issue where a DependencyResolutionException could occur on the Login page and prevent use of site until an IIS reset was performed.
- Fixed issue with SSH password rotation/Heartbeat connections that were reporting "Unexpectedly inactive."

- Fixed issue where the Secret Server Clipboard Utility could not be installed with Chrome 67.
- Fixed issue where the dashboard Add Content dropdown displayed below the Secrets table.
- Fixed null reference bug that occurred when autocomplete textboxes were used in lieu of a dropdown for the Group/User selector.
- Fixed bug in Password Changing where a large number of Secrets targeting the same resource for certain password changers could prevent processing.
- Fixed issue where root folders could be created through the CSV import process while that user did not have the Create Root Folders role permission.
- Fixed an issue that could cause occasional black flickering to appear in Session Recording videos.
- Fixed issue where users could be logged out of Secret Server due to inactivity while actively browsing certain pages.
- Fixed issue where new Secrets displayed the option to save to a user's Personal Folder even if Personal Folders were disabled.
- Fixed issue where Discovery local account scans were parsing unnecessary data and taking more time than necessary in large Active Directory domains
- Fixed issue where changes to Users would not save when extremely large numbers of AD groups were being synchronized.
- Fixed issue with custom PowerShell Ticket System integrations where entering a ticket number to view a Secret would produce an error.
- Fixed issue where creating a new Event Subscription would fail when specifying a user or group.
- Fixed issue where the REST API would not correctly implement the "Require Two Factor for Web Services" configuration option.
- Fixed issue where Heartbeat could be stuck in Pending status.
- Fixed issue where creating new Folders would fail when there were no other Folders.
- Fixed condition in certain environments where the auto-change Secrets were not changing properly.
- Fixed issue where Dashboard searching was slow in environments with large numbers of Secrets.
- Use of SAML while Virtual Assist Keyboard is disabled no longer causes Virtual Assist Keyboard to appear.

Security Fixes

- Fixed issue with Unlimited Vault Access permissions and managing Groups.
- Deprecated TLS 1.0 in Security Hardening Check.
- Fixed issue with script names.
- Fixed issue with Upgrade Status log.

Secret Server Release Notes 10.4.0

Release Date: 1/17/2018

Note: Customers with trial licenses in their Secret Server instance who upgrade to 10.4 will be required to activate those licenses.

Enhancements

- Secret Server SDK: The Secret Server SDK replaces and improves upon the existing functionality of the Java API and .NET/Application API. Users can leverage this SDK to tokenize credentials in scripts and configuration files for .NET web applications. The SDK can also call for a REST Web Services authentication token for added functionality. Finally, the SDK has a local encrypted cache for every location it is installed in to allow for quicker transit times and resiliency in case communication with Secret Server is lost.
- Session Monitoring Multiple Nodes: Clustered Secret Server environments will now automatically split the processing load for Session Monitoring events.
- AD Credential Cache: Secret Server can create an encrypted storage for hashes of Active Directory users' credentials that is updated on every successful authentication to Secret Server and allows for users to continue to access Secret Server even if communications are lost between Distributed Engine and the Domain Controller (s).
- Secret Server now has a REST endpoint to manage Secret dependencies.
- Secret Server now has a REST endpoint to manage groups.
- Secret Server's Firefox browser extension has been updated so it can continue to work with the latest versions of Firefox.
- Secret Server can now communicate to SIEM tools using a TLS connection.
- TLS connection successes and failures with Active Directory Synchronization and SIEM integration are now audited.
- Secret Server can now send audits to Windows Event Logs.
- Enhanced Dashboard search performance.
- Enhanced Active Directory synchronization performance.
- File uploads on Secrets now have file extension and size restrictions.
- Added a Security Hardening report to indicate whether email communications are set to use HTTPS.

Bug Fixes

- Fixed issue where SSH custom password changers failed Heartbeat when using SSH Key authentication.
- Fixed issue where Discovery would incorrectly show as misconfigured despite having configured Discovery sources.
- Fixed issue where random password generation may generate a password containing 2 consecutive characters contained in the Active Directory username.
- Fixed issue where the login assist for Chrome would not work if an IP address was in the URL field of a Secret.
- Fixed issue where numerous domains in Discovery could cause failures in communicating with the SQL database.

- Fixed issue where Discovery would only use the correct Distributed Engine Site on the first dependency type when scanning for all dependencies across multiple domains.
- Fixed issue where a significant number of Secrets that were failing a password change would freeze Distributed Engine.

  Security Fixes
- Fixed XXE issue on Web Launcher configuration page.
- Fixed XXS issues on New Engines management page.
- Fixed XSS issue on Secret Dependency Changers page.
- Fixed issue where Secret Server upgrade logs written to the server hosting Secret Server were accessible via a URL.
- Fixed issue where Remember Me for 2FA bypassed Duo's deny logon security settings on users in some cases.
- Updated PuTTY client for Session Launching to v0.70.
- Fixed potential security issue where the RDP service port on the client machine could be used to open a concurrent RDP session to the target machine when RDP connections were proxied through Secret Server.
- Fixed LESS Injection issue on Theme management page.
- Fixed issue where language resource ASHX files in Secret Server could be accessed by any user with access to the application.
- Fixed issue where default settings on PuTTY logging settings could expose the password of a user.

Secret Server Release Notes 10.3.x

Release Notes 10.3.000015

Release Date: 9/25/2017

Enhancements

- Secret Server now supports SafeNet Luna Network HSM 7.

Bug Fixes

- Fixed issue where Active Directory Synchronization may become slow or unresponsive when synchronizing a significant number of Active Directory groups.
- Fixed issue where users may be removed from a group in Secret Server if that group contains users from multiple Active Directory domains and one of the domains cannot be reached during a synchronization. Secret Server
- Fixed issue where Secret Server Free customers could not manually add Active Directory users.
- Fixed issue where selecting specific Organizational Units for an existing Active Directory discovery source may not work properly after a manual host range is added to it.
- Fixed issue where Unix machines discovered using PowerShell may reflect an incorrect Organizational Unit.

- Fixed issue where users were no longer forced to change their password upon first login if the Enable Local User Password Expiration configuration setting was enabled.
- Fixed issue where using Discovery for dependencies over Distributed Engine may return incorrect results.
- Fixed issue where multiple Discovery host range scans could cause redundant machine loads.
- Fixed issue where using search in Secret Server while on the Notifications page may cause an application error. Secret Server
- Fixed issue where users who have an externally facing IP address that could not be resolved from the web server hosting Secret Server may experience performance issues throughout Secret Server.

Security Fixes

- Fixed XSS issue on the Secret Template Permissions page.
- RabbitMQ Helper has been updated to install RabbitMQ 3.6.12 which now supports Erlang 20. This patches Erlang 18's vulnerability CVE-2016-10253. We do not believe that Erlang 18's vulnerability has a direct impact on Secret Server's use of RabbitMQ, but we recommend updating current Erlang and RabbitMQ deployments to these versions to keep systems patched.
- Fixed potential security issue with Secret Server's scripting functionality.

Release Notes 10.3.000014

Release Date: 8/29/2017

Enhancements

Secret Template Edit Launcher Configuration Enhancements for PuTTY Launchers $1 $2

- Added a report in Secret Server to display what Secret Template permissions a user or group has.
- Added an option in Secret Server to backup Privilege Manager.
- Secret Access Requests can now be found under the Tools menu.
- "Share Secret" Role permission has been renamed to "Own Secret".
- Upgraded the module responsible for Office 365 and Azure Active Directory password changes to ensure continued support.

Bug Fixes

- Fixed an issue where pages involving groups could not be saved if there were 5,000 groups or greater in Secret Server.
- Fixed an issue where Active Directory users in child domains may not be properly disabled in Secret Server when they are disabled or removed from Active Directory.
- Fixed an issue where ambiguous errors were logged when the username or password is correct on any password changers, dependencies, or scripts using SSH.
- Fixed an issue where the Share button would disappear on Secrets on the dashboard when a user does not have the Share Secret Role permission. Users should still be allowed to view the permissions on a Secret even if they cannot decide who that Secret is shared with.

Security Fixes

- Fixed potential security issue where a formulae injection could occur on exports from Secret Server.

Release Notes 10.3.000000

Release Date: 7/12/2017

Enhancements

SSH Key Management Enhancement

- SSH Keys as Dependencies (May require an additional license): Multiple Public keys that reference a single Private key can now be stored as dependencies on the Private key Secret. For more information, please see the Remote Password Changing section of the "Secret Server Documentation" on page 1.

EMEA Cloud

- Secret Server Cloud is now hosted out of Germany as well as the US.

Secret Template Granular Enhancements

- Added ability to restrict Secret creation for users by Secret Template.
- Added ability to set the allowed Secret Templates for a folder.
- For more information, please see the Folders and Secret Templates sections of the "Secret Server Documentation" on page 1.

SAML

- SAML Single Logout is now supported.

UI Updates

- The Dashboard load time performance has been optimized.
- Add auditing for configuration changes.
- Added a button to export all logs under Admin | Diagnostics.
- Refined user experience around creating dependencies on Secrets.
- Added bulk operations for Dependencies.

REST

- Added endpoint for IP Address Restrictions.
- Added endpoint for generating a password.
- For more information on these REST endpoints, please see the 10.3 REST API Guide.

WARNING: Customers who are upgrading from 10.2.000018 and use Windows Integration Authentication to the database may see an error message titled "Login failed for user" during the validation step of the upgrade process. To bypass this error, please use the legacy installer by navigating to `[Your Secret Server URL]/installer.aspx?patch=true&useLegacyInstaller=true`

Bug Fixes

- Fixed issue where Local Account Discovery used unnecessary calls.
- Fixed issue where Secret Server removed dependencies that were not found by Discovery and would not re-add them if found again.
- Fixed issue where the Delinea RDP Launcher would not allow fullscreen mode.
- Fixed issue where Discovery did not properly detected Scheduled Tasks on Windows 10 machines.
- Fixed issue where testing a SSH script in Secret Server would only display an exit status when it failed.

Security Fixes

- Fixed potential security issue with multi-line files and Secret fields.

Secret Server Release Notes 10.2.x

Release Notes 10.2.000019

Release Date: 6/19/2017

Enhancements

- Privileged accounts assigned on a Secret Template now take precedence over privileged accounts assigned on Secret Policy.
- Secret settings are now able to be modified via the SOAP web services API when a Secret is checked out.

Bug Fixes

- Fixed issue where Secrets with privileged accounts assigned for password changing could not be moved to a folder with a Secret Policy that contained a privileged account.
- Fixed issue where Secret Server could delete recordings stored on a disk.
- Fixed issue where users without the View Deleted Secrets role permission received errors when expanding the advanced search bar on dashboard.
- Fixed issue where some accounts discovered by Discovery were not matched to existing Secrets.
- Fixed issue where upgrade may fail when the database connection is configured to use Windows Authentication.
- Fixed issue where "Show Proxy Credentials" on a Secret will fail when generating credentials for connecting to the SSH Proxy.

Security Fixes

- Fixed XSS issue on Secret Share.

Release Notes 10.2.000018

Release Date: 5/17/2017

Enhancements

- Added additional RDP Launcher type to facilitate future customization.
- The connection bar text will show the target machine's address in a tunneled RDP session.
- Added the ability to search for a Secret Template by name using REST.
- Added the ability to set Secret permissions using REST.
- Added the ability to delete Folders using REST.
- Added the ability for Secret Server to discover COM+ dependencies.
- Added a new Secret Template and password changer for Watchguard Firewalls.
- Distributed Engine site selection drop down will now autocomplete with 50 or more Sites.
- Added option to specify whether a domain in Secret Server will be used for logging into Secret Server.

Bug Fixes

- Fixed issue where the SSH Machine scanner would not use multiple Secrets or Filters for scanning.
- Fixed issue where Discovery machine scanners set to authenticate did not throw errors when authentication failed.
- Fixed issue where PowerShell dependency information was cleared when editing the dependency after initial creation.
- Fixed issue where REST calls to update a Secret incorrectly bypassed Request Access.
- Fixed issue where scheduled Report emails did not include the full URL to view the Report in Secret Server.
- Fixed issue where PowerShell dependency arguments incorrectly referenced Secret field display names.
- Fixed issue where creating a new PowerShell Ticket System would throw an error.
- Fixed issue where the PowerShell script tester did not reference Distributed Engine if it was enabled on the Local Site.
- Fixed issue where the Site list shown when creating a new Discovery source contains an invalid entry.
- Fixed issue where users without the Share Secret Role permission were able to share Secrets.
- Fixed issue where clicking the Back button on the View Audit page of a Secret and clicking the Back button again on the Secret view page would cause a redirect loop.
- Fixed issue where converting a Secret to a new Secret Template does not recreate dependencies.
- Fixed issue where resetting the database connection could throw an error.
- Fixed issue where Discovery did not handle CredSSP and WinRM correctly on specific Organizational Units.
- Fixed issue where session launchers would occasionally fail in a Secret Server environment where a Load Balancer was present.
- Fixed issue where saving a Secret's audit to a file would throw an error.
- Fixed issue where Discovery rules occasionally created duplicate Secrets.
- Fixed issue where Reports could be sent without specifying an email address.

- Fixed issue where Engines did not display that they were offline after failing connection verification checks.
- Fixed issue where using REST to delete a user threw an error.
- Fixed issue where Secret Server could not be upgraded using Internet Explorer.
- Added support for application account impersonation via SOAP web services.

Security Fixes

- Fixed XSS issue on Discovery Network View.
- Fixed XSS issue on Dashboard.
- Fixed Frame Blocking issue on Dashboard.
- Fixed potential security issue with the Chrome Login Assist Extension.

Release Notes 10.2.000001

Release Date: 4/25/2017

Security Enhancements

- Fixed an issue in 10.2.000000 where a highly privileged Secret Server administrator could, in certain select circumstances, be inadvertently granted read access to Secret data that is protected by Secret Workflow. This issue was found during routine internal testing and review.
- Enhanced security around various ajax calls.

Release Notes 10.2.000000

Release Date: 4/12/2017

Enhancements

Session Monitoring

Remote Desktop Metadata (May require an additional license)

- New session monitoring agent records additional data from the RDP sessions including process activity, keystrokes, and more.
- The Monitoring agent adds support for recording remote sessions on servers that were not launched directly from Secret Server.
- Updated the session search UI to support cross session searching for data within the session and additional filtering options
- Updated the session playback UI to support in browser playback and activity points in the session
- Performance enhancements to session processing speed

Discovery

- Added out of box discovery to find Active Directory accounts on the domain
- Added option to discovery import rules to limit the number of Secrets to import to prevent unexpected takeover of accounts

Upgrades

- Added a Setup console to manage upgrades and core product configuration across different Delinea installations
- New Secret Server upgrade manager that gives more detailed messages and support upgrading multiple products from a single interface.

UI Updates

- The Secret Server header has been modified for more logical grouping of menus
- Moved user specific menu items under a new user icon header
- Added a new Alert Notification Center header icon with a badge to show pending alerts.
- Removed support for customer defined HTML help pages.
- Added new in app help messages to page headers

REST

- Added endpoint for Launcher lookups
- Added Session Monitoring endpoints

SAML

- Added support for SHA256 for SAML request signing
- Added support for ForceAuth to support forcing credentials when first navigating to Secret Server even if logged into the identity provider.
- Added support for signing SAML requests in a CNG Key Storage Provider

Note: The upgrade to 10.2 will migrate the saml.config to a new format to support added features.

- Running a script test from the UI now has an option to select the Site to run it on
- Added an option to select a Secret to run a test script as
- Added internal site connector for background message processing.
- Added support for 2FA for SOAP winauth web services.
- Added timeout setting for RADIUS authentication
- Updated SSH Library for heartbeat and password changing to support more ciphers.
- Added a $$CHECKNOTCONTAINS check to the SSH password changers

- Added custom port support for SSH password changing and heartbeat
- Added default mainframe password requirement

WARNING: SQL Server 2005 is no longer supported.

- A new desktop client is available. For instructions and download links please see the Desktop and Mobile App Guide

Bug Fixes

- Fixed issue where scheduled backup wasn't working for Free edition
- Fixed HSM session leaking for Safenet Luna PCI cards
- Fixed upgrade issue that could cause database errors in some cases where discovered Dependencies were not able to properly map to a Scan Template.
- Fixed issue where the default WinRM endpoint was not used by an engine if the WinRM endpoint was left blank on the Site configuration.
- Fixed unnecessary logging in Discovery
- Fixed issue with engines not upgrading after a Secret Server upgrade
- Fixed locking errors that could occur on the file system when debug logging was enabled.
- Fixed issue with scanning specific OU's with a custom PowerShell Discovery script.

Secret Server Release Notes 10.1.x

Release Notes 10.1.000023

Release Date: 2/22/2017

Enhancements

- Added additional actions to user audit for when 2-factor is changed on the user.
- Added status icon to the Heartbeat field on Secrets. Going forward new Heartbeat and Password Change errors can be viewed in a Secret's audit log for quicker diagnosis and reporting. Note that these error messages are not backfilled so only new errors will show in the log going forward.
- Added support for multiple domain controller IP addresses in the domain field of an Active Directory Secret for cases when the domain name isn't resolvable for heartbeat and password changing.
- Updated behavior in the SOAP API for disabling Check Out on Secrets that are currently checked out to match bulk operations behavior. A Secret Owner can now call SetCheckOutEnabled to turn off check out on a currently checked out Secret.
- Added a new role permission for creating application user accounts.
- The SSH Proxy now restricts the default cipher suite for incoming connections.
- SOAP API – Added new method for GetReport to get report data via the API

Bug Fixes

- Fixed issue where password changing through Distributed Engine would not run in Professional Edition
- Fixed localization issues in logs
- Fixed engine upgrade error when upgrading from the legacy agent to distributed engine.
- Fixed issue where the database field tracking when the Secret expiration field was initially set using the server time instead of UTC
- Fixed issues with the Secret Search Filter for Discovery
- Fixed issue where getting redirected to the Logged in at other Location could cause the user to be logged out at both locations.
- Fixed issue in AD sync where an error was logged in some cases if the client was accessing from behind a load balancer.
- Fixed issue where using the Folder Slider on dashboard and deleting the currently selected folder would break dashboard search.
- Fixed issue where you could set an approval group that only contained an application account user
- Fixed exception that could occur in the system log for license expiration checks.
- Fixed issue where the only privileged account options in Secret Policy were for LDAP or Active Directory Secrets.
- Fixed issue where the Configuration Edit Event Subscription didn't fire if email settings were modified
- Fixed issue where a large custom expiration data, such as 12/1/9999 on a Secret caused 500 errors on Dashboard search
- Fixed SQL Replication issues where web server nodes connected to subscribers redirected to replication page and audit insert errors could occur.

Security Fixes

- Fixed XSS issue on Discovery Scanners.
- Fixed XSS issue on Secret View for certain launcher configurations.

Release Notes 10.1.000000

Release Date: 1/18/2017

Enhancements

SSH Key Management (May require an additional license)

- Added ability to automatically generate new public / private key pairs and rotate the public key on servers.

z/OS RACF Support (Requires Premium Edition or higher)

- Added support for automatically manage IBM z/OS RACF credentials

Dual Control

- Added options to enforce dual control when viewing recorded sessions, shadowing sessions, and running reports to enforce 4 eyes principle for potentially sensitive audit information.

New Built in Reports

- Unlimited Vault Access Activity: Shows actions done by users with the Unlimited Vault Access permission when break the glass mode is enabled.
- What Secrets Changed Passwords in Last 90 Days: Shows Secrets that have had their passwords changed in the last 90 days.
- What Secrets Have Not Had Passwords Changed in Last 90 Days: Shows Secrets that have not had a password change in the last 90 days.
- What Folders Have Policies Assigned: Shows what Secret Policies are assigned to folders.
- What Secrets Have Different Policies Than Their Folders: Shows Secrets that aren't inheriting their policies from their Folder.
- What Secrets have Policies Assigned: Shows what policies are assigned to each Secret.
- User Activity Report: Added User's current locked out status to the user activity report.
- Added ability to auto enable Google Authenticator, Duo, and email two factor as part of domain synchronization.
- Dependencies on Secrets can now be grouped so they can be assigned to different Sites when a service account is used across segregated networks.
- The Delete Secrets role permission has been split into separate permissions for delete secrets and delete secrets from reports.
- When session recordings are stored to disk rather than in the database there is now an option to encrypt the videos.
- Renamed Domain Friendly Name to NetBIOS name on Active Directory administration page.
- Application API Accounts can now log in directly to both the SOAP and REST API's

REST API

See "REST API PowerShell Scripts" on page 1525.

- **Token Expiration:**

  New expiration endpoint to invalidate an issued token
- **File Upload / Download:** Upload and download files from Secrets
- **Field Update / Get:** Get or update a specific Secret field value with a single call rather than getting the full Secret object and posting an updated Secret object
- **SSH Keys:** Added options to change password and create Secret for generating new SSH keys and passphrases.

> **Note:** As of 10.0 the REST API and SOAP API tokens are not interchangeable due to added support for OAUTH. Each API requires its own authentication call and token.

Bug Fixes

- Fixed issue where emailing reports wouldn't use the selected date range.
- Fixed issue where a backslash in the dashboard search wouldn't return any results.
- Fixed issue where scheduled backups were not available in Free edition.
- Updated the Windows Password Changer to support changing the built in administrator accounts without having to specify a privileged Secret due to Microsoft Patches 3177108 and 316769.
- Fixed issue where an admin could convert the only local admin account to an Active Directory Account.
- Fixed foreign key error in Discovery when an OU is deleted that is part of a discovery import rule
- Fixed issue where testing PowerShell scripts failed when a PSObject was returned by the script.
- Fixed issue where reports did not email with the correct date range.
- Removed special characters from SSH Proxy one time credentials to prevent issues with some custom launchers where special characters break command line arguments.
- Fixed issue where SSH Command Sets were not available in Professional Edition for Discovery.
- Fixed issue where Discovery could return an error when matching found accounts against Secrets with an inactive Secret Type.
- Fixed issue where adding an Active Directory Domain with the same name as an SSH based Discovery Source would cause an error.
- Fixed issue with REST tokens that could occur in some environments when FIPS mode was enabled.
- Fixed issue where the Database verify step fails in the web installer when Maintenance Mode is enabled. Note that since this is a change to the installer it will not take effect during the upgrade to 10.1 because the upgrade is running off of the current version.
- Fixed issues with the Mac Session Launcher when running on Sierra.
- **REST API:** Fixed permission check issues in the REST API where editing a Secret with check out enabled was improperly allowed.
- **REST API:** Fixed permission check issues in the REST API where users with View access could see the AutoChangeNextPassword field

Secret Server Release Notes 10.0.x

Release Notes 10.0.000006

Release Date: 10/20/2016

Enhancements

- Added Secret Search Filter to Discovery Scanners to dynamically find a Secret to authenticate to a machine for scanning. See this KB for instructions on creating Secret Search Filters.
- Custom PowerShell password changers are now configured and defined in Remote Password Changing rather than on the Secret Template. See this KB for updated instructions on creating PowerShell Password Changers

- Added option for matching Dependencies to Secrets based on a remote machine in addition to a domain for better support of database links and other local account type Dependencies
- Scan Item Template has been renamed to Scan Template in the Scriptable Discovery Admin UI
- Added Scan Template column to the Discovery Network View results view

Bug Fixes

- Fixed issue where launchers could periodically fail in a load balanced environment because session information was only stored on the web server the session was started from.
- Fixed issue where UNIX host ranges were not removed in the Discovery Network View after they were removed from the Discovery Source.
- Fixed issue where testing PowerShell scripts that returned PowerShell objects on the Admin Scripts page could return a 500 error from the server.

Security Fixes

- Fixed issue in REST web services discovered during internal review. Only customers running 10.0.000000 are affected. See this advisory for more information

Release Notes 10.0.000000

Release Date: 10/13/2016

- Scriptable Discovery (Enterprise Plus or Advanced Scripting Add-On)
  - Administrators can create PowerShell scripts to customize Discovery for local accounts and service accounts
  - Domain specific settings for service accounts, remote connection type, and extended account information have been moved to the relevant scanner on the Discovery Source page
  - NOTE: Custom SSH, SQL, and PowerShell script Dependencies are now managed as Dependency Templates for simplification of administration and integration with custom Discovery sources. Custom scripts will no longer be directly assignable as Dependencies on Secrets.
  - See the Scriptable Discovery Overview KB article for more information and example usage
- Distributed Proxying
  - Distributed Engines can be set to proxy Secret Server sessions as an alternative to the Secret Server web server.
- Privilege Manager for Windows
  - Secret Server and Privilege Manager for Windows can be co-deployed and share authentication and management
  - Requires separate purchase of Privilege Manager for Windows (formerly Application Control Solution)
- Added Secret as an option for the Domain Synchronization credential
- Added CAPTCHA support for logins
- Added configuration setting to prevent password re-use when changing a Secret's password.

- Added support for AES-CTR with SSH password changers when running in FIPS mode.
- Added support for MFA tokens with AWS password changing
- NOTE: Secret Server 10.0.000000 requires configuring integrated pipeline mode on the Secret Server Application Pool Please see this KB for details on configuring integrated pipeline mode in IIS. If using Integrated Windows Authentication you will also need to update IIS authentication settings as detailed in this KB.
- Step Upgrade: Upgrading to 10.0.000000 requires that you first upgrade to 9.1.000001, which has changes to the upgrader to support moving to 10.0.000000.
- NOTE: As of Secret Server 10.0 REST and SOAP API tokens are not interchangeable. Each API requires it's own authentication call and token. Bug Fixes
- Fixed issue where discovery would return an error if there was a duplicate deleted user on a windows machine.
- Fixed issues where 2-factor remember me and inactivity timeout could conflict
- Fixed issue when synchronizing cross domain groups
- Fixed issue where Remote Password Changing and Heartbeat would fail on the same machine as a Distributed Engine
- Fixed issues with checking empty fields in REST API
- Fixed issue where the REST API folder search permissions were too restrictive
- Fixed impersonation error when running a SQL Script Dependency
- Fixed issue in Audits when using mapped IPv4 addresses that exceeded 40 characters.
- Fixed issue where Password Changing, Heartbeat, and Discovery did not consistently work on the same machine as a Distributed Engine
- Fixed issue where the Syslog RT field did not respect the UTC time setting.
- Fixed issue with engine licensing enforcement.
- Fixed issue where a foreign key constraint from a deleted Discovery Rule could stop Discovery
- Fixed issues with SonicWALL password changers
- Fixed incorrect text warning when creating an Application Account
- Fixed impersonation issue with SQL Dependencies
- Fixed issue where the delete action on Event Subscriptions could delete the incorrect row. Security Fixes
- Fixed Open Redirect issues on multiple pages
- Fixed XSS issues on multiple pages
- Added an upper limit to local user passwords to prevent a denial of service attack with extremely long passwords
- Fixed issue where Distributed Engine did not work when restricted to TLS 1.2
- Fixed issue with MS SQL password changing where the new password showed in SQL Trace on the target database server Are you an IBM Security Secret Server customer? Access IBM-specific documentation here.

Secret Server Release Notes 9.x

Release Notes 9.1.000001

Release Date: 10/13/2016

Enhancements

- It is required to upgrade to 9.1.000001 before Secret Server will upgrade to 10.0.000000
- Added installer enhancements to support the 10.0.000000 release. Release Notes 9.1.000000 Release Date: 7/13/2016 Enhancements
- REST API
  - REST based web services API for managing Secrets, Users, and Groups.
  - For more information see the REST API Guide on the Secret Server documents page
- Web Password Filler
  - A new Chrome extension for website logins is available, for more info see this KB article.
  - NOTE: After upgrade, Chrome users will be prompted automatically to install this extension. Firefox and Internet Explorer users will continue to use the existing add on or bookmarklet.
- Site per OU in Discovery
  - Assign an Engine Site at the OU level in Discovery
  - Set a different Secret per OU in Discovery
- Added option to set owners on user accounts to delegate account management
- Added support for SCP through the SSH proxy
- Added additional options to the Secret Expiration event subscription
- Disabled dependencies are hidden by default on the Secret Dependency page
- Added additional option for windows password changers to help handle multiple IP addresses in DNS for a single machine
- Editing a password field on a Secret with password changing enabled now gives the user a dismissable prompt to help prevent mistaken password edits
- Domain user accounts can now be marked as Application Accounts for integrated auth web service access only

Bug Fixes

- ConnectWise integration now uses the API rather than database table integration. See this KB for information on setting up API access to ConnectWise.
- Fixed issue where multiple syslog destinations using the FQDN did not work
- Fixed issue where a user viewing a Secret after a password change within the Secret View interval after their last Secret View did not result in an audit.
- Fixed issue where Oracle error ORA-12170 was treated as heartbeat failed rather than unable to connect.

- System log truncation notification email goes to users with Administer System Log permission rather than Administer Configuration
- Fixed issue where commas in group names were not parsed correctly on AD Sync
- Fixed issue with AD sync when a group had more than 1500 members
- Fixed issue with AD sync when the OU has asterisks in the name
- Fixed issue where Session launchers did not trim spaces from username and machine fields
- Fixed syslog error when the event details exceeded 4000 characters
- Performance updates for the Recents Secrets widget and Secret Load when there are a large number of audit records on a Secret
- Check In web service method now respects the Force Checkin role permission.
- Fixed access denied message when doing a bulk operation for convert secret template without the view deleted secrets role permission
- Fixed potential licensing error when running the PowerShell password changer
- Fixed issue where setting AutoChange schedule through Secret Policy would not use UTC
- Added support for HMAC-SHA2-256 and HMAC-SHA-512 ciphers for SSH Heartbeat and Password Changing
- Fixed issue with SSH dependencies on Cisco devices where the setenv command was not available
- Added additional information to the Subscription Dependency failure email to include machine name and dependency name that failed
- Added additional logging for Heartbeat and Password Change monitors Mobile Updates
- The Delinea PAM Android app has been republished. Existing Android users will need to uninstall and re-install to get the new version.

Release Notes 9.0.000000

Release Date: 4/13/2016

Enhancements

- Mac Session Launcher
  - RDP, SSH, and Custom Launchers are now supported with the new Mac OS X protocol handler.
  - For more information see this KB.
- Geo Replication
  - MS SQL Replication is now supported as an additional add on module. Contact your account rep if you are interested.
- UNIX Privilege Manager
  - Administrators can configure SSH command menus to limit what users can do with root and other privileged credentials.
  - Requires a separate add on, contact your account rep if you are interested.

- Remember Me is now available for 2 factor.
- New option for SSH launchers to specify a Connect As Secret to make the initial connection before switching to the current Secret's user for cases when accounts are denied SSH login.
- Dependencies and Secret Audit are now copied to the new Secret when converting Secrets.
- The Tree View on Dashboard and Discovery Network View is now collapsible.
- Windows Discovery now finds:
  - If an account is Local Administrator
  - If an account is in the Local Administrators Group
  - Password last set date
  - Password expiration date
  - Password expiration status

Bug Fixes

- Fixed issue where domain FQDN wasn't populated during Active Directory Sync.
- Fixed issue with syncing an Active Directory Group with more than 1,500 members.
- Fixed issue where SSH proxy wouldn't restart after web server failover.
- Fixed issue where searching wouldn't work on Secret name's starting with ":"
- Fixed issue where selecting an approval user or group could cause an error on Secret Policy creation.
- Added optional remember me setting for two factor authentication.

Security Fixes

- The version of PuTTY shipped with Secret Server has been updated to version 0.67 to include the latest security fixes. For more information please refer to the PuTTY change log.

Secret Server Release Notes 8.x

Release Notes 8.9.300008

Release Date: 3/8/2016

Enhancements

- Secret Script Dependency Parameters can now reference associated Secrets by Secret ID in addition to the Secret order number in the associated Secrets list. See this KB for more information.
- Added new Time to Live and Retry Time settings to Distributed Engine configuration
- Secret Server Express Edition is now called Secret Server Free. There are no changes in capabilities available between the two editions.

Bug Fixes

- Fixed issue where domain password changing failed when target credential was on different domain than Secret Server and no privileged account was used
- Fixed issue with running Discovery over LDAPS
- Fixed issue where nested groups would not import correctly in AD synchronization when the group is nested within multiple AD groups
- Fixed issue where Folder was not added to the Dependency when importing Scheduled Tasks through Discovery
- Fixed issue where scheduled task discovery could get incorrectly marked with an error and prevent import
- Fixed authentication issues when using the Web Password Filler with Integrated Windows Authentication
- Fixed RDP proxying error when using FIPS compliance mode
- Fixed Session Launcher error if TLS 1.0 is disabled on the web server.
- Fixed Discovery issue when scanning using credentials from a different domain.
- Fixed issue where new domain users were not getting a personal folder.
- Fixed issue where Distributed Engine could create excessive database entries for background threads
- Oracle Script Dependencies will now ignore extra parameters passed in from Secret Server
- Fixed potential error during upgrade if there were users that had never logged in

Security Fixes

- Fixed reflected XSS issue
- Removed ASP.NET version disclosure from response headers

Release Notes 8.9.300000

Release Date: 1/13/2016

Main Focus: Active Directory Synchronization Through Engine

- Active Directory sync through Distributed Engine
  - Active Directory synchronization and user authentication can now be routed through a specified site. This allows for AD authentication even if the Secret Server web server does not have direct access to the domain.
- Password Requirements now support starting character rules.
  - When target systems disallow certain characters, users can now set a rule for which characters a generated password is allowed to start with.
- Dates are now stored in UTC format
  - Customers with servers in different time zones no longer need to set the servers to use the same timezone or UTC time. Existing dates in the database will be retrofitted to UTC if the web server is not already in UTC time.

- Installer updates
  - Improved installer to pre-configure IIS and .NETfor fresh installation
  - Added configuration wizard for the initial setup of Secret Server
  - New users will see a dashboard overlay highlighting key features.
- Added configuration option to allow for concurrent login sessions.
- The session launcher .NET framework support has moved from .NET 3.5 to .NET 4.5.1 and higher.
- Added configuration option to enable frame breaking.
- FIPS support is now available in Enterprise Edition.

Bug Fixes

- Fixed issue where local windows account heartbeat and password changing didn't work on the same machine as an engine.
- Fixed issue where ticket links weren't clickable in audit logs when generated by an access request.
- SOAP web services now respect the ZeroInformationDisclosureMessage setting recommended in the Security Hardening Report.
- Fixed issue where local account discovery scanned domain controllers in some scenarios.

Security Fixes

- Fixed security issue with named pipe permissions when passing credentials to the PuTTY launcher.
- Fixed an XSS vulnerability.

Release Notes 8.9.000022

Release Date: 10/1/2015

Main Focus: Ticket System Integration and Security Fixes

- Ticket System Integration
  - Secret Server will validate whether a ticket is open in either BMC Remedy or ServiceNow as part of the require comment and approval for access workflows.
  - Enterprise Plus customers can create PowerShell scripts to create a custom workflow or integrate with other solutions.
- API Updates
  - AddGroupToActiveDirectorySynchronization: Adds a group to the Active Directory Synchronization list.
  - RunActiveDirectorySynchronization: Kicks off the Active Directory User Synchronization Process.
  - AddSecretPolicy: Adds a new Secret Policy.
  - AssignSecretPolicyForSecret: Set a Secret policy on a Secret.
  - SearchSecretPolicies: Search existing Secret Policies.

  - GetScript, AddScript, GetAllScripts: New methods for managing the PowerShell, SSH, and SQL scripts.
  - The Folder Extended Windows Authenticated Web Service methods no longer have the token parameter.
- Added NAS attributes to the RADIUS messages.
- The SonicWALL Web Admin and SonicWALL Web Local User password changers have an option to validate or bypass remote SSL certificates.
- The RDP Session Launcher now shows the end target machine name in the RDP window when RDP Proxying is used.
- Logging to the Remote Password Change log when a Secret isn't changed because it's outside its AutoChange Scheduled time is now only logged once.
- Added new option for Active Directory Discovery Sources to resolve based on machine name only.
- Added new options for how the custom process launcher runs to help handle UAC prompts.
- SSH, SQL, and PowerShell Dependencies can now use the $CURRENTPASSWORD token.
- Updated the web password filler to prioritize exact matches in the search results to help show matching Secrets when on sub-domains.
- IP Address Restrictions can now be applied to Active Directory Groups.

Bug Fixes

- Fixed issue where Dashboard would not display in Firefox 41.
- Fixed performance issue some customers were seeing after upgrades to 8.9.
- Fixed issue where SSH Dependencies were suppressing the full error details.
- Fixed issue where SSH connections were not being closed after Heartbeat.
- Fixed test dialog for custom UNIX password changers with linked Secrets.
- Fixed incorrect display of the SSH Log link in Secret Audit trails.
- Fixed issue where pressing enter in the quick search area when viewing a Secret would run the Secret Launcher in some browsers.
- Secret Server will no longer override root level IIS HTTP Redirects on upgrade.
- Fixed issue where the Web Password Filler didn't work with SAML integration.
- Fixed error in test dialog for custom UNIX password changers when no key was present.
- Fixed copy to clipboard issue in IE11.
- Fixed issue where hitting Enter on Secret Edit would prompt to generate a new password.
- Fixed password strength error alert on Secret View.
- Fixed issue where SSH Discovery would leave hanging sshd processes on AIX instances.
- Fixed issue where duplicate Active Directory discovery sources could be created. Security Fixes
- Fixed security issue with update checks with update process. See our security advisory for more details.

- NOTE: It is recommended to perform an offline upgrade to 8.9.000022. See this KB article for instructions on performing offline upgrades. Upgrading Without Outbound Access
- Fixed DOM XSS issue.

Release Notes 8.9.000000

Release Date: 8/7/2015

NOTE: Secret Server version 8.8 will be the last version to support Windows Server 2008. If you wish to upgrade to a version higher than 8.8, you will need to upgrade your server to Windows Server 2008 R2 or higher.

Main Focus: Distributed Engine

- Distributed Engine – SITES
  - Distributed Engine is a NEW feature. All existing customers will receive unlimited Sites to replace our Agent feature. A Site can be assigned to a Secret or a Discovery Source.
  - Discovery can be run through the Sites to provide discovery on remote sites.
  - Customers using Agents will need to install an additional service. Review this KB and this KB prior to upgrade. ▪PLEASE NOTE: After upgrading, Secret Server will automatically upgrade all Agents to Sites. Agents will not be available after upgrading to 8.9.
  - API Change: The web service method "AssignToAgent" has renamed to "AssignSite". Use the new method, or use Secret Policy to assign Sites to Secrets.
- Distributed Engine – ENGINES
  - All existing customers will receive enhanced performance through our new Engine technology. Engines are installed on remote networks and are grouped by Site in Secret Server. The new Engines will provide improved performance for Heartbeat, Remote Password Changing, and Discovery. See this KB for additional information.
- RDP Proxying
  - RDP Sessions can now be proxied through Secret Server.
  - Secret Proxying can now be set per Secret and in Secret Policy, as well as through the API.
- Advanced Permissions
  - Several new Permissions have been added and the folder and Secret Permission UI enhanced. Permissions on folders and what Secrets inherit can now be set separately. ▪List Folder – Allows user to traverse a folder without seeing the contained Secrets. ▪Add Secret – Allows a user to Add a Secret to a folder. ▪List Secret – Allows a user to see that a Secret exists and view the audit, but not see the Secret contents
- Added support for literal arguments in SSH Dependency Scripts.
- Custom icons can now be set on custom launchers.
- Added new #FOLDERID and #FOLDERPATH parameters for custom reports. API Changes
- New API methods

  - FolderExtendedUpdate – Allows updating a folder with permissions and policy.
  - FolderExtendedGet – Retrieves an existing folder with extended settings.
  - FolderExtendedGetNew – Retrieves a new blank object.
  - FolderExtendedCreate – Add a new folder with permissions and policy settings.
  - Impersonate – Allows web services impersonation of other users for API integrations. Requires the new "Web Services Impersonate" role permission be assigned and that the target user approve the request.
- Updated API Methods
  - AddNewSecret, GetBlankSecret, GetSecret, and UpdateSecret have been updated to account for new permissions. These methods will continue to be backwards compatible, but it is recommended to review the WSDL prior to upgrading if making use of these methods

Bug Fixes

- Fixed issue with SSH Proxying when using the Safenet HSM.
- Fixed issue where the IsFile element in the XML export was not properly set.
- Fixed issue where SSH Dependencies would attempt to use a password first even when a key was set.
- Fixed issue where the Dependency Discovery Import did not apply Secret Policy for newly created Secrets.
- Fixed issues with web password filler in IE 11 enterprise mode.
- Fixed issue where testing SSH scripts would not use a test SSH key for authentication.
- Fixed memory issues in Scheduled Task Discovery.

Release Notes 8.8.000020

- Fixed an XSS vulnerability. For more information, see our Security Advisory.
- Added option for SIEM messages to use UTC date instead of Server Date.
- Added an option to load the user profile when running custom launchers.
  - If you have deployed the protocol handler through Group Policy to your users, it will need to be updated.
- Fixed issue where web password filler would not recognize some password fields correctly.
- Added new web service methods for searching Secrets by exposed fields.
- Fixed an error that would happen if an SSH key was not provided when testing custom SSH remote password changing commands.

Release Notes 8.8.000018

Release Date: 3/16/2015

Enhancements

- Added Per Secret Key Encryption
- Administrators can rotate these keys periodically (Enterprise Plus). For more information please refer to this KB article on Secret key rotation.
- Updated local user hashed passwords to use PBKDF2 going forward.
- Administrators can now choose an RSA key size when configuring the HSM integration.
- Managing Dependencies on a Secret now only requires Edit access to the Secret. Importing Service Accounts from Discovery requires Edit on the Folder the Secrets will be created in.

Bug Fixes

- Fixed issue with Daylight Savings time offset in approval for access.
- Fixed issue where the bookmarklet would return Secrets that did not have URL fields.
- Fixed issue with importing duplicate Secrets with the XML import.
- Fixed issue with Google Auth two-factor when HSM is enabled.

Release Notes 8.8.000005

Release Date: 2/20/2015

- Fixed an XSS vulnerability. For more information, see our Security Advisory.

Release Notes 8.8.000004

Release Date: 2/10/2015

- Added new extended mapping for specifying a public key digest when connecting to a server for password changing, Heartbeat, Discovery, or through a Launcher. If the public key digest is present, it will be validated. For more information, see our Security Advisory and KB article on how to add public keys.
- Fixed performance issues with Web Password Filler, caused by many Secrets containing matching URLs.
- Fixed issue where Secrets that have an Auto Change Schedule might not change if there are many Secrets failing password changing.
- Fixed issue where the Regex file dependency wouldn't work with a privileged account on an untrusted domain.
- Fixed issue where Active Directory Synchronization wouldn't find users on a domain if a group being synchronized had zero members.

Release Notes 8.8.000001

- Fixed IE 8 compatibility issue. Release Notes 8.8.000000 Main Focus: SSH Key Support and Dependency Scripting
- SSH Key Support

  - SSH Keys are now supported for authentication with PuTTY, Dependencies, Remote Password Changing, and Discovery.
  - Added a new SSH Key Secret Template and added Key and Passphrase Fields to default UNIX Secret Templates.
- SAP
  - Updated the SAP libraries used by the SAP Password Changer NOTE: In order for SAP Password Changing to work after an upgrade, the SAP libraries on the Secret Server instance need to be updated. Please follow the steps in this KB.
- Dependency Updates
  - Admins can now create SSH and SQL Scripts to run as Dependencies in addition to the existing PowerShell Dependency types
  - The Dependency UI has been reworked for information density in cases when there are lots of Dependencies for a single Secret
  - Dependencies can now be retried and additional logging is now available per Dependency
  - When updating Dependencies for an Active Directory Account Secret, Secret Server will try to automatically unlock the account if it gets locked out, if there is a privileged account set on the Secret.
- HSM
  - Thales HSM's are now supported
  - Safenet Network HSMs are now supported.
- Administrators can use custom created PowerShell scripts for password changing.
- Added a new Office365 password changer.
- File Attachments now can keep history.
- New API methods
  - SearchUsers
  - GetUser
  - UpdateUser
  - GetSecretItemHistoryByFieldName
- Added a new widget for managing access requests.
- Approvers can now set a start time for an approval for access request.
- Approvers are now required to enter a reason when approving an access request within Secret Server.
- Added a new role permission Administer Create Users for creating users only. To edit user accounts, administrators will still need the Administer Users role permission.
- Maximum Attempts can now be set for Password Changing on the Secret Template.
- A custom field for displaying to users on the Basic Home can now be set on the Secret Template.
- The Protocol Handler is now the default launcher option for fresh installations of Secret Server.

- Computers not in specified OU's for an Active Directory Discovery Source will no longer be shown on the Discovery Network View.
- Added enrollment URL for Duo authentication for when the user is not enrolled.
- Added support for control characters in the SSH command sets.
- Added support for Secret values in the Approval for Access email customization.
- Added a Administer Create Users role permission which gives user account creation permissions only. Administer Users role permission still allows an admin to create and edit user accounts.
- Added View Audit button on the Dashboard Secret view for users that have the View Audit role permission but not the View Secret role permission.
- Syslog change: Syslog events now pass the Username instead of the Display Name of the user. Display Name has been moved to cs4 and cs4label fields. Please refer to the syslog guide for full field listing.
- NOTE: 8.8 supports running Secret Server on Windows Server 2008, but support for this will be deprecated in a future version of Secret Server. Server 2008 R2 will continue to be supported.
- Fixed an issue that would allow users with permissions to view a Secret to access the password history directly without going through Check Out or Approval for Access flows THY-Secret Server-002.

Bug Fixes

- Custom proxied SSH Launchers can now use custom fields in process arguments
- Fixed issues where Secrets created through the web password filler would not respect default field values or Secret Policy settings.
- Fixed issues with folder searching in some dialogs.
- Fixed bug where an admin could not add application accounts if the user count was already at the licensing limit.
- Fixed issue where the some OU's could not be selected in a Discovery Source when there were several OU's named similarly on the domain.
- Fixed issue where a failed password change on check in would write additional audits for Secret Set for Check In.
- Fixed memory issues in scheduled task discovery.
- Updated the query to retrieve computers from the domain to only return computers in specified OU's.
- Fixed issues with Active Directory Sync connection failures potentially disabling users.
- Fixed issue with using the attempt user password setting for RADIUS and integrated windows authentication.
- Fixed issue when creating a folder shared with hundreds of users and groups.
- Fixed workflow issues in web password filler when a Secret has check out or other security settings applied.
- Fixed issue where web password filler would not work properly if the URL was extremely long.
- Tokens are now supported for use with Duo Security.
- Events written to the Windows Event Log now have unique identifiers.
- Fixed performance issues in dashboard searching for deep folder structures.

- Fixed searching behavior where a found value is on multiple Secret fields.
- Fixed issue in dashboard searching where a backslash in the search terms would not return results in Firefox only.
- Fixed display issue on Service Account Discovery when using an account to run the scan on a child domain.
- Fixed URL encoding issues on the Basic Dashboard.

Release Notes 8.7.000000

Main Focus: ESX/ESXi and Unix Account Discovery

- Unix Account Discovery
  - In addition to Windows Local Account and AD Service Account Discovery, Secret Server can now scan and import Linux local accounts.
- ESX/ESXi Local Account Discovery
  - Discovery has been expanded to support scanning and automatically importing local accounts on ESX/ESXi systems.
- ESX/ESXi Password Changing
  - Added a new ESX Secret Template and a new ESX password changer to perform changes via VMware's API. SSH is no longer required to be enabled on the ESX/ESXi system if this password changer is used.
- Search Updates
  - Multiple search terms will use implicit ANDs rather than ORs for more accurate results.
  - Reduced the number of search hashes created in the database to help limit database growth.
  - Improved performance of searching on unencrypted Secret fields.
- There is a new option to delete secrets shown in a report.
- Added password masking in all entry fields
- Folder deletes and renames are now audited.
- RADIUS authentication now handles multiple consecutive access challenges.
- Added support for Duo Security as a two-factor option.
- Added support for optionally using a user's login password as the RADIUS password if prompted.
- Added search bar for web password filler to filter returned Secrets.
- Unmasked passwords on Secrets now use a different font to help distinguish between certain similar characters.
- Added option to specify a Secret for running Discovery in Active Directory Sources rather than using the Active Directory Synchronization credentials.
- Added "Password Changed" event subscription event.

Bug Fixes

- SSH Proxy now respects the client terminal type settings.
- Users can now edit notes fields in cases where they do not have access to the privileged account on the Secret.
- Fixed an issue where the launcher may not start when configured to use a protocol handler in Chrome and Firefox.
- Users will be able to see the name of the privileged account on the Secret if they do not have access to it.
- Logging in via the Windows Authenticated Web Services now sets the Last Login on the user.
- Enable Approval from Email is no longer on the Security Hardening report for editions without Approval for Access available.
- Fixed issue where an admin in Unlimited Vault Access mode would bypass entering in a comment when both Check Out and Require Comment were enabled on a Secret.
- Fixed issues with the Web Password Filler in IE8.
- Fixed issue where failover with the web servers could occur even if clustering was disabled.
- Fixed issue where there were inconsistent permission checks for adding and deleting between the web interface and the web service methods.
- Fixed issue where the MSI installer would not detect a local SQL 2014 instance.
- Fixed issue where a file could be uploaded to a non-File field using the web service API.
- Fixed issue where service account import could fail because the saved folder no longer exists.
- Fixed issue where Check Out and Require Comment workflows could send a user back to the dashboard instead of to the Secret.
- Fixed error where email report options were available when no SMTP server was set.
- Fixed issue where the SalesForce password changer would not correctly work on sandbox instances.
- Fixed incorrect display of line breaks in Notes fields on the Basic Dashboard view.
- Windows account discovery now uses the LastLoginTimestamp AD attribute rather than LastLogin to better support replicated domains.
- Fixed performance issues on Dashboard when loading large numbers of Secrets.
- Fixed issue where Access Request approvals could not be accessed by Email.

Release Notes 8.6.000010

Main Focus: Security Update

- Fixed an issue that would prevent the Windows Remote Desktop Launcher from cleaning up generated RDP files, which contain DPAPI encrypted passwords. This report was acknowledged within 24 hours. CVE-2014-4861.
- Fixed an issue that would prevent users in certain time zones from viewing SSH Proxy logs.

Release Notes 8.6.000009

Main Focus: Security Update

- Fixed security issues reported by a customer. This report was acknowledged within 24 hours.
- Added built-in support for HTTP Strict Transport Security (HSTS).
- Improved performance of loading dashboard for very large installations.
- Administrators can now disable HTTP GET functionality for web services.
- Added additional HTTP headers to improve Secret Server's security policies.
- Added additional options to the new Theme Roller to change font size and padding between elements.
- Added new web service methods for adding dependencies to Secrets.

Bug Fixes

- Fixed issue where users with non-ASCII characters in their username could not be issued a valid token for web services.
- Fixed issue where Discovery scanning may not occur at expected times due to Application Pool recycles.
- Fixed issue where Windows Authentication web services did not respect the Require Two Factor for Web Services configuration option.
- Fixed issue where the Agent installer would incorrectly report the .NET Framework was not installed when the .NET Framework 4.5.2 was installed.

Release Notes 8.6.000000

Main Focus: UI Refresh and Secret Policy

- Secret Policy: Administrators can now define a policy for Secret Security and Auto Change settings. This can be applied at the Folder level and Secrets in that Folder automatically inherit those settings.
- The Secret Server UI has been significantly updated for look and feel, including a new basic dashboard view for non-admin users who just need core functionality.
  - Added a theme roller for creating new themes and uploading corporate logos.
  - Warning: Users with custom themes will be moved to the default theme on upgrade and will need to use the new Theme Roller to create a theme.
- Added Personal Folders option for users to store work related Secrets. These are only accessible by a named user by default, but can be accessed in Unlimited Vault Access mode by an administrator.
- Added support for mobile app authenticator soft tokens for Two-Factor.
- Added a built in SSH password changer for F5 root accounts.
- Added a Salesforce password changer. See this KB article for more information.
- DoubleLocked Secrets can now be accessed through web services.

- Added a new option to run Local Account Discovery using WMI, which can provide a performance boost in some environments where WMI is properly configured.
- Added optional Domain Controller field to the LDAP based Password Changers: LDAP (Active Directory), LDAP (openLDAP), and LDAP (DSEE).
- Reorganized the bulk operation drop down list for usability.
- Added AssignUserToGroup and GetAllGroups API methods.
- When proxying is enabled users can manually make a connection to Secret Server using the get proxy credentials API method or button on Secret.
- SSH Proxying can now be specified on a per node basis for clustered environments.
- Check Out and Approval for Access end times are now synchronized. A user will not be able to keep a Secret checked out past the approval period end time.
- Added in a configuration option for whether launched sessions automatically close on Check In.
- Added additional logging and event subscriptions for when DPAPI encryption is enabled or disabled.
- Improved performance for the SearchSecrets API call.
- Cluster computer objects are now ignored by default in Discovery.

Bug Fixes

- Added extra error handling to the Discovery process.
- Fixed issue with running user audit report with the Exclude Changed and Deleted Secrets.
- Updated the web password filler to handle different zones in IE. Due to security restrictions users may now be required to log in to the web password filler in addition to Secret Server. Other browsers are unaffected.
- Fixed performance issues in reports with large amounts of data.
- Fixed issue where the Secret Export incorrectly reflected the Secret count for a Folder.
- Fixed date range search in Session Monitoring.
- Fixed issue where automatic backups were not available in Express Edition.
- Fixed issue with email two-factor in Express Edition.
- Fixed issue where an incorrect SMTP configuration could cause an Application Pool Recycle.
- Fixed issue where bat file launcher would require a port field when mapping to the Secret Template.
- Fixed issue where bat file launcher did not handle parameters enclosed in double quotes correctly.
- Added performance enhancements for session video processing.
- Secret fields marked as Exposed for Display on the Template will no longer have their history encrypted for consistency and reporting.
- Fixed paging on Report Schedule History grid.
- The Out of Sync Report now shows the reason in the saved report.
- Added additional error handling for RADIUS authentication.
- Added additional error handling for Discovery machine scanning.

Release Notes 8.5.000000

Main Focus: Session Monitoring and SSH Proxying

- Upgrade to .NET Framework 4.5.1: This will require downtime and a manual change of the application pool. .Net 4.5.1 is a prerequisite for the web server. You will need to make other changes, see Considerations for Upgrading to 8.5 for details.
  - .NET 4.5.1: Secret Server now runs on .NET 4.5.1 to provide better support for the latest Microsoft technologies. To find out what this change means for you, view our KB Article.
  - PowerShell 3.0: Changes were made to the PowerShell scripting in order to fix certain remote authentication issues. These changes require an update to PowerShell 3.0.
  - Agent: If using the Agent, .NET 4.5.1 will need to be installed on machines where the Agent is installed.
  - Step Upgrade: Before upgrading to the 8.5 release, you must be running 8.4.000004. The Secret Server updater will update you to 8.4.000004 first, then allow you to update to 8.5
- Session Monitoring: The Session Monitoring administrators can now view sessions launched from Secret Server, watch activity, and even terminate the session or send a message to the end-user while the session is in progress.
- SSH Proxy: SSH Launchers can now be proxied through Secret Server. Admins can review full SSH logs of proxied sessions as part of the Session Recording feature.
- Discovery and Password Change Performance: Speed of Discovery scanning, password changing and Heartbeat checks are significantly faster for management of very large environments.
- Session Recording Retention: New configuration options are available for moving stored session movies out of the database and establishing a retention period.
- Group Owners: Owners can now be assigned to local groups. Group owners can manage membership for the group.
- Added support for PostgreSQL password changing.
- Added support for custom ODBC based password changing.
- Session Recording now uses differential images to reduce network bandwidth and database size.
- Added new Video Codec option for Microsoft Video 9, which provides high levels of compression.
- Secret Audits now include field and setting names that were changed.
- Automatic Backups now support Copy-Only database backups.
- User Audit report now has option to exclude deleted Secrets.
- Added new search options to help performance for choosing groups for Active Directory Synchronization.
- User drop down on User Audit report will properly switch to an autocomplete based on user count.
- Passwords are now masked on Secret Edit.
- Secret Check In will now terminate any open launched sessions.
- Added configuration option to check in Secrets when a launcher session is closed.
- Added P3P policy to help with cross domain issues with the Web Password Filler in IE.

- Added new configuration option to specify a custom Secret Server URL for use by the Session Launchers and Emails. This is for cases when Secret Server is behind a proxy or load balancer and a client machine cannot resolve the Secret Server web server name.

Bug Fixes

- Fixed issue with Scheduled Task Discovery on Windows Server 2003.
- Added additional checks to installer to help validate access to update files.
- Fixed a performance issue with Service Account Discovery attempting to resolve domains.
- Fixed issue with searching inside Folders on Dashboard with query string parameters.
- Fixed improper display of Edit button on custom reports.
- Web service view audits now respect the Secret View interval in configuration.
- Fixed issue where disabling check out did not clear the user it was checked out to.
- Fixed issue with bulk operation for Set Privileged Account when setting to "Credentials on Secret".
- Fixed issue where user could get an error on the Hooks tab of Check Out Secrets when not assigned the Owner permission.
- Fixed issue in 8.4 where scheduled task dependencies could be disabled from Service Account Discovery. If the instance has Service Account Discovery for tasks running these dependencies will be re-enabled. Please contact support if there are issues with Scheduled Task dependencies staying disabled.

Release Notes 8.4.000004

Main Focus: Usability and Configuration Enhancements

- Administrators can now require ticket numbers or comment for Secrets with Require Comment and Approval for Access enabled.
- The Require Comment interval when viewing a Secret can now be set on configuration so users are not prompted multiple times when accessing a Secret for the same reason.
- Added configuration option to require two-factor for API and Web Access separately.
- Added new whoami web service method to the standard web services to return what user a token is for.

Bug Fixes

- Fixed variable replacement for custom launchers in some cases when field names contained other field names.
- Added additional database connection properties for MS SQL Always On configuration.
- Fixed issue where the background processing of expired Secrets for password changing could overwrite changes in the UI in certain cases.
- Fixed issue where a custom report with a Secret ID column would cause an error if there was a row with no Secret ID value.
- Added performance enhancements for the GetSecretsByFieldValue web service method.

- Fixed potential upgrade issue for customers upgrading from versions below 7.9.000012.
- Fixed issue where copy to clipboard for Internet Explorer 10 and 11 would cause the page to scroll to the top.

Release Notes 8.4.000000

Main Focus: Service Account Discovery and Launcher Enhancements

- Multiple Launchers
  - Secrets can now have more than one Launcher, so if the same credential is used to run different tools admins can set up multiple Launchers per Secret Template.
- Added support for scanning for Scheduled Tasks and IIS Application pools as part of Service Account Discovery.
- Auto-Create Dependencies (Enterprise Plus)
  - Secret Server can now automatically link any found IIS Application Pools, Windows Services, and Scheduled tasks as Dependencies to existing Secrets.
- User added Dependencies that don't exist on the machine are now shown on the Discovery grid.
- Added new Bulk Operations
  - Heartbeat Run Now
  - Heartbeat Enable / Disable
- The Secret Server Launcher can now be optionally run using a Protocol Handler instead of Microsoft ClickOnce. This may be needed in some virtualized environments where ClickOnce does not function properly. You can read about the Protocol Handler configuration here
- Added performance improvements for Dashboard search.
- Added option to force expire Secrets from any report with a Secret Id column.
- User Bulk Operations are now available.
- Added new User preference and Secret preference for the size of the launched Remote Desktop Window.
- Web Service Change: The Secret object used in the Web Service API has new fields in the SecretSettings section for setting privileged Secrets for RPC. This is documented in the Web Service API Guide .
- .NET 3.5 SP1 Support
  - This will be the last minor version of Secret Server to run on .NET 3.5.1. The next subsequent minor version (8.5) will require the .NET Framework 4.5.1. You can read more about why this move is happening in this KB Article

Bug Fixes

- Secret IDs on reports are now links, not link buttons.
- Reports on Dashboard now show rows with background colors if specified.
- Fixed error when viewing a secret set for check out by the bulk operation and a next password was already specified.
- Fixed issue where viewing the password history would not produce an audit for password displayed.

- Fixed issues with password changing for Oracle accounts without the Alter User privilege.
- Fixed potential issues with Service Account Discovery importing duplicate dependencies.
- Fixed issue where the password strength indicator on Secret View could be incorrect.
- Fixed issues with Dependencies not matching correctly in Discovery if the username format was different.
- Fixed issues with Service Account Discovery import not properly matching to existing Secrets.
- Fixed issues with Local Account Discovery rules importing accounts from OUs excluded from the domain level scanning.
- Individual computer discovery scan logs are now limited to the number of entries stored to prevent excessive database growth.
- Fixed issue where the search results on Dashboard could sometimes be incorrect due to timing of search.
- Fixed issues with the header search box ignoring custom columns in the returned results.
- Fixed issue with an incorrect validation for Folder permissions when saving a Secret through web services.
- Fixed issue where the password strength icon on Secret View was incorrect in some cases.
- Added missing Check In method to the windows authenticated web service API.
- Fixed issue where the Check Out information was not correctly populated by the return value of the GetCheckOutStatus web service method.
- Fixed issue with enter key not starting the launcher when a drop down list was used for the target machines.

Release Notes 8.3.000019

Main Focus: SAML Support

- Added support for SAML 2.0 for authentication to Secret Server. Additional information on configuring SAML can be found here.
- Added configuration option to allow approval or denial of access requests directly from the email notifications.
- Updated Discovery to use the DNS name of the target machines for environments where that differs from the machine name.
- Added an additional configuration option to allow a separate timeout option for API sessions.
- Added the option to set a custom password requirement on the Secret.

Bug Fixes

- Fixed several places that had double encoded HTML.
- Fixed issue with the Create button getting disabled in some cases when making a new Discovery Rule.
- Fixed searching issue with Discovery Rules when searching in Child OUs.
- Fixed error exporting Secrets to CSV for large numbers of Secrets.

Release Notes 8.3.000002

Main Focus: Security Fix

- Fixed issue where administrators could export Secrets they had access to via inactive groups. This was reported by a customer and a fix was released within 24 hours.
- Exported Secret history can be viewed through this report.

Release Notes 8.3.000001

Main Focus: Bug Fixes

- Fixed issue with editing Security properties on a Secret where the Template did not have a Remote Password Changer mapped.
- Reduced timeout on Web Password Filler to streamline automatic logins where only one Secret matched.
- Added performance index for stored session images.

Release Notes 8.3.000000

Main Focus: Website Password Changing and Bug Fixes

- Website Password Changing. Secret Server now supports password changing on Amazon and Google Accounts in addition to improvements to Windows Live password changing.
- Administrators can limit Discovery to only search certain OUs for Windows Local Accounts and Service Accounts.
- Added new SonicWALL password changers for latest SonicWALL firmware versions.
- Added French Language Support
- The recipient email address is now displayed when testing email on SMTP Configuration.
- Added SearchSecretsLegacy Web Service API method to allow calls for Search Secrets via GET requests.

Bug Fixes

- Fixed issues with Windows Live password changing due to changes on Microsoft's site.
- Fixed issue where the File Dependency could get a logon failure due to privileged account username format.
- Fixed issue where Web Service authentication failed if the user did not have the View Deleted Secrets permission in some cases.
- Fixed double encoding of text in a few places in the UI.
- Save to File on the Admin Performance page now exports Fastest Time.
- User IP Address Restrictions redirects properly if navigated to with an incorrect query string.
- Fixed issue where the Discovery Import could break if an Active Directory Secret was Double Locked.
- Fixed issue when searching using Unicode characters in search terms on Dashboard.
- Fixed display issue with editing multiple file attachments on a Secret.

- Removed obsolete warning on Secret Template regarding write access to file system.
- Fixed display issues with Copy Secret button.
- Fixed issue where a required Secret File Field could be saved without an attachment.
- Added required field indicators on the Password Requirements page.
- Fixed issue where emails could be configured in Discovery Rules even when an SMTP server was not configured.
- Added validation to prevent users from enabling email two-factor when an SMTP server was not configured.
- Fixed issues with Sharing Secrets with large numbers of individual users.
- Fixed error when setting up ConnectWise integration in a new Secret Server installation.
- Added timeout to the RADIUS login page.
- Added validation for day of month when creating a Secret AutoChange Schedule.
- Fixed visibility issue with the Add Secret button on the Web Password Filler.
- Fixed issue with clear search button in IE 10.
- Fixed issue with updating Secrets via web services if some fields were left blank.
- Fixed issue with the Reset Password test action on Remote Password Changers using privileged accounts.
- Fixed performance issue in some environments when authenticating via web services.

Release Notes 8.2.000001

Main Focus: Web Password Filler Updates and Bug Fixes

- Notes Fields can now be marked as "Exposed for Display".
- The Web Password Filler will now try to automatically fill out login information even if the Secret has not been configured by an owner.
- For Heartbeat on Windows Accounts, the error condition of "RPC Service Is Unavailable" is now considered to be an Unable to Connect result.
- Webservice Functionality Change: GetSecretsByField now only returns Secret Items that have been marked as "Exposed for Display" and no longer writes an audit record for each Secret returned.

Bug Fixes

- Fixed occasional error with processing Session Recordings for certain resolutions.
- Fixed default sort order on Dashboard.
- Fixed issues with Web Password Filler in IE8.
- Fixed issue where users were not prompted to enter a comment, or request access when logging into a website with the Web Password Filler.

Release Notes 8.2.000000

Main Focus: Custom Columns

- Secret Server now requires the database to be set to 2005 Compatibility Mode or higher. Please refer to this KB article for steps on how to set that property.
- Added ability to specify custom columns on the Dashboard search. They can be Secret status information such as Heartbeat Status, or Days until Expiration, and allowed Secret Values.
- Updated and added new methods to the Web Services API. For full descriptions of the Web Services methods, please refer to the Web Service Guide.
  - SearchSecretsByFieldValue
  - AddNewSecret
  - GetNewSecret
  - UpdateSecretPermission
  - UpdateSecretPermission
  - CheckInByKey
  - Potential Breaking Change: The CheckOutEnabled property moved from Secret to the new Secret Settings section.
  - Potential Breaking Change: The GetSecret, SearchSecrets, and SearchSecretsByFolder methods now have additional parameters.
- New Audits and Event Subscriptions for Displaying Passwords, and Copying to Clipboard.
- RADIUS Two Factor can be set to be automatically enabled on new users per Domain.
- Discovery Network View now remembers the last selected tab.
- Increased performance on the Discovery Network View.
- Increased performance for Reports.
- Added optional retry interval on Secret Template for failed password changes.
- Added TimeZone configuration option.
- Added a timeout setting for automated backups.
- Inactive Users can now be selected in Reports.

Bug Fixes

- Updated the session recording video processing to work on Server 2012 x64 environments.
- Fixed issues with the XML Import / Export not applying permissions correctly when inheritance should be used.
- Fixed button layout for some resolutions on the User Edit page.
- Fixed bug where GetSecretAudit API method required Secret View permission.
- Fixed layout of Weekly and Monthly schedules for reports in Internet Explorer.
- Users can no longer click the RADIUS login button multiple times.

- Fixed paging on Discovery Network View.
- Fixed searching in Service Account Discovery log.
- Fixed potential incorrect Secret matches for Local Account Discovery when machine names were too similar.
- Discovery for Service Accounts now correctly handles the stored record if the Windows Service no longer exists or is running under a different account.
- Fixed issue where Service Account Discovery would not run automatically in Enterprise Edition.
- Fixed Windows Service Dependencies for connecting by IP Address for Local Accounts.
- Fixed bug where RADIUS could be disabled if login security settings were modified and the user didn't have permissions to the RADIUS configuration.
- The Regular Expression in the Flat File Dependency type is no longer case sensitive.
- Fixed potential exception during audit when adding large numbers of users to a group.

Release Notes 8.1.000014

Main Focus: Default Privileged Account

- Added ability to set a default Privileged Account for Windows and Active Directory Secret Templates.

Bug Fixes

- Fixed issue where personal Secret settings required Edit permission.
- Fixed bug with Copy Secret not showing field values.

Release Notes 8.1.000011

Main Focus: Web Service API & Secret Field Security

- Added Assign Agent method to Web Service API.
- Added Create User method to Web Service API.
- Added Get Secrets in Folder method to Web Service API.
- Added the ability to restrict edit access at the Secret Template Field level.
- Added the ability to set Secret Fields to not display in View mode.
- Added the ability to restrict Session Launcher computers to a specified list for when the computer is selected by the user.
- Minor display fixes on the Dashboard.
- Improved usability of the Web Password Filler.
- Sorted Bulk operations on Dashboard.
- Added the ability to set a default domain for the login screen.
- Added an 'Inherit' option to Discovery Rules to allow optional overriding of the configuration setting for created Secret permissions.

- Customers with Event Subscriptions for Configuration Edit will receive an email during the upgrade, for more information refer to this KB article.

Bug Fixes

- HSM Encryption integration fixes
  - Fixed session-use issue.
  - Fixed threading issue.
- Fixed an issue where certain event subscriptions did not fire for web services and bulk operations.
- Fixed an issue with email two factor login.
- Prevented AutoChange Schedule drift on start times.
- Improved the performance of Service Account Discovery and fixed issue due to duplicate names.
- Fixed a display issue on the AD sync user preview.
- Added an audit for Enable and Disable Role.
- Fixed issue with auto linking on the first column in Custom Reports.
- Enhanced Folder security related to root folders when being moved.
- Prevented issue where manual failover to a different web server may not occur in certain configurations.
- Fixed an issue where the Web Password Filler displayed duplicate Secrets.
- Fixed Sybase reference errors that could occur during Sybase password changing.

Release Notes 8.1.000000

Main Focus: SAP Platform Support and Languages

- SAP Platform support (Enterprise Plus)
  - A new SAP Secret Template was added to include all the fields required by the SAP Password Changer.
- Web Password Filler
  - Users can now install a bookmarklet that will fill in website login forms with Secret data. This is simpler to configure, and will work on more websites than the existing Web Launcher feature.
- Check Out Hooks using PowerShell
  - Custom PowerShell Scripts can be run as "before" and "after" actions for CheckOut enabled Secrets.
- New Languages
  - Dutch (Thank you to our partner Jan Dijk and his team at MCCS in the Netherlands for providing this translation)
  - Chinese (Simplified)
  - Spanish
  - Portuguese

- Added new API method GetSecretsByFieldValue that will return Secrets based on an exact match of a search term on a specific field.
- Increased Session Recording efficiency, movies now take up less storage in the database.
- Users can now add Folders and Edit Folders from the Dashboard.
- Users now have access to community and support resources from the Help Menu.

Bug Fixes

- Fixed bug where importing multiple service accounts created multiple Secrets.
- Fixed bug where certain special characters in the Dashboard Search could not be used.
- Fixed error where a Custom Launcher could throw an error if no parameters were set.
- Fixed bug where Admins could not disable a user with the same username but for a different domain.
- Fixed issues with PowerShell scripts impersonating as Privileged Accounts. PowerShell scripts now require that the WinRM service is configured.
- Updated the collation check on installation and upgrades to better handle different SQL language collations.
- Fixed bug where movies longer than 24 hours could not be processed.

Release Notes 8.0.000005

Main Focus: Bug Fixes

- Fixed bug where Associated Secrets for certain SSH Password Changers were hidden in the UI after upgrading.
- Fixed bug where Active Directory Groups with a symbol in the name weren't able to be synchronized.
- Fixed issues found during internal security review.

Release Notes 8.0.000004

Main Focus: Minor Improvements and Bug Fixes

- Improved long term SQL performance in heavy load scenarios.
- Fixed an issue related to privileged account visibility on the Secret Remote Password Changing page.
- Loosened collation restrictions.
- Updated contact information.

Release Notes 8.0.000000

Main Focus: New Dependencies And HSM Integration

- PowerShell Dependencies (Enterprise Plus)
  - Administrators can upload custom PowerShell scripts which can be set as Dependencies on Secrets.
  - After a password change Secret Server can execute Administrator created scripts as custom actions.
- IIS Application Pool Recycle

  - Adds the ability for Secret Server to recycle an application pool without updating the Application Pool's service account.
- New installations have an option to specify a SafeNet HSM for encryption. (Enterprise Plus)
- Added functionality for an Administrator to upload a batch file for use with a Custom Launcher.

Bug Fixes

- Fixed issue where the Launcher failed in IE in certain security zones.
- Fixed error that could appear in the system log due to OU's being deleted after the Discovery Process ran.
- Fixed duplicate checking in the CSV import.
- Fixed layout issue with the Report Widget in lower resolutions.
- Inactive Application Accounts are now hidden by default on the User Administration page.
- Fixed potential XSS vulnerability on the Dashboard.
- Fixed issues with Custom Launchers running as Privileged accounts of different Secret Types.
- Exporting reports or logs to CSV will now include the timestamp instead of just the date.

Secret Server Release Notes 7.x

Release Notes 7.9.000004

Main Focus: Security Update

- Fixed issue with launchers and Secret Check Out.
  - (This was reported by a customer – the issue was confirmed, fixed and released within 24 hours by the Secret Server team./>

Release Notes 7.9.000003

Bug Fixes

- Fixed issue that prevents upgrades on a non-default collation on the SQL Server database.
- Fixed issue where a scheduled report email would show an image link when no image was specified on the report.

Release Notes 7.9.000001

Main Focus: Layout and Bug Fixes

- Fixed display issue in Folder Tree for Bulk Move to Folder for Chrome.
- Fixed layout issues in Admin Network View for IE 7.
- The Windows Auth Web Services will now resolve an authenticated user by friendly domain name in addition to the previous authentication methods.
- Fixed error when manually emailing a report with parameters.

Release Notes 7.9.000000

Main Focus: Automatic Import of Local Accounts

- Secret Server Discovery now includes automatically creating Secrets when Local Accounts are found using "rules" (Enterprise Plus Edition)
  - Administrators can specify users that should be alerted when Local Accounts are discovered.
  - Administrators can create search rules to create Secrets when Local Accounts are discovered.
- Service Account Discovery for all Service Accounts (Enterprise Edition)
  - Secret Server will scan machines on the domain and retrieve Windows Services that run under a domain service Account.
  - Administrators can manually import these as Secrets with Dependencies, or if the Secret already exists, import the Windows Service as a Dependency.
- Linked Accounts for Custom Launchers
  - If a Secret Template is tied to a custom launcher, the owner can link other Secrets to either run the custom process, or to use for command line parameters.
- Added bulk operations for "Hide Launcher Password".
- When Unlimited Vault Access is turned on, a banner is displayed on the dashboard warning users that it is on.
- Added Check In / Check Out events to Event Subscriptions and SIEM events.
- Updated error display icons to be more prominent on Event Subscription, and Password Rule screens.
- The search grid on Dashboard now expands to full screen if no widgets are in the rightmost column.
- Added installer check to prevent installation on non-compatible SQL Server collations.
- Improved performance for reports that checked Folders and Permissions.

Bug Fixes

- Fixed issue where certain unpatched versions of IE8 would not display Dashboard correctly.
- Fixed bug where th" pas"word compliance status of a Secret was not updated after a remote password change.
- Fixed issue on the Discovery page where Accounts linked to deleted Secrets were not returned when searching for Unmanaged accounts.
- Fixed error in the system log due to incorrect parsing of Dates in certain locales.
- Fixed bug where Application Accounts could be set as Secret Approvers.
- Fixed bug where Secret Owners could change Share permissions on Secrets that were set for Approval for Access without getting approved.

Release Notes 7.8.000062

Main Focus: Security/Bug Fixed

- Fixed security issue found during internal security review. (All customers are recommended to upgrade)
- Fixed locale issue on web browsers for unusual locales.

Release Notes 7.8.000061

Main Focus: Scheduled Reports

- Added scheduled reports
  - Administrators can now set up Report generation on specific schedules.
  - Reports can be emailed to a subscription list.
  - Reports can be set as "Health Checks" that will only be delivered if the conditions of the Report are met.
- Added #STARTWEEK and #ENDWEEK as dynamic Report parameters.
- Updated Active Directory Synchronization to make adding synchronization Groups in large Domains easier.
- Added Event Subscription for support license expirations. Admins can now be notified when support licenses need to be renewed.
- Updated calendar and search controls throughout the application for formatting and consistency.
- Improved inactivity timeout
  - If a tab is closed but not the browser, inactivity timeout will now work.
  - If multiple tabs are open for Secret Server, being active on any tab will prevent inactivity timeout from occurring (Except for IE).
  - If inactivity timeout occurs, all open Secret Server tabs will be redirected to the logout page (Except for IE). Bug Fixes
- Recorded IP Address in the Secret Audit record when a Dependency is updated.
- Added guard to prevent the expiration of Secrets through web services when Expiration is disabled on the Secret Template.
- Fixed the installer so it properly detects a local instance of Microsoft SQL Server 2012.
- Fixed Windows Live Password Changer due to updates on the Windows Live site.
- Updated Chrome Copy To Clipboard extension, it now installs from the Chrome web store to comply with the latest release of Chrome.
- Fixed bug where updating personal notifications for a single Secret could update personal notifications for other Secrets.

Release Notes 7.8.000048

Main Focus: Windows Live password changer and COM+ dependencies

- Added support for changing Windows Live web passwords.
- Added support for COM+ Applications as Dependencies.
- Added new Bulk Operations

  - Disable AutoChange
  - Disable Comment On View
  - Undelete
- Added Folder Name on Secret Audit header.
- Added Configuration option to prevent duplicate Secret names.
- Added name of Template created to Create Template Event Subscription emails.
- Added additional web service methods to the windows authenticated web service.
- Added Copy Secret Template.
- Added new Folder Slider on Dashboard to make navigating highly nested Folder trees simpler.
- Added additional tooltips to the Secret View page.

Bug Fixes

- Fixed issue where Agent connections could sometimes fail due to the version not being handled properly.
- Fixed issue where SQL Password Changing could fail when the target SQL instance was configured to use a dynamic port.
- Added missing audit"record for when a Secret moves to the root folder due to the Folder getting deleted.
- Fixed missing localizations on the IP Address page.
- Fixed issue where users could import Secrets without Folders when the configuration option to require Folders was turned on.
- Fixed bug where Template Name could be set to blank.
- Fixed bug where Secret permissions could get in an inconsistent state when Bulk Changing permissions and inheritance was enabled. Java API Release Notes
- Added file attachment support.

Release Notes 7.8.000040

Bug Fixes

- Added support for Next TokenCode mode for RADIUS servers.
- Fixed performance issues in Folders for IE on dashboard.
- Fixed issue where the custom commands for UNIX Remote Password Changers would not correctly parse Fields with adjacent special characters in the test dialogs.
- Fixed issue where a Secret Field specified in the Parameters value of a Custom Launcher would not get masked if Hide Launcher Password was enabled.
- Fixed incorrect display width of Folders in Folder Administration.
- Fixed duplicate Folder name shown in Reports for highly nested Folders.
- Fixed bug where OK button would not enable on folder picker for bulk operations sometimes in certain browsers.

Release Notes 7.8.000039

Main Focus: SonicWALL Integration and SSH

Enhancements

- Added support for changing passwords on SonicWALL NSA devices.
- Added support for SSH password changing where no user authentication is required to establish a connection. Used for BlueCoat Packet Shaper devices.
- CSV Import with Folder now creates the Folders if they do not exist.
- Added a column to show whether a Group is Active on the Group Membership report.
- Updated the Get Secret Audit API method to not check out a Secret if Check Out is enabled.
- Made it more clear when a folder is selected for non-default themes. Bug Fixes
- Fixed potential issue with heartbeat on SSH Secrets that would cause heartbeat to stay in pending and shut down the web application due to incompatible SSH versions.
- Fixed issue where Folders might not return in a sorted order on Dashboard.
- Fixed display issues on Dashboard for IE 9.
- Fixed bug where Configuration Change event subscriptions did not fire.
- Fixed line ending issue that caused password changing on HP iLO devices to not work.
- Fixed bug that caused Windows Authentication Web Services to not work.

Release Notes 7.8.000036

Main Focus : Application API and Ticket System Integration

- Added Application User type for use with the Application API.
- Added support for Authenticated SMTP.
- Added LDAPS support for Active Directory.
- New Bulk Operations
  - Change Check Out Status.
  - Convert Secret Template.
- New Web Service API methods
  - Secret Status to show whether a Secret is checked out.
  - Import XML to automate the advanced import.
  - Enable Check Out.
  - Expire Now.
  - Get Secret Audit.
- Discovery

  - Added new Reports for Discovery diagnostics.
  - The Full Scan log is now stored per computer.
  - Added Re-Scan button for each computer.
- Ticket System Integration
  - Administrators can enter a support system URL to navigate to Tickets from the Secret Audit.
  - Users can enter a ticket number for Require Comment and Approval for Access.
- Configuration option to change Default Secret permissions to Secret Creator only.
- Added option to allow Editors to bypass Approval for Access.
- Increased the maximum length on all Secret fields from 1991 characters to 10000 characters.
- Added new role permission for the Advanced Import.
- Increased security in the PuTTY launcher to prevent password exposure in the command line arguments.
- Added option to exclude Secrets from the User Audit Report that have been changed since the User last viewed them.

Bug Fixes

- Fixed issue when removing more than one field during a Template Convert.
- Fixed issue with Event Subscriptions Dependency Failure Events that caused the alerts to be sent every time a dependency was changed.
- Fixed issue where Application Pool Dependencies would sometimes not verify due to casing in Dependency Name.
- Added support for UTF-8 characters for the service account's password for Active Directory Synchronization.
- Added support for UTF-8 characters for RADIUS two factor.
- Fixed issue where password requirements would validate on non-required password fields.
- Updated the Automatic Backup so it will not try to delete backup types that are not enabled.
- Fixed issues with data grid paging on the Event Subscriptions screen.
- Fixed error when saving the Backup Log to a file.
- Fixed issue with Telnet Password Changer not always respecting the correct line endings.
- Fixed issue where Active Directory Group renames would not correctly resolve when synchronizing a low number of Groups.
- Fixed error on Event Subscription page when running Secret Server in FIPS compliant mode.
- Fixed display issues on Dashboard for Internet Explorer 9.
- Fixed error when returning a large number of Secrets in a Dashboard search.
- Improved email address validation for Activation.
- Improved performance on Discovery Network View.

- Fixed issue where Secrets with a 1 Day Expiration interval could change every 2 days.
- Prevented potential XSS attack on the Discovery dialog.

Release Notes 7.8.000015

Main Focus : Bug Fixes

- Fixed issue with Active Directory Synchronization for some cases where if a group was disabled, it did not get re-enabled after being resynchronized.
- Fixed issue with Active Directory Synchronization where groups with a custom schema would not be synchronized correctly.
- Fixed issue with Active Directory Synchronization where distribution groups would incorrectly get synchronized if manually added to the synchronization group list. Distribution groups will no longer work in AD sync – you must use Security Groups in AD.
- Fixed issue on Password Requirement Edit screen where a Password Requirement would fail validation if a description was not entered.
- Fixed issue with the advanced XML import where Secret data would not be created properly if there was a case sensitivity difference in the Secret Field Name and the Secret Template Field Name.
- Fixed issue with the advanced XML import where a Folder with trailing spaces in the Folder Name could be created, but no Secrets in the import would be added to the Folder.

Release Notes 7.8.000014

Main Focus : Bug Fixes and Usability

Enhancements

- Added extra detail to the Export and Unlimited Vault Access email alerts.
- Added arrow key support for the Folder search on Dashboard and the quick search in the header.
- Dependency Searcher now alpha sorts machines and shows the target OS when possible.
- Added Check All option for Windows Services found by the Dependency Searcher.
- Domain and Username are remembered on the Dependency Searcher.
- Added support for updating Windows Services Dependencies that are on the same machine as an Agent or the Secret Server application.
- Added help text for IP Address ranges.
- Added explanation on the Secret Audit page and the Secret Security tab for how often View Audits are recorded.
- Added option to separately backup the application and database.
- Changed "Indexable" to "Searchable" in the Secret Template Designer.
- Added IP Address auditing for the imports.

- Modified privileges required to change a Secret's Folder. Secret Owners can change a folder regardless of whether they have the "Share Secret" permission and the Folder is inheriting permission. See the User Guidefor the full details on Folder and Secret inheritance rules.
- Removed option to specify minutes for offline access in Configuration.
- Improved error notification for the Advanced Import dialog.
- SecretID Columns are now clickable links in the Reports.
- Added Audit record for when Hide Launcher Password is changed.
- Added additional validation for Active Directory Domains to automatically resolve the Domain Name to the Fully Qualified Domain Name.

Bug Fixes

- Fixed issue with Dollar signs in custom UNIX\Cisco accounts.
- Fixed bug with large result sets when searching for linked accounts.
- Fixed issue with inactivity timeout on the server prompt for launcher for AD Secrets.
- Fixed bug where `$$CHECKFOR` and `$$CHECKINFO` commands did not work on the Password Changer test dialogs.
- Fixed issue where the Keep Alive monitor would log an error if the site certificate wasn't trusted.
- Fixed a bug where the database backups would not get deleted if in a separate folder from the web application backups.

Release Notes 7.8.000010

Main Focus: Configuration file support for Service Accounts

- Configuration files can now be managed for Service Accounts.
  - Secret Server can update hardcoded values stored in configuration files using Regular Expressions when changing service account passwords.
- Secret Dependency Page updated to more easily handle ordering (drag and drop) and Dependency specific information.
- Added Active Directory synchronization optimizations for large domains.
- New Folders default to inherit permissions.
- Added Group handling to Advanced XML Import.
- Diagnostics page now includes database name for configuration purposes.
- Secret Template edit automatically re-focuses to next row when adding fields.

Bug Fixes

- Fixed XSS vulnerability with the privileged account picker control.
- Fixed open redirect vulnerability on the Login page when already logged in.

- Fixed possible database connection error for long running Active Directory synchronizations and other background threads.
- Fixed auto complete issue on some sensitive fields.
- Heartbeat status is now automatically updated when RPC succeeds.
- Fixed issue with Oracle password changing failing on passwords with certain special characters.
- Fixed issue with Agents not properly failing over in clustered instances.
- Fixed issues in advanced XML import when loading items with duplicate permissions.
- Fixed issue with incorrect lockout warning on Group and Role Assignment page.
- Fixed error for Event Subscriptions with inactive users.
- Fixed potential timeout errors on Diagnostics page.

Release Notes 7.8.000002

Bug Fixes

- Fixed issue with web services for Windows Authentication not enabling properly.

Release Notes 7.8.000001

Bug Fixes

- Fixed wording of confusing instruction text when changing a Secret's Template.
- Fixed header version to reflect the correct version.

Release Notes 7.8.000000

Main Focus: Password Changing Integrations and Custom Launchers

- Created Java API for use in embedded scripts without hardcoding a password.
  - Examples: Java API Examples KB
  - Deployment instructions : Java Console Instructions KB
- Added MySQL Password Changer and Template.
- Added OpenLDAP Password Changer and Template.
- Added DSEE Password Changer.
- SQL Server password changes can now use a privileged account.
- Admins can now create configurable LDAP based Password Changers.
- Added Custom Process Launchers to start user specified applications on a client machine with credentials from the Secret.
  - Added PowerShell, SQL Management Studio, and Sybase iSQL custom launchers.
- Added XML Export option to simplify restoring or migrating from an export.

- Added support for sys accounts for Oracle password changes."
- Updated Activation to handle VM environments better.
- Added Convert Secret Template.
- Added option to Check Out a Secret without changing the password on Check In.
- Added new report to show Secrets with pending approval requests.
- Added change password web service method. Bug Fixes
- Fixed bug where disabled accounts in Active Directory did not get automatically disabled in Secret Server.
- Fixed bug with dependency finder when using Agent.
- Fixed issues with Oracle connection strings exceeding allowed length.
- Fixed bug with Login Other Location in Firefox.
- Fixed bug with Secret Server

Release Notes 7.7.000012

Main Focus: Secret Server Installer Improvements

- Added MSI for initially installing Secret Server.
- Added ability to create the database if it does not exist during installation.
- Added support for a RADIUS failover server.
- Added more descriptive message when secret is checked out and then accessed from mobile devices.
- Added message to Role page to highlight any permissions that are not currently assigned.

Bug Fixes

- Fixed bug with visual keyboard that caused it to not submit correctly.
- Fixed bug where error occurred when using Unlimited Vault Access and attempting to checkout a Secret.

Release Notes 7.7.000009

Main Focus: Secret Template Improvements

- Added auditing to all Secret Template and Secret Field actions.
- Updated Secret Fields to use a soft-delete so the data can be retrieved.
- Added Chrome support for Copy-to-Clipboard.
- Added clustering support for Remote Password Changing Agents.
- Added embedded searching and Page Size settings to most Admin Logs and Grids.
- Added exception logging to SQL Account Password Changing.

Bug Fixes

- Fixed issue with Expired Secrets not sending event alerts.
- Security Fix for restricting the search textboxes to a max length.
- Security Fix to prevent XPath expressions with the language resources.

Release Notes 7.7.000002

Enhancements

- Created the Password Compliance Report Category.
- Renamed the Non-Alphanumeric Character Set to Symbol.

Bug Fixes

- Fixed bug where the Remote Desktop Launcher was not properly cleaning up configuration files.
- Updated the Password Requirement edit page to prevent overriding the minimum length while entering the maximum length.

Release Notes 7.7.000001

Bug Fix

- Fixed bug where Secret Update email alerts are triggered by checking Password Compliance. Release Notes 7.7.000000

Main Focus: Advanced Password Requirements

- Advanced rules can now be applied to password fields on the Secret Template.
  - Multiple custom character sets can be created and used in these rules to more exactly limit the type of password generated.
  - New reports to show what passwords do not meet complexity requirements.
  - Validation can be enabled to prevent saving Secrets that do not meet the password complexity requirements.
- Added audit record for machine when using an Active Directory account to launch Remote Desktop and PuTTY.
- The advanced XML import now includes Secret dependencies. Bug Fixes
- Fixed bug in the color column on custom reports.
- Fixed bug that could cause the Local Account Finder in Discovery to fail for some sets of credentials.
- Fixed bug where the default folder was not always being set on Dashboard.

Release Notes 7.6.000000

Main Focus: Discovery

- Discovery: Account Import (Enterprise Plus)
  - Administrators can now scan for domain joined machines and import local Windows accounts into Secret Server.
- Dependency Ordering
  - Dependencies can now be ordered and a wait time can be specified which will be observed before the Dependency is updated.
- Added new Password Changers for Juniper, HP ILO, and Blue Coat Devices.
- Added option on custom password changers to specify line ending type (CR/LF).
- Added new Web Services methods for file upload and download from Secrets.
- Added new Bulk Operation to set the privileged account for Windows and AD Secrets.
- Added Secret Copy event for use in Event Subscriptions.
- Added configuration option to send Syslog/CEF messages by TCP instead of UDP.

Bug Fixes

- Fixed bug where Secret Copy created an Edit Audit Record.
- Fixed bug where dates in reports did not observe the user's date format preference.
- Fixed bug with dates as report parameters on non-US SQL installations.
- Fixed bug where unchecking All on Secret Template History caused error.

Release Notes 7.5.000002

Bug Fixes

- Fixed cross-site scripting (XSS) vulnerability on Secret View screen related to URL fields.
- Fixed command injection vulnerability in the PuTTY Launcher.
  - (These were reported by a customer performing a security audit – the issues were confirmed, fixed and released within 24 hours by the Secret Server team.)
- Fixed issue with limited number of concurrent Agents being able to connect.

Release Notes 7.5.000001

Bug Fixes

- Fixed Configuration page to only show video codec option when Session Recording is on.
- Fixed bug where Secret Server uses excessive CPU resources related to new Discovery capabilities.

Release Notes 7.5.000000

Main Focus: Discovery and Session Recording

- New Discovery Network View (Enterprise Plus)
  - Brings together the view of the network and the Secret Server repository to show Administrators whether local accounts on Domain Computers have corresponding Secrets.
- Session Recording (Enterprise Plus)
  - Remote Desktop or PuTTY sessions can now be recorded and the full movie is available as part of the audit. This setting can be configured per Secret and role permissions control who can access the audit movie.
- Hide Launcher Password setting can now be configured per Secret as an alternative to the role permission.
- Users are now automatically redirected from the pending request page when their request for access has been approved.

Bug Fixes

- Fixed copy to clipboard bug in Remote Desktop launcher.
- Fixed bug where users were not correctly removed from Groups in Secret Server during synchronization when the AD Group is empty.
- Fixed bug where CEF port defaulted to -1 in Configuration.

Release Notes 7.4.000002

Bug Fixes

- Fixed bug in Approval for Access Quick Pick control.

Release Notes 7.4.000000

Features and Enhancements

- New Enterprise Plus Edition
  - Added SIEM integration using CEF and Syslog formats.
  - Support for front end server clustering.
- Added Group filter on Active Directory Synchronization screen.
- New Copy Secret option.
- New Delete Secret Role Permission.
- New Events for Users.
  - Login, Logout, Login Failure, and Password Change
- File attachments are now stored in the database rather than the file system.
- Added new Advanced Import option from XML. Bug Fixes

- Calendar on Approve Access now respects all date formats.
- Fixed Tab and Copy to Clipboard bugs in IE9.
- Fixed issue where users assigning groups needed Administer Roles permission.
- Search box on Dashboard is now automatically given focus.
- Fixed bug with Secret data not always formatting correctly in Dashboard Widgets.
- Fixed bug where option to view deleted secrets showed incorrectly on Dashboard.
- Fixed bug with single quote in search breaking not working on dashboard.
- Fixed security issue with Ajax services.
- Fixed bug with alternative Active Directory account name formats not being supported.

Release Notes 7.3.000002

Security Update

- Fixed potential cross-site scripting vulnerabilities on Administration screens. (This was reported by a customer who performed a security audit – the issue was fixed and released within 24 hours by the Secret Server team.)
- View this Knowledge Base article for having Secret Server require secure cookies. This is done through changing a setting in the web.config.

Release Notes 7.3.000001

Main Focus – Bug Fixes

Features and Enhancements:

- Updated the Browse widget on Dashboard to highlight the search term when the tab loads.
- Added Activate Offline button. Bug Fixes:
- Updated License Activation to support Unicode characters in the license name.
- Fixed bug in the phonetic icon on Secret View. 7.3 Main Focus – User Interface Improvements Features and Enhancements:
- Added a new front end home page called Dashboard. For a movie preview click here
  - Multiple Customizable Tabs.
  - Dragable Widgets.
  - Report Widgets.
  - Expandable Secret View in search results.
  - Streamlined Folder and Secret search.
- Added new setting for how unmasking a password works (hold versus single click).
- Added new header menu with drop down navigation.
- Added additional auditing to the upgrade process.

- Added license activation to Secret Server, existing customers have 30 days to activate. Bug Fixes:
- Fixed bug in DBConnectionReset page.
- Fixed bug in Users Activity Report.
- Fixed bug where the application would sometimes give an error after a fresh install.
- Fixed validation bug in assigning Role by User.
- Fixed bug in Dependency finder where unchecking the 'select all' did not unselect all computers.
- Fixed bug in Search having to do with inactive groups.
- Extended RADIUS two factor timeout. 7.2.000003 Features and Enhancements:
- Added Folder Path, whether child folders were exported, and number of secrets exported to Export Log grid.
- Added audit records to each secret when exported. 7.2.000002

Bug Fixes

- Fixed issue in 7.2.000001 that could cause duplicate users to be created during an AD sync.

Release Notes 7.2.000001

Bug Fixes

- Fixed bug in Active Directory Synchronization for custom schemas.
- Fixed memory issue in Active Directory Synchronization for large domains.
- Fixed bug in the Event Engine administration section for Professional Edition.
- Fixed bug with two factor pin code email timeouts.

Release Notes 7.2

Main Focus: Event Subscriptions ("Custom Alerts") and Active Directory Synchronization Performance

Features and Enhancements

- Event Subscription feature:
  - Users can receive email alerts for custom event subscriptions.
  - Subscription events include: Unlimited Administration Mode toggle, Secret Edit/Add/View, Role and Group Assignment changes, Secret Expiration, Configuration changes, and many more.
- Improved Active Directory Synchronization to reduce time spent retrieving domain information.
- Added option to additionally force owners and approvers to request access on a Secret.
- When approving access to a Secret, users can specify the access window down to the minute.
- Added optional port field to the default Oracle Template and Oracle Remote Password Changer.
- Increased performance for folder permission updates.
- Removed Security Code from Credit Card Template for new installations for PCI compliance.

Bug Fixes

- Fixed bug where duplicate Secrets could occur during create.
- Fixed bug with assigning groups by users for administrator role validation.
- Fixed bug where the custom command test action did not correctly replace all parameters.
- Updated Heartbeat to perform additional validation in cases where accounts may not have the login privilege.
- Fixed web launcher for Chrome and Safari.

Release Notes 7.1.000015

Main Focus: Usability and Performance

> NOTE: An important security update has been released for the Microsoft .NET Framework. Please ensure that this update is installed on your server to ensure maximum security. For further detail and how to obtain the patch, please click here.
>
> NOTE: We are phasing out support for Microsoft SQL Server 2000. Future releases will not support Microsoft SQL Server 2000. Features and Enhancements:

- Added support for changing Scheduled Tasks on Windows Server 2008 and Windows 7 instances.
- Improved Search performance for highly nested folders.
- Offline upgrades can now be performed by uploading a local zip file.
- Database Connection Reset page now resets the application automatically.
- Require Comment to View and Approval for Access can now be applied to the same Secret.
- Require Comment to View coincides with checking out a Secret.
- Secret Access Request now shows full request history on Pending Requests page.
- Notification emails sent for Request Reason now contain the user entered reason comment.
- Added ability to encrypt the instance encryption key with DPAPI for added security.
- Backup file path now allows all valid special characters.
- Allow setting an AutoChange schedule on a Secret before enabling AutoChange. Bug Fixes
- Fixed bug in Integrated Authentication with local Windows Accounts.
- Secrets mapped to Users through inactive groups are no longer visible in custom reports.
- Fixed exception that occurs on Remote Password Changing Agents after upgrades.
- Fixed issue where updating file attachment did not save in certain situations.
- The Enter key now works on home page search box.
- Fixed sort for inactive users on User Administration page.
- Fixed Active Directory Synchronization login error on Domain search when fully qualified username was not used.
- Fixed bug in Oracle password changing by updating template to allow additional parameter specifications.

- Fixed bug in the autopopulate search where clicking a Secret failed to navigate to the Secret view page.
- Fixed error when running "Test Action" on remote password changer custom commands. 7.1.000001 Security Update
- Updated Error Reporting in order to address a vulnerability in ASP.Net. For more information see this Knowledge Base article

Release Notes 7.1.000000

Secret Server Agent

- Use Remote Password Changing, Heartbeat, Dependency Finder on external networks.
- Easy Agent Installation with MSI.
- High Security: Full over-the-wire Encryption.
- Requires no incoming ports on the Agent network.
- Customizable URL and Server Port.
- Light-weight bandwidth usage.
- Client automatically upgrades when Server is upgraded. Require Comment
- Require Comment when a Secret is Viewed (useful for tracking change control numbers).
- Bulk Operation to enable Require Comment on Secrets. More
- Major Database Performance increases in Home, Secret View, and background threads.
- Added Bulk Operation for Remotely Changing the Password. This can be used to keep multiple accounts in-sync with the same password.
- Improved Search in Navigation Bar to go directly to the selected Secret (when unique name).

Bugs

- Updated Search Indexer to run as a batch process.
- Fixed performance issue when Unlimited Administration Mode is turned on.
- Fixed RDP Launcher to work consistently for local Windows Accounts on Windows XP machines.

Release Notes 7.0.000040

Remote Password Changing

- Added Cisco password changing support (SSH and legacy Telnet).
- Added Unix Root Account password changing using separate Secret for login.
- Added the Remote Password Changing tab for configuring options on a Secret (moved AutoChange checkbox to this tab).
- Password change can be set up for Active Directory and Windows accounts using a privileged account instead of the account changing its own password.

- Added the ability to create configurable command sets for handling different platforms and operating systems to do password reset using SSH or Telnet (including using credentials from other Secrets).
- Added the ability to test Password Reset and Verify from an admin dialog.
- Added the ability to specify the port for password changes when using SSH and Telnet.
- Added button to allow cancellation of Change Password Remotely.

Heartbeat

- Secret Heartbeat will test the credentials stored in Secret Server on a periodic basis to ensure they are still valid.
- Receive email alerts when a Secret fails the Heartbeat.
- Supports all Remote Password Changing templates and Password Verify. Web Launcher
- Web Launcher to automatically login to websites using credentials stored in Secret Server.
- Web Launcher bookmarklet for single click login from the browser (supports all browsers).
- Note: Secret Assistant is being retired in favor of the Web Launcher and bookmarklet (Secret Assistant is still supported but no longer recommended).
- Automatic download option for the latest Web Launcher settings for commonly used sites from #{COMPANY}#.com. Search
- Made extended Search Indexer split indexed terms into 3-12 character segments instead of just 3 character segments.
- Made extended Search Indexer not split the search term before searching.
- Improved order of search results. Exact matches on name will be on the top, followed by 'like' matches in the name (ordered by name) and then secret item hash matches (ordered by name). More
- Added webservice to use Integrated Windows Authentication to allow scripts to run without having embedded username/password and retrieve passwords from Secret Server.
- Updated Active Directory synchronization to support Child, Parent, and Sibling Domain Credentials.
- Changed all random number generation to use System.Cryptography.RandomNumberGenerator for improved security.
- Increased the hash iterations on both local user passwords and DoubleLock passwords to provide additional security against brute force attacks on the hashes.
- Extended IP Address Range restrictions to work for class A and B networks.
- Added Maximum Offline Minutes feature so that mobile devices can only cache data for a limited time.
- Added a Generate Password button to the "Change Password Remotely" page.
- Split Unlimited Vault Access role into "Administer Unlimited Vault Access Configuration", "Unlimited Vault Access", and "View Unlimited Vault Access Configuration".
- Changed minimizing on Copy to Clipboard to be a per user preference.

Bug Fixes

- Fixed "No process is at end of pipe" SQL exception that occasionally occurred after doing an iisreset.
- Added email addresses to all users during Active Directory synchronization even if disabled in Secret Server.
- Fixed URL field on Secret to open correctly if http:// is not included.
- Fixed SSH issues when changing passwords on SUSE Linux.
- Fixed the ActivityDirectorySynchronization page, the AvailableGroups listbox no longer displays Groups that have been removed in AD.
- Added saving of the ADGuid for new groups when Save button clicked on the Group Synchronization page (instead of waiting for first AD sync).

Release Notes 7.0.000001

Features and Enhancements

- Added the ability to specify the characters to separate on when building the Search Index. Note: On upgrade the current search index will be rebuilt.
- Updated Dependency Finder to allow the user to manually specify the machine names to search.
- Disabled the trace and debug settings from the Web.config by default.
- BUG: Fixed Administration Export for IE when SSL is enabled.
- BUG: For XP machines, fixed the unsupported hash algorithm error for both the Email Pincode process and the Search Indexer.
- BUG: Updated RADIUS login to process passwords greater than 16 characters long to support Yubikeys.

Release Notes 7.0.000000

Main Focus: Custom reports, support for RADIUS, and more

Features and Enhancements

- Add-ons are now Professional and Enterprise Editions (explain Editions)
- Reporting
  - Reports page allows administrators to view standard reports, or to create reports with SQL and charting options. Reports can use a variety of 2D or 3D charts.
  - Reports can be displayed with all their associated data points (grid).
  - Reports can be placed into categories, and these categories and their reports can be organized using drag and drop.
  - Reports can have rows with different colors based on data values
  - Reports can be created using parameters such as start date, end date, and user ID.
- Added support for RADIUS integration to authenticate to Secret Server. This will work with AuthAnvil tokens, RSA tokens, and any other authentication scheme that supports RADIUS.

- Secret Server now uses FIPS 140 compliant algorithms and operates normally when limited to FIPS 140 only under Windows Security/Group Policy.
- Auto-complete added to Secret search textbox.
- Terminology change – renamed "inactive" to "deleted" for Secrets.
- Added scrollbars to Search and Browse tabs in homepage – makes it easier when you have lots of folders.
- Added icons to permission grids to indicate person or group.
- Groups in permission grid are clickable, which shows the list of users in the group.
- Date time picker works with the user's preferred date/time format.
- Added "copy to clipboard" support for Chrome and Safari.
- The layout of the Configuration page is now categorized into tabs for better organization.
- Added IP address logging for all failed authentication attempts. Previously, only attempts that caused lockouts were logged.
- Improved localization so that messages that do not exist in the localized XML file are rendered as "Resource Not Found:".
- Changed the inactivity timeout timer to reset on partial postbacks. This means that users will not get redirected due to inactivity when browsing folders or searching for secrets on the home page.
- Added on-screen notification for support license expiration.
- Added Configuration settings for an instance level default Time and Date format.
- Added separate page (DBConnectionReset.aspx) to allow users to change their database connection information without going through the installer.
- Added the ability to reset a forgotten DoubleLock password.
- Added Folder Search to the Folder picker.
- Added Folder Templates to support Folder (default), Customer, and Computer.
- Greatly improved Home page performance for running BulkOperations for larger instances.
- Improved the Change Password screen to give instructions for the password complexity guidelines.
- Improved System log to support having a maximum number of rows and to alert administrators when the log is truncated (by 50%).
- Updated the Launcher to support having a "blank" domain for local accounts.
- Updated the Launcher to support credentials for launching into multiple hosts. The user will be prompted to enter the Machine or Host before the RDP or Putty instance is opened when wired to the "user input" field.
- Added a User and Group picker to replace the dropdown list for user and group assignment for large instances.
- Updated the User create process to automatically assign the "User" Role by default.
- Added a grid of the user's Roles on the user view page.
- Webservice additions and updates:

  - Added FolderId to the Secret get methods
  - Added the ability to specific the folder on Secret Create and Update ▪Added Folder webservices for Get, Create, Update, and Search
- Added support for RPC support for Sybase databases.
- Added the ability to migrate a local user to an Active Directory user and maintain the existing groups and permissions.
- Added the full Folder Path on the folder edit and create pages.
- Search Indexer will split by newline.
- Added icon for NATO phonetics translation of Secret field on Secret View page for reading information verbally.
- Added Login form to the "Logged in at another location" page.
- Update the Resource Provider to support changing a single element with custom resource such as the Help link.
- Session Timeout has been moved to external config file to prevent overriding settings on upgrade.
- Added folder picker and "include subfolders" option to the User Audit report.
- Added "Last Date" column to the user audit report page.
- Added "Save to File" functionality for many grids.
- Added common table expression functionality to folder database queries to improve performance on SQL Server 2005 and SQL Server 2008.
- Updated code signing certificate for Launcher.

Bug Fixes

- Fixed bug that caused Dependency Finder to time out prematurely for some systems.
- Changed "lock out" for Web Services to be consistent with logging in through the Web interface.
- Removed unnecessary validation when entering a new domain that required the domain account to have reset password permissions.
- Fixed issues with Admin Secret Export for some browsers.
- Fixed Dependency to show all computers found in Active Directory.
- Fixed the Keep Alive thread and other background threads to avoid spamming the system log when thread cannot be stopped.
- Fixed the Active Directory Group Synchronization page to display the listboxes with a proper width for all Browsers.
- Expanded the SQL timeout on backups to support large instances.
- Updated Active Directory synchronization to properly assign membership for groups made up of both child and parent domain users.
- Fixed the display of login policy to fit inside the box.
- Turned off autocomplete for password textboxes on the "Secret Edit" screen.

Secret Server Release Notes 6.x

Release 6.2.000013

Main Focus: Bug fixes

- Fixed bug where Folders would not be visible in Unlimited Vault Access Mode.
- Fixed bug when adding a new domain with a non-Administrator account.
- Fixed bug that caused Active Directory synchronization to crash if an AD user could not be accessed.
- Fixed bug that would incorrectly enable an AD user that exists in AD and Secret Server but are not in a synch group.
- Fixed bug related to Remember Me value and Inactivity Timeout.

Release 6.2.000012

Main Focus: Responding to customer requests

- Added support for child domain users being members in parent domain groups.
- Remote Desktop Preferences for the Launcher o Copy to clipboard, admin/console, attach drives, share printers
- Ability to Delete IP Address Ranges
- Embedded mode to Hide Headers and Footers o Running Secret Server in Embedded Mode KB
- Improved support for Database access through Windows Authentication to have the background thread run with identity of the site instead of AppPool
- Added Permission and confirmation for force expiring secrets on the User Audit Report.
- Added Full Path to folder in Secret View and Edit alerts.
- Improved the performance on the Domain Synchronization for selecting AD groups.
- Made Favorites click through to its own bookmarkable page.
- Terminology Change: "Owner" permission replaces "Share."
- Improved and fixed bugs in Backup: o Backup respects setting for not sending failure emails to Administrators o Fix scheduled backup inconsistencies for some users o Limited to 3 retries
- Added better support for incomplete language files, so defaults to English if item is not found.
- Increased folder performance for renaming and editing permissions.
- Updated Domain Synchronization to set the DisplayName for new users and support username changes in Active Directory.
- Updated display issues with listboxes being too small on the Group Edit page and Domain Synchronization page.

Release 6.2.000006

- Fixed bug with the Role Assignment screen showing duplicate groups.
- Fixed bug where the Everyone group was not appearing in the Group assignment dropdown list on the permission screens.

Release 6.2.000005

Main Focus: Remote Password Changing enhancements and performance tuning

Features and Enhancements

- Disabled autocomplete on the Next Password textbox for Remote Password Changing.
- Service account credentials in these formats are now found by the dependency finder:
  - o username@fulldomainname
  - o username@shortdomainname
  - o shortdomainname\username
  - o fulldomainname\username
- Updated the Expired Secret log to include when the Secret is not changed due to the expiration time schedule.
- Performance improvements when using Unlimited Vault Access Mode.
- Performance improvements on the Folder edit page.

Bug fixes

- Remote Password Changing will no longer fail when a privileged account on a dependency is not set. Instead, it will attempt to use the credentials on the Secret.

Release 6.2.000004

- Fixed minor bug that incorrectly displayed encrypted values after saving a Secret.

Release 6.2.000003

Main Focus: Usability and Workflow

Features and Enhancements

- Streamlined the Secret creation process
  - o Single click for folder selection
  - o Remembers last selected folder o Allow changing Secret Template on the Create page
  - o Combined Search and Browse last selected Folder
- Option to allow Secrets to require approval for access o Email Notifications to approvers and requestors o Audit is kept of all approve and deny actions o Secret Access Request Manager page

Bug fixes

- Fixed the missing folder indentation in IE

Release 6.0 6.2.000000

Main Focus: Responding to customer requests

Features and Enhancements

- Users can now reset their login password through a password reset email.
- Added configuration option to AD synchronization to prevent enabling and disabling users during synchronization.
- Added ability to synchronize email addresses for AD users.
- Added "LockedOut" feature so that failed authentication attempts locks out a user instead of disabling them.
- Added ability to specify whether or not Windows Service dependencies should restart after a password is changed remotely.
- Added ability to handle AD hierarchies that contain cycles in their groups.
- Added several new webservice methods to support the new Secret Server iPhone application.
- Added a password migration tool for Password Corral (See the Tools page in Secret Server for more details).
- Added option to enable a Keep Alive thread so that the ASP.NET worker process never gets shut down.
- Added an audit record for when the launcher is used.

Bug fixes

- Fixed bug where inactivity timeout did not work correctly.
- Fixed bug that allowed users to delete folders containing Secrets when the "Require folder for Secret" option was turned on.
- Fixed bug where Windows Integrated Authentication through AD did not work for domains not hosting.
- Fixed bug where some AD hierarchies that had root folders with no users in them could cause null reference exceptions.
- Fixed bug where JavaScript was not getting cleared from cache on upgrades.
- Fixed bug that allowed users to view folders and their audits without the appropriate permission setting.
- Fixed bug where a Secret could be created from an inactive Secret Template if the query string was entered.
- Fixed webservices to observe IP address restrictions.
- Fixed bug where inactive roles were being displayed on Admin Role Assignment pages.

Release 6.1.000002

Main Focus: Minor updates to 6.1

Features and Enhancements

- Introduced the Failover Partner on Step 3 of the installer to support mirrored database environments.
- Added the use of the legacy Search / Browse functionality before 6.1 as a preference.
- Added an option to allow Browse to also include the subfolders.
- Added a Diagnostics page to assist troubleshooting.

Bug fixes

- Fixed bug where certain operating system settings would prevent users from being able to create a DoubleLock password.
- Fixed bug where the Launcher application did not start correctly.
- Fixed bug where URLs contained in email alerts did not contain the right link.
- Fixed link to a Knowledge Base article on the Backup Configuration page due to KB article restructuring.
- Fixed minor security issue where creating a user with a special sequence of characters would cause unexpected behavior.

Release 6.1.000000

Main Focus: DoubleLock for sensitive Secrets and bug fixes

Features and Enhancements

- Implemented DoubleLock to provide an additional security layer for sensitive Secrets
- Enhanced performance for Active Directory authentication
- Separated the "Search" and "Browse" functions on the Home screen
- HTML now renders using "standards mode" (may affect user customized themes)

Bug Fixes

- Passwords generated for expired Secrets now meet domain credential requirements
- Fixed bug pertaining to an infinite redirect loop related to session expiration and password expiration
- Fixed bug where exception occurred on SecretGet webmethod when user has no permission to a particular secret
- Fixed bug with bulk operations where progress was not reported to the user
- Fixed bug where file attachments with spaces in their names didn't download properly
- Fixed bug where folder name appeared outside of the dialog when viewing a folder
- Fixed bug where multiple PIN codes were sometimes sent when using Windows Integrated Authentication
- Fixed bug to not allow Checkout to be enabled when Remote Password Changing is disabled
- Fixed broken Upgrade link in Firefox

- Fixed bug where users with permanent cookies disabled were always redirected to LogoutAnotherLocation screen
- Fixed bug to prevent users disabling Autochange on Secrets that require Checkout
- Fixed bug where IOException was occasionally thrown during installation due to file permissions
- Fixed bug in client-side JavaScript on installer
- Fixed bug that caused NullReferenceException when inactivating a Secret without the required role permission
- Fixed bug that occurred in user auditing when using an IPv6 address
- Fixed UI layout on the dependencies tab related to the explain link
- Fixed bug on Minimum Password Age validation when all fields are zero and checkbox is unchecked
- Fixed bug when unmasking passwords that have XML special characters 6.0.000001 Main Focus: Minor Updates to 6.0 Features and Enhancements
- Added support for encrypted connections to SQL Server.
- Changed installer to not overwrite customized configuration files in future releases.
- Extended password length to 127 characters on AD credential used for AD Synchronization. Bug fixes
- Fixed bug where expired password and expired license caused redirects.
- Fixed bug where user with an expired local password could still use webservices.
- Improved stability of AD Synchronization capabilities.

Release 6.0.000000

Main Focus: Remote Password Changing and user experience

Features and Enhancements

- Enhanced Remote Password Changing to allow setting a specific date and time schedule for changing service account passwords and their dependencies.
- Dependent Windows Services are now automatically restarted when a service account credential is changed.
- Added Remote Password Changing support for Oracle accounts.
- Users can now specify their preferred date/time format.
- Added new role permission to use the launcher feature without being able to view the password on the Secret.
- Added AJAX support to various features to enhance the user experience.
- Disabled the 'Search by Active Secrets' option for users without the 'View Inactive Secrets' permission.
- Improved performance of initial AD sync page load.
- Updated Russian Localization to support new features.

Bug fixes

- Fixed bug where content was not correctly displayed on the 'Expired Secret' report page.
- Fixed intermittent JavaScript error related to the scroll position on pages. Compatibility:

- Secret Server 6.0 no longer supports Windows 2000 due to our upgrade to the Microsoft .NET Framework 3.5.

Secret Server Release Notes 5.x

Release 5.1.000001

Minor Updates to 5.1

- Changed link on Administration pages, from "Languages" to "Language Maintenance"
- BUG: Fixed issues with URL case sensitive localization causing mixed languages to be displayed.

Release 5.1.000000

Main Focus: New email alerts and support for PuTTY Features and Enhancements

- Added support for launching PuTTY for UNIX-based secrets
- Added ability to receive email alerts when secrets are viewed
- Added ability to receive email alerts when a dependency fails to update on an automatic password change
- Added new role permission for searching/viewing inactive secrets
- Changed folder creation/movement to only require edit permissions on the parent folder
- Added support for Remote Desktop launcher with Windows Integrated Authentication
- Added new bulk operations for deactivating and setting autochange on secrets
- All pages now maintain scroll position on postback
- Added a Languages page for Administrators to update and translate content to their language of choice
- Added an OK button to the top of the Folder picker
- Added additional folder management buttons to the top of the Folder Administration screen
- Added functionality to make Secret Server 64 bit compatible
- Searching on all fields no longer splits words up by periods Bug fixes
- Fixed bug on Login where a minimum password age error was shown when creating a local user
- Fixed bug with Windows Service Dependency Changers when using Windows Accounts due to a missing prefix of the machine name
- Fixed bug related to unlimited setting on Remember Me
- Fixed null reference bug on Secret Audit when user does have "View Secret" role permission
- Fixed bug where an incorrect validation message was displayed when password history was set to 'all'

Release 5.0.000002

Main Focus: Minor enhancements to 5.0

- Improved database indexes for search functionality.
- BUG: Fixed issue that intermittently occurred in older Secret Server instances when upgrading.

- BUG: Fixed to not send alerts when search indexing.
- BUG: Fixed Secret Template to not allow search indexing on file attachments.
- Fix: Cleaned up the CSS and layout on several pages.

Release 5.0.00000

Main Focus: Changing Passwords for Scheduled Tasks and Service Accounts Features and Enhancements:

- Enhanced Remote Password Changing to update dependent Scheduled Tasks, IIS AppPools and Windows Services.
- Added Checkout option to provide accountability for the use of a secret – the password gets changed automatically on checking.
- Enhanced search functionality to allow users to search by all fields.
- Implemented 'Change Password Remotely' feature to allow users to immediately change a password on a remote server.
- Added new default theme to enhance the readability of the UI.
- Export by folder now includes all child folders.
- Added the SecretID field to Secret Server webservices to provide integration for custom development.
- Administrators can now force local user password expiration.
- Added configurable minimum password age requirements for local user passwords.
- Added password history configuration options to prevent users from using past local user passwords.
- Webservices and Secret Assistant usage now creates view audit records.
- SSH Remote Password Changing now works for "root" accounts.
- Added ability to automatically delete excess database backups on the application server. Bug fixes
- Fixed bug that occurred when trying to access the Administer Groups page with no active local groups.
- Fixed unlimited remember me bug with Secret Assistant.
- Fixed bug when trying to create a new secret from a Secret Template with no fields.
- Fixed bug where SSH remote password changing left open connections.
- Fixed bug where Secret Assistant would return inactive secrets.

Secret Server Release Notes 4.x

Release 4.3.000000

- Implemented 'SH for password changing on Linux accounts.
- Fixed bug with Active Directory Synchronization when pulling users and groups from an organizational unit.
- Fixed issue with the 'next password' component of Remote Password Changing. 4.2.000000 Main Focus: Enhancing Folder Functionality and Security Features and Enhancements:
- Added configuration option to allow Secrets to inherit folder permissions by default.

- Added configuration option so that a user must have view permission on a folder to see it.
- Users can now create and manage their own folders without them being visible to all users.
- User now requires Edit permission on a folder to be able to add secrets to it.
- Added a new 'Everyone' group to include each existing user for easier management and legacy folder permission support.
- Tightened folder restrictions to require share permission on a parent folder in order to add a child folder.
- Implemented audit records for when Groups are created, made inactive/active within Secret Server.
- Implemented audit records for when users and groups are created or made active/inactive from Active Directory.
- Renamed two Role Based Security permissions: Administer Roles is now Administer Role Permissions and Administer Group Roles is now Administer Role Assignment.
- Secret Types are now labeled as Secret Templates.
- Added an 'Evaluation Expiry' notice to alert users when their evaluation is about to expire. Bugs:
- Fixed bug when users were made inactive when Secret Server could not connect to Active Directory.
- Fixed bug where Backup did not work properly if a database name contained certain characters.
- Fixed error that occurred on the AdminGroupByGroup page when no groups exist.
- Fixed error when trying to import folders with line breaks in a Secret field.
- Fixed issue with Password Type configuration not saving correctly in certain situations.

Release 4.1.000000

Main Focus: Addressing Role Based Access Control Features and Enhancements

- Implemented Role Based Access Control (Role Based Security) to set granular, assignable permissions for users.
- Added the ability to launch Remote Desktop from a secret.
- Added the ability to import secrets by folder.
- Secrets can now be exported with a folder name.
- Added "Run Now" button to the Remote Password Changing screen.
- Implemented a visual keyboard on the login screen to thwart keyloggers.
- Added the ability to create custom web.config files to override the default impersonation settings that will not be overwritten on upgrades.
- Added a dropdown on the results screen for users to define the amount of secrets to display.
- Created a Security Hardening Report that displays the security level of your system's installation.
- Created the SecretTypeSetActive.aspx page for quickly setting the active status on Secret Types.
- Improved the "Help" documentation.
- Groups deleted from Active Directory will now be disabled.

- Improved performance by adding caching for theming.
- Specific passwords can be set on the Remote Password Changing – AutoChange feature.
- Added a preference for showing a full folder path on the home search grid.
- Implemented robot.txt file to stop search engines from indexing Secret Server installations.
- Folder creation and editing is now an assignable permission.
- Added a search textbox to the Users screen.
- All cookies are now HTTP only for additional security.
- Added "Save and Add New" button SecretView.aspx.
- Increased the visual size of the notes field. Bug Fixes:
- Fixed bug where an exception was thrown when invalid information was entered in the "minimum password length" configuration option.
- Fixed bug where the folder picker modal did not work properly when Secret Server was viewed inside a frame.
- Fixed error where Secret Type export XML format was incorrect.
- Fixed bug where notification emails did not contain the full URL for the installation.
- Fixed bug where Integrated Authentication was not setting last login.
- Fixed bug where permission checkboxes were being displayed when the secret was set to inherit permissions from folder.
- Fixed bug where duplicate users appeared in the Active Directory synchronization preview.

Release 4.0.000003

Main Focus: Improving Permission Inheritance and Bug Fixes

Features and Enhancements

- Bulk operations now supports enabling folder inheritance on a secret.
- Deleted Synchronized Active Directory groups are now disabled within Secret Server.
- Added support for automatic backups on servers at different locations. Bug Fixes:
- Fixed bug when editing folder permissions that include a disabled user.
- Fixed padding error for secret item history for very large values on secrets.
- Fixed bug in Remote Password Changing due to new column for inherited permissions.
- Fixed broken "unmask password" image on 'Secret Edit' page.
- Fixed 'Remember Me' bug due to .NET 2.0 migration.
- Fixed 'Close' image on dialog.
- Fixed paging problem on AdminExport grid.
- Fixed bug where expiration date did not decrease on old secrets.

Cloud Archived

This section contains versions of Secret Server Cloud that are over a year old.

For changes pushed to cloud between major releases, see the Secret Server Change Log.

Secret Server Cloud Release Notes for June 3, 2023

Release Dates and Notes

Cloud: June 3, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.8.0

Protocol Handler: 6.0.3.26

New Features

Checked Out Secret View

Implemented the Checked Out Secret view to Quick Access in the Secrets Folder panel. This is a quick view, showing users all of the secrets that are currently checked out to them.

RADIUS Silent Answer

Silent Answer is a new RADIUS configuration option that allows setting the response to a predefined string value. This is to support push notification and other interactive variations in advanced RADIUS authentication configuration. The new setting replaces "Attempt User Password" and allows for sending the user password or another predefined string.

Check Out Recovery

We updated "Force Check In" to enable secret owners with the "Force Check In" role permission to force a check in of secrets that are configured to change their password upon check in. When a force check in is initiated, the secret is automatically checked out to the owner. This enhancement is particularly useful in scenarios where a secret is checked out with a failing RPC configuration and cannot be checked in by the current user. With this change, the owner can take over the checkout session, resolve the secret configuration issue, and then perform a standard secret check in.

Syslog Metadata for Launched Sessions

For built-in launchers, during a launch event, the launch target host is included within the details of the Syslog message as an additional "Host" field. Previously, this was only sent for launchers requiring host selection but now includes launchers with a static host-target mapping.

Launcher Administration Page Conversion

We updated the Launcher Administration pages under Secret Templates to use our new UI patterns with a modern design. No functionality is affected, but the page is more responsive and intuitive.

SSH Key Authentication Passphrase Requirement

We added a new configuration setting to the login configuration page that allows administrators to enable a mandatory requirement for passphrases when users generate SSH keys for SSH Terminal key authentication.

Enhancements

- Added a Managed field to the Discovery Network view to show when a discovery item is managed.
- Added a Password Age column to the redesigned Discovery Network View.
- Added a Quick Access link to see all Secrets you currently have checked out.
- Added filters to the Secret Search API endpoint to allow filtering results by checked-out status: *paging.filter.showSecretsCheckedOutByUser and paging.filter.showCheckedOutSecrets*
- Added info to logs to indicate why users cannot match or create users in SSC. Find this at Secrets > Admin > Platform Integration > Logs tab. Common notifications include DuplicateUserMappedToDifferentProviderName: The user was initially setup to a different Platform source, the URL or userid (provider key) changed, indicating the original use was deleted. MaxLicensedUsersException: All licenses are taken so additional users cannot be added.
- Added integration support for Platform users matching local SS users that do not have an @ in their name. If platform user is username@local or username@tenantname then the username portion will be used to match local users on the SS side.
- Added support for LDAP RFC2307 group membership, used in OpenLDAP.
- Added the option to require a passphrase for user public SSH keys.
- Added validation messages to password requirement rules for when password requirements are too complex to reliably generate a password.
- The Discovery Service Accounts detail page now displays both the services running under a directory account and the computers on which those services run.
- Distributed engines no longer need directory services enabled to perform discovery.
- Introduced a new Launch Secret role permission, which is needed to use launchers. This permission is automatically granted to roles with the View Secret permission, which previously controlled this behavior.
- Removed the secretitemvaluetransitionhistory.aspx page and replaced it with an API endpoint, removing the possibility of bypassing the Hide Launcher Password control.
- RPC heartbeat and password change logs are now full screen instead of a dialog box.
- The PowerShell script timeout no longer defaults to 90 seconds. Instead, it now uses the value from the Event Pipelines Maximum Script Run Time (Minutes) setting in advanced configuration.
- The new folder icon in the secret panel no longer shows if the user does not have the Administer Folders role permission.

- The user audit report now has a filter panel and a description for how rotated secrets are calculated for this report.
- There is now a pending RPC screen and a timer that checks you back in, blocking seeing secret info indefinitely.
- Users can no longer access secrets that have failed processing a password change. Instead, they are shown a message stating the change failed.
- We now initially load 60 secrets when viewing a grid to support 4k monitors. This was previously 30.
- Within the details of the syslog message, there is now a username field that contains the mapped username for the launcher on a launch event. It appears as Username: [<username>] for the built in launchers.
- Within the details of the syslog message, there is now a Host field with the value of the mapped host for the launcher on a launch event. It appears as Host: [<host>] for the built in launchers.

Bug Fixes

- Fixed an issue where Platform integration user synchronization failed if duplicate usernames existed in Secret Server.
- Fixed an issue where a secret template could be saved without RPC mappings configured.
- Fixed an issue where all event subscriptions did not fire for secrets in subfolders of the target folder.
- Fixed an issue where Disaster Recovery (DR) email alerts failed to send.
- Fixed an issue where extended fields were not properly exported to CSV files.
- Fixed an issue where keystroke data from the advanced session recording agent did not appear in the keystroke activity details area of the playback page.
- Fixed an issue where large messages from distributed engines to engine workers would not process. Engine workers may have crashed especially frequently in environments having four or more workers, including Secret Server Cloud.
- Fixed an issue where LDAP sync via distributed engines would not work when the base DN was different from DC.
- Fixed an issue where links on the Session Monitoring page while in grid mode would not correctly link to Secret Server Cloud with authentication.
- Fixed an issue where the API endpoint api/v1/secrets/{id}/fields/{slug}/ logged an audit that the password was displayed when the actual password was not returned to the user due to hide launcher password being enabled.
- Fixed an issue where the Confirm Action button in the bulk operation dialog box would remain active while the operation is processing. This is now correctly disabled to prevent initiating the action multiple times.
- Fixed an issue where the SubscriptionName condition for a notification rule would display the event subscription ID instead. It now correctly uses the name when the user has the appropriate roles to list the subscriptions.
- Fixed an issue where the terminate session mouseover tooltip displayed incorrect text.
- Fixed an issue with a secret template name validation message not showing.
- Fixed an issue with negative numbers exporting incorrectly when exporting a CSV.
- Fixed an issue with new Platform trials not creating personal folders in Secret Server.

- Fixed an issue with secret search producing SQL errors for customers with a lot of secret templates.
- Fixed an issue with stacked dialog boxes. The CSS styles for the Platform Opt In dialog box have been adjusted to align with Angular15.
- Fixed conditions that prevented users from being removed from a group due to the system incorrectly identifying that they would be unable to complete the same operation.
- Fixed issues with user and group syncing between Secret Server Cloud and Platform.
- Improved usability in specific UI areas to enhance the user experience.
- Updated `Createuser.aspx` to redirect users to the new User Management page.

Future and Recent Deprecations

This section describes planned future deprecation of feature or platform support in Secret Server.

Not applicable for the current release.

Secret Server Cloud Release Notes for May 6, 2023

Release Dates and Notes

Cloud: May 6, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.7.0

Protocol Handler: 6.0.3.26

Enhancements

Secret Folder Panel Redesign

We reworked the secret folder panel for additional functionality and a more streamlined user experience. Direct access to the folder panel from outside of the secrets view was found to unnecessarily clutter the navigation menu, and the panel is now visible on the Secrets page. In addition, we enhanced the following:

- We added a "Quick Access" section to the folder panel, which offers a single page combining the following sections:
  - Search
  - Favorite Secrets
  - Most Used Secrets
  - Session Secrets–Secrets accessed this session, allowing the user to return to a secret they have accessed in this browser session

  - Recent Secrets—Most recently accessed secrets, within this session or others
  - Shared With Me—Secrets that are shared with you but not in folders that you may view
- Added a "New Folder" button to the top of the folder tree.
- Pinned folders are now placed at the top of the tree instead of listed in a dropdown. Pinned folders give easier access to your favorite folders. When a pinned folder is selected, the displayed folder tree is based on the that pinned folder rather than the entire tree. The same applies to the content of "Quick Access," which displays secrets in the selected, pinned folder.
- A guide now displays for new users the first time they view the secrets page, introducing components and changes.

Other Enhancements

- DR: Created more robust data ambiguity handling when data replication processes a table where there is a multi-field unique key. These included giving precedence to source data when applicable or throwing an error when an ambiguity cannot be resolved.
- DR: Added an advanced configuration setting (defaulting to 3 hours) so that a long-running DR process will detect the configured amount of elapsed time and end the DR process, forcing the business user to manually run it again.
- DR: Read-only mode can now be enabled in Secret Server Cloud on the disaster recovery configuration page.
- Added a discovery import rule to the new network viewer.
- Added a link to the public SSH keys, when enabled, on both the user preference page and the administration tools section.
- Added a knowledge base link for Platform regions as part of the Platform Optin Experience.
- Added support for LDAP RFC2307 group membership, used in OpenLDAP.
- Discovery rules and dependencies grid can now be filtered by discovery source. Rule grid now also has discovery source available as a column.
- Local Admin column added to new discovery network view.
- Secret template name on the secret general tab is now a direct link to the template.
- The "Send Test Email" button now functions in read only mode.
- The report CSV download is now encoded so that certain Turkish characters appear, and the mime type was changed to text/csv.
- The Unlimited Vault Access page in configuration preview now has a link to open the Unlimited Vault Access audit.
- HSM Integration—RSA OAEP Padding Support. We added OAEP padding as a new configurable option when enabling or rotating the HSM integration. This is in anticipation of the planned deprecation of PKCS padding by NIST. Current configurations are unaffected, but this option is available when rotating the HSM key, or configuring a new integration.

Bug Fixes

Disaster Recovery

- Fixed an issue where DR email alerts were not being sent out.
- Fixed issues for password-requirement character-set data replication in the DR feature.
- Fixed an issue with disaster recovery replication where replicated custom launchers were not visible on their associated secrets.
- Fixed an issue with the disaster recovery logging process so that only error-free data replications are marked as successful.
- Fixed issue when replicating data for disaster recovery where pre-existing users on the replica that do not exist on the source could lose their All Vault Users group membership.
- Fixed replication to allow duplicate names to be replicated individually during disaster recovery. Groups with the same name will still be consolidated during replication when they share values for AD Guid, IsPersonal, IsPlatform, and DomainId.
- Password requirements are now replicated from source to replica as part of disaster recovery.

Other Bug Fixes

- Corrected logic that allowed password requirement consumers to bypass non-replicated secrets
- Dates in the report export no longer include the "Z" for UTC when server time is used and ISO date format is selected because the date/time is the server configured time and not necessarily UTC. That is, the date is ISO format and the server-configured time but does not include the offset. In some specific configurations when user format was selected, the timezone offset would be applied based on the actual server timezone and not the configured timezone.
- Discovery-specific OUs now returns results when the page is initially loaded.
- Due to security reasons, we removed the GET endpoint for /secretserversettings/export and replacing it with a POST endpoint where we can transmit the password securely. The contents of the payload are the same, except for new "password" and "doubleLockPassword" fields, and the entire payload is contained within a parent "data" object.
- Fixed a bug that caused launcher session failure on secrets that were expired on checkout but then disabled checkout via policy. Also, retroactively fixed this situation on secrets.
- Fixed a string truncation error. Expanded the user setting size to resolve issue for some customers with lots of columns for a grid.
- Fixed a timing problem where secret favorites might not initialize if the secret grid loads very quickly.
- Fixed an CSS issue where clicking the "Browse all folders" button caused folder names to overlap.
- Fixed an issue that had platform logout redirecting to a different tenant.
- Fixed an issue where "Web Launcher requires Incognito Mode" was not being respected when enabled. Descriptive text added on web launcher mapping for restricting input fields.

- Fixed an issue where a bulk action was applied to all secrets when select all is checked but a template or folder filter was applied.
- Fixed an issue where a default error page was presented when accessing certain URLs as opposed to a more technical error.
- Fixed an issue where a dependency fails to work when moved to another group or order due to the run condition. When a secret dependency is updated to the first sort order or to a new group, the run condition is cleared. This addresses an issue where a secret dependency with a run condition would not run when it was the first secret dependency in its group.
- Fixed an issue where a Get Folders API call did not returns all descendants, breaking some customer integrations. To retrieve direct children only, use the new LimitToDirectDescendents parameter.
- Fixed an issue where an HSM could not be disabled.
- Fixed an issue where Azure domain accounts were unable to access Secret Server SSH Terminal with a public key. You can now log into Terminal with an Azure Active Directory account using SSH Key Integration. AAD logins to Terminal via password cannot be done.
- Fixed an issue where changing the time zone on the secret audit page did nothing and refreshing the page returned to the default time zone. When the server time zone is different, the time zone picker should show and the date column for audit should render in the selected time zone.
- Fixed an issue where connecting using an SSH key on another secret did not work with "SSH key only" secrets.
- Fixed an issue where data retention under PII removed monitored recordings or user audits related to monitored recordings. Data retention under database size management will still remove monitored recordings and related user audit records.
- Fixed an issue where duplicate user names were throwing an error. When logging in as a local user, we now ignore any Platform native users that may have the same login name, instead of erroring.
- Fixed an issue where event pipeline email notifications were not sent if the email task had an email template selected.
- Fixed an issue where exported computer scan logs were incomplete. Discovery logs now export more than 250 records.
- Fixed an issue where folders and sub-folders were missing secrets with UAM enabled. Left nav max folders default limit increased to 1,000. Setting dialog added to set the user preferred limit. Folder browser now loads 100 records at a time on scroll instead of just 30.
- Fixed an issue where GET /internals/secret-detail/{id}/launcher/{launchertypeid} threw an exception. We now show a friendly error message when launching a secret With Jumpbox Route with RDP that it is missing an SSH launcher
- Fixed an issue where OpenLDAP directory services group-search filter was not working.
- Fixed an issue where PowerShell dependency changer arguments were not being passed into the script.
- Fixed an issue where secret field data over a certain length may be rejected by the database upon replication.
- Fixed an issue where Secret PasswordComplianceCode was not updated after password field/PasswordReq change.

- Fixed an issue where secret template fields of type file no longer showed the drop down options when editing the field.
- Fixed an issue where session monitoring grid view showed the system and not the Secret Server. The secret session search date in the grid and card both now show in the selected time zone and the grid has the timezone picker when relevant.
- Fixed an issue where the folder list disappeared if UAM is enabled and when the "All Folders" toggle is selected in the sidebar. Folders in the tree will now be limited to only show 125 folders per tree. Once there are 125+ subfolders a "Browse all folders" option will appear in the folder tree. This link will take the user to a grid that only shows folders with a search. The grid has paging so it will load 30 folders at a time as the user scrolls. This will help support instances when users have thousands of subfolders. If there are more than 30 subfolders in a folder the secret grid will show a link to the new folder browser. This used to open a dialog to the folder tree which would also run into performance issues when users had over 1,000 subfolders.
- Fixed an issue where the folder tree disappeared when there were more than 1,000 folders accessed and UAM was enabled.
- Fixed an issue where the pipeline activity status stopped updating after the "Send to Email" task
- Fixed an issue where the Preserve Client SSH Process did not appear for process launchers
- Fixed an issue with heartbeat failures if a secret had checkout enabled.
- Fixed an issue with secret search would produce an excessively long URL that would sometimes throw an HTTP 404 error. The secret search API endpoint now accepts a filter param called ExtFieldsCombined, which is a comma delimited list of all extended fields to include in the results. This field is now used by the secret grid to help reduce the size of the URL when many secret fields are exposed for display to avoid the IIS 2k length restriction on GETs.
- Fixed an issue with SSH proxy "Tunnel RDP Connections" performance degradation (high CPU usage).
- Fixed an issue with the data retention page background color.
- Fixed discovery network view to ensure when searching you should be able to find all items under your current levels. However, when looking at a level you only see that level.
- Fixed issue with the password compliance report updating very slowly or not refreshing after either a template or direct PasswordRequirement password field change.
- Fixed issues related to RabbitMQ channel and queue growth and corruption-related issues due to connection interruption causing premature queue deletion.
- Fixed the default timestamp format for CEF.
- The "All Secrets" CSV download now correctly shows the folder name instead of the folder ID.
- The secret policy approvers "default only" option now displays correctly when updated.
- Updated the advanced session recording agent version label on the agent issues page to correctly state that it is the minimum required version, not the current version.
- Fixed an issue where a purge of inactive sessions longer than three minutes was occurring when the Sessions Monitoring page was displayed. It did not take into account the SSH proxy timeout. The page now obeys the timeouts.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server Cloud Release Notes for March 31, 2023

Release Dates and Notes

Cloud: March 31, 2023 (including April 4, 2023 update)

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.6.0

Protocol Handler: 6.0.3.26

Enhancements

- Secret MFA: Block indirect API calls (Updated secret access logic for MFA).
- Updated disaster recovery data integrity checks to prevent replication when the replica is a higher version than the primary. In this scenario, the replica may have different schema and system data than the primary, causing replication issues.
- During disaster recovery replication, secret items from the source are combined with ones from the replica when they have matching SecretIDs and SecretFieldIds.
- "Save" buttons are no longer disabled when a form is invalid. Clicking the button will now show and trigger form validation messages.
- Color palette updated to improve accessibility and brand.
- Added option to duplicate a discovery scanner.
- Added the ability to sort in the new Discovery Scanner UI.
- Added credential validation message for the new Discovery scanner page.
- Launcher icons updated on secret general and inline secrets.
- Updated the new scripts UI to allow testing of remote scripts.
- Updated Delinea Platform opt-in flow to allow region selection and have explicit confirmation.
- Secret panel is now always open when on any secret section page. My Secrets page added to give a quick overview or dashboard of secrets, including favorites, recent, and search secrets and folders. My Secrets has a session secrets section which will show any secrets that have been opened during the web session. Favorites, recent, most used, and shared with me are now linked in the secret panel. Pinned folders now show a scoped version of My Secrets and only search within that pinned folder. New folder icon is always on top of the secret panel. A guide walkthrough will appear the first time a user goes to secrets. Folder URL path is now contained in /secrets/folder... Secret detail URL is now plural to be consistent and prevent reloading of the secret panel.
- A new checkbox has been added which enables requiring all users who log in through the Delinea Platform to have used Platform's multi-factor authentication when logging in.
- Unlimited Vault Access notification now appears in the header instead of floating as a transparent block.

- Unlimited Vault Access page in configuration preview now has a link to open the Unlimited Vault Access audit.
- CreateUser.aspx now indicates that provisioning is in progress if accessed during the unified trial (platform) provisioning flow.
- When pages still using the legacy UI underpinnings, the Unlimited Vault Access notice will show on .aspx pages when it is enabled.
- Added a Discovery import rule to the new network viewer.
- SDK Client Management pages have been converted to the new UI page format.
- The password changers list/grid has been updated to the new UI design.
- Converted list options ss-grid to thy-grid. Allows for resizing of columns.
- Discovery rules and dependencies grid can now be filtered by discovery source. Rule grid now also has discovery source available as a column.
- The secret detail page now includes a button to copy the current URL to the clipboard with rich text, including the secret ID and secret name. Plain text copy will just include the URL.
- Read-Only mode can now be enabled in Secret Server Cloud on the Disaster Recovery Configuration page.
- Local Admin column added to the new Discovery network view.
- Secret template name on the secret general tab is now a direct link to the template.

Bug Fixes

- Fixed a bug that caused launcher session failure on secrets that were expired on checkout but then disabled checkout via policy. Also, fixed this situation on secrets retroactively.
- Fixed issue so that when a PBA URL is configured through the UI, the host and certificate are now validated.
- Updated file-attachment selection process for data replication so that file attachments for secrets in the root folder are selected when the user has specified a folder block list.
- Fixed a problem with Azure AD / OpenIDC in April 1st monthly release prevented login.
- The report CSV download now encodes specific Turkish characters and has an updated mime type of text/csv.
- The sessions monitoring page used to purge inactive sessions longer than three minutes, disregarding the SSH proxy timeout. Now, it abides by the specified timeouts.
- The export secrets feature has been changed into an asynchronous job. The export process starts a job and continues polling until completion. Users should remain on the page until the job finishes to avoid timeout issues.
- An issue was resolved where a secret dependency with a run condition would not execute when it was the first secret dependency in its group or moved to a new group. Now, updating a secret dependency to the first sort order or a new group clears the run condition.
- The all secrets CSV download now correctly shows the folder name instead of the folder ID.
- Folder permission now correctly shows "None" in secret role drop down when in edit mode.
- Dates in the report export no longer include the "Z" for UTC when server time is used and ISO date format is selected, since the date/time is the server configured time and not necessarily UTC. This means the date is in

ISO format and the server configured time, but does not include the offset. In some specific configurations when user format was selected, the time zone offset would be applied based on the actual server time zone and not the configured time zone.

- After changing field properties on a secret template, the UI cache is cleared to allow selectable columns in grids to be updated without requiring a browser refresh.
- Corrected a bug where converting or duplicating a secret with an assigned secret policy would cause launcher settings to apply multiple times, causing a UX constraint violation.
- An audit entry is now made for the user that enabled maintenance mode during an upgrade (on-premises only).
- Event subscription now publishes the event for when a user is enabled or disabled.
- Discovery logs will now export more than 250 records.
- Logging into Terminal with an Azure Active Directory account using SSH Key Integration is now possible. AAD logins to Terminal via password cannot be done.
- License server activation grid updated to resolve layout clipping issues.
- Secret dependency API variable name changed from id to secretDependencyId to help clarify which parameter is needed.
- Deleting folders will now also indicate that subfolders will be removed as well.
- Due to security reasons, we are removing the GET endpoint for /secretserversettings/export and replacing it with a POST endpoint where we can transmit the password securely. The contents of the payload are the same, except for the addition of "password" and "doubleLockPassword" fields, and containing the entire payload within a parent "data" object.
- Lookup folders (api/v1/folders/lookup) and search folders (api/v1/folders) will now return only direct children when searching by parent ID. They will no longer return grandchildren.
- Enabling heartbeat for the first time on a secret template will no longer subtract 1 minute from the heartbeat duration.
- The duration field on session monitoring now shows as a friendly time duration instead of just total seconds.
- "Automatic sudo or su privilege elevation" was fixed to work with Solaris OS.
- Connect using SSH key on another secret now works with SSH key only secrets.
- Addressed issues where secrets configured for checkout on the source could cause errors on the replica.
- Added documentation in a tooltip to point users to audit on proxy page (proxy audit).
- FOLDERPATH parameter now works with report schedules and running a report.
- The secret search API endpoint now accepts a filter param called extFieldsCombined, which is a comma delimited list of all extended fields to include in the results. This field is now used by the secret grid to help reduce the size of the URL when many secret fields are exposed for display to avoid the IIS URL length restriction on GETs of 2,048 characters.
- Inline row added to secret dependency log dialog to expand the row.
- Edit inbox rule condition dialog title now says "Edit condition" instead of "Add condition."
- Fix to allow heartbeats even if the secret has checkout enabled.

- Addressed an issue with disaster recovery replication where replicated custom launchers were not visible on their associated secrets.
- The report SQL editor no longer has options to download or configure columns on the report as it is not supported in that mode.
- Disaster recovery data replication errors caused by out of sync encryption keys are now automatically resolved properly.
- The "Most used secrets" grid on dashboard overview now downloads the folder path instead of the folder ID.
- The secret search API now returns the folder path on the secret. Secret grid download now includes folder path on all records accordingly.
- Fixed issues related to RabbitMQ channel and queue growth. Channel and queue growth should no longer be experienced.
- Resolved an issue with disaster recovery folder synchronization selection. Personal folders can now be selected for either allow or block lists.
- Fixed an issue with folder name collisions during disaster recovery data replication sync.
- Fixed older character sets that failed to replicate when running disaster recovery.
- Handled issue when replicating data for disaster recovery where pre-existing users on the replica that do not exist on the source could lose their All Vault Users group membership.
- Descriptive text added on web launcher mapping for restricting input fields.
- Fixed an issue with the secret log length validation in the UI.
- Fixed issue where secret field data over a certain length may be rejected by the database upon replication.
- Corrected an issue where when created as part of the unified trial flow for Platform, the first user created did not have admin access to Secret Server Cloud.
- Folders in the tree will now be limited to only show 125 folders per tree. Once there are 125+ subfolders, a "Browse all folders" option will appear in the folder tree. This link will take the user to a grid that only shows folders with a search. The grid has paging, so it will load 30 folders at a time as the user scrolls. This will help support instances when users have thousands of subfolders. If there are more than 30 subfolders in a folder, the secret grid will show a link to the new folder browser. This used to open a dialog to the folder tree which would also run into performance issues when users had over 1,000 subfolders.
- Fixed issues for password requirement character set data replication in the DR feature.
- Corrected the default timestamp format for CEF.
- Expanded the user setting size to resolve issue for some customers with lots of columns for a grid.
- Left navigation maximum folders default limit increased to 1,000. Setting dialog added to set the user preferred limit, folder browser now loads 100 records at a time on scroll instead of just 30.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server Cloud Release Notes for February 11, 2023

Release Dates and Notes

Cloud: February 11, 2023

Component Versions

Distributed Engine and Advanced Session-Recording Agent: 8.4.3.0

Protocol Handler: 6.0.3.26

New Features

User Interface Streamlining: Classic UI Removed

The classic UI is no longer available as an option, and can no longer be enabled. This followed notifications of phased deprecations in prior releases. Several improvements have been made to the UI based on feedback from customers regarding this change.

Checkout Extension Maximum Limit

We created a global configuration setting that allows administrators to set a maximum secret-checkout extension interval. This provides additional admin control by specifying granular limitations to users extending a checked out secret. The time limitation begins at the point of checkout extension and extension time defaults to the set checkout time

Disaster Recovery Enhancements

"Replicated User Status on Disaster Recovery Source" configuration can now be set to:

- Mirror Source, which is the existing behavior
- Disabled by default

New Synchronization Items:

- Character sets
- AD users and groups

Discovery User Experience Improvements

We updated the discovery user experience to reflect the style and design of the application. The legacy pages are still available; however; the new interface items are ready for use, and we welcome feedback on these items. The legacy pages can be accessed by browsing to the relevant new interface and clicking the "View Legacy Page" button. The improvements are:

- Network view is available as a tab on the main Discovery Sources page.
- Network view displays the same results as the legacy page, in a single filterable grid, as opposed to individual tabs for different types of scanners. The new page has the functionality of the legacy page but in a more-responsive and updated design.

- There is a new filter menu, allowing extensive filtering options of this data.
- Each item in the network view list links to a details page allowing review of the discovered data, as opposed to being viewed inline.
- The grid data is exportable as a CSV, similar to other grids.
- Scanner, scan template, command set and search filter configuration are available from the Discovery Configuration Options > Scanner Definition button on the Discovery Configuration page.
- Source scanner configuration is available in the Discovery Source Configuration page as a tab.
- We extensively redesigned the scanner configuration UI to make this experience more intuitive, and scanners are now displayed in a workflow view.

Generated and Created Password Improvements

Password Complexity Indicator

There is a new visual indicator in the password complexity rules that provides the user with a better understanding of the strength of their password. The combined score considers both entropy score (brute force defense) and character limitations (social engineering defense). In the case that the score is deemed too low, the UI provides recommendations to the user on how to increase password strength

New Password Rules

We introduced character rules to password complexity selection to enhance the strength of generated and created passwords, if enabled. The new rules provide flexibility in the granularity of the rules. Each selection impacts both entropy and overall strength score. The rules include minimum characters from:

- Lowercase letters
- Symbols
- Numerals
- Uppercase letters

Opt-In Engine Upgrades

Distributed engine upgrades are no longer mandatory for every release. We added a new setting to the Distributed Engine Configuration page to set the minimum required engine version. Modifying this will trigger an automatic update for any engine below this version.

In the action menu for an engine on the Sites page, a manual upgrade can be triggered for individual engines below the latest version, which prompts the engine to update when it next calls in.

When changes are made needing an upgrade, the minimum required version is updated during the update process, and all engines update immediately.

"Run Scripts" Role Permission

We created a new "Run Scripts" role permissions to separate privileges in script management. Holders of the "View Scripts" role permission cannot execute test runs of scripts, and the new role permission must be assigned to perform this task.

Administer Scripts remains unchanged and allows view, edit, and run permissions.

Syslog Timestamps

There is a new setting in Syslog configuration allowing the selection of timestamp formatting. The standard for Syslog indicates that ISO timestamps should be used; however, some consumers use the legacy format. There is now a selection between Syslog and ISO format. Syslog will be the default for upgrades to allow current configurations to retain their behavior, and ISO format is the default in new instances.

Enhancements

- Added a configuration option to disable the SMB heartbeat fallback check.
- Added a secret policy setting to control "Change Password Upon Check-In" behavior. Previously, this was automatically enabled if "Require Check Out" was enabled.
- Added additional debugging output for SSH proxy when using the "ALL" logging level.
- Added audits for emailing and downloading reports.
- Added endpoints for Update Password Type Auth, Get Password Type Auth, and Create Password Type Auth. These allow you to create and update records for the command arguments on RPC command set up.
- Added the configuration setting "Allow Files without Extension" to the configuration preview.
- Added the internal site connector configuration to the configuration preview.
- Added the User parameter to the IBM iSeries Mainframe connection for launching, password changing, and heartbeat.
- Bulk edit share now has a "None" permission which allows removing permissions.
- Changed IIS web.config configuration to disallow access to the file uploads folder.
- Enabled more connection classes to use read-only mode.
- Enhanced secret export logging.
- Improved performance of dependency matching within discovery.
- Improved performance of the role assignment page and added a user panel on the same page.
- Improved performance of the secret to computer matching operation that runs as part of discovery.
- In the data replication summary log now lists in alphabetical order, success and version number will appear before the list of items and any errors are appended at the end.
- Optimized application caching.
- Updated the new UI to allow newly generated SSH keys to have a blank passphrase, which matches legacy UI functionality.

- **Bug Fixes**

- Fixed a memory leak in SSH proxy.
- Fixed a SAML audit error.
- Fixed an error that occurred when multiple identical domains were created.

- Fixed an error where the new SSH proxy custom SSH cipher suite settings were not picked up by distributed engines.
- Fixed an issue in the heartbeat status by day report that would cause the same secret to be counted twice on days where the secret transitions between heartbeat failure and success.
- Fixed an issue where "Days Until Expiration" value on the secrets grid would show a large negative number if expiration is forced. This now displays "Expiration forced."
- Fixed an issue where "requires approval type" could not be set by policy.
- Fixed an issue where a user with edit permissions could not rename a folder.
- Fixed an issue where an "invalid SQL error" was incorrectly displayed when a report timed out.
- Fixed an issue where an error was displayed in an edit field dialog box.
- Fixed an issue where an inbox notification was not clearing in Secret Server Cloud.
- Fixed an issue where completed master encryption key rotation would not show as such.
- Fixed an issue where converting a secret in a folder with a launcher settings policy threw an error.
- Fixed an issue where deleted Active Directory groups were not correctly marked as inactive when synchronized.
- Fixed an issue where disaster recovery would log many password requirement errors.
- Fixed an issue where failing Syslog/SIEM messages did not respect updated Syslog Server configuration.
- Fixed an issue where file contents during SFTP/SCP file transfers were included in the session keystroke recordings.
- Fixed an issue where installation on specific dates on servers with a dd/mm/YYYY localization configuration would prevent some configuration settings from being read.
- Fixed an issue where Local site could not be configured to use Custom SSH Cipher Suite settings when set to process on the Web Site.
- Fixed an issue where manual backup did not work in maintenance mode.
- Fixed an issue where master encryption key rotation would fail due to discovery import rules running at the same time.
- Fixed an issue where missing file attachments caused DR replications to fail.
- Fixed an issue where monitoring and termination of live sessions was not displayed in the UI. This now takes the user to the regular session playback page, which displays the live session.
- Fixed an issue where PowerShell-based dependency changers would not correctly pass arguments.
- Fixed an issue where PuTTY would close immediately following a session error. This was due to a default setting change in PuTTY, which is now explicitly set to remain open on installation or update of the protocol handler. This requires a protocol handler update.
- Fixed an issue where reports generate an application error if users navigated away from the report while it was loading.
- Fixed an issue where scrolling the secrets grid view would deselect items.

- Fixed an issue where Secret Server did not correctly react when two templates have the same field if one had spaces that the other did not.
- Fixed an issue where secrets would not open when users have folder view and secret list permissions. The secret audit within that folder should be accessible.
- Fixed an issue where session recording would sometimes show a 500 error, even though the client would retry. Replaced this with a HTTP 429 response, explicitly informing the client to retry.
- Fixed an issue where session recordings could not be saved to a UNC file path due to missing permissions on the root of the path.
- Fixed an issue where sorting by folder path in the secret grid view would return an error.
- Fixed an issue where SSH dependencies would not process on distributed engines.
- Fixed an issue where SSH Proxy would not allow a launcher to connect in maintenance mode. This is now possible in non-recorded sessions—recording is not possible in maintenance mode.
- Fixed an issue where the advanced session recording agent would attempt to make many reconnections in a short time span.
- Fixed an issue where the 64-bit protocol handler would not function when "Enable Protocol Handler Auto-Update" was enabled.
- Fixed an issue where the folder picker would not populate when adding folders in event pipeline policies while in Unlimited Vault Access mode.
- Fixed an issue where the IBM iSeries password changer was not properly adding the model value to the connection string.
- Fixed an issue where the light/dark mode toggle displayed "Enable Dark Mode" even though the UI was already in dark mode. This was due to a dark mode browser preference and no explicit user preference having been set.
- Fixed an issue where the SAML AuthnRequest was sending a blank RequestedAuthnContext when Authentication Context was set in the Identity Provider Configuration.
- Fixed an issue where the Secret Server website would not load if the internal site connector is unavailable at startup.
- Fixed an issue where the terminate option on the session playback page was missing.
- Fixed an issue where the test buttons would not function for the Oracle Account Ver. 2 password changer.
- Fixed an issue where the UI session monitoring search required additional permissions to load.
- Fixed an issue where the Unlimited Vault Access watermark could block interaction with some page elements.
- Fixed an issue where the wrong error message would be shown when trying to apply an invalid data source key under data replication.
- Fixed an issue where user permissions on replica instances were removed erroneously when data replication ran.
- Fixed an issue with check in when the "Check In Secret on Launcher Close" and "Close Launcher on Check In Secret" settings were both false.

- Fixed an issue with DR replication where some operations would give an error "The incoming request has too many parameters."
- Fixed an issue with excessive CPU usage for RDPWin.exe. Protocol handler and session connector no longer track or record processes using WMI. Now they use native Windows calls, reducing CPU usage of the Windows WMI Provider. The exception is when "Run as secret credentials" is used—it still uses the WMI process tracking.
- Fixed an issue with replicating domain users. This now correctly links the user with the replicated domain.
- Fixed an issue with slow loading sessions failing to load when using session connector. This required an update to the latest protocol handler (RDS) on the session connector server.
- Fixed an issue with the group filter in event pipelines to ensure precise name matching is correctly used.
- Fixed an issue with the SearchSecretsByFieldValue SOAP API function that caused it to return a 500 error.
- Fixed bug where email filters click through approval links.
- Fixed an issue where OIDC platform connection failed for previously imported users after a domain change.
- Mitigated the possibility of an error in SSH Proxy command processing.
- Removed parameters from ASRA installer to accommodate long secret URLs.
- Resolved an issue with RADIUS challenges in Secret Server Cloud.
- Session recordings which are invalid due to no data are now recorded as an error to prevent failure upon playback.
- Updated discovery SSH scanners to handle messages coming back without the stdout marker.
- Updated logging around Azure AD Sync to make it clearer when the sync stops due to configured groups missing in Azure AD.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server Cloud Release Notes for December 3, 2022

Component Versions

Distributed Engine: 8.3.1.0

Protocol Handler: 6.0.3.23

New Features

None

Enhancements

- Improved custom date functionality when running data replication. Users can now access it through a dialog that pops up when clicking "Run Data Replication."
- Added the User parameter to the IBM iSeries Mainframe connection for launching, password changing, and heartbeat.

- Improved performance of discovery dependency matching.
- Added "Run Scripts" role permissions to ensure users with the "View Scripts" role permission cannot run test scripts.
- Improved the secret grid-view filter and column settings.
- Added extra logging for CSV export failures.

Bugs

- Fixed an issue where service dependency changers would fail due to Windows using a different naming format than the secret. Added error handling for several possible cases.
- Fixed an issue where session recording would sometimes show a 500 error, even though the client would retry. Replaced this with a HTTP 429 response, explicitly informing the client to retry.
- Fixed a memory leak in SSH proxy.
- Fixed an issue with slow-loading sessions failing to load when using session connector.
- Fixed an issue where launchers were not working in maintenance mode for proxied connections.
- Fixed an issue where PuTTY would close immediately following a session error. This was due to a default setting change in PuTTY, that is now explicitly set to remain open on installation or update of the protocol handler.
- Fixed an issue where the checkout timer expired and caused an infinite redirect loop resulting in the secret page blinking after check-in time out and the secret still in use for RDP.
- Fixed an issue where "Days Until Expiration" value on the secrets grid would show a large negative number if expiration is forced. This now displays "Expiration forced."
- Fixed an issue where converting a secret in a folder with a launcher settings policy threw an error.
- Fixed an issue where the folder picker would not populate when adding folders in event pipeline policies while in Unlimited Vault Access mode. Other areas with the same dialog should be checked too.
- Fixed an issue where master encryption key rotation would fail due to discovery import rules running at the same time.
- Fixed an issue where the test buttons would not function for the Oracle Account Ver. 2 password changer.
- Fixed an issue where the secrets.csv file was not downloaded.
- Fixed an issue with the group filter in event pipeline to ensure precise name matching is correctly used.
- Fixed an issue with an activation banner saying activation was required but no entries where returned from the activation site.
- Fixed an issue where spatial pattern validation password requirements with large passwords took a long time to generate or threw a 500 error.
- Fixed an issue where PowerShell-based dependency changers would not correctly pass arguments.
- Fixed an issue where file contents during SFTP/SCP file transfers were included in the session keystroke recordings.
- Fixed an issue with disaster recovery synchronization not replicating deleted launcher mappings.

- Fixed an issue where disaster recovery would log many password requirements errors.
- Fixed an issue where the light/dark mode toggle displayed "Enable Dark Mode" even though the UI was already in dark mode. This was due to a dark mode browser preference and no explicit user preference having been set.
- In the summary log for Data Replication, items replicated will now be listed in alphabetical order, success and version number will appear before the list of items and any errors will be appended at the end.
- Added the internal site connector configuration to the configuration preview.
- Optimized application caching.
- Fixed an issue where removing an RPC Schedule from a secret policy did not update a secret assigned to the policy.
- Fixed a SAML audit error.
- Fixed an issue with check in when the "Check in Secret on Launcher Close" and "Close Launcher on Check In Secret" settings were both false.
- Fixed an issue where sorting by folder path in the secret grid view would return an error.
- Fixed an issue where monitoring and termination of live sessions was not displayed in the UI. This now takes the user to the regular session playback page, which displays the live session.
- Fixed an issue where deleted Active Directory groups were not reflected as disabled during Active Directory synchronization. This now correctly registers as a disabled group and is disabled if configuration is set to "Mirror the AD Status."
- Fixed an issue where FileZilla failed to fallback if SFTP subsystem is not enabled on target.
- Fixed an issue where the UI session monitoring search required additional permissions to load.
- Fixed an issue where installation on specific dates on servers with a dd/mm/YYYY localization configuration would prevent some configuration settings from being read.
- Fixed an issue with RADIUS challenges in cloud.
- Fixed an issue where the terminate option on the session playback page was missing.
- Updated the IBM launcher name.
- Fixed a policy-activation validation issue for the "Secret Has RPC Enabled" filter.
- Fixed an issue where reports generate an application error if users navigated away from the report while it was loading.
- Fixed an error where the new SSH proxy custom SSH cipher suite settings were not picked up by distributed engines.
- Fixed an issue where missing file attachments caused DR replications to fail.
- Added a banner displaying the Classic UI deprecation planned for December 10, 2022.
- Fixed an issue where secret items were not hashed for indexing if updated from an empty value.
- Fixed an issue where an "invalid SQL error" was incorrectly displayed when a report timed out.
- Added a row button in secret view to indicate that rows can be expanded for preview.

Future and Recent Deprecations

Note: This section describes planned future deprecation of feature or platform support in Secret Server.

Secret Server Cloud Supplemental Release Notes

October 24, 2020

The following are changes to Secret Server Cloud that supplement the Secret Server on-premises release 10.9.000002.

Security

Added an administrator configuration option for Web Password Filler to require a fully qualified domain match.

Enhancements

- Scheduler role logging improved when a service provider disables an instance of Secret Server.
- Failure prevention processes for mitigating service outages improved.
- Delivery and loading of UI frameworks improved.
- Discovery dependency scanning performance improved.
- Discovery Active Directory OUs scanning via the engine worker improved.
- Error logging improved when a user enters an invalid AD credential.
- Secret Server Cloud platform stability improved.
- Secret names in reports are now links to the corresponding secret (also appears in 10.9.000002 on-premises release).

Bug Fixes

Fixes applying only to Secret Server Cloud:

- Fixed an intermittent issue with the bulk exportation of event logs.
- Fixed an issue where a secret's audit log accumulated an excessive number of encryption and decryption event messages.
- Fixed additional infrastructure bugs affecting the overall stability of Secret Server Cloud.

Fixes in common with the 10.9.000002 on-premises release:

- Fixed discovery rules to correctly handle OUs with bracketed names.
- Fixed issue so that on log off from Secret Server no longer sends the `Clear-Site-Data` header, which could log users out of unrelated Web applications.
- Fixed issue where SSH connections via SSH proxy closed incorrectly.
- Fixed an SSH proxy connection timeout when connecting via a distributed engine.

Secret Server Cloud: Release Notes 2019-12-21

Upgrade Notes

- This release launches a new web password filler. To update your web password filler extension, go to the extension download site for your browser and platform.
- Users will be directed to the dashboard Overview tab for their first login after upgrading.
- New Secret Server Cloud (SSC) installs now have stricter default local password policies. The policies remain customer configurable. Search for **Local User Passwords**.

New Features

Data Retention

Secret Server now allows administrators to permanently delete audit records for tables that either contain Personal Identifiable Information (PII) or tables that can grow large in enterprise environments. To configure these settings admins need to add the permission "Administer Data Retention" to the user's role and then the user can Search for **Data Retention**. Only users with the "Unlimited Vault Access" permission can assign this new permission.

Time-Based One-Time Passwords (TOTP)

Added a new feature where Secret Server can now generate time-based one-time passwords (TOTP) for web secrets. This allows users to implement TOTP on shared secrets. Configuring secrets for TOTP begins at the secret template level.

Truncated Log Data

Added the ability to truncate table logs for several types of data that log to the "Status Message" table. These messages can contribute to excessive log data and slow performance. The option to truncate each message type is called "Days to Keep Operational Logs" and is under the "Advanced" sections on the following list of configuration pages. Minimum message retention time is one day and the default is 30 days. The logs include:

- AdminDiscovery.aspx (**Admin > Discovery**)
- AdminSearchIndexer.aspx (**Admin > Search Indexer**)
- ConfigurationActiveDirectory.aspx (**Admin > Active Directory**)
- ConfigurationPasswordChanging.aspx (**Admin > Remote Password Changing**)
- ConfigurationSshProxy.aspx (**Admin > Proxying**)
- ConnectWiseConfiguration.aspx (**Admin > Folder Sync**) Setting only available when using the "Database" Folder Synchronization Method on this page.

Technical details: A background task was added that scans the status message table every 12 hours and checks the status messages against configured values for how long they should be retained. These configured values were added to applicable UI pages.

Web Browser Extensions

The Web browser extensions for Secret Server were rebuilt with a new look and feel and now have additional browser and site support. These new plugins are available for:

- Google Chrome
- Mozilla Firefox

These features from the old browser plugins have been improved to allow more flexibility:

- Create secrets
- Select secret template
- Generate complex password

Users can now authenticate to Secret Server directly from the Web plugin, including support for 2FA options, such as DUO. Log in via Secret Server is also available for users with single sign-on, SAML, or other multi-factor authentication mechanisms. Web plugins automatically identify manual entry of new credentials in a Web page and offer to save the credentials as a secret. There is also improved support for sites that use multi-page login mechanisms.

Enhancements

Advanced Session Recording

Added a new setting to disable keystroke data from advanced session recording metadata. The new setting is called "Default Keystroke Recording Configuration" and can be configured under **Admin > Configuration > Session Recording > Configure Advanced Session Recording.** Click **Collection name** to edit individual collection settings or agent settings. By default, advanced session recording keystrokes are enabled.

Database SQL Indexes

Added new SQL indexes for the following areas:

- Column LauncherSessionGuid on the Launcher Session Video (tbLauncherSessionVideoSegment)
- Event Queue Monitor (tbEventQueue)
- Expired Secret Monitor (tbSecretDependency table)
- Folders (tbFolder, tbFolderGroupPermissions)
- General Navigation (tbUserSession)
- Launcher Activities (tbSecretSession)
- Log In (tbUser)
- Node Activation Check (tbNodeLicenseActivation)
- Secret Log table (tbSecretLog)
- System Reports (tbAuditUser, tbAuditSecret)

Discovery

Added messaging for when computer or dependency scans do not run due to having no scanners configured for a discovery source.

Distributed Engine Offline Status

Updated the definition of distributed engines' offline status to be the configured heartbeat interval times three. For instance, if your heartbeat interval is configured at 5 minutes, the engine will report offline if Secret Server and the engine do not successfully communicate within a 15-minute time period. Engine online and offline states were also added to subscription actions to allow notification to admins when engine states change.

Licensing

A second distributed engine is now available, by default, for the local site.

New User Interface

- Redesigned the Admin landing space. Click **Admin > "See All"** to explore the new layout.
- Redesigned DoubleLock.
- Added new "Recent Activity" section to the Home dashboard page to display recent activity at a glance.
- Updated the Security Hardening tab in the Reports page.
- Updated the IP Address Management pages under Admin.
- Added custom logos. Added custom "full-sized" and "collapsed" logos for the new UI in **Admin > Configuration** under in the **User Interface** section.
- Added dark mode theme option in the new UI. To change theme mode preferences, go to **Account Settings > Color Mode**. Options include Light Mode, Dark Mode, or Default (mode will update based on user's OS color mode settings).
- Added a new setting to configure the inactivity time before the new UI goes into dark screen "sleep mode." To configure Search for **UI Inactivity Timeout**.
- Converted the Groups page to the new UI.
- Updated error messaging in the new UI to display folder synchronization and deletion errors.
- Updated the date picker to allow for future start dates and time selection without first adjusting the end date when requesting secret access. End dates are automatically adjusted to align with the start date +1 hour.
- Updated grid downloads in the new UI to download according to new options. User options now include choices to download all data or specific rows of data, and specify date format. You can also choose time zone options of UTC, server time zones, or the local browser time zones.

  Note: for downloaded reports users' time zone options are limited to UTC or the server time zone.
- Updated behavior of new UI so that clicking the "Select All" check box at the top of a secret grid selects all rows. Previously the check box selected only the items currently loaded on the page.
- Added the "View Audit" button to the reports page of new UI.
- Added the "Upgrade Available" banner to display in the new UI.

- Added the ability to drag-and-drop child folders into the root folder. Folders will automatically re-order alphabetically in the left navigation pane.

  Note: This action is only allowed if users have the "Create root folder" permission and own folders that they are attempting to move.
- Added folders to the "Shared With Me" page.
- Added new inbox notifications including "getting started" notifications for new installs and administrator alerts when an instance is close to hitting licensing limits.
- Added the ability to mark Inbox notifications as read or unread for most notification types.
- Added the ability to browse by folder name using the URL format `[SecretServerURL]/SecretServer/app/#/lookup?folderPath=[FolderName]`. If multiple folders exist with the same name, this URL search schema only directs users to the first folder listed within the left navigation pane.
- Updated Favorite star icons to remain in column view when the Name column is resized.
- Expanded file-size allowance on file uploads. File uploads can now be up to 10 MB.
- Grid results updated to auto-load 30 results instead of 15.

Remote Password Changing upon Regex-Defined Error

Added a new regex setting to automatically retry a remote password change (RPC) with a regenerated password if the original RPC failed due to a specific type of error.

Search for **Remote Password Changing**, click **Advanced** under the **Configure Password Changers** section. The new setting is **Attempt Password Change with new password when error contains (regex)**. Edit it to provide the regex failure code that will trigger the automatic next password RPC.

Reports

- Updated several reports to no longer show deleted secrets.
- A new out-of-the-box report called "Secret Templates without an expiration field" was added to display any secret templates that have a password field but do not have an expiration field set.

Secret Template Import and Export

Updated secret template settings for importation and exportation to include:

- Is Required?
- Edit Requires
- Hide on View
- Secret template icon
- Keep Secret Name History
- Validate Password Requirements on Create/Edit
- Field Slug Name

- Type Description
- One Time Password settings

The secret template settings that do **not** transfer include:

- Launcher settings
- Password changing settings
- Session recording enabled
- Associated secrets

SSH Proxy

- Updated "connect as" to accept key-based SSH authentication without also requiring a manual password.
- For SSH proxy sessions, added the option set:
  - Only record keystrokes
  - Only record video for sessions.

  By default new installs will only record keystrokes on SSH proxy sessions to preserve disk space. To configure this setting go to **Admin > Configuration > Session Recording tab > Secret Server Proxy Session Recording**. Edit the **SSH Proxy Session Recording Options** dropdown list. The options include:
  - Record keystrokes and video
  - Record keystrokes only
  - Record video only
  - Do not record

Terminal

- Added terminal instructions for how to view SSH proxy credentials in the new UI under **Secret Options > Show SSH Terminal Details**.
- Removed restrictions from the allowed number of concurrent logins for SSH terminal. Previously, terminal logins were tied to the "Maximum concurrent logins per user" setting that establishes this number for UI-based users.
- Added Unicode support for SSH command menu items (names and descriptions).
- Added "clear" command to terminal.

Unique Field Slug IDs

Added a new "Unique Field Slug" ID column for secret templates to allow users to create secrets with duplicate field names without compromising the ability to target each field name with a unique identifier for API calls.

User Variables for Scripting

Added the following user-based script variables to be used in API calls as arguments:

- $SECRETSERVERUSERID
- $SECRETSERVERUSERNAME
- $SECRETSERVERDISPLAYNAME
- $SECRETSERVEREMAILADDRESS

This allows, for example, that when a specific user runs a check-out hook, they can pass a user email, ID, username, or display name as a parameter into the script to use a check-out hooks and related AD functionality in Secret Server through the API.

Verbose Logging

Added Verbose Logging for:

- AWS password changers
- AWS discovery scanner
- ComPlus dependency scanner
- PowerShell discovery scanner
- Flat file discovery scanner
- ODBC discovery scanner
- SSH discovery scanner
- ESX discovery scanner

API and Scripting

API General

Added a setting that allows users with view permission on a secret to get the secret's "autoChangeNextPassword" field in the API. This setting is enabled under **Admin > Configuration > Permission Options**. Set **Allow View User To Retrieve Auto-Change Next Password** to **Yes**.

New API Calls

- Get one time password code and seconds: `GET /one-time-password-code/{id}`
- Search secrets by URL: `POST /secret-extensions/search-by-url`
- Get AutoFill values for URL by secret ID: `POST /secret-extensions/autofill-values`
- Update secret field: `PUT /secrets/{id}/fields/{slug}`
- Update secret: `PUT /secrets/{id}/restricted`
- Get SSH Terminal details: `POST /secrets/sshterminal`
- Get extended regex values by secret: `GET /extended-fields/regex/{secretId}`

Removed API Calls

- Search app clients: `GET /app-clients`
- Update secret: `PUT /secrets/{id}`
- Update secret field: `PUT /secrets/{id}/restricted/fields/{slug}`

Integrations

- Added support for Open ID Connect to integrate with Secret Server authentication.
- Added Connection Manager as a tools option in the grid menu and under the Admin space in the new UI.

Performance Improvements

- Significantly improved shutdown and restart times for engines connected to SSC.
- Added server-side paging to reports in the new UI to address performance issues when attempting to load reports with large numbers of records.
- The new UI will no longer load the subfolders If a parent folder has more than 30 subfolders within it on the grid page. Instead, a folder picker will display above the folder's secrets that will allow users to select a specific subfolder.
- Applied enhanced SQL querying logic on the groups pages so that environments with large groups no longer experience page timeouts when processing group data.
- Improved the shutdown performance in distributed engine.
- Removed the welcome widget from the dashboard on the classic UI due to page load issues in large environments.
- Enhanced SQL query for the Unlimited Vault Access report to improve performance for large environments.
- Added a new "use database paging" setting for the custom reports page. Database paging allows the database to load large reports more quickly. We recommend database paging if the query is expected to pull large amounts of data for the report. Implementing database paging may not work if the SQL query uses some keywords, including TOP, OPTION, UNION, WITH, or aliases containing the word FROM.

  Example queries:

  - Works using database paging: `SELECT * FROM tbSecret WHERE NAME LIKE 'Test%'`
  - Does not work using database paging: `SELECT TOP 10 * FROM tbSecret WHERE SecretName LIKE 'Test%'`

Security

- Updated PuTTY to version 0.73. Updated version addresses several PuTTY vulnerabilities, including one critical and two high severity items. CVE-2019-17067, CVE-2019-17068, CVE-2019-17069
- Addressed a vulnerability with the SDK client account handler.
- Fixed a permissions issue in the new UI where password requirements did not obey the "administer custom password requirements" permission.

- Added audits and event subscriptions for viewing passphrases and SSH keys.
- Addressed a Remote Code Execution (RCE) vulnerability that allowed parameter changes for an action without validating user permissions.
- Resolved an issue for SSH scripts and SSH remote password changers where sensitive information was being written to log files:
  - SSH remote password changers will now only log the comment for each command as it runs.
  - SSH scripts will only log that they ran because they have no comment for each command.

  Note: If you manually test an SSH script or password changer, the full output will still be shown for debugging purposes, because you just entered the credentials yourself.
- Resolved a URL redirection vulnerability.
- Added configurable parameter quoting for custom launchers.
- Resolved three cross-site scripting (XSS) vulnerabilities.
- Fixed an XML external entity (XXE) injection vulnerability.
- Removed user information that was returned in an API call.
- Added auditing for changes made to the session recording configuration page on the **Admin > Configuration > Session Recording** tab.
- Added auditing for test script actions in the **Custom Command Edits** section in the **Admin > Scripts** pages.
- Added auditing to the **Admin > Configuration > Ticket System** tab. Audits are logged under **Admin > Configuration > General tab > View Audit.**
- Updated missing secure cookie attributes when "Force HTTPS" is enabled.
- Added SHA1 and SHA256 hashes for protocol handler.
- All Delinea DLLs and EXEs are now signed with the Delinea Software certificate, including distributed engine and advanced session recording agent.

Bug Fixes

- Fixed an issue where creating folders through the API failed to set a secret policy.
- Fixed a memory leak issue where leaving Mac launcher sessions open for extended periods of time consumed increasing amounts of memory on the machine hosting the session. This issue was incorrectly believed to be fixed in the Secret Server version 10.7.000002 release.
- Fixed an issue where Unix secrets were not reported in the "Password Last Changed" report because the Unix Account template did not have a password expiration field by default. Unix password fields are now set to expire at 30 days by default.
- Fixed an issue where pressing Enter with the cursor in the Search bar on the Discovery Network View page would open the create rule dialog.
- Fixed an issue where new users were not adequately loading in the dropdown option for subscribers in the "discovery rule alerts" setting if users increased from under 40 to over 40 users.
- Added clear error and validation in entering credentials for a discovery scanner.

- Fixed an issue where localized language customization did not apply to some product pages due to default cache keys or inconsistent HtmlHelper methods implemented on those pages.
- Fixed a bug where some pages in the old UI did not follow customized headers from CSS stylesheets.
- Fixed an issue where extended search terms were not applied for URLs. Updated BookmarkletSecretSearcher so that it will not do extended hashes on URLs that might result in many erroneous matches. For instance, `facebook.com` would match `face.org`.
- Fixed issue where non-AD discovery sources (ESX, PowerShell) would not match dependencies with domain to an existing AD Domain. If the dependency scan item has a field called "domain," it will attempt to map to an existing domain.
- Fixed a bug where the REST API "daysUntilExpiration" field returned a blank value when calling for a secret summary.
- Added a query to resolve sort ordering issues for dependency numbering.
- Fixed an issue in the new UI where deleted secrets remained on display on the favorites widget in the home tabs.
- Fixed a "bad token" error on login for mobile apps (Windows Desktop, iOS, or Android) for local users.
- Fixed an issue where SSH keystroke data was not searchable from the session playback page due to proxy session data not being correctly hashed in the database.
- Fixed a ticketing system bug where the option to require users to either provide a ticket number or a comment for requesting access incorrectly required both a comment and a ticket number to access the secret. This issue existed when requesting access to the secret through the UI, workflows, or terminal.
- Fixed a bug where hashed terms were intermittently slow to return search results in the new UI.
- Fixed a rendering issue for the group edit page when using the IE browser.
- Fixed a localization issue in the SSH command menus where setting non-English as the global or user preference threw an exception when trying to save a secret policy.
- Fixed an issue where an "object disposed" exception was thrown when navigating away from the new UI soon after application pools were recycled. This occurred because of an incorrect re-use of a service that is for processing the first Web request to the application.
- Fixed a bug in the new UI where personalized preferences for launcher settings on a secret were not allowing users with view access to save.
- Fixed a bug where custom columns on grids in the new UI occasionally tried to display the same column twice and threw an error.
- Fixed an issue where a syslog header was missing the hostname when logging from an engine.
- Fixed an issue where Duo authentication was not checking for valid fallback device options when the configured "default device" failed to authenticate.
- Updated the "find new dependencies" feature to be available to users with edit permissions on the secret. Previously the new UI required users to have owner permissions.
- Resolved a timing issue where secrets with scheduled password changes enabled would get erroneous heartbeat fails due to remote password change (RPC) expiration and heartbeat occurring at the same time. Now

heartbeats are skipped for an interval of five minutes before and after a scheduled password change to allow password change completion before heartbeat is attempted.

Secret Server Cloud: Release Notes 2019-09-21

Upgrade Notes

Secret Server Cloud users may need to perform a **hard refresh to clear local browser cache files** for certain 10.7 upgrade changes to take effect in the new UI.

New Features

AWS Discovery

Added discovery for AWS accounts.

SSH Terminal

Added an SSH terminal to Secret Server, allowing users to connect to Secret Server via SSH to search for secrets, access secret data, and initiate proxied SSH connections.

Integrations

Updated ConnectWise API calls to pass in the ClientID object due to version updates by ConnectWise that requires a ClientID for all API calls. Updates released by ConnectWise in Aug 2019.

Enhancements

Security

- Secret Server 10.7 uses jQuery 3.2.1, which is listed as vulnerable to the jQuery CVE-2019-11358. Updated Secret Server to resolve this jQuery vulnerability.
- Updated PuTTY version (0.71) in the Secret Server protocol handler to support the elliptic curve cipher for handling keys during the SSH connection process.
- Addressed a security issue where reusing Active Directory usernames could expose secret data.
- Resolved an issue affecting FIDO2 authentication. Security Issue Discovered by : Vladimir Skuratovich.
- Two cross-site scripting vulnerabilities were fixed in Secret Server.
- Removed a server-side request forgery issue in the legacy Web launcher.
- Addressed a security issue that could result in folder name disclosure.
- Addressed a security issue with dual control where an approver could approve their own access.
- Resolved a URL Redirection issue.

New User Interface

Drag and Drop Folders

Users can now drag and drop folders in the left navigation pane into other folders. Users must have "Owner" permissions on both folders.

Note: You cannot drag and drop folders to the root folder. To move folders back to the root folder level, right-click a child folder, select "Move Folder" and select Root from the option list.

Updated Search

Special characters (percent signs, brackets, and underscores) are no longer treated as wildcards.

Password Strength Indicator

Redesigned the password strength indicator.

Column Resizing

Users can now re-size columns on secret grids in the new UI. Column re-sizing is sticky per page across user sessions. Column resizing is not available in Internet Explorer.

Duo Push Notifications

Added option to send secret access request notifications as DUO push notifications instead of emails.

Duo User Preferences

Duo login now remembers user preferences and auto-initiates them (after initial login).

Secret Grid Top-Row Anchors

Added top-row anchors for secret grids.

Home Dashboard Redesign

Redesigned the Home Dashboard page.

Alert Improvements

Redesigned the Inbox and added more alert types (Approvals and Requests, System Alerts, Subscription Alerts).

Domain Name Searches

Added searching for users by domain name.

Secret Audit Access

Audit-only users can now view secret audits on secrets that require checkout or are setup for request access without needing to go through the checkout or access approval workflows.

WEBSERVICES Naming Prefix

Removed the redundant "WEBSERVICES" naming schema from secret audits where the service is also used by the new UI. "WEBSERVICES" still appears in audit reports where the service is not also used by New UI.

Messaging for Permission Changes When Moving Folders

Updated messaging when moving folders so that users are aware of permission changes.

New and Classic UI Feature Sync

We are incrementally porting features from the classic to the new UI. In this upgrade the new UI added support for:

- NATO Phonetics.
- Deleting dependency groups.
- Scrolling for the groups and users picker.
- Secret checkout hooks and corresponding REST API endpoints.
- Showing proxy SSH login credentials information on SSH secrets.
- Setting custom password requirements per secret to override secret template requirements as needed.
- Launcher preferences on the secret-level to override launcher template requirements as needed.
- SSH command restrictions option.
- Launcher settings for SSH launchers to the new UI. Settings not yet implemented include mapped Web launchers, non-mapped Web launchers, and form filler.
- Added a "Save to File" option for audit history and secret grids.

ESXi Support Improvements

Added a configuration option for Secret Server to allow ESXi TLS connections to ignore self-signed certificates, allow certificates from specific issuers (even if issuer is not in trusted certificate lists), or completely skip certificate validation when using ESXi password changer, heartbeat, or discovery.

Important: For security reasons, we do **not** encourage customers to use self-signed certificates. Therefore, the new configuration settings listed below are not accessible through the UI. If you need to alter the default ESXi certificate validation settings, **submit a case through Delinea's Support Portal** for assistance.

New advanced configuration settings include:

- ESXi.IgnoreSelfSignedCerts: If true, ignores any self-signed certs (subject = issuer) from ESXi hosts during heartbeat, RPC, and discovery.
- ESXi.CertIssuersToIgnore: Semi-colon delimited list of issuer names (in format shown on certificate---such as "O=Issuer Name"). Ignores partial chain errors due to certificate being issued by any issuer in this list when that issuer is not in the trusted root or intermediate CAs lists on the server.
- ESXi.IgnoreAllCertErrors: If true, certificate validation will not be performed. All certificate errors will be ignored.
- ESXi.CertificateChainPolicyOptions: Identical to TLS Audit option, but specifically for ESXi. Allows setting X509 options to be applied to certificate validation. This is a comma-delimited list of options.

- ESXi.ClientCertificateIds: identical to TLS Audit option, but specifically for ESXi. If ESXi host requires the client to present a valid certificate, this is a semi-colon delimited list of client certificates on the server to try to present.
- ESXi.AuditTlsErrorsDebug: Identical to TLS Audit option, but specifically for ESXi. If set to true and Secret Server (or DE) auditing is set to DEBUG, detailed debug messages about the certificate chain will be written to the log file.
- ESXi.IgnoreDefaultHostCert: Sets all the TLS configuration options necessary to not fail due to a default ESXi host certificate and its issuer not being in the trusted certificates lists. This is a combination of setting the issuer to ignore and not performing a revocation check. Setting this to true should be the first change to make when attempting to resolve heartbeat, RPC, or discovery issues to ESXi hosts when using PowerCLI versions later than 5.5.

Note: Issues with self-signed certificates previously implemented by customers were caused by a security update to the VMware vSphere PowerCLI in versions after 5.5 that no longer permits the use of self-signed certificates.

Webservices REST API

- The webservices API is now enabled by default for all new Secret Server customers, regardless of licensing. Existing customer settings will not change on upgrade.
- Added a safeguard to the API to prevent license activation attempts when licenses are already activated.
- Added a new REST call to favorite a secret through the API. Favorite a secret by running a POST request to <secret_server_url>/api/v1/secrets/<secretId>/favorite Favorite a secret by setting IsFavorite: Boolean. If left without a value, the favorite status will be toggled. If set to true or false, the favorite status reflects the value of IsFavorite.
- Added a new REST call to get current user's favorite secrets through the API. Get the current user's favorite secrets by running a GET request to <secret_server_url>/api/v1/secrets/favorite An array of secret-related information is returned: {id=1; folderId=4; folderPath=\FavoriteTest; secretName=test1}
- Added refresh tokens for the REST API. Refresh tokens allow users to continue using tools like the Web plugin beyond the normal timeout internal, as long as they remain active. Refresh token expiration is set to "session timeout" value plus 15 minutes. By default, three refreshes are allowed before re-authentication. Enable refresh tokens for Web services under General Configuration
- Added new API Calls:
  - Create Domain: POST /active-directory/domains
  - Create Domain: POST /active-directory/domains
  - Create Script: POST /scripts1
  - Create Secret Dependency Group: POST /secret-dependencies/groups/<secretId>
  - Create Secret hook: POST /secret-detail/<secretId>/hook
  - Delete Secret Hook: DELETE /secret-detail/<secretId>/hook/<hookId>
  - Export Report: POST /reports/export
  - Favorite a Secret: POST /secrets/<secretId>/favorite
  - Get Domain: GET /active-directory/domains/<id>

- Get Domain: GET /active-directory/domains/<id>
- Get Domains: GET /domains
- Get Script: GET /scripts/<id>
- Get Secret hook details: GET /secret-detail/<secretId>/hook/get/<hookId>
- Get Secret Hooks: GET /secret-detail/<secretId>/hooks
- Get secret launcher details: GET /launchers/secret
- Get SSH Proxy Information: POST /secrets/sshproxy
- Launch a secret: POST /launchers/secret
- List a User's Favorite Secrets: GET /secrets/favorite
- Search Domains: GET /active-directory/domains
- Search Domains: GET /active-directory/domains
- Search scripts: GET /scripts1
- Stub Hook: GET /secret-detail/<secretId>/hook/stub/<scriptId>
- Update Secret Hook: PUT /secret-detail/<secretId>/hook/<hookId>

- Updated API calls:
  - Update Secret Field : PUT /secrets/<id>/fields/<slug>
  - Update Secret : PUT /secrets/<id>

Verbose Logging

Enhanced verbose logging for diagnostics to increase clarity and support troubleshooting. This ongoing project began in 10.6.26. Added additional logging for:

- Protocol Handler: Delinea.ProtocolHandler.
- SAML Response Processor: SAML.SamlResponseProcessor.
- SAML Legacy Configuration: SAML.LegacySamlConfiguration.
- Secret Notification Emailer: SecretNotiificationEmailer.
- Event Subscriptions: EventSubscriptions.

General

- Enabled the setting "Enable Local User Password History" to be enabled by default for customers. This blocks a user from re-using an old password when setting a new password.
- Added a configuration option to automatically disable inactive users if they have been inactive for a minimum of one month. Enable this setting if your environment is setup for AD Synchronization. Go to **Admin > Active Directory** in the **Active Directory User Synchronization** section. Click **Advanced (not required) > Set Automatic User Management** and select **yes**.

Bug Fixes

REST API

- Fixed a bug in REST API documentation for recorded session searching to properly detail URL array parameters and display the available values for searchTypes. Also updated the check for searchTypes to be case-insensitive for searching in the documentation. The check for searchTypes is now case-insensitive. Some work was done previously to return an error if no search types were provided. REST documentation was not properly detailing URL array parameters, they are now being displayed correctly and the available values for searchTypes are detailed in the documentation.
- Fixed an issue where creating a folder through the REST API always set the permission inheritance to false on the folder, even when the parent folder was set for inheriting permissions. This meant that upon create, the folder itself inherited permissions from its parent folder but future objects created in the folder did not inherit permissions. The create-folder REST endpoint no longer always copies permissions from the parent folder down on to the sub-folder. Instead, if you set the inherit permissions property in the request to true, permissions will copy down from the parent on to the newly created folder. Should the user omit the inherit permissions property from the request body, the default value is also set to true. In order to **not** inherit permissions from the parent folder for a newly created folder thru the REST API, a user must set the inherit permissions property to false in the request body.
- Fixed a REST API issue where the "View Secret Audit" permission was incorrectly required to access a secret summary through the API. During the permissions check for the REST API, a default route was being taken which included checking for View Secret Audit permissions. A more specific series of permissions checks are now being used which allows the View Secret Audit permission to be ignored.
- Fixed an issue where the search results returned for InheritSecretPermissions in the REST API were not accurate.
- Fixed a bug where REST API calls on systems using Windows Auth would fail after the first call due to logic that incorrectly flagged for cookie expiration.
- Fixed a re-introduced issue where the "Webservice Password Displayed" audit was logged incorrectly when API calls to Get secret fields that were not password-related occurred. This issue was originally fixed in version 10.6.26 but reintroduced in version 10.6.27. The SecretGetQuery.SecretItemsViewed was not being forwarded to the actual GetSecret method which handled the auditing logic. By omitting it, it assumed all secret fields were being viewed by the user hence the password viewed audit was being recorded.
- Fixed a bug where Oauth tokens were deleted for a current user when attempting to change the password of another user through the REST API.
- Fixed a REST API bug where if enableInheritPermissions was set on FolderModel and UpdateFolder objects, updating secrets through the API in those folders did not respect the inherited permissions.
- Fixed an issue where existing file attachments were removed when editing or saving secrets through the REST API.

Mac Launcher

Note: To update your Mac launcher and apply this fix, you must first fully uninstall the Mac protocol handler.

- Fixed a Mac launcher issue where a launched session would hang if user attempted to scroll using a mouse wheel or a track pad. This issue occurred because the 9-bit signed value for handling mouse wheel events was not properly parsed for "coarse-grained" mouse movements within FreeRDP. To update your Mac Launcher and apply this fix, you must first uninstall the Mac Protocol Handler fully.
- Fixed an issue in the Mac Launcher Protocol Handler where FreeRDP was calling to re-sync specific modifiers (Caps Lock, Num Lock) and not the current pressed state of the other modifies on every key-down event during Mac launcher sessions. This caused the other modifiers (such as Shift and Ctrl) to reset back to their base state even when the keys were being pressed.

General

- Fixed an issue where Secret Server could not correctly identify the state of a ServiceNow ticket. Ticket status in ServiceNow is indicated by both a state label (such as New, Open, WorkInProgress, ClosedComplete, ClosedIncomplete, ClosedSkipped, Assess, Authorize, Scheduled, Implement, and Review) and a state value. An update from ServiceNow changed both the labels and the values corresponding to each state, resulting in the issue.

Note: Validating custom ticket states will be addressed in a future release.

- Fixed an issue where heartbeat failed as a bulk operation on ESXi Servers. When a bulk operation ran, multiple threads would try to access the same file on the machine at the same time. A check whether the file was in use was added to resolve this issue.
- Fixed an issue where secret templates containing custom fields caused an error when key management was enabled.
- Fixed an issue on environments with multiple domains where the dropdown for users on the AD synchronization page only displayed members from one domain instead of displaying all users across all domains.
- Fixed a bug where two-factor PIN emails were not sent on initial login if the user's login, the local admin account, and another user were all configured to use the same email address. The SMTP client and application name are now resolved on the initial login page. That way the PIN Code page can read those values and send the e-mail even if the lifetime scope is lost before the PIN Code page is loaded.
- Updated some instances where a browser's built-in auto-complete feature would incorrectly enter data into fields when a Secret Server page was loaded. The root of this issue was that the mechanism for disabling a browser's auto-population for username and password fields on page load changed across all browsers. The old mechanism added the attribute autocomplete="off" to the target input or form field if you did not want the browser to auto-populate on page load with user credentials. The new way changed the value of the added attribute to be autocomplete="new-password" for populated fields.

Note: Clear browser history cache to apply these fixes.

- Fixed a bug where changes were saved even after canceling on the **Admin > Configuration > Login** tab.
- Fixed an issue where checkout and check-in hooks caused an exception error for a user if they only had list permissions on a privileged account when attempting checkout. This issue occurred when attempting to load the privileged secret with the user's permissions, which would fail unless the user had view or greater permissions on the privileged secret. A change was made to load the privileged secret using the system identity to prevent access issues.

- Updated extensible discovery for the PowerShell scanner to automatically fill in an AdGuid and DistinguishedName when those values are not present on the scan item for OU/Host Ranges and Machines. If scanning Active Directory, adding DistinguishedName to the scan item is recommended. In this instance, you must remove the domain portion of the DistinguishedName.
- Fixed an issue where saving a secret policy on a new secret template did not allow the latest password changer templates to be selected for password rotation. This prevented secrets of the latest template types to be assigned as a privileged account for the password rotation.
- Updated the group picker for editing users in groups so that users are now sorted consistently via alphabetical ordering. Before this update, usernames in the two sides of the group picker were sorted differently. Updated all of these, Group Create, Edit and View pages, to sort by the "Known As" field. If DomainId is null, the field returns DisplayName. Otherwise, it returns DomainName\DisplayName.
- Fixed an issue where Delinea One (T1) users were unable to login to Secret Server through the mobile and desktop app when Delinea One was enabled for Secret Server. There's a new configuration option "Enable Delinea One Integration" in Secret Server to do API authentication against Delinea One (the old way) or not (the new way). This is under **Configuration > Login**. When checked, the mobile app should accept Delinea One credentials. When unchecked, the mobile app should accept local account credentials. If T1 is turned off, or if the user doesn't have a T1 mapping, it will always accept local account credentials.
- Fixed a bug that blocked workflows from being enabled on a secret in the new UI for Cloud Professional users if no approvers were defined on the workflow. When no approvers were defined for a workflow step an error was thrown trying to retrieve the max number that could be set for required approvers at that step.
- Fixed an issue where custom reports that contain "Permissions" as a field name were not successfully created.
- Fixed an issue where disabling two-factor authentication using the "Lost Phone" option did not trigger a "Two-Factor Changed" event notification. The event logs did not track resetting 2FA auth. Added two new events, one for a successful TOTP reset and one for a failed TOTP reset.
- Fixed a bug where the "Last Scanned Date" for AWS and domain accounts were not properly updated on the Discovery Network View. Updated the Last Polled Date for the Domain Accounts to use the LastDiscoveryCompletedDate from the tbDiscoveryConfiguration table.
- Updated error messaging when Secret Server is unable to connect for heartbeat status. Added exception handling for Socket timeouts and errors to be treated as unable to connect instead of as an Unknown error.
- Fixed a bug where custom launchers that passed the port field from a secret as a launcher argument would fail because the launcher was using the port value from the secret template launcher configuration instead of the port value from the secret. For non-proxied custom launchers, this caused the port argument to always be zero.
- Fixed an issue where users synchronized from Active Directory through Distributed Engine did not have their UserPrincipalName populated.
- Fixed a bug where disabling users for an event subscription blocked the event subscription from being saved. This issue was related to a Linq expression which used Single instead of SingleOrDefault, which caused the respective exception when no elements were returned from collection.
- Fixed an issue where creating sub-folders from the folder menu did not use "No Policy" default settings when set to not inherit a policy.

- Resolved an application error that occurred when the expiration interval was set too high on a Secret Template. When the expiration was set to a large number the date calculation would overflow causing both secret search and secret view to break since they both tried to calculate it. Now both cap the expiration days at 9999 as the UI currently limits expiration to that maximum.
- Fixed an issue in the new UI where deleted secrets remained on display on the Favorites page after a page refresh.
- Fixed an issue in the new UI that occurred when fields in a column in a secret grid view could appear blank if a secret template had multiple fields with the same name.
- Fixed an issue in the new UI where folder breadcrumbs were incorrectly sorted by Folder ID instead of by the location in the folder tree. Folder breadcrumbs were being incorrectly sorted by ID on the server before the API response was generated, which only works if no folders have ever been moved. That ordering was removed and now the folder order is returned properly from the API.
- Updated tooltip messaging for the user interface configuration options.
- Fixed an issue in the new UI where users were not always directed to the All Secrets page upon login. When a user was logged out in angular, the ReturnUrl was not always set. The ReturnUrl query string is used after logging in to know where to redirect a user.
- Updated the new UI to hide reports under admin options when a basic user does not have the "View User Audit Report" permission.
- Fixed a Firefox browser issue for versions 60.0 and greater where search prompted errors in the new UI. A nonstandard JS property was being used that isn't supported in all browsers. Property was replaced with its standard equivalent to ensure support in all browsers.
- Fixed an issue where the password field did not re-appear after removing the "hide launcher password" policy on a secret.
- Fixed an issue in the new UI where Danish Characters did not display correctly in the Folder list.
- Fixed an issue where the Heartbeat Status column did not always display on page load in the new UI.
- Fixed a bug where allowlisted launcher options did not properly populate in the new UI.
- Fixed a bug where the password history for a secret did not display the correct password if the password included a less than symbol (<).
- Fixed an issue in the new UI where Approval, Access Request, and Checkout secrets incorrectly blocked access from administrators when Unlimited Vault Access Mode was enabled. State service was returning state values without considering Unlimited Vault Access mode.
- Fixed an issue where read-only mode was set as default in the new UI until the interface fully loaded, resulting in brief displays of the Read-Only mode notification if a user's browser experienced slow load times.
- Fixed an issue where editing a secret policy would throw a null ref error in the new UI if the policy applied to a folder but was not enforced.
- Fixed an issue where discovery was unable to recognize special characters (such as Ã, ‡, ƒ, and ±) in organizational unit (OU) objects when scanning an entire domain.
- Fixed an issue with Active Directory synchronization where using the SynchronizeNow group flag could cause users not in that group to be disabled when AD sync was set to "Mirror AD."

- Optimized SQL query used to process large result sets in the tbSecretPasswordResetSecrets table. This addresses an issue where expired secrets failed to process due to large volumes of secrets.
- Fixed a bug where domains listed with friendly names did not adequately check for uniqueness of Fully Qualified Domain Names (FQDNs) therefore allowing FQDN duplication. If FQDN duplication occurred, AD Synchronization domain mismatch failures resulted when running AD Sync.
- Enhanced performance for discovery when one endpoint returns large numbers of accounts (20k+).
- Fixed an issue with search in the new UI where searches were locally cached instead of cleared on route navigation within the app.
- Updated the new UI to accept non-ASCII usernames.
- Fixed an issue where the Reports page in the new UI did not process HTML-encoded data, leading to special characters like "é" not displaying correctly on the page.
- Fixed an issue in the new UI where the "Save to File" option on tables was not created in a download method that Internet Explorer 11 supported.
- Fixed an issue where copy and convert actions on a secret template could apply parent folder policies to the new secret rather than applying the original secret's policy. This occurred due to using a cached version of the secret template instead of the updated version.
- Fixed an issue where non-standard UTF8 characters were not saving properly when saving reports to file in the new UI.
- Fixed an ordering issue when querying reports where the user-identification audit ran after the report query instead of before.
- Fixed an issue where live view-session videos did not work in the Internet Explorer 11.
- Fixed an issue where outbound queue messages overloaded in some environments. Added expiration time to outbound discovery and Active Directory sync messages. AD sync and discovery scan messages now expire based on their configured interval.
- Fixed an issue where the bulk conversions for secret templates did not populate the target template list.
- Fixed an issue where naming patterns were not properly enforced in the new UI when creating secrets.
- Fixed an issue where the approval-request expiration time did not properly handle time zone differences. We changed validation to compare minutes instead of days.
- Fixed a bug where the "confirm action" button did not activate on bulk actions when assigning the "inheriting permissions" action.
- Fixed an issue where changed fields on the edit page for assigning secret auto-schedules could block a schedule from saving.
- Resolved issue with SSH key password rotation for some versions of Unix and specific templates.
- Fixed issue with IAM Token rotation over distributed engines.

Secret Server Cloud: Legacy Release Notes

Note: This document covers releases prior to 9/21/2019.

Cloud Release 6/15/2019

Security Advisory

Cloud instances are no longer vulnerable to this issue.

Upgrade Notes

New UI Wizard

After June's Cloud upgrade, the first admin who logs in to Secret Server Cloud (SSC) is prompted with a wizard that walks through the new user interface (UI) configuration settings for their instance. Users can adjust these settings at any time from Admin > Configuration in the User Interface section.

Radius IP Addresses

Important Note: IP addresses used by SSC for Radius clients will change during this release.

If you use Radius with SSC and have firewall rules or Radius configuration that specifies the SSC IP addresses, then you must update those rules prior to June 15th to maintain continuity of service. The new IP addresses will be active after the upgrade on June 15th:

- US Cloud: 40.76.197.147 and 40.121.181.52
- EU Cloud: 51.4.141.94 and 51.4.194.120
- AU Cloud: 20.36.47.199 and 20.36.45.106

Zero Downtime for Cloud Upgrades

Scheduled releases no longer block access to the website during the upgrade window. The SSC UI remains accessible during the migration process as customers are moved to the new version. A customer's typical migration period is 5 to 15 minutes.

New Features

New User Interface

We are incrementally introducing feature parity between the new and classic UIs. In this upgrade the new UI added support for:

- Emailing reports to users.
- Deleting reports.
- Converting secret templates.
- Uploading files to secrets.
- Copying and converting file attachments.
- Setting automatic password change rotations when creating new secrets.
- Rotating SSH Keys and Passphrases for SSH secrets.
- Rotating SSH Keys and SSH passwords using a bulk operation.

- Displaying custom columns in the folder view.
- Updated the Secret Picker to include a folder tree browser when selecting a privileged secret for Remote Password Changing.
- Added a password complexity indicator that displays when editing a Secret's password.
- Updated Search functionality to include folders.
- Users can now "favorite" folders by clicking stars on folders in a table view or by right-clicking folders in the left navigation pane.
- Additional "View" audits were added to the new UI to track users who view Next Passwords, SSH Keys, and Passphrases.
- Optimized SQL queries when searching for secrets in the new UI. This includes:
  - Faster searches, the paging and sorting is now performed in the database instead of the web server
  - Ability to filter by secret permission, extended type id, password type id, RPC enabled, recently used date range
  - Can now return extended fields
  - Sorting by an invalid field now returns an exception instead of sorting by the secret ID

Advanced Session Recording Without Launcher

- Added video recording capability to the Advanced Session Recording agent, with a new configuration setting that can enable recording of a video on an endpoint even when a launcher is not used to begin a session.
- Advanced "headless" session recordings will show a 'Session Minimized' notification for periods during which the session was minimized, or otherwise hidden from the user such as during the final stages of logging out.
- To prevent unnecessarily long session recording sessions, added a "Max Session Length" setting for recorded videos. The default for Cloud users is 8 hours. Administrators can set this to a maximum of 12 hours.

Secret Templates

- Added a new "No Password" template for SSH/Linux Key rotation. These templates allow users to rotate SSH and Linux keys without the password field requirement that exists on other Unix secret templates in Secret Server. When creating a new secret, select Unix Account (SSH Key Rotation - No Password) as the template to use this new feature.
- Added a native Amazon (IAM key) rotation template. When creating a new secret, select Amazon IAM Key as the Template to use this new feature.
- Updated launcher and password changing for the IBM iSeries secret template.

Integrations

Added a new biometrics eWBM integration for FIDO2 authentication with Secret Server. eWBM's website at http://www.e-wbm.com/. A connector application is now available to link Secret Server to identity management tools using the System for Cross-Domain Identity Management (SCIM) standard. For further information please see the SCIM Connector documentation:

- Install Guide
- Getting Started Guide

Enhancements

Session Recording

- Updated the "View Session Data" feature for session recording to keep users from viewing session data on any ongoing session.
- Added searching by date and time for session recording videos.
- Updated the advanced session recording agent (ASRA) so that the SecretLauncherSessionMatchingService can now match the ShortName to the NETBIOS name of domain objects in Secret Server. Windows terminal sessions report the pre-2000 domain NetBIOS name, which is relayed from the ASR agent to Secret Server and used for matching Windows terminal sessions to secret launcher sessions. This is an issue if the domain on the secret is the domain FQDN or friendly name and matching fails. For example:
  - You have the ASR agent installed on a machine which is joined to a domain (mydomain.com) with a pre-2000 NetBIOS domain name "SOMETHINGELSE"
  - Your secret has the domain name "mydomain.com"

  When you launch into the machine, Secret Server attempts to match "mydomain.com" (from the secret) with "SOMETHINGELSE" (the domain NetBIOS which the ASR agent relays) and fails. Secret Server resolves this issue by trying multiple methods to get the appropriate FQDN for the Windows terminal session and using the best result from those methods, which should result in matching correctly more frequently.
- Updated advanced session recording matching by automatically mapping to the secret template's RDP fields automatically. Matching was improved by checking the secret template's RDP launcher mappings. Now, no matter what the fields are named on the secret template, the correct username and domain fields are used, based on the launcher mappings.
- Advanced session recording can now match sessions using DNS resolution. When using an RDP launcher on a secret with a machine or computer name, instead of an IP address, the protocol handler does a DNS resolution of the hostname and reports the IP back to Secret Server, which is saved for the entry in tbSecretSession. This helps advanced session recording find additional matches when the hostname does not match the computer name, only if the hostname resolves to an IP address found directly on the target computer. If there is any NAT used, this will still fail to find a match because the NAT IP is not found on the target computer.

Secret Folder Import and Export

- Added subfolder creation during secret importation.

Performance

- Enhanced performance of request/response time for SecretsController API methods by resolving Autofac dependency chain issues.

Search

Added default index separators to include the following characters:

- ? Question mark
- ! Exclamation point
- @ At symbol
- # Pound symbol
- (left parenthesis
-) right parenthesis
- [left square bracket
-] right square bracket
- { left brace
- } right brace
- ' apostrophe
- " double quotation mark
- - hyphen

Configure indexing separators at Admin > Search Indexer.

Discovery

- Updated the ESX discovery scanner to updated versions of the VMWare/VSphere SDK. Logs
- Enhanced verbose logging. Added additional logging for the Scheduled Task Scanner, Discovery Classes, Active Directory, and Password Changer logs.

Bug Fixes

Launchers

- Fixed an issue where the Mac launcher was not automatically populating unique password prompts when connecting with PuTTY.
- Fixed an issue where the Custom Launcher screen resolution setting for Mac Launchers was not properly applied. Previously, custom launcher sessions used full-screen resolution. Note: If there are no custom values set, session resolution will default to 1024×768.
- Fixed an issue where using a Windows account launcher with a domain account would fail if the launcher was configured with an IP address in the machine field. The logic detected the computer name as an IP address and then returned before setting the domain field.
- Updated the Mac Launcher to hide the session recording indicator for users when Configuration > Session Recording > Hide Recording Indicator is enabled for the launcher. The mac launcher now uses the "hideRecordingIndicator" variable stored in the sessionInfo object. Initially, there was no logic involving hiding the indicator. Added the "hideRecordingInidicators" function to the object ALaunchedTask. Updated logic under "refreshRecordingIndicator" under TaskMonitor to call "hideRecordingIndicators" when determining if it should show any icon for active watchdogs. Updated watchdog to contain a public property that is passed on

instantiation--"hideWatchdogMessages". On watchdog start or stop, it now validates the "hideWatchdogMessages" is false before displaying alerts about the session being recorded.

- Fixed a custom URL issue where launcher images did not properly display when accessing Secret Server from different sites. The custom URL was a different sub-domain from the URL that the site was accessed from. The images were served from the custom URL and our content security policy was blocking those requests. The content security policy is used to prevent cross-site scripting attacks. The solution uses the URL given instead of the custom URL.
- Updated the Mac launcher to include support of TLS versions 1.2 and 1.3.
- Changed the default launcher setting for RDPUseComputerForDomain to "True" to allow the launcher to work on all Windows versions currently supported by Microsoft upon install. This was tested on Windows 8.1, 10, Server 2008, Server 2012, Server 2016, as well as on MacOS 10 Sierra, High Sierra, and Mojave. It prevents launchers from failing unintentionally when connected to some Windows OS versions.
- Updated launchers to accept upper case characters in URL strings on a Web password secret. Previously, launchers set all uppercase characters to lowercase before launching, which caused launch failures for URLs that are case sensitive.
- Fixed an issue where a user launched a session recording but then immediately exited, Secret Server still attempted to record the session, resulting in inaccessible videos that were 00:00 seconds long. To resolve, zero-length sessions are no longer turned into videos and now returns the error: "Session too short - no video."

New User Interface

- Fixed a bug in Internet Explorer for the new UI where the Download File button threw an "access denied" error.
- Fixed a bug where the dependency log view did not sort correctly on the Date Recorded column.
- Fixed a bug in the new UI where users with "edit" and "administer folders" permissions were unable to create subfolders within a parent folder.
- Fixed a bug in the new UI where users without the "Assign Secret Policy" role permission were unable to create new secrets in a folder. The internal logic for validating whether a user may assign a secret policy to a secret did not consider the special case of secret creation. The user's personal permission to assign a secret policy should be ignored during the creation process if they did not assign one, but the code acted as if the user had assigned the policy, not that the policy was assigned by the folder.
- Fixed a bug in the new UI where breadcrumbs for the Workflow and Teams audit pages displayed "audit" instead of the component's name. This issue also caused breadcrumbs to reload when switching between tabs on the page.

Time Conversion

- Fixed a date-time issue where abbreviations for the month of the year in languages other than English were not properly logging to Syslog.
- Fixed an issue where records in custom reports were logging as the UTC time zone

Scripting

- Updated REST API call "Get Folder Permissions" parameter for filter.userId to return all user permission information.
- Added enhanced error logging for Oracle scripts.
- Fixed a bug where the API incorrectly required Owner permissions on a secret to change the password on that secret. Edit permissions are now required when changing a password through the API.
- Fixed an issue where the "Webservice Password Displayed" audit was logged incorrectly when non-password-related API calls to "Get Secret Fields" occurred. The REST endpoint GET /secrets/{id}/fields/{slug}, when used to view a non-password secret's field was incorrectly recording an audit stating "WEBSERVICE PASSWORD DISPLAYED." This was due to the endpoint's implementation using the existing GetSecret REST logic, which manages the creation of this audit. This logic assumed you would respond or display to the user with the secret's fields (items and data) when getting a secret that contains a password, recording an audit. To correct this, the GetSecret logic now supports an optional parameter that specifies which of the secret's fields (items or data) you will be responding with (displaying) to the user. If the items supplied to this method do not contain a password field, then the password displayed audit is not recorded. The corresponding GET /secrets/{id}/fields/{slug} endpoint was then updated to supply this method with the requested secret field, fixing this bug.
- Fixed a bug where Web services incorrectly returned SecretDependencyTemplateIDs as null. The SecretDependencyTemplateId is now returned with every dependency found by GetDependencies in SSWebServiceHandler.
- Fixed a bug where an "Application Account License limit has been reached" error was incorrectly displayed after editing existing application accounts, instead of only when creating new user accounts. This bug was due to a flaw in the user license logic where application account licenses were incorrectly returning the API_MetApplicationAPILimit error code when editing and attempting to save an existing application account user, while at the current application account user limit. Specifically, the logic assumed the addition of a new application account user--it did not support editing an existing user. The error occurred at the application account user limit where adding a new user is not permitted. The fix was to check if users were adding a new application account user or editing an existing user when determining whether to return the error code, API_MetApplicationAPILimit.
- Fixed a bug where API group membership changes were not properly audited. This bug was due to a lack of auditing logic in the CreateGroupUser and DeleteGroupUser REST endpoints. The fix was to observe what audits the UI were doing upon adding and removing users to and from groups, then applying that same logic to the CreateGroupUser and DeleteGroupUser REST endpoints. Some extra logic was added to prevent recording audits if no operation was executed, such as moving a user to a group it already belonged to or removing a member from a group it was not a member of.
- Fixed a bug where users were unable to create subfolders that inherit folder permissions through the REST API, despite the user having "Edit Folder" permission.
- Updated REST API documentation for SSC.

Authentication

- Fixed a SAML login issue that could cause login failures if multiple users had the same User Principle Name (UPN) in Secret Server. The account that was created first would be prompted for SAML authentication even if

that account was in a disabled state. This caused login failures with an error saying the user's account was disabled. Updated GetUserByUserPrincipalName to return a user only if there was exactly one user found with that UPN that was active. If there is not exactly one, it returns null. Handled a few logic flows where a GetUserByUserPrincipalName request is followed with a request to GetUserbyUsername. In cases where a valid UPN is entered, an error is produced at GetUserByUsername. These errors are now handled and logged. Secret Server.

- Fixed a bug where if an instance had two users with the same username (one active user, one disabled user) across different domains two-factor authentication (2FA) enabled for login, a user trying to reset their login might get a validation error because the reset code they entered would be checked against the code of the other user with the same name. Secret Server now checks the domain of the user who is trying to login when determining which user account should be used for the 2FA reset request. This removes ambiguity when users in different domains have the same username, thus ensuring the correct 2FA validation is used.
- Fixed an issue where 2FA failures were not showing up in the "Failed login attempts" report. The 2FA failure message was different from a normal login failure message. The report SQL was changed to display any login failure message.
- Corrected a configuration error that changed the 'Disable Radius NAS-IP-Address Attribute' setting to have the opposite effect. The logic using the DisableRadiusNasIpAddressAttribute setting was set to return if false instead of true. This was an old application setting that would normally be false for most customers. When it was added to the UI configuration pages, the setting was implemented incorrectly, reversing the logic. In versions 10.5.14, 10.6 and 10.6.1, it is being disabled by default due to the backwards logic. This release corrects the configuration setting to work as described in the UI.
- Fixed a bug where the authentication function for the "Attempt User Password" Radius setting did not work when using the REST API.

Discovery

- Updated the PowerShell local account and dependency scanners to timeout after a set timeout. The application settings DiscoveryScannerTimeout and DependencySearchTimeout have been moved to settings on the individual scanners. If this setting was only set in an application setting, it needed to be reset on the scanner setting. Wrapped the PowerShell dependency and local account scanners in a System.Task to cancel after a timeout period.
- Fixed an issue where out-of-the box dependency scanners (scheduled tasks, application pools, and service accounts) were not correctly copying as the same specified scanner's type.
- Fixed an issue where discovery imported group-managed service accounts (gMSAs) as new computers and subsequently attempted to scan them for accounts.

Password Changing

- Fixed an issue with Oracle privileged password changers. Before this update, Oracle password changing logic for privileged accounts was not correctly using the designated privileged secret to perform password rotations, leading to failed password change attempts.
- Fixed an issue where missing parameters in the Sonic Wall password changer resulted in multi-factor-authentication (MFA) failure. The info sent to the Sonic Wall password changer now includes default values for MFA code and future MFA codes so those do not reference null. The PhantomJS script for Sonic Wall now looks

for the host name at a different place in the parameters list.

- Fixed a bug where the IBMi mainframe password changer timed out during process cleanup. IBM iSeries password changer has two threads during a session, the primary thread processing the session or request and a subsequent one that is spooled up during the process to ensure the interface framework (ws3270) does not get stuck in the wait state when the wait command is called. The second thread may detect false stuck wait states and attempt to close the session. If this happens after the primary session has completed the wait and has already closed, an "Access Denied" exception occurs. That exception can still be due to permissions, so it is worth checking, but most of the time this is the error thrown by the .Net Process framework when attempting to exit a process that has already exited.
- Resolved issues with error handling, command pause handling, and session termination/logoff when using remote password changing (RPC) with IBM z/OS and IBM iSeries. IBM z/OS and IBM iSeries use the same base architecture within RPC to manage and execute commands. In some cases, the password change process did not correctly resume after a pause command. In others, the pause did not take effect, causing commands to execute prematurely and showing incorrect failures. Code was also added to clean up failed RPC/heartbeats once a user is logged in. An identifier to the logoff command now informs RPC of the correct command to kill sessions in cases where it needs to terminate prematurely.
- Fixed an issue after a Google update where changing Google account passwords returned incorrect messaging whether a password change failed or succeeded.

  Important Notes:

  - The Google RPC only works if the user has previously logged into the Google account from the IP address that is trying to change it. In other words, the user needs to log into their Google account from a Web browser and allow the sign-in from an unrecognized IP address before attempting to rotate the password from that IP.
  - If there are too many failed login attempts, Google may block the login for some time.
  - If Google prompts a reCAPTCHA field to verify a human is changing the password, the RPC for the Google account will fail.

  Technical Details:

  Updated the URL check for the password changed test to fix the failed password change when it was a success. Updated the missing error code to fix the successful password change when it was failing. Also added better error checks to inform the user of the specific password change error.
- Added logging to provide details when password change attempts for Google accounts fail, including:
  - NewPasswordLengthTooShort
  - NewPasswordLengthTooLong
  - InvalidCharactersInNewPassword
  - NewPasswordNotComplex
  - IsAPreviousPassword
  - SameAsCurrentPassword

Secret Import and Export

- Fixed an issue where a user was able to edit the error message in the "Import Secrets' dialog box after importing a secret.
- Fixed an issue where secrets were not displaying for users when a left bracket appeared in the parent folder name. We replaced any instance of [in a LIKE clause with [[] The first [opens the character comparison list. The second [is the character we allow for comparison. Finally, the closing] closes the character comparison list. It is unnecessary to replace additional instances of] because they mean nothing without a matching [
- Fixed an exportation issue where the double quotation mark (") was not included in CSV files.

Security

- Resolved a security issue in the Protocol Handler.
- Fixed a security issue where users retained Unlimited Vault Access permissions for a short time after the Unlimited Vault Access Mode was turned off, due to a caching issue in the background worker. The issue was related to caching configuration data for 5 minutes and how the cache was being managed by the ServiceLocator used by the background worker. Turning Unlimited Vault Access Mode on or off would clear the configuration from the cache used by the UI, but the background worker had its own cache, which did not get cleared. The fix was to reinitialize the cache provider on the ServiceLocator whenever starting a bulk operation or secret importation to ensure these functions get a fresh copy of the configuration and Unlimited Vault Access setting.
- Resolved inconsistent behaviors in role-based permissions.

Other Bug Fixes

- Updated session recording to address an issue where video recordings intermittently returned black frames during the session's video playback. This was observed on older laptops running Windows 7 (either 32-bit or 64-bit) with integrated Intel graphics. Neither metadata nor keystroke logging (for advanced session recordings) were affected by this issue, only the viewing experience of the video, which could be interrupted by black frames. The fix was to use a different Windows API call as a fallback whenever a black frame is returned from the original screen capture attempt. A drawback to this approach is that fallback API simply captures the whole window including whatever might be on top of it. To counter this, logic was added to ensure that the RDP window is topmost during image capture. There remains a small possibility of capturing an isolated black frame or two if another window is moved on top of the maximized RDP window when an image is captured.
- Fixed an issue where some Secret Server background threads attempted to perform tasks when Secret Server was disconnected from its database. The issue was that some background threads would exit their continuous monitoring loop. Specific conditions caused new SQL server connections to time out, but the open connections continued working. This resulted in Secret Server working normally but caused the monitoring loop to exit and fail to restart, breaking the monitoring of the thread. This was fixed by catching the error that caused the loop's exit, allowing the monitoring process to continue.
- Fixed a bug where removing an event subscription item deleted the wrong item. When editing the events to trigger the event subscription, the ID of the event stored in the database identified which event to remove when an item was deleted. If an item was added, but the updated event subscription had not been saved, that ID was not generated yet. This caused the first event in the list to be deleted every time a newly added event was

removed while editing. A temporary ID is now generated when a new item is added to the list so that if the item has not been saved to the database, the correct item in the list can now be identified.

- Resolved an issue where backups were unable to complete if a Web application file was in use by a worker process. When looping through the files to be backed up, we now catch errors for any files that cannot be accessed by the backup process due to being locked by another process. When an error is caught, the issue is logged, and the backup process continues to the next file.
- Fixed a bug in the old UI where a Safari browser repeatedly prompted Mac users to download and install the plug-in when attempting a copy-to-clipboard action. The old UI prompts for our Safari plug-in to be downloaded for using the user's clipboard. This is no longer used in the new UI. The link to the plug-in was removed. Now, the user loads the password by clicking the "load" image and then can copy the secret's value to the clipboard by clicking the copy image.
- Fixed an issue where a Distributed Engine would return "Unknown Error" for a secret heartbeat if there was a transient error publishing the real secret heartbeat result back to Secret Server.
- Fixed a bug where sorting groups by the "Created" field did not properly order groups in the table.
- Improved page size restrictions when assigning roles and editing groups for customers with large numbers of users.
- Fixed a bug where searching from a tab did not correctly output search results until the user navigated back to the Home Dashboard. To fix this bug, users now are automatically redirected to the Home tab when performing a search.
- Fixed a bug that allowed Secret Server Professional Edition users to set a Workflow Access Request secret policy that should be unavailable in Professional Edition, causing an error when adding secrets to folders using that policy.
- Lengthened the default maximum value for the transaction timeout on the installer from 10 to 90 minutes to prevent installs from failing due to longer database setup. The issue was caused by lengthy transaction times when running the installer against an Azure SQL database. The default maximum value for a transaction timeout is 10 minutes. We added code to allow us to make the transaction larger and set the timeout to 90 minutes.
- Fixed a bug where converting a secret to a different template created two active copies of the secret: one converted, one unconverted. Inside the SecretDataCopier, when setting permissions, the code did not know it was due to a conversion. It then copied the folder permissions down onto the secret, instead of using the secret permissions that were on the secret originally. This meant that in the scenario above, the user did not have edit rights, throwing an "Access Denied" error.
- Fixed an issue where launcher-based sessions were not displaying proper messaging during session recording. Message boxes are now correctly bound to their parent process (the launched process), and message box behavior has changed. Before this update, message boxes launched without a proper parent process would be minimized and would not display or block input if you restored the launched process, because they did not belong to the launched process. After this update, message boxes are launched with a proper parent process always appearing on top of that process and preventing input to that process until the message box is acknowledged.
- Fixed a bug where Distributed Engines configured to callback to multiple Web servers did not work if the server names were separated by semicolons.

- Fixed an issue where after an SSH key expiration occurred, uploading a new key remained in an expired state instead of properly updating the key.
- Resolved an exception error that occurred when closing an RDPWin session window after a secret-checkout session ended.
- Fixed an issue in customer environments configured with ticketing systems where approving a request from an event notification email caused an exception error to occur, rather than completing the approval.
- Fixed an issue where reports containing the #CUSTOMTEXT dynamic parameter failed to send emails.
- Fixed an issue where secret templates containing custom fields caused an error when Key Management was enabled.
- Fixed an issue where creating sub-folders from the folder menu did not use "No Policy" default settings when set to not inherit a policy.

Cloud Release Date 3/9/2019

This Secret Server Cloud (SSC) release corresponds loosely with the on-prem version 10.6.00000. The release date varies with location. First release is scheduled for March 9, 2019.

Upgrade Notes

Installing the New Advanced Session Recording Agent

Customers using Advanced Session Recording need to deploy the new agent once their SSC instance upgrades to Secret Server 10.6. Secret Server 10.6 does not support the RDP Monitoring Agent from Privilege Manager for recording keystrokes or process auditing. For details, please see the Secret Server Advanced Session-Recording Agent Installation Guide.

New Features

New User Interface

SSC offers a new user interface (UI) with a redesigned left navigation panel and other improvements. New SSC users default to the new UI on first access to SSC 10.6, and existing users can enable the new UI as desired. For an overview of the SSC UI.

Workflows

- Added a new enterprise feature--multi-tiered secret approvals, which grants secret access after navigating multiple approval layers. This feature is available in Secret Server's new UI only.
- Added two new Roles to support multi-tiered secret approval workflows:
- Workflow Administrator–can administer workflow permissions.
- Workflow Designer–can create new workflows.

Advanced Session Recording

- Enhanced speed and performance for both basic and advanced session recording.
- Added a new agent to Secret Server for advanced session recording that captures metadata from launcher sessions to targets. Secret Server
- Customers using advanced session recording must deploy the new agent when upgrading to Secret Server 10.6. Secret Server 10.6 does not support the RDP monitoring agent from Privilege Manager for recording keystroke or processing start data.
- The new advanced session recording agents uninstall themselves when deactivated from SS.
- Secret Server must have appropriate permissions required to access all file paths listed for saving the configuration and recordings.
- When creating a new site, a specific site-to-folder-path relationship will not be created automatically. Instead, the secret will use the default path (whatever path is used for the local site). When you edit, a row will show up with the default value per site already loaded.
- Added a warning for session recordings experiencing many unprocessed videos.

Teams

- Added a new "teams" feature so that Secret Server administrators can segment users and groups within one Secret Server instance.
- Designed as a convenience feature, users that lack an elevated role permission within a team cannot select users, groups, or sites that exists outside their team, including in dropdown options and searches.
- Added three new roles to support teams:
- Administer Teams--Can create, edit, and view teams.
- Unrestricted by Teams--Can view all users, groups, and sites. The default User role in Secret Server now has this permission, so role permission customization is needed for teams to take effect.
- View Teams--Can view all teams.

FIDO2 (YubiKey) Authentication

Added a new integration with Yubico and other FIDO2 implementations. Secret Server can now be configured to use FIDO2 tokens (YubiKeys) as a method for multi-factor authentication.

Launcher Compatibility

Added backwards and forwards compatibility to the Secret Server launcher protocol handler.

Telemetry

Added a new feature that sends anonymized usage data to guide future research and development plans at Delinea.

Remote Password Changing

- The Secret Server API can now conduct remote password changing on AWS secrets. That is, the API now supports PowerShell script password and dependency changes for AWS IAM token rotation. Generated values are passed back for saving on the secret. This is useful for tokens generated by an external system during rotation. This is only the underlying architecture for use via PowerShell scripts, not a full password changer.
- Added a new IBM iSeries password changer template to enhance 5280/IBM Series 7.1-7.3 systems support including features such as program functions.
- Added a $$Pause command for the Custom SSH password changer so that administrators can prevent run commands executing immediately after login, which can cause failed executions.
- Added support for VMware password changing and discovery to work with PowerCLI up to version 10.1.1.
- Increased default RPC retry interval to run every 15 minutes and to cap at 10,000 consecutive tries. "Unlimited max attempts" is no longer an available option. Retry Interval can be manually configured by 5-minute increments. Heartbeat interval is also now capped at minimum of 15 minutes.

SDK

A new SDK version is on nuget.org that supports targeting for .NET Framework 4.5.1 in all packages. The only external dependency is Newtonsoft.Json (v11.0.2). See https://www.nuget.org/packages/Thycotic.SecretServer.Sdk.

Enhancements

- Added the ability to download a recorded session with the API. This new API call will not download metadata and only applies to basic session recordings. The call is api/v1/recorded-sessions/{id}/session-recordings.
- Added a PrefetchCount application setting to allow customization of engine response message processing and to enhance processing speed.
- Enhanced load performance for discovery.
- Added a cache for session configuration to prevent excessive callbacks to SessionRecordingConfigurationProvider.Load during discovery scanning.
- Added a new setting for configuring the SSH RPC timeout interval to all applicable SSH secret template settings pages. Prior to this fix, users were not notified when a group name exceeded the maximum character length and instead experienced a web session hang.
- Added a setting to discovery that can check whether IIS is installed before scanning for application pools. To enable the "Verify IIS is Installed" setting:
  1. Navigate to Admin > Discovery.
  2. Click the Edit Discovery Sources button.
  3. Click the link for the desired source. Its page appears.
  4. Scroll down to the Find Dependencies section.
  5. Click the edit (pencil) icon next to the Application Pool Scanner entry.

In extensible discovery, scanners are setup to run in consecutive order across many organizational units within large environments. This setting was added to allow Secret Server to skip the process of scanning for application pools whenever a machine does not have IIS already installed to enhance performance and cut down on run times. Secret Server

- Added support for a RADIUS challenge in web services. Secret Server will now return a "RadiusUSAccessChallenge" error if an additional prompt is needed. To use this functionality, on-premises Secret Server needs to connect to the same node on both authentication calls. Previously, Secret Server could only handle a single request from the RADIUS authentication process. This enhancement uses caching, so authenticating scripts need to hit the same web node to use a challenge authentication. This fails when using REST + Secret Server On-Prem + Load Balancing + RADIUS Challenge Authentication combined. The workaround is to hardcode REST scripts by IP or FQDN.
- Added various enhancements to the Upgrader. Enhancements will not take effect until your next upgrading process.
- Upgrade enhancements include updated logging, the removal of unchanged files during the upgrade process, re-ordering of tasks to improve performance, and enhanced messaging.
- Enhanced error messaging when heartbeats fail due to an unavailable machine state. Prior to this enhancement, when heartbeats failed on a machine due to disconnection it flagged an "Unknown Error." Now, the machine will return an "Unable to Connect" status.
- Added and enhanced the Custom SSH password changer's console output logging for debugging. Prior to this issue, command set logging was removed from Custom SSH password changers due to a security concern in the logging messages. To resolve this issue, the original security messaging was addressed, and then debug logging was reinstated.
- Fixed an issue where heartbeat failed when changing a AS/400 Mainframe secret due to versioning requirements. When setting up an AS400 Password Changer for V7R1 or V7R2 systems, the a timeout response error was thrown from the password changing that failed to manage the WS3270 utility properly. We updated the supported versioning for the IBM iSeries Password Changer template to resolve this issue.
- Added the option to include subfolders when configuring event subscriptions. Users can now optionally apply event subscriptions to subfolders, previously folder subscriptions were limited to individual folders.
- Enhanced performance of the Event Subscriptions page. Page performance on the event subscription page in Secret Server was increased by rearranging the logic and ordering of the event subscription processes. Secret Server
- Increased the default LDAP processing throttling limit on Secret Server distributed engines (SSDE) from 100 to 1000. SSDE performance was slowed down by the low throttling threshold. Increasing the limit allows faster performance for engine tasks like heartbeat or password changing.
- Enhanced audit logging messages when viewing and displaying secrets and passwords. Unmasking a password or viewing a password's history is only logged in Secret Server every five minutes when the same user performs the same action on a secret within a short period of time. Prior to this update, the description of behavior on the Audit View page did not include the action for "Password Displayed."
- Two-Factor Authentication now supports the User Principal Name (UPN) as a default for usernames when logging into SS. Configure this setting in Admin > Configuration > Login > RADIUS Default Username when

RADIUS is enabled.

- Renamed the "Google Authenticator" dropdown option for multi-factor authentication to "TOTP Authenticator" (Time-based One-time Password algorithm) for accuracy.
- Updated SSDE to use REST instead of Windows Communication Foundation (WCF) when using HTTP to contact Secret Server. WCF is no longer a prerequisite for installing SSDE.
- Added log message buffering. By default, log messages are not buffered and are written to logs immediately. For very active systems, log message buffering can increase performance. In the web-log4net.config file, the Delinea.BufferingForwardingAppender parameter should be uncommented and then IIS reset. Buffer size can be configured using the bufferSize parameter in that configuration file.
- Increased the number of default index separators to include the following characters (separators can be configured under Admin > Search Indexer): ?, !, @, #, (,), [,], {, }, ', ", -
- Significantly improved performance of UI operations through SSDE, such as AD login through SSDE and site validation.
- Blocking calls on AzureServiceBus in cloud no longer create temporary queues, instead they use a persistent queue with a unique session within the queue. This substantially improves the performance of blocking calls.

Bug Fixes

- Fixed a bug where manually added fields in custom templates would not display in the table view. Prior to this fix, when creating a custom template with the "expose for display" option selected, the field would not display in the table as a new column.
- Corrected error messaging when deleting a dependency on secrets with large numbers of dependencies. When a secret had 1000+ dependencies, deleting one of them resulted in a "Failed to Execute" error prior to this fix.
- Fixed error reporting when a user enters a group name that exceeds the maximum character length.
- Resolved an issue with Amazon secret heartbeats and rotations because of a change in Amazon login page layout and flow. To create a new Amazon Web Services (AWS) secret, create a new web password secret, then select Remote Password Changing tab > Password Type (Amazon, Google, and Salesforce options).
- Fixed an issue where a RADIUS Authentication timeout would block other RADIUS requests from authenticating to Secret Server, causing login delays for RADIUS users. Prior to this update there was a lock in the RadiusUSRequest.GetResponse() that only allowed one connection at a time. This fixes an issue when making more than one UDP connection to the same client port.
- Removed unnecessary logging on the OperationCanceledException in the system log.
- Fixed a bug where SSH key-rotation commands were not properly authenticating. The "Verify" command for password changing was ignored if no "Post Change" command existed in a Custom SSH Key Rotation template, resulting in being able to use the same key to connect for the verify command and the password change in certain cases.
- Fixed a broken documentation link on the Server Nodes page.
- Fixed a bug where duplication errors occurred if scheduling a report with the same name as another, already disabled, report in Custom Reports. The workaround for this issue was to undelete the original report and rename it before deleting it, but users are now able to delete and create reports with the same name, if the duplicated reports are not both active.

- Fixed an issue that prevented users from creating or editing an SSH command menu on individual secrets.
- Fixed an issue where the "Allowed" and "Available" Secret Templates columns did not populate on the "Create New Folder" page when restricting secret templates.
- Fixed a bug where editing checkout hooks saved changes instead of allowing users to cancel out of the edit page. After clicking cancel on the checkout hooks edit page, the updated data was not saved to the database but was updated on the page behind the UI modal.
- Edited PUT /secrets/{id}/fields/{slug} parameters in API documentation to use Secret ID instead of the secret name.
- Edited /secrets/{id}/check-in REST API call in API documentation. In this script, "Force Checkin" could bypass the access responses, then successfully check-in the secret, before attempting to return the access responses it previously skipped. This failed.
- Fixed an issue where ExpiredSecretMonitor stopped running in certain conditions due to a session recording call. Users were experiencing several days in between this issue. The SessionRecordingBlobWriter registered an exception error that stopped background threads from processing. This SQL call was irrelevant, and its elimination allowed the ExpiredSecretMonitor to update every minute as normal.
- Fixed an issue where "Language Resource Not Found" errors were thrown on the Themes page under the Advanced section. This issue resulted from missing resource strings on the page.
- Fixed an issue where the SSMS launcher did not send the correct password if a caret symbol (^) was in the password. This issue was specific to SQL Server Management Studio (SSMS.exe). The fix for this involved updating the SSMS process launcher configuration to allow for an optional escape character to be added, now configurable in the advanced section when setting up a launcher for a SQL Server Account secret.
- Fixed a bug where failed password changes on custom SSH secrets would not stop processing when CheckContains command failed. This issue stemmed from the CheckContains command script in the Custom SSH password changer.
- Fixed an issue where items could be imported into the root personal folder. Prior to this fix, administrators were able to migrate secrets into the Personal Folder (root) using the upload XML tool, which allowed all users to see the imported items.
- Fixed an issue where a language setting caused errors. Some language settings could cause an IIS crash with HTTP Error 503: The Service is Unavailable.
- Edited tooltip wording for the advanced "Auto Change Schedule Interval" setting.
- Fixed an issue where SSH key rotations were not properly rotating and then deleting the old SSH key at endpoint when the SSH Custom password changer was configured in a specific way. Key rotations for Linux SSH keys failed to cleanup old SSH keys on target machines after a key rotation occurred due to a missing command in the success script.
- Fixed an issue where users were unable to delete reports. Deleting and undeleting Reports threw an exception error due to a database ReportCategoryId mismatch.
- Fixed an issue where the API call "GET /secret-templates" did not support the inactive filter ("filter.includeinactive").
- Updated API Rest documentation to not label a dictionary object (enumerated KeyValuePair) as an object[].

- Fixed an issue where scheduling reports failed if the time zone was set to time zones ahead of UTC. Prior to this fix, any time zone that was UTC+x failed to properly populate ScheduleCustomReportEdit.aspx "Recurrence Scheduled Start Time."
- Fixed an issue with the API Folder Create method where folders created through the API would error when trying to access permissions. After creating a new folder via the REST API, a Get command for the new folder would return null permissions prior to this fix.
- Fixed a bug where Basic Users were not able to use the "Create New" secrets template when Active Directory template permissions were revoked. In Basic User mode the "Create New" secret templates dropdown list incorrectly started with `<active directory="">`, causing permissions errors when the Active Directory template was revoked for Basic users. The dropdown list now starts with `<select>` in all user modes.
- Fixed a bug where searching for a subfolder would not return results when the user did not have permissions to view its parent folder.
- Fixed a bug where the bulk operation mode did not move multiple secrets to a folder. This issue specifically involved the search feature on the bulk operation dropdown when filtering for the folder location. Users were required to manually select the folder rather than being able to find it through search.
- Fixed issue where "Require Approval Access" on a secret policy did not follow default settings to not enforce the policy.
- Fixed a bug where a user's display name could be left null when creating new users.
- Fixed an issue where discovery computer scans using a "machine only" resolution type resulted in an exception error rather than completing the scan. A null exception was thrown when scanning for machine names rather than using the "Use Fully qualified name (recommended)" setting in discovery.
- Enhanced error messaging when running dependency scans in discovery. Error message fixes included:
  - If all scanners worked but did not find anything: "No Dependencies."
  - If one scanner fails, then it shows a failure message for the scanner.
  - If multiple scanners fail, it only has room to show one failure.
  - If a scan fails but no failure message exists, it shows "Unknown Error."
- Updated two collation settings in session recording tables to allow case insensitivity on table names and prevent collation errors when the SQL server collation mismatches.
- Fixed a bug where the "Only change password when Secret is expired" check box would not save if Auto-Change Schedule was set to None.
- Fixed an issue where SAML authentication check could not be disabled. Prior to this fix, some accounts would receive an 'Invalid Relay State' error when logging in. This had to do with disabling the "SAML authn context" in Secret Server.
- Enhanced error messaging when heartbeat is not assigned to a PowerShell Script password changer.
- Fixed a bug where log file exports were not downloading from the Manage Secret Access Request page.
- Fixed a bug where the "Use Custom Window Size" launcher setting was not implementing the correct resolution. Prior to this fix, when attempting to launch at a smaller 1024 × 768 resolution, a session launched instead as full screen.

- Fixed an issue where if the Response Bus Site Connector disconnected, it prevented the web site from loading. Updates were made to BackgroundScheduler, BackgroundWorker, and the EngineWorker. If a role cannot connect to its response bus an error will now be logged and the site will still load.
- Fixed a bug where heartbeat on local administrator accounts on Windows Server 2012 pre-R2 was not compatible with PowerShell v3.0.
- Fixed a bug where API calls against restricted secrets threw an object reference error. This fix allows accessing "require comment," checkout, or other restricted secrets through the API. These secrets were returning errors due to a null reference linked to a "ViewTracker" secret attribute.
- Fixed an issue where web password secrets caused Bookmarklet JQuery Exceptions when the web password filler was used in the IE11 browser.
- Fixed a bug where EnableFrameBlocking was not respected on certain pages in Secret Server. Middleware was added to send X-Frame-Options / SameOrigin header for everything but the bookmarklet if not installed, no one was logged in, or FrameBlocking was enabled. MainLayout also changed for MVC pages so that they will render with the frame blocking script.
- Fixed a bug where email configurations were not properly saving applied settings. Prior to this fix, changes to Email configuration page did not properly update the database.
- Fixed workflow issue where users were directed to the Setup Home page after saving changes on the Email configuration page.
- Fixed an issue where AD users were not receiving approval emails after an access request for a secret in some environments.
- Fixed a bug which caused audit tables to display date and time in UTC rather than the configured time zone.
- Fixed a bug that could cause a "Failed to load history" error when viewing the history data for a secret.
- Fixed a timeout on secret audit when there are very many audit entries. Audits with very large result sets only display the top 1000 entries.
- Resolved an error reporting issue with Unix Account (SSH) and Unix Account Custom (SSH) account types so that connection failures and login failures are correctly reported. Previously, Unix Account (SSH) would report login failure as UnknownError and Unix Account Custom (SSH) would report login failure as UnableToConnect.
- Updated the REST API call [Get folder-permissions] parameter for [filter.userId] to return all permission information specific to a user.
- Fixed an issue where discovery imported group managed service accounts (gMSAs) as new computers and subsequently attempted to scan them for accounts.
- Fixed a bug where a Java script "page unresponsive" error was caused after moving multiple dependencies into multiple groups; then editing multiple dependencies.
- Fixed an issue where out-of-the box dependency scanners (Scheduled Task, Application Pool, Service Account) were not correctly copying as the same specified scanner's type.
- Fixed an issue where "Optimize Start Menu Cache Files" Windows 10 tasks were logging as dependencies during discovery for some customers, resulting in excessive logging that slowed cloud performance.
- Fixed an issue where converting a Unix Account (SSH Key Rotation) secret template did not allow the target field for "File" types to populate.

- Fixed a bug where incorrect domain names passed on the logon window for RDP Launcher sessions.

Cloud Release Date 12/22/2018

Bug Fixes

- Fixed an issue where SSH Keys were not being passed to the launcher.
- Fixed an issue where the Captcha script was prevented by Content Security Policy on the login page.
- Fixed an issue where processing recorded session failed with Null Reference Exception.
- Fixed a bug where data could be truncated when saving new user.
- Enhanced login workflow in Delinea One

Cloud Release Date 11/03/2018

Enhancements

User Interface

- The new and improved redesign of Secret Server is here. Click the banner in Secret Server to enable for use. For feedback opportunities please inquire at ux@thycotic.com.
- Included a "24 hours" option to the expiration Quick Picker for the Secret Access Request form.

Time Zone Enhancements

Improved timezone handling in Remote Password Changing to correctly account for daylight saving time.

APIs

- Added new service to API to Cancel Password Change.
- Updated the UserCreatedArgs to include AD Guid to account for possible duplicate users in Active Directory through the API.

Launchers

Added backwards & forwards compatibility to the Secret Server Launcher Protocol Handler.

Business Users

SSC now has licensing to support Business users.

- The minimum RPC Retry Interval was increased to 5 minutes. Existing customers with RPC Retry Intervals set lower than 15 minutes will notice an increase upon upgrade to automatically run every 15 minutes, but this setting can be manually configured by 5-minute increments.
- RPC Retries are now limited to 500 consecutive attempts.
- The minimum Heartbeat interval was increased to 60 minutes.
- Added the ability to use a $$Pause Command for the custom SSH Password Changer to allow the option to prevent run commands executing immediately after login.

Security Fixes

- Fixed an issue with Request Access when set to be required for Owners and Approvers where an Approver could approve their own request through JavaScript manipulation. Note an email detailing the approval would have been sent to all other approvers.
- Fixed a Security Vulnerability that allowed Cross-Site Scripting.

Bug Fixes

- Fixed a bug where users with the "Administer Configuration" Role Permission could see but not access option settings under Admin > Configuration.
- Fixed a bug where the Application Pool scanner and IIS tester did not properly initialize the ManagementScope for WMI calls to Local Machines.
- Fixed a bug where only one Discovery Scanner worked when Active Directory had more than one local account scanner setup.
- Fixed a bug where valid REST/SOAP API tokens did not permit login access.
- Fixed an issue with the Mac Launcher.
- Fixed an issue that allowed personal folders to be moved to the top level of the folder tree.
- Fixed an issue where after adding and saving an Identity Provider in advanced settings (SAML), the user observed an error stating 'Object reference not set to an instance of an object.'
- Fixed a bug where a user was unable to delete an approved user from the Edit Secret Policy page.
- Fixed a bug where there were inconsistencies in the time zone handling.
- Fixed a bug where there was an error message of 'Connection Failed' during Custom Unix (SSH) Remote Password Changing but the password changed successfully.
- Fixed a configuration issue with the SSH Key Rotation Privileged Account Password Changer that is used by the Unix Account (Privileged Account SSH Key Rotation) template and caused RPC to fail with an error saying 'Associated Secret is required.'
- Fixed a bug where new users assigned to Google/OATH 2FA could not login if the Remember Me time interval elapsed.
- Fixed a bug where Scan Item on Password Type would not save upon changing scan templates.
- Fixed an issue where Web Password secrets caused Bookmarklet JQuery Exceptions when the Web Password Filler was used in the IE11 browser.
- Fixed a bug where EnableFrameBlocking was not respected on certain pages in Secret Server.
- Fixed an issue where high volume of approvers were not all receiving approval emails after an Access Request for a Secret.
- Fixed an issue where users were able to disable Site Connectors assigned to the Response Bus.
- Added messaging to notify when a user enters a group name that exceeds the max character length.
- Fixed workflow issue where users were directed to Setup page after saving changes on the Email configuration page.

- Fixed a bug where changes to Email configuration page did not update the SQL database.
- Fixed a bug where SSH Key rotation commands were not properly authenticating.
- Fixed an issue where a Radius Authentication timeout would block other Radius requests from authenticating to Secret Server, causing login delays for Radius users.
- Enhanced a permission-related error message within Secret Server to be 'You do not have Owner permission on [Secret Name].'
- Fixed a bug where log file exports did not download from the Manage Secret Access Request page.
- Fixed a bug where the "Maximum Number of Entries" field was disabled after changing it from "Unlimited" on the System Log page.
- Fixed an issue where a WinRM warning message displayed even when WinRM is running and correctly configured on a server if authentication account did not have access to running services.
- Performance enhancement fixes to Distributed Engine.

Cloud Release Date 8/17/2018

Enhancements

- Customers are now able to configure the time when session recordings are moved from the database to disk.

Bug Fixes

- Fixed an issue where new Delinea One customers were unable to access their personal folders after provisioned
- Fixed issue where after 10.5 upgrade, session recording could not be configured to use a file share
- Fixed an issue where there was an intermittent first login fail on fresh install
- Fixed issue where selecting "Now" for a password change in Autochange Schedule could set the incorrect time in situations where the user's computer is in a different time zone than the Secret Server host.
- Fixed issue where dependency scanning would miss Scheduled Task dependencies in situations where two domains with the same name (ex: example.com andexample.net) were used.
- Fixed an issue where Distributed Engines were inconsistently failing after upgrade.
- Fixed issue where the password for an account would be changed multiple times in a row if the "Only Change password when Secret is expired" box was selected in Autochange Schedule.
- Fixed issue where bulk operations could cause database deadlocks.
- Fixed issue where Distributed Engine callbacks could cause a race condition.
- Added a warning to the schedule page that specified the time will be saved in Secret Server configuration time

Cloud Release Date 8/4/2018

Enhancements

Login Flow

- New Login authentication flow in Delinea One is now available
- SAML
- Added ability to a new SAML configuration page so SSO providers can be configured without modifying the saml.config file.

Cloud Key Management

AWS Key Management is now supported

Session Recording

- Cloud support for Session recording
- MP4 conversion through Azure Media Services
- Improved Robustness and speed when generating videos

SIEM

Added new Syslog event messages for SIEM integration and enhanced log messaging.

UI Updates

- Subfolders can now be created within a user's Personal Folder.
- The login screen domain dropdown menu can now be disabled for customers that wish to hide the list of domains.
- Added auditing for the following configuration changes: Character Sets, Password Requirements, Event Subscriptions, Role names, Backups, Custom Password Changers, Licenses, and Database Connections.
- Added export functionality for Heartbeat logs, Remote Password Changing logs, Discovery logs, and Computer Scan logs.
- Failed password changes now display an error within the Secret View UI and a link to a password changing errors KB article.
- If using multiple devices per user in Duo Security for Two-Factor logins, Secret Server will now show the Device Name set in the Duo admin portal next to each device.

Discovery

- Added Discovery settings to scan for open ports on target machines, connect to specific ports, and set a default timeout for port scanning.
- Added a Discovery scanner setting for excluding services, tasks, or application pools by name.
- Added new Diagnostic logs to address duplicate Discovery Scan items.

Password Changing

- Auto Change Schedules can now be configured so that they will trigger a password change even if the Secret is not expired.
- Added the ability to rotate SSH Keys with no passphrase required.

Reporting

- Added Session Revocations to the User Audit report.
- Added IP addresses to the login failure report.
- Added new chart options for custom SQL reports.

Other Notable Enhancements

- Enhanced Secret Server's ability to process larger message sizes. Secret Server'
- Distributed Engines now send operation results back to Secret Server through the Site Connector instead of sending them via website.
- Ticket System Integration can now be configured to work over Distributed Engine.
- Improved System Log Searching in active environments.

Security Enhancements

- Added a configuration setting to change the default role that a new user receives.
- Added a configuration setting to limit the file type and file size of files that are uploaded and attached to Secrets.
- Added the ability to audit certificate verification errors for Active Directory calls over LDAPS and syslog connections using Secure TCP.
- Added the ability to send a client certificate with Active Directory calls over LDAPS or syslog connection using Secure TCP.

Bug Fixes

- Fixed issue where Secret Policy changes would not apply to all Secrets.
- Fixed issue where Service Account Discovery could timeout and flag Secret Dependencies for removal.
- Fixed issue where Two-Factor could prevent a "Login Failed" audit on the user; added new logging details in the Audit User Log if errors do occur from Two-Factor authentication.
- Fixed issue where excluding OUs from Discovery scans prevented computers from being deleted when they were removed from AD.
- Fixed condition in certain environments where the auto-change Secrets were not changing properly. Improved performance of the Discovery Stored Procedure for specific OUs scanning to avoid timeout in large environments.
- Fixed a logging exception in Monitor Logging.
- Resolved a permission error in certain environments that occurred during Local Account Discovery Scans.

- Fixed issue where integrated Windows login requests were building up in the tbOauthExpiration table.
- Fixed issue where columns could not be sorted in Discovery Network View.
- Fixed bug where an email config port change was logging the new port as the old port.
- Fixed an issue with SQL Replication where indexes on indexed views were not replicated.
- Fixed issue where a DependencyResolutionException could occur on the Login page and prevent use of site until an IIS reset was performed.
- Fixed issue with SSH password rotation/Heartbeat connections that were reporting "Unexpectedly inactive."
- Fixed issue where the Secret Server Clipboard Utility could not be installed with Chrome 67.
- Fixed issue where the dashboard Add Content dropdown displayed below the Secrets table.
- Fixed null reference bug that occurred when autocomplete textboxes were used in lieu of a dropdown for the Group/User selector.
- Fixed bug in Password Changing where a large number of Secrets targeting the same resource for certain password changers could prevent processing.
- Fixed issue where root folders could be created through the CSV import process while that user did not have the Create Root Folders role permission.
- Fixed an issue that could cause occasional black flickering to appear in Session Recording videos.
- Fixed issue where users could be logged out of Secret Server due to inactivity while actively browsing certain pages.
- Fixed issue where new Secrets displayed the option to save to a user's Personal Folder even if Personal Folders were disabled.
- Fixed issue where Discovery local account scans were parsing unnecessary data and taking more time than necessary in large Active Directory domains
- Fixed issue where changes to Users would not save when extremely large numbers of AD groups were being synchronized.
- Fixed issue with custom PowerShell Ticket System integrations where entering a ticket number to view a Secret would produce an error.
- Fixed issue where creating a new Event Subscription would fail when specifying a user or group.
- Fixed issue where the REST API would not correctly implement the "Require Two-Factor for Web Services" configuration option.
- Fixed issue where Heartbeat could be stuck in Pending status.
- Fixed issue where creating new Folders would fail when there were no other Folders.
- Fixed condition in certain environments where the auto-change Secrets were not changing properly.
- Fixed issue where Dashboard searching was slow in environments with large numbers of Secrets.
- Fixed an issue where after adding and saving an identity provider in advance settings (SAML), the user observed an error stating 'Object reference not set to an instance of an object.'

Security Fixes

- Fixed issue with Unlimited Vault Access permissions and managing Groups.
- Deprecated TLS 1.0 in Security Hardening Check.
- Fixed issue with script names.
- Secret data is now authenticated with HMAC-SHA-256.
- SOAP API updated to use the same token generation as the REST API.
- Previously issued SOAP or REST tokens are no longer valid. If you have a saved token in your scripts or code, you must get a new token after updating Secret Server.
